The colour obtained by the addition of an acidified solution of antipyrine with a nitrite solution varies somewhat with the particular acid used, and its permanence depends on the concentration; for the most part, a solution containing not more than 0·1 per cent. of nitrite gives the best results. Rise of temperature lessens the permanence of the coloration. When either hydrochloric or sulphuric acid is used, a permanent green coloration is formed, the tint in the former case being, however, much bluer than in the latter. With oxalic acid the tint is hardly distinguishable from that with hydrochloric acid; with tartaric or acetic acid, the blue tint is intensified; and with trichloracetic acid the colour is pure deep green. The addition of strong acids or of alkalis to any of these green solutions changes the green tint to deep yellow. The reaction between antipyrine and nitrous acid is one of extreme delicacy, and affords an excellent means of detecting the latter; but owing to the variations in the tint which so readily occur, it is not to be recommended as the basis of a method of colorimetric quantitative estimation. As far as the author's experience yet goes, organic nitrites and nitro-compounds (*e.g.*, picric acid) do not behave similarly to the inorganic nitrites and nitrous acid, with antipyrine. (See also this J., 1896, 743.) —J. T. D.

INORGANIC—QUANTITATIVE.

Prussian Blue; Analysis of ——. C. Coffignier. Bull. Soc. Chim., 1904, 31, 391—396.

The author has further examined the solubility of Prussian blue in mixtures of hydrochloric acid and fatty alcohols (see this J., 1902, 1032, 1337; 1903, 472), propyl alcohol having been finally chosen as most suitable. Pure blues dissolve completely (0·5 grm. in 50 c.c. of the solvent); and on pouring the solution into water, filtering through a weighed filter, washing (this can be readily accomplished if alcohol be added to the water after the second washing), drying at 100° C., and weighing, 98·0 to 100·4, mean 99·7 per cent., of the substance taken, was recovered. The author applies this to the analysis of commercial blues. The chief of these are Wheelwrights' blue, Mineral blue, Paris blue, and Fecula blue, in which the Prussian blue is mixed respectively with barium sulphate, kaolin and barium sulphate, alumina, and starch; but other additions sometimes found are calcium carbonate and sulphate. Known mixtures of Prussian blue with these substances were treated as follows:—2 grms. were treated with 100 c.c. of the solvent, and made up, after complete solution of the blue, to 200 c.c. If the solution were clear (calcium carbonate, starch) 100 c.c. were at once taken; if not, the liquid was filtered through a dry filter, and 100 c.c. of the filtrate were precipitated by water, filtered on a tared filter, washed, dried, and the weight of blue determined. Results were very satisfactory with mixtures containing from 70 down to 3 per cent. of blue. Blues mixed with alumina dissolved much more slowly than those containing other substances. The amount of water necessary to precipitate the whole of the blue increased very rapidly as the proportion of blue in the mixture diminished. The liquid filtered from the precipitated blue was colourless or slightly greenish, and contained traces of ferric chloride, which proceeded in part from the existence of minute amounts of ferrous chloride in the blue, and in part from slight decomposition of the blue by the hydrochloric acid in the solvent.—J. T. D.

Iron in the Ferric State; Iodometric Determination of ——. R. Namias and L. Carcano. Monit. Scient., 1904, 18, 254—255.

The method of determining ferric iron by addition of potassium iodide, and titration of the liberated iodine, gave unsatisfactory results, due, in the author's opinion, to the ease with which the reverse reaction takes place, *viz.*, the oxidation of ferrous salts by iodine in presence of acids, to ferric salts. By removing the iodine from the solution by means of chloroform, however, quantitative results were obtained. The solution, oxidised with nitric acid, was evaporated to dryness, and the residue dissolved in the smallest possible quantity of hydrochloric acid, and diluted till it contained 1 to 2 per cent. of iron: it was then nearly neutralised with sodium carbonate, and concentrated hydrochloric acid, potassium iodide, and 5—10 c.c. of chloroform were added; the solution was then allowed to stand for about 12 hours, with occasional agitation, and the iodide determined by titration with standard sodium thiosulphate solution.—T. F. B.

Thiocyanates in presence of Salts giving Precipitates with Silver Nitrate; Determination of ——. A. Dubosc. Ann. Chim. anal. appl., 9, 45—46. Chem. Centr., 1904, 1, 1035.

Thiocyanates can be oxidised to sulphates quantitatively by the liquid obtained by the electrolysis of pure chloride solutions. A quantity of the thiocyanate solution sufficient to yield 0·2—0·4 grm. of barium sulphate is treated with 50 c.c. of water and 50 c.c. of a solution containing 2 grms. of barium chloride, and then 50 c.c. of the oxidising solution (containing 18—20 grms. of available chlorine per litre) are gradually added, the whole is allowed to stand for 10 minutes, 10 c.c. of hydrochloric acid are added, the liquid is boiled, and the barium sulphate filtered off. A correction must of course be made for any sulphate present in the material which is being tested. Any soluble sulphides present are first converted into insoluble sulphides and the latter filtered off.—A. S.

Manganese [in Iron, &c.]; Determination of —— by the Persulphate Method. H. Lüdert. Zeits. angew. Chem., 1904, 17, 422—423.

The following simple modification of von Knorre's method (this J., 1903, 1104) is recommended for rapid and accurate determinations in technical analysis. In the case of iron, for instance, known to contain 0·60 per cent. of manganese, 4 grms. were dissolved in 50 c.c. of boiling nitric acid (sp. gr. 1·2), and the solution diluted (without previous filtration) with about 400 c.c. of water, and treated with 40 c.c of sulphuric acid (sp. gr. 1·18) and 50 c.c. of ammonium persulphate solution (120 grms. per litre). The liquid was then vigorously boiled for 30 minutes, cooled, and treated with 15 c.c. of a recently standardised solution of hydrogen peroxide, of which 10 c.c. corresponded with 9·4 c.c. of a standard solution of potassium permanganate (1 c.c. = 0·00577 grm. of iron). As soon as the precipitate had completely dissolved, the liquid was titrated back with the permanganate solution, and the excess of hydrogen peroxide found calculated into the corresponding amount of manganese, viz., 0·62 per cent.—C. A. M.

Manganese in Presence of Iron [in Iron Ores, &c.]; Volumetric Determination of —— by Potassium Permanganate. Guyart-Volhard-Wolff Method. L. L. de Koninck. Bull. Soc. Chim. Bel., 1904, 18, 56—62.

In the determination of manganous salts in presence of ferric salts according to the equation—

$$K_2Mn_2O_8 + 3MnCl_2 + 2H_2O = 5MnO_2 + 2KCl + 4HCl$$

the author recommends that the accuracy of the process adopted, should be checked by means of manganous chloride prepared from the same permanganate solution as is used for the titration, since, according to the equation, the manganese in a certain volume of permanganate should require two-thirds of that volume for its titration. 50 c.c. of the permanganate solution are evaporated to dryness with 10 c.c. of strong hydrochloric acid, care being taken to avoid loss by spurting, and the manganous chloride produced is dissolved in dilute hydrochloric acid. The manganese in the iron ore is then titrated by the method selected [*e.g.*, Ledebur's method], a second titration being subsequently made with the addition of the manganous chloride prepared from the permanganate. From the difference between the two titrations, the real manganese value of the permanganate is readily calculated.—J. F. B.

Chromium [*in Ferrochrome, &c.*] ; *Colorimetric Determination of* ——. A. Moulin. Bull. Soc. Chim., 1904, **31**, 295—296.

The author applies Cazeneuve's reaction with diphenylcarbazide to the determination of chromium. The solutions are:—Diphenylcarbazide, 2 grms., dissolved with the aid of heat in 100 c.c. of alcohol and 10 c.c. of acetic acid, and diluted with alcohol to 200 c.c.; and a solution of chromic acid, 0·50 grm., made up to 1 litre and then again diluted tenfold. The sample (0·25 to 0·50 grm.) is dissolved, the chromium converted into chromate (for ferrochromes, boiling with hydrogen peroxide and excess of potassium hydroxide is a good method), excess of potassium hydroxide added, the solution filtered, exactly neutralised with acetic acid, and made up to 100 or 200 c.c. Into graduated test-glasses are put 2 c.c. of the diphenylcarbazide solution and 70 c.c. of water, then 0·5, 1, 1·5 c.c., and so on of the chromic acid solution, and varying amounts of the solution to be tested; after standing 20 minutes the tints are compared.—J. T. D.

Chromium and Vanadium; Separation of —— [*in Ferrovanadium, &c.*]. P. Nicolardot. Comptes rend., 1904, **138**, 810—812.

Separation of the Chromium as Chlorochromic Acid.—The substance is fused with a mixture of potassium chlorate and sodium carbonate. The iron and manganese are separated by the usual methods. The solution of alkali salts is evaporated to dryness, and the residue is fused and transferred to a small flask. The crucible is rinsed by fusing potassium chlorate in it until no coloration remains. The flask is connected with a scrubbing apparatus containing strong sulphuric acid, the gases evolved being decomposed in a dilute solution of sodium carbonate; the whole apparatus is connected with an aspirator pump. After the apparatus has been scrubbed by the passage of a current of dry air, a few drops of sulphuric acid containing a little sulphuric anhydride are admitted to the flask. When the reaction has moderated, a little more acid is introduced and dry air or hydrogen chloride is slowly aspirated through the apparatus, the flask and scrubbing vessel being finally heated at 60° C. until no more red fumes are evolved. The vanadium remains in the flask and scrubber; it is treated with alcohol and titrated with permanganate. The precipitate of chromium hydroxide is liable to contain traces of vanadium, in which case it must again be treated as above.

Separation by means of Ferric Oxide.—If the substance contain a large proportion of iron along with vanadium and chromium, it is dissolved in hydrochloric acid, and the solution is oxidised by chloric acid and evaporated on the water-bath with excess of hydrochloric acid. Under these conditions, a precipitate of ferric oxide separates out, "which contains all the metalloids," leaving the metals in solution. The ferruginous deposit should not be subjected to a higher temperature than that of the water-bath, and should be treated with a few drops of dilute alcohol in order to remove the last traces of chromium from the precipitate. The mixture is then treated with hot water, boiled with the detached precipitate in suspension, and ammonium sulphate added. All the chromium remains in solution, whilst the vanadium is removed with the ferric oxide, which is freed from vanadium first by washing with ammonia and finally by fusion with alkali salts.—J. F. B.

Titanium in Iron Ores; Determination of ——. S. Burman. Zeits. Berg.-Hütt., 1903, **51**, 743. Chem. Centr., 1904, **1**, 970.

One grm. of the finely-divided substance (or 0·5 grm. if the ore contain more than 8—10 per cent. of titanium) is heated for three-quarters of an hour in a tube of refractory glass in a current of hydrogen, then allowed to cool in the hydrogen, boiled with 8—10 c.c. of hydrochloric acid and 200 c.c. of water, and the solution filtered. The filter, without being washed, is burnt in a platinum crucible and the residue fused with 10 times its weight of sodium carbonate. The melt is treated with water and the insoluble sodium titanate filtered off and washed with water containing sodium carbonate. The residue is washed from the filter, and the paper burnt in a weighed platinum crucible. The residue washed from the filter is treated with hydrochloric acid, the titanium re-precipitated from the solution by caustic soda, filtered off, and the filter burnt in the platinum crucible containing the ash of the other paper. The contents of the crucible are fused with 10 grms. of potassium bisulphate till a clear melt is obtained, and after cooling, the latter is dissolved in 400 c.c. of water, the solution treated with about 10 grms. of alkali bisulphite, filtered, the filtrate almost neutralised with alkali, some sodium or ammonium acetate added, and the whole boiled, whereby flocculent hydrated titanic acid, $Ti(OH)_4$ is precipitated. Some platinum is dissolved during the fusion with potassium bisulphate, and is precipitated with the titanic acid, and a correction, *viz.*, the difference in weight of the crucible before and after the fusion, must be made.
—A. S.

Available Cyanide; Determination of ——. J. E. Clennell. Eng. and Mining J., 1904, **77**, 513—514.

The following method is recommended for the determination of the "solvent activity" of cyanide solutions. A quantity of pure metallic gold is dissolved in *aqua regia*, the solution evaporated, and the gold chloride dissolved in water to form a solution containing 0·5 mgrm. of gold per c.c. Into each of a number of flasks, 10 c.c. of the gold solution are introduced, the gold precipitated by a few drops of sulphurous acid solution, the excess of sulphur dioxide expelled by boiling, and the liquid made faintly alkaline by the addition of a few c.c. of sodium hydroxide solution. Equal volumes of the various solutions to be tested are run into the flasks, and the latter are agitated at intervals during 15 minutes, the undissolved gold is filtered off and washed free from cyanide, and the filter-paper and contents are dried, wrapped in lead-foil, and cupelled.
—A. S.

Sulphuric Acid in Tanning Liquors or Extracts; Determination of ——. J. G. Parker and E. E. M. Payne. Collegium, 1904, 95—96.

Ten grms. of liquid extract or liquor, or 5 grms. of finely powdered solid extract, are shaken with 90 c.c. of absolute alcohol in a stoppered cylinder, and filtered through a dry filter, the residue being washed with 90 per cent. alcohol. The filtrate and washings are acidified with 1 c.c. of concentrated hydrochloric acid, and precipitated with 2—3 c.c. of 10 per cent. solution of barium chloride. The method is accurate and is not affected by the presence of normal or acid sulphates nor of sulphites, the former being insoluble in 80 per cent. alcohol.—R. L. J.

Basic Slag; Determination of the Phosphoric Acid Soluble in Citric Acid in ——. R. Sorge. Zeits. angew. Chem., 1904, **17**, 393—397.

The author states that in the determination of phosphoric acid in basic slag, the precipitate contains the same amount of silica after "separation" of the silica by the method adopted by the German Association of Agricultural Experiment Stations (Landw. Versuchs. Stat., 1903, **59**, 312) as when the separation is omitted. It was also found that the solubility of the ammonium magnesium phosphate in ammonium citrate is considerably increased, presumably owing to the long time required for filtering. The errors due to the phosphoric acid precipitate carrying down silica and other impurities, and to the slight solubility of ammonium magnesium phosphate in ammonium citrate solution, compensate one another. The modification adopted by the Association (*loc. cit.*) can only give incorrect results, since it attempts to eliminate the *plus* error, and at the same time increases the loss of ammonium magnesium phosphate.

Böttcher's modification of the Association's method (Chem.-Zeit., 1903, **27**, 1205) and Wagner's method are also said to be open to objection. It is only in exceptional cases, with slags abnormally rich in silicate, that the *plus* error is liable to exceed the *minus* error; and in such cases it is easy to ascertain the amount of silica in the precipitate. —N. H. J. M.

Alkaline-Earth Metal Carbonates; Decomposition of —— by Ammonium Chloride in Presence of Water. H. Cantoni and G. Goguelia. VII., page 440.

Methyl, Ethyl, and Propyl Alcohols; Critical Temperatures of Solution of [Determination of Water in]——. Preparation of the Anhydrous Alcohols. L. Crismer. XVII., page 451.

ORGANIC—QUALITATIVE.

Alkaloids; Analysis [Identification] of ——, by the Refractive Indices of their Crystals. P. Kley. Zeits. anal. Chem., 1904, **43**, 160—167. (See this J., 1904, 207.)

A small crystal of the alkaloid is broken by pressure and a fragment is mounted in a drop of a medium of known refractive power. The Nicols being crossed, the stage is rotated until the crystal causes extinction, the upper Nicol is then removed, and the object is examined both in that position and in a position at right angles to it. The various media on the scale are then tried until accurate determinations of the refractive indices in the two positions have been made. The difference between the two values gives the strength of the double refraction. The crystal is positive if the refractive index of its extraordinary ray (*i.e.*, dark position between crossed Nicols and lying in the direction of the edges of the prism) be the greater, and negative if the reverse be the case. A table and graphic illustration are given of the values obtained with various alkaloids. —J. F. B.

Cocaïne; Some New Reactions for Detecting ——. C. Reichard. Chem.-Zeit., 1904, **28**, 299.

(1) When a concentrated solution of sodium nitroprusside is added drop by drop to a cold solution of cocaïne hydrochloride, a precipitate is formed immediately which appears under the microscope in the form of well-defined, reddish-coloured crystals of cocaïne nitroprusside. The crystals are dissolved on warming, and reappear on cooling; they are soluble in excess of water. A distinct reaction can be perceived in solutions containing 0·004 grm. of cocaïne hydrochloride per 1 c.c. This test serves to distinguish cocaïne from morphine. (2) If a cold, saturated solution of uranium nitrate be added drop by drop to a solution of cocaïne hydrochloride, a yellow, crystalline precipitate appears immediately. This precipitate is also soluble on heating, and appears to be soluble in water. (3) A pinch of pure titanic acid is treated with just sufficient concentrated sulphuric acid to dissolve it on heating. If a trace of solid cocaïne hydrochloride be added to the cooled solution and the mixture be warmed until the liquid assumes an oily appearance, a violet or blue coloration is gradually developed. (4) If a trace of solid cocaïne hydrochloride be ground up with a little solid potassium ethyl sulphate, and a few drops of strong sulphuric acid be added, a distinct odour of peppermint is developed on heating. (5) If solid cocaïne hydrochloride be ground up with urea, and concentrated sulphuric acid be added to the mixture, an increasing blue coloration is developed on heating strongly. Certain other organic amides give a similar reaction.—J. F. B.

ORGANIC—QUANTITATIVE.

Glycerol; Determination of —— in Fats. R. Fanto. Zeits. angew. Chem., 1904, **17**, 420—421.

Lewkowitsch (this J., 1903, 576) was unable to obtain satisfactory results by Zeisel and Fanto's method (this J., 1902, 992). The author has therefore made further experiments. He finds that it is not possible to obtain correct results by treating the fat directly with the hydriodic acid, and that it is necessary to saponify it, to separate the soap, and to take an aliquot portion of the aqueous glycerol solution for the determination:—About 10 grms. of the fat are saponified in the usual manner, the alcohol is nearly evaporated off, the soap dissolved in about 100 c.c. of hot water, and the fatty acids are separated by the addition of concentrated acetic acid The flask is then cooled and the aqueous layer separated from the solidified fatty acids, which are subsequently washed about five times with successive portions of 15 to 20 c.c. of hot water. If the fatty acids are liquid, a little hard paraffin may be advantageously added to accelerate their solidification. The aqueous layer and washings are filtered, concentrated to about 60 to 70 c.c., cooled, and diluted to 100 c.c., 5 c.c. of this solution being taken for the determination of the glycerol by the iodide method. A series of experimental determinations of glycerol in lard, butter, oils, &c., is given to show that the results thus obtained agree closely with those given by other methods.—C. A. M.

Tannin; Gravimetric Determination of —— in Tanning Materials and Extracts. J. Paessler. Collegium, 1904, 81—88, 90—95.

The author gives a detailed report on the method of tanning analysis as discussed at the meeting held by the German section of the International Association of Leather Trades Chemists at Frankfort on 25th October, 1903, together with criticisms and notes on certain details of the process where modification may in time become necessary. The following list of quantities of tanning materials, which should usually be weighed out to give the special amount of tannin in the liquor prepared for analysis (*viz.*, 0·35—0·45 grm. of tannin per 100 c.c.) has been compiled:—

	Grms.		Grms.

Pomegranate Bark, Coca Leaves, and Belladonna Leaves, Determination of Total Alkaloids in ——. E. Léger. J. Pharm. Chim., 1904, **19**, 329—337.

Pomegranate Bark.—A quantity of the finely-powdered bark, equivalent to 15 grms. of dry substance, is intimately mixed with 5 grms. of magnesia and 10 c.c. of water, and the moist powder allowed to stand for two hours in a closed flask. 150 c.c. of chloroform are then added, and the whole weighed. The mixture is then boiled for an hour under a reflux condenser, cooled, the original weight made up by the addition of chloroform, and the whole filtered 100 c.c. of filtrate (= 10 grms. of bark) are distilled, in two portions until 80 c.c. of distillate have been collected. The residue is transferred to a separator, the distilling flask being washed with two washings of 20 c.c. of neutral ether, sp. gr. 0·721, the washings being added to the chloroformic solution. The ether-chloroform solution is shaken out with 10 c.c. of N/10 hydrochloric acid and about 20 c.c. of water, and twice washed out with 30 c.c. of water. The acid extract and washings are titrated back with N/10 potassium hydroxide solution, with iodeosine as an indicator. The number of c.c. of N/10 acid thus found to be combined with the alkaloids × 0·1475 gives the percentage of total alkaloids in the bark. It is important to ensure exact neutrality of the ether employed by washing it, first with a trace of N/10 potassium hydroxide, then titrating back the free alkali with N/10 acid, using iodeosine as indicator.

Coca Leaves.—The equivalent of 25 grms. of dried powdered leaves is mixed with 5 grms. of magnesia and 15 c.c. of water, the moist powder is treated in a closed flask with 625 c.c. of ether, sp. gr. 0·721, previously saturated with water. The mixture is frequently shaken during 12 hours, then allowed to stand overnight, again shaken up, and filtered. The ether is then distilled off from 500 c.c. of filtrate, the residue taken up with 20 c.c. of neutral ether, treated with 10 c.c. of N/10 hydrochloric acid and 20 c.c. of water, the flask closed with a rubber cork, and the contents well agitated. The acid liquid is separated, the distilling flask twice washed with 25 c.c. of distilled water, these washings being used for successive shaking out of the ethereal liquid in the separator, then added to the first acid liquid. The whole of this is then filtered through a small moistened filter, which is then thoroughly washed. Sufficient water is added to bring the volume of the filtrate to 150 c.c., and the free acid is titrated back as described above; the number of c.c. combined with the alkaloids × 0·1535 gives the percentage of total alkaloids in the powder.

Belladonna Leaves.—The process is the same as that given for coca leaves. The number of c.c. of acid combined with the alkaloids × 0·1445 gives the amount of bases, as atropine, in the sample.—J. O. B.

Cinnamon Oil; Determination of Value of ——. A. Pouchand. Schweitz. Woch. Chem. Pharm., 1904, **42**, 126; through Chem.-Zeit., 1904, **28**, Rep. 80.

Ten grms. of the oil are heated on the water-bath, with constant agitation, with 20 c.c. of a 30 per cent. solution of sodium bisulphite. After the yellow mass at first produced has re-dissolved, a further quantity of 40 c.c. of the bisulphite solution is gradually added, whilst agitating and heating. After the flask containing the mixture has cooled, the liquid is transferred to a separating funnel, the flask is rinsed out twice, each time with 10 c.c. of ether, which together with another 10 c.c. are added to the liquid in the funnel. The liquid is shaken and allowed to separate, the aqueous layer is run off, the ethereal solution is collected in a tared Erlenmeyer flask, the aqueous portion is again shaken with 20 c.c. of ether, the combined ethereal solution is evaporated, and the residue is dried at 95°—100° C. and weighed.—J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Colloids; Bibliography of the ——. A. Müller. Zeits. anorg. Chem., 1904, **39**, 121—151.

Colloidal Bodies; Mutual Influence of Dissolved ——. W. Biltz. Ber., 1904, **37**, 1095—1116.

The author deals with the preparation of colloidal solutions of various inorganic substances, and the polarity of the dissolved colloids under the influence of the electric current. Some colloids are attracted to the anode (negatively charged relatively to water) and others to the cathode (positively charged), this latter class consisting of the colloidal hydroxides of the metals. The author has found that solutions of oppositely charged colloids will precipitate each other in the form of mixed jellies ("adsorption compounds") without the addition of an electrolyte, whilst similarly charged colloids will not. For the mutually complete precipitation of oppositely charged colloids, certain definite limits of relative proportions (equivalents) are necessary. Variations on either side of the optimum proportion cause incomplete precipitation until points are reached at which no precipitation occurs. In the precipitation of the negative colloids by salts (electrolytes) of the positive colloidal hydroxides, the actions of the electrolyte and the positive colloid are superimposed.—J. F. B.

Aromatic Hydrocarbon; New —— [*Phenylacenaphthylmethane*]. C. Dziewonski and E. Dotta. Bull. Soc. Chim., 1904, **31**, 373—38:.

By heating a mixture of benzyl chloride and acenaphthene with zinc dust, or better with zinc chloride, and fractionating the product, *phenylacenaphthylmethane*, or *benzylacenaphthene*, is obtained. After several crystallisations from alcohol it forms long white silky needles, soluble in most organic solvents, and in cold sulphuric acid. It melts at 112° and boils at 340°—345° C. On oxidation it yields a mixture of *benzylnaphthalic acid* and its anhydride, which on further oxidation are converted into the corresponding *benzoyl*-compounds—

$$C_6H_5.CH_2.C_{10}H_5<\begin{matrix}CH_2\\CH_2\end{matrix};\ C_6H_5.CH_2.C_{10}H_5:(COOH)_2;$$

$$C_6H_5.CO.C_{10}H_5:(COOH)_2.$$

The imides of both these acids, and the oximes of the latter, were prepared and described.—J. T. D.

PATENTS IN CANADA.

U.S. Cons. Reps., *No.* 1913, *March* 29, 1904.

The following refers to amendments to the Patent Act passed at the last session of the Dominion Parliament:—

A patentee must commence manufacture within two years from the date of issue of his patent, otherwise it is null and void. There are some classes of patents, however, that would be difficult to manufacture in advance of the public demand. In such cases the commissioner of patents has power to place the applicants under the terms of section 7 of the Act, the effect of which would be to delay manufacture until application is made for a licence to sell the patent invention. Then, if the commissioner is satisfied there has been neglect or refusal to manufacture or sell the patent, he may grant the licence applied for. The commissioner of patents has issued a circular indicating the kinds of patents which come under section 7. They are as follows:—Patents for an art or process; patents for improvements on a patented invention, when both patents are not held by the same person; patents for certain appliances or apparatus in connection with railways, telegraph, telephone, and lighting systems, and other works usually under the control of public or large private corporations, and which appliances or apparatus cannot be installed or constructed without the consent of such corporations; and patents for inventions which are manufactured or constructed only to order and are not, according to custom, kept in stock. At present the patent office is in frequent receipt of petitions from patentees asking to come under the provisions of section 7.

SWEDEN; EXPORT TRADE OF ——, IN 1903.

Foreign Office Annual Series, No. 3123.

The exportation of matches from Sweden amounted to 1,316 tons more than in the previous year. Paper of all kinds shows a large increase—from 69,550 tons in 1902 to 82,206 tons in 1903—in fact the amount has more than doubled itself in the last four years. Wood-pulp (chemically prepared, dry) rose from 178,421 tons in 1902 to 224,573 tons in 1903. Iron ore shows an increase of from 1,719,293 to 2,827,551 tons.

Skins and hides were exported in considerably larger quantities and were valued at 5,894,000 kr. (327,440*l.*); their value in 1899 came to 3,686,000 kr. (204,700*l.*)

In regard to Swedish brandy and spirits, the exportation of which, in former years, came to from 150,000 to 200,000 litres per annum, the quantity exported last year was only 36,400 litres; it should, however, be noted that the production of these spirits is meant for home consumption.

III.—TAR PRODUCTS, PETROLEUM, Etc.

TRINITROTOLUOL: U.S. CUSTOMS DECISION.

March 16, 1904.

Trinitrotoluol was decided to be dutiable at 20 per cent. *ad valorem* as a "preparation of coal tar, not a colour or dye," under paragraph 15 of the present tariff act. The importers claimed free entry under paragraph 524, which provides, among others, for toluol, nitrotoluol, and dinitrotoluol. Since trinitrotoluol is not included in this enumeration, the assessment of duty was affirmed, as above stated.—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

CHILEAN NITRATE TRADE.

Eng. and Mining J., *March* 31, 1904.

Last year the export tax, which is 56 cents per quintal, yielded the Chilean Government a revenue of 17,742,645 dols.

The exports in the year 1903 amounted to a total of 31,683,294 quintals. Prices were unusually high; 6*s.* to 7*s.* 3·5*d.* per quintal for 95 per cent. quality, and 6*s.* 6*d.* to 7*s.* 4·5*d.* for 96 per cent. alongside steamer. At these prices last year's exports had a total value of over 10,200,000*l.*, which is nearly 12 per cent. better than 1902, and the highest for some years past. At the ruling ocean freights of 12*s.* 6*d.* to 21*s.* 3*d.* per ton, the cost of shipping nitrate of soda to the distributing markets abroad reached a total of nearly 1,000,000*l.* This is less than in 1902.

The exports of nitrate of soda in the years 1902 and 1903 are given below, in quintals of 101·4 pounds.

——	1902.	1903.	Changes.
	Tons.	Tons.	Tons.
Belgium	1,277,068	1,775,457	I. 498,389
France	3,034,217	4,759,355	I. 1,725,138
Germany	7,362,216	8,488,434	I. 1,126,218
Holland	1,416,306	2,051,351	I. 635,045
Italy	1,162,662	562,123	D. 600,539
United Kingdom	1,322,445	1,606,178	I. 283,733
Miscellaneous	589,826	375,345	D. 214,476
Continent, for orders	7,924,414	5,556,511	D. 2,367,903
Total, Europe	24,089,154	25,174,754	I. 1,085,605
United States, East Coast	5,042,382	4,931,629	D. 110,753
United States, West Coast	558,457	982,646	I. 424,189
Total, United States	5,600,839	5,914,275	I. 313,436
West Indies	..	49,232	I. 49,232
South America	42,958	42,779	D. 179
Africa	113,877	90,291	D. 23,576
Australia	..	26,844	I. 26,844
Japan	440	55,881	I. 55,371
Mauritius	..	53,627	I. 53,627
Other countries	242,172	275,681	I. 33,509
Grand total	30,089,440	31,683,294	I. 1,593,854

This increase in exports was due to heavy shipments to the beet-sugar growers in Germany and France, and to purchases by powder manufacturers and others in the United States.

Tarapaca shipped 24,140,459 quintals, or over 76 per cent. of last year's total exports; Tocopilla, 4,246,929 quintals; Taltal, 1,668,263 quintals; Antofagasta, 895,352 quintals, and Caleta Coloso, 732,291 quintals. Both Tarapaca and Taltal shipped less than in 1902, but this is more than offset by the increased movement from the other ports and the initial exports from Caleta Coloso.

SULPHUR; SICILIAN ——.

Eng. and Mining J., *March* 31, 1904.

There are exported annually over 475,000 long tons of sulphur from Sicily. A feature is the heavy accumulation of stocks in Sicily, amounting, on Dec. 31, 1903, to 361,220 tons.

By far the largest consumer is the United States, which takes annually nearly one-third of the Sicilian exports. In 1903 that country received 155,996 long tons, of which 121,845 tons were best unmixed seconds, consumed principally by sulphite pulp manufacturers, and 34,151 tons taken by acid manufacturers and others. During recent years the high prices asked for brimstone have encouraged greatly the consumption of the cheaper pyrites sulphur. In 1993 imported and domestic pyrites furnished nearly 60 per cent. of the entire sulphur used in the

Destination.	1902.	1903.	Changes.
	Tons.	Tons.	Tons.
Austria	19,086	17,926	D. 1,160
Belgium	12,323	15,233	I. 2,910
France	67,249	74,372	I. 7,123
Germany	25,906	32,553	I. 6,647
Greece and Turkey	20,548	22,133	I. 1,585
Holland	8,648	5,157	D. 3,491
Italy	45,603	45,572	D. 31
Russia	17,295	15,068	D. 2,227
Scandinavia	24,918	28,292	I. 3,374
Spain and Portugal	12,863	18,163	I. 5,300
United Kingdom	25,477	19,210	D. 6,267
United States	168,919	155,996	D. 12,923
*Other countries	18,434	25,833	I. 7,349
Total	467,319	475,508	I. 8,189

* In 1903: Australia, 4,756 tons; Canada, 808; East Indies, 3,182; North and South Africa, 9,393; South America, 2,357; Switzerland, Roumania, Bulgaria, Malta, Egypt, Syria, and Asia, 5,337: total, 25,833 tons.

United States, whereas in 1896, the first year of the Sicilian compact, the proportion was less than 50 per cent. During this period consumers have been obliged to pay from 5 dols. to 6 dols. and more for crude brimstone.

The Sicilian brimstone export trade is shown in the foregoing table in long tons.

The increase in exports in 1903 is comparatively small when we consider the heavy falling off in the American and British purchases.

Following are the selling prices per long ton, f.o.b. shipping ports in Sicily :—

Quality of Sulphur.	High.		Low.		Average for Year.	
	s.	d.	s.	d.	s.	d.
Best unmixed seconds, bulk	83	9	80	9	82	6
Best unmixed seconds, ground, bags	89	6	87	6	88	3
Best unmixed thirds, bulk	79	9	78	0	79	2
Current thirds, bulk	79	0	76	9	77	9
Refined block, bulk	88	6	85	9	87	5
Refined roll, bags	94	9	92	9	93	10
Refined roll, casks	100	0	96	9	98	6
Refined roll, usual size sticks, cases	103	9	101	9	102	11
Refined roll, small sticks, cases	106	6	103	9	104	9
Sublimed flowers, pure, bags	108	6	103	6	106	2
Sublimed flowers, current, bags	99	9	97	0	98	5
Sublimed flowers, commercial, bags	94	9	92	3	93	3

Compared with 1902, these prices show a substantial increase, excepting crude seconds, which are fractionally less, owing partly to the introduction in the market of ground seconds, and also to the improved quality of best thirds. Prospects for lower prices are not favourable.

THE POTASH SYNDICATE.

Eng. and Mining J., March 31, 1904.

After nearly 25 years of successful operation the German Potash Syndicate is threatened with dissolution. The older members will not acquiesce in a reduction of their quotas of production—for the purpose, apparently, of suppressing the modern works. Nor will the members sanction the purchase by the syndicate, as is contemplated, of the mines optioned in 1902 by Americans.

The syndicate was founded in 1879, after 22 years of competition and limited consumption. In 1879 the output of crude potash salts amounted to only 768,971 metric tons, but 23 years later, in 1902, it had increased to 3,250,835 tons. Simultaneously, prices have improved, as a result of the growing consumption which has been encouraged by systematic propaganda among agriculturists. At the same time the industry has been consolidated by the periodical renewal and revision, for a term of years, of the agreement. The last compact was signed June 30, 1901, and expires on December 31, 1904. The number of works represented by the Verkaufs Syndikat has been gradually increased, and now amounts to 27, or 10 more than were officially recognised prior to the invasion of the American fertiliser combinations, in 1902.

LIQUID AIR ; TRANSPORTATION OF ——.

U.S. Cons. Reps., No. 1913, *March* 29, 1904.

An experiment for the purpose of testing the durability of liquid air has been made between Berlin and Geneva. For the further growth of this industry the question of how far liquid air can be transported without serious loss by evaporation is a vital one.

Two quarts of liquid air were delivered to the railroad at Berlin, packed in a special manner for transportation to Geneva. The shipment arrived in Geneva in five days, and after a further delay of half a day it was delivered to the chemical laboratory of the University of Geneva. The glass vessel in which the liquid air was sent still contained one-fourth of a quart thereof, which was at once experimented with.

It is stated that this was the longest distance over which liquid air has been transported, and the result was encouraging to make larger shipments, where the loss would be relatively less.

BARIUM SULPHIDE : U.S. CUSTOMS DECISION.

March 16, 1904.

Barium sulphide was held to be properly dutiable at 35 per cent. *ad valorem* as a "chemical salt," under paragraph 3 of the present tariff.—R. W. M.

BORAX GLASS : U.S. CUSTOMS DECISION.

March 23, 1904.

It was decided that borax glass is dutiable at 5 cents per lb. as "borax," under paragraph 11 of the present Tariff Act. The claim of the importer was that it was dutiable as "borate of soda containing over 36 per cent. of anhydrous boracic acid." The testimony showed that it was simply anhydrous borax, and was used as a flux in metallurgical operations in the same manner as borax. While recognising the fact that the most common form of borax contains 10 mols. of water, it was also noted that there are other varieties also known to trade and commerce, of which borax glass is one, differing from the others only in the absence of water of crystallization. The term "borax" being more specific than "borate of soda," was therefore held to correctly describe borax glass.—R. W. M.

X.—*METALLURGY.*

CHROMIC IRON ORE IN CUBA.

U.S. Cons. Reps., No. 1906, *March* 21, 1904.

An extensive and rich deposit of chromic iron ore has been found on the coast of Cuba, 30 miles from Baracoa. It aggregates from 8 to 12 ft. in thickness. It is said that the freight rates by water will permit of its transportation.

XII.—*FATS, FATTY OILS, Etc.*

COTTON-SEED ; UTILISATION OF INDIAN ——.

"Agricultural Ledger," 1903, *No.* 9. (*See also this J.,* 1904, 279.)

The export of cotton-seed from India increased from 43,485 cwts. in 1899—1900 to 3,974,000 cwts. in 1902—1903. The seed at average Indian prices can be profitably exported when the price of cotton-seed oil in England is 20*l.* or more per ton.

Egyptian cotton-seed commands a higher price, as it contains a larger percentage of oil and has no adherent "fuzz." The Indian cake is about 10*s.* per ton cheaper at Hull than the Egyptian.

The quantities of oil seeds exported from India during 1901–2 and 1902–3 were as follows :—

Kind of Seed.	1901-2.	1902-3.
	Cwts.	Cwts.
Linseed	7,328,000	6,328,000
Rape-seed	6,925,000	3,927,000
Sesamum	2,447,000	3,733,000
Cotton-seed	2,036,000	3,974,000
Poppy-seed	934,000	966,000
Earth nuts	1,085,000	1,036,000

These exports are considered more profitable than if oil industries were fully established in India, because the cakes obtained are worth much less in India than in Europe. In the larger villages of India excellent cakes are prepared from seeds capable of easier manipulation. Hydraulic press mills capable of treating cotton-seed have, however, now been established at Lahore and elsewhere.

The Director of Agriculture has investigated 100 indigenous and exotic varieties. The comparative values are shown by tables giving the number of seeds per tola, and the percentage quantities of oil and crude fibre contained in the seeds. Some samples of American and Egyptian seed contain 10 per cent. more oil than any Indian seed and average at least 5 per cent. more.

COPRA EXPORTS FROM SAMOA.

Foreign Office Annual Series, No. 3132.

Copra, at present the only important Samoan export, was subject to a serious decline in price at the beginning of the year, as the value in Samoa is now only 9*l.* 15*s.* per long ton f.o.b. steamer, when, last year, it was eagerly sought for at 14*l*; trade suffers accordingly. The Sydney market absorbs Samoan copra to the extent of 3,000 to 4,000 tons yearly. The total quantity of Samoan-made copra shipped from Western Samoa during 1903 has been 7,000 tons, worth, at say 10*l.* per ton, 70,000*l.* There is no export duty.

The value of copra exported was as follows:—1899, 90,000*l.*; 1900, 46,000*l.*; 1901, 35,000*l.*; 1902, 94,000*l.*; 1903, 70,000*l.*

The quantity of copra made yearly in Western Samoa ranges from 5,000 to 8,000 tons, of which, say, two-thirds are supplied by the natives, the rest coming from the plantations of the Deutsche Handels und Plantagen Gesellschaft. This article is not likely at present to have its yield increased. Tutuila produces yearly about 500 tons, now purchased by the United States Government from the natives at fixed rates, and then resold by sealed tenders. In 1902 they obtained from the agent of a Hamburg firm 12*l.* to 13*l.* per ton, delivered in the Government sheds.

Soap from the Castor Bean.

U.S. Cons. Reps., No. 1907, *March* 22, 1904.

Parties in the State of Durango are interested in processes or machinery for the making of soap from the castor bean. The plant (*Ricinus communis*, also known in Spanish countries as *Palma cristi*) grows extremely well there, very speedily coming in places to be as high as a small tree, and produces in abundance. A great deal of common soap is made in the "Laguna district" of Durango and Coahuila, the great cotton district of Mexico, especially by one large factory. The cotton seed is used for this purpose, but the soap produced for common use hereabouts, not being perfumed, has a very bad odour. Some time since a large experiment was undertaken with a view to extracting the oil of the castor bean, and also for making soap from it if possible, but failed, and the plant has lain idle for several years.

XVI.—SUGAR, STARCH, Etc.

Sugar Production of Germany.

Bd. of Trade J., March 31, 1904.

According to statistics published in the *Reichsanzeiger*, the quantity of raw sugar produced in Germany during the period from 1st September, 1903, to 28th February last, being the first six months of the 1903–4 sugar campaign, was 1,625,299 metric tons, as compared with 1,461,944 metric tons during the corresponding months of 1902–3. The quantity of refined sugar produced decreased from 777,763 metric tons during the six months September, 1902, to February, 1903, to 753,477 metric tons during the six months September, 1903, to February, 1904.

The total quantity of beets used during the first half of the present campaign was 12,706,527 metric tons, as compared with 11,255,958 metric tons during the corresponding months of 1902–3.

Sugar Production of Italy.

Bd. of Trade J., March 31, 1904.

According to statistics published in the *Bolletino delle Finanze*, the production of sugar by the 33 sugar refineries of Italy during the year 1902–3 was 954,091 quintals, of the value of 64,115,038 lire. These figures exceed those of 1901–2 by 211,102 quintals, and 1,416,343 lire respectively.

XVII.—BREWING, WINES, SPIRITS, Etc.

Clarifying Powders: U.S. Customs Decisions.

March 24, 1904.

A mixture, which on analysis was shown to contain 39·13 per cent. of tannin, 5·35 per cent. of mineral matter, with the balance non-tannin organic matter, was decided to be dutiable at 50 cents per lb., as "tannin," under paragraph 1 of the present tariff. The evidence showed that it was a mixture and not a definite chemical compound, as claimed by the importer, and that the tannin was the component material of chief value.—R. W. M.

XVIII. B.—SANITATION.

Sewage; Treatment of ——.

The Commissioners appointed to inquire and report upon the methods of treating and disposing of sewage have issued a third volume of their fourth report, consisting of a copiously illustrated folio Blue book of 316 pages, the whole of which is devoted to reports by Dr. Houston on bacteriological investigations, with special reference to the contamination of shell-fish. The following results are stated as general inferences, which are, perhaps, warranted "on a broad and common-sense view of the whole investigation":—(*a*) That a water which, from the bacteriologist's point of view, would be considered very impure, may, after filtration, although still containing an appreciable number of bacteria seemingly of intestinal derivation, be used for domestic purposes without any very definite or detectable harm resulting. (*b*) That the water of a tidal river grossly polluted in its lower estuarial reaches may, after a flow of some 25 miles, become so far purified by sedimentation, dilution, and the operation presumably of bactericidal agencies, as to become seemingly as little objectionable, or in some respects less objectionable, bacteriologically, than certain of our public water supplies. (*c*) That the deposition in the sea of chemically precipitated sludge in enormous quantities, if carried out under proper conditions, need not result necessarily in the production of nuisance or serious pollution of the surrounding water, and that such deposition may be thought of as an economical and seemingly not unsatisfactory means of disposing of this material. Conclusion (*a*) is somewhat modified by an appended note setting forth that, in the opinion of the writer, who holds rather a contrary view, it in no way implies that impure waters, even after careful filtration, are necessarily uniformly safe for potable purposes. The question to be dealt with in the report concerns the facts elicted during the period of observation, and these seem to indicate the danger of hastily condemning waters and other materials without a wider knowledge of comparative bacteriology, and of the correlation of bacteriology and epidemiology, than is at present available. Perhaps it may be said, in other words, that the results so far obtained are only contributions towards the attainment of a final decision on the questions which are involved.

XX.—FINE CHEMICALS, Etc.

Thorium; Occurrence of —— in Ceylon.

Imp. Inst. J., March 31, 1904, 13.

Specimens of minerals, supposed to be monazite and uraninite, sent from Ceylon, have proved to be thorite, a silicate of thorium, containing 66 per cent. of thorium oxide, and a new mineral, which it is proposed to name "thorianite." The latter contains 75 per cent. of thorium oxide, with small quantities of cerium, uranium, and lead oxides. Thorianite is richer in thorium than any mineral at present known, is strongly radio-active, and may prove to be a source of radium. The Imperial Institute expects shortly to receive further specimens and information as to the occurrence of these minerals in Ceylon.

Hexamethylenetetramine: U.S. Customs Decision.

March 22, 1904.

Duty was assessed on this article at 55 cents per lb. unde paragraph 67 of the present Tariff Act, as a "medicina preparation in the preparation of which alcohol is used." The importers claimed that it was dutiable either as a "chemical compound," under paragraph 3, at 25 per cent *ad val.*, or as a "manufactured article unenumerated," unde section 6. As no conclusive evidence was offered to show that alcohol had not been used, the assessment of duty a above was sustained.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

„ 14,335 (1903). Bridson. Generation of gas from petroleum oils. April 7.

„ 25,763 (1903). Hovine and Breuille. Manufacture of producer gas, &c. April 7.

„ 1887 (1904). Hoffman and Clark. Artificial fuel. April 7.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 7481. Kuess. Process for solidifying petroleum and other mineral oils for their application as fuel. [Appl. in Tunis, Nov. 6, 1903].* March 28.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 7363. Imray (Soc. Chem. Ind. in Basle). Manufacture of amidothiophenyl derivatives and dyestuffs therefrom. March 28.

„ 7398. Johnson (Badische Anilin und Soda Fabrik). Manufacture of alizarine. March 28.

„ 7692. Newton (Bayer and Co.). Manufacture of anthracene dyestuffs suitable for dyeing and printing. March 31.

„ 7725. Abel (Act.-Ges. f. Anilinfabr.) Manufacture of new sulphurised dyestuffs. March 31.

„ 7863. Lake (Oehler). Manufacture of mono-azo dyes. April 5.

„ 7953. Newton (Bayer and Co.). *See under* XIII. A.

„ 8282. Newton (Bayer and Co.). Manufacture of new anthraquinone derivatives. April 11.

[C.S.] 8503 (1903). Iljinskij and R. Wedekind and Co. Manufacture of halogen derivatives of oxyanthraquinones, April 20.

„ 11,003 (1903). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new green sulphurised colouring matters. April 13.

„ 12,099 (1903). Newton (Bayer and Co.). Manufacture of anthracene derivatives. April 20.

[C.S.] 12,298 (1903). Imray (Soc. Anon. Mat. Col. et Prod. Chim. de St. Denis). Manufacture of sulphurised dyestuffs. April 20.

,, 12,681 (1903). Johnson (Badische Anilin und Soda Fabrik). Manufacture of soluble compounds or salts of basic colouring matters. April 13.

,, 12,879 (1903). Ellis (Chem. Fabr. Sandoz). Manufacture of blue sulphur dyes. April 7.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 7360. Bartelt. Apparatus for preparing bleaching liquor. March 28.

,, 7475. Stables (Eyres and Sons). Waterproof fabrics. March 29.

,, 7745. Pope and Hübner. Engraved bowls or rollers for producing reflected finish on textile fabrics, paper, or other lamellar materials. April 2.

,, 7780. Lendrum. Scouring, milling, and dyeing of fabrics and other analogous materials. April 2.

,, 8084. Parkinson. Method of producing light waterproof cloths for garments. April 8.

,, 8107. Ostersetzer. Finishing woven and other textile fabrics printed with patterns in metal powder.* April 8.

,, 8288. Johnson (Badische Anilin und Soda Fabrik). Production of blue to blue black shades on wool. April 11.

,, 8409. Gruschwitz and Herminghaus. Jigger dyeing machines. April 12.

,, 8433. Serkowski. The waterproofing of materials such as fabrics, tissues, paper, &c. April 12.

,, 8531. Palmer. Figuring or shading velvet.* April 13.

,, 8545. Cross. Treatment of cotton hulls to obtain useful products therefrom. April 13.

,, 8551. Möller-Holtkamp. Manufacture of size for cotton yarn. April 14.

,, 8570. Partridge. Machines for dyeing yarn and slubbing. April 14.

,, 8813. Mandleberg. Manufacture of waterproof fabrics. April 16.

[C.S.] 6731 (1903). Lake (Mattei). Apparatus for dyeing sliver and other textile fibres. April 7.

,, 7206 (1903). Maunsell - Smyth. Process for colouring, decorating and treating paper and like substances, fabrics, and other materials. April 7.

,, 8635 (1903). Wiley. Method of and apparatus for waterproofing garments. April 20.

,, 8636 (1903). Wiley. Method of and apparatus for applying certain waterproofing agents to textile fabrics and garments. April 20.

,, 10,035 (1903). Rawson and Lodge. Machine for dyeing, scouring, bleaching or treating with liquids, textile fibres in the form of cops, cheeses, &c., with or without perforated broaches or tubes. April 20.

,, 13,116 (1903). Imray (Meister, Lucius, und Brüning). Printing fabrics with indigo. April 20.

,, 27,483 (1903). Keefer. Method of printing yarns or threads. April 7.

,, 1502 (1904). Rowland. Aniline dyeing compound. April 20.

,, 1596 (1904). Détré. Tubes for holding yarns or threads during dyeing, bleaching, mordanting, and like operations. April 7.

,, 4610 (1904). Willard. Apparatus for dyeing raw stock, wool, &c. April 7.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

[C.S.] 7206 (1903). Maunsell-Smyth. *See under* V.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 7397. Johnson (Badische Anilin und Soda Fabrik). Manufacture of stable dry hydrosulphites. March 28.

,, 7452. Grätzel. *See under* I.

,, 8377. Leslie. Apparatus for the manufacture of carbonic acid gas. April 12.

[C.S.] 8819. (1903). Trivick. Process for the manufacture of dry sulphates of the alkali metals, and the products thereof. April 20.

,, 10,053 (1903). Smithson. *See under* I.

,, 10,356 (1903). Hills and Lane. Production of pure or nearly pure hydrogen. April 7.

,, 10,624 (1903). Pearson. Manufacture of lime and fuel gas. April 20.

,, 14,831 (1903). Glogner. Treating graphite for the separation of impurities therefrom. April 7.

,, 2541 (1904). Hegeler and Heinz. Glover tower process. April 7.

,, 4409 (1904). Feely. Slaked lime and process of preparing the same. April 7.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 8440. Richardson. Process of and apparatus for manufacturing glass articles.* April 12.

,, 8602. Fleming. Manufacture of pottery ware. April 14.

[C.S.] 4501 (1904). Hays. Working of glass. April 20.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 7343. Nusch (Westdeuts. Thomas-Phosphat Werke). Manufacture of an artificial floor covering. March 28.

,, 7385. Potter. Treatment of concrete. March 28.

,, 7736. Spatz. Manufacture of fireproof stone, stoneware, and mortar. March 31.

,, 8413. Latham. Utilising old plaster casts and other hydrated sulphate of lime and apparatus therefor. April 12.

,, 8504. Glossop. Manufacture of artificial stone. April 13.

,, 8542. Goddard. Asphaltic-mosaic flooring or paving composition.* April 13.

,, 8619. Goldsmith. Machine for applying colours glazing-matter, &c., on tiles, bricks, and similar articles. April 14.

[C.S.] 7128 (1903). Kirkland and Cooke. *See under* I.

,, 1617 (1904). Crew. Brick kilns. April 7.

,, 4409 (1904). Feely. *See under* VII.

,, 4606 (1904). Liebold. Manufacture of cement. April 7.

,, 5985 (1904). Frydenlund. Manufacture of tiles or other glazed articles from slate or slate refuse. April 20.

,, 6007 (1904). Steger. Manufacture of artificial stone blocks or bricks. April 20.

X.—METALLURGY.

[A.] 7344. Simpson and Batt. Treatment, dressing, and separation of mineral matters. March 28.

,, 7367. Simmersbach. Process and apparatus for smelting ores, more particularly iron ores. March 28.

[A.] 7412. Beckett. Removing molten slag from open hearth furnaces. March 28.

„ 7426. Izzett. Regenerative gas furnaces for melting steel, &c. March 29.

„ 7478. Rouse and Cohn. Manufacture of briquettes from powdered iron ore or iron wastes, or from iron sand or mixtures thereof for reduction in furnaces. March 29.

„ 7602. Defays. Reverberatory furnaces. March 30.

„ 7658. Kunicke. Precipitating boxes for gold or other metal bearing solutions. March 31.

„ 7935. Minnis. Method and apparatus for galvanising iron and steel sheets. April 6.

„ 7936. Traubel and Schultze. Process of disintegrating or granulating blast furnace or similar slag. April 6.

„ 7981. Mercadier. Manufacture of spongy or porous lead and of articles therefrom. [Fr. Appl., April 7, 1903].* April 6.

„ 8026. King. Removal of furnace slag and utilisation of the heat thereof. April 7.

„ 8102. Sulman and Kirkpatrick-Picard. Recovery of mercury from its ores and compounds. April 8.

„ 8216. Gin. *See under* XI.

„ 8311. Kurzwernhart. Siemens regenerative furnaces.* April 11.

„ 8605. Webb. Apparatus for extracting liquid from finely crushed minerals or the like. April 14.

„ 8677. Hyatt. Gold extraction. April 15.

„ 8683. Meadows. Apparatus for the manufacture of metallic alloys. April 15.

„ 8817. Malzac. Process for desulphurising by the damp method nickel, copper, zinc, and other ores, and hydroxidating their metals with a view to their extraction. [Fr. Appl., May 6, 1903].* April 16.

[C.S.] 12,186 (1903). Gührs and Gührs. Treatment of metallic zinc. April 7.

„ 13,033 (1903). Glinsky. Protection of metallic surfaces from oxidation and from the action of liquids, steam, and air. April 7.

„ 4263 (1904). Swindell (Johnston). Process of coating metal objects. April 7.

„ 4973 (1904). Trezel and Montby. Alloy for and process of soldering and brazing aluminium and its alloys. April 7.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 8188. Taylor. Electrical insulation. April 9.

„ 8216. Gin. Electric furnace for converting pig iron into steel.* April 9.

„ 8686. Delafon. Galvanic battery. April 15.

[C.S.] 15,317 (1903). Collis, Collis, and Head. Construction of apparatus for the electro-deposition of metals. April 20.

„ 28,805 (1903). Schneider. Electric furnaces. April 13.

„ 3790 (1904). Keller. Electric furnaces. April 7.

„ 5921 (1904). Soc. Anon. l'Ind. Verrière et ses Dérivés. Electric melting furnaces. April 20.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 8104. Burdon (Pierard). Manufacture of tapers, wax vestas, candles, and the like. April 8.

„ 8233. Nicloux. Material for saponifying fats, and method for obtaining it. [Fr. Appl., Oct. 14, 1903.]* April 9.

„ 8304. Nicloux. Method of separating from castor oil seeds or the like a material for saponifying fats or oils. April 11.

„ 8359. Westaway. *See under* I.

[C.S.] 8588 (1903). Breda. Process of separating liquid constituents from fats and waxes. April 20.

„ 12,159 (1903). Mapleton. Butter substitute. April 13.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—Pigments, Paints.

[A.] 7953. Newton (Bayer and Co.). Manufacture of new colour lakes. April 6.

„ 8082. MacIvor and Burnett. Manufacture of white lead. April 8.

„ 8800. Raynes and Raynes. Coloured marking inks for marking linen, cotton, and silk fabrics and the like. April 16.

(*B.*)—Resins, Varnishes.

[C.S.] 14,554 (1903). Terrisse. Treatment of gums and resins and the preparation of varnishes. April 20.

(*C.*)—India-Rubber.

[A.] 7795. Karavodine. Treatment and utilisation of waste vulcanised rubber and ebonite. [Fr. Appl., July 25, 1903.]* April 2.

„ 8691. Az. Treatment of vulcanised caoutchouc. April 15.

[C.S.] 14,001 (1903). Pensa. Substance similar to rubber and process of manufacturing same. April 20.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

[A.] 7761. Taylor. Treatment and finish of leather. April 2.

„ 8368. Russell. Adhesive compound or cement. April 12.

„ 8551. Möller-Holtkamp. *See under* V.

„ 8788. Faucheux and Boissière. Process for the manufacture of gelatine and glue.* April 16.

XV.—MANURES, Etc.

[A.] 7841. Sangster. Ammoniacal and phosphatic fertilisers. April 5.

[C.S.] 8931 (1903). Cross and Dunbar. Combination of organic and inorganic materials and substances for manuring and fertilising agricultural and horticultural soil, &c. April 20.

„ 26,150 (1903). Horteloup. *See under* XIX.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 7560. Sharp. Starches March 30.

„ 8544. Cross. Manufacture of a crystalline sugar. April 13.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 7329. Dewar. Malting and apparatus therefor.* March 28.

„ 8461. Street and Street. Purification or filtration of liquid refuse discharged from distilleries, breweries, paper works and other places.* April 13.

[C.S.] 8766 (1903). Harvey. Means for aërating beer or the like. April 13.

„ 3682 (1904). Lapp. Process for providing iron vessels, such as those in which beer is prepared or stored, with a protective coating, more particularly applicable to pasteurising vessels. April 20.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—Foods.

[A.] 7594. Thorp. Preservation of food products. March 30.

,, 7631. Ohlsson. Method of sterilising food products and the like. March 31.

,, 7667. Butler. Production of milk in the dry condition known as milk powder, applicable also to the treatment of analogous matter for reducing it to a dry or powdered condition. March 31.

,, 7895. Braga. Manufacture of extract of meat.* April 5.

,, 7896. Braga. Manufacture of extract of meat.* April 5.

,, 7955. Graham. Flour, &c., and bread and other foods made therefrom. April 6.

,, 8129. Fürst. Dietetic food preparation. April 8.

,, 8167. Wrigley and Chapman. Manufacture of custard powder. April 9.

[C.S.] 12,159 (1903). Mapleton. *See under* XII.

,, 15,606 (1903). Thompson (Act.-Ges. f. Chem. Ind.). Nutritive substance. April 7.

,, 26,150 (1903). Horteloup. *See under* XIX.

,, 3682 (1904). Lapp. *See under* XVII.

(*B.*)—Sanitation; Water Purification.

[A.] 7383. Porion. Process and apparatus for disinfecting sewage and like waters.* March 28.

,, 8461. Street and Street. *See under* XVII.

[C.S.] 14,258 (1903). Eichen. Purification of sewage. April 7.

(*C.*)—Disinfectants.

[A.] 8415. Lake (F. Stearns and Co.). Antiseptic compound, and process for manufacturing same.* April 12.

[C.S.] 27,889 (1903). Raetz. Process of solidying such liquid compounds of phenol or cresol and soap which are soluble in water and form emulsions, intensifying at the same time their antiseptic properties. April 7.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 7819. Ortmann. Manufacture of celluloid or like compositions. April 2.

,, 7885. Elias. Process of paper manufacture. April 5.

,, 8298. Fell (Bigelow). Pulp washing and filtering machine.* April 11.

,, 8433. Serkowski. *See under* V.

,, 8461. Street and Street. *See under* XVII.

[C.S.] 7341 (1903). Lederer. Manufacture of variously shaped industrial objects from cellulose compounds. April 7.

,, 10,243 (1903). Balston and Briggs. Manufacture of soluble acetylised cellulose derivatives. April 13.

[C.S.] 26,150 (1903). Horteloup. Treatment of furze to obtain a food for cattle, paper pulp, and an ammonium salt which may be used as a manure. April 7.

,, 5126 (1904). Voigt. *See under* XXII.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 7534. Hamel. Manufacture of concentrated formic acid from formates. March 30.

,, 7875. Johnson (Koepp and Co.). Manufacture of formates. April 5.

,, 7954. Newton (Bayer and Co.). Manufacture of a new pharmaceutical product. April 6.

,, 8302. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of derivatives of barbituric acid. April 11.

,, 8543. Abel (Act.-Ges. f. Anilinfabr). Manufacture of derivatives of barbituric acid. April 13.

[C.S.] 8095 (1903). Ritsert. Manufacture of medical anæsthetic compounds. April 7.

,, 11,137 (1903). Imray. (Meister, Lucius, and Bruning). Manufacture of derivatives of cyclohexane and cyclohexene. April 7.

,, 12,282 (1903). Zimmerman (Chem. Fabr. Schering). Manufacture of products useful in therapeutics. April 13.

,, 12,773 (1903). Johnson (Kalle and Co.). Manufacture of colloidal products containing bismuth oxide. April 13.

,, 12,798 (1903). Langheld. Therapeutic products. April 13.

,, 13,889 (1903). Howorth (Knoll and Co.). Manufacture of certain new cotarnin salts. April 7.

,, 14,430 (1903). Newton (Bayer and Co.). Manufacture of the monoformyl derivative of 1·3-dimethyl - 4·5 - diamido - 2 6 - dioxypyrimidine. April 13.

,, 26,089 (1903). Verley and Givaudan. Manufacture of ionone. April 20.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 7490. Rusher and Baudinet. Explosive.* March 29.

,, 7511. Selwig. Nitrating fibrous matter. March 29.

,, 7893. Wetter (J. D. Riedel). Sulphur compounds and priming compositions suitable for the manufacture of matches. April 5.

,, 8041. Mikolajczak. Manufacturing dinitroglycerine and dinitroglycerine explosives and powder.* April 7.

,, 8678. Tulloch. Manufacture of a high explosive. April 15.

[C.S.] 8278 (1903). Thomson and Thomson. Manufacture of nitrocellulose and apparatus therefor. April 13.

,, 15,268 (1903). Johnson (Chem. Fabr. Griesheim-Elektron). Manufacture of matches. April 13.

,, 5126 (1904). Voigt. Process of manufacturing nitrated cellulose. April 20.

Printed and Published by Eyre and Spottiswoode, East Harding Street, London E.C., for the Society of Chemical Industry.—P 9654.

JOURNAL OF THE
Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 9.—Vol. XXIII. **MAY 16, 1904.** **No. 9.—Vol. XXIII.**

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum:
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each; 1902 *et seq.*, 1/9 each.

The Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D. F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
F. Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.

COUNCIL FOR YEAR ENDING JULY 1904.

President: Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.

Vice-Presidents:

Prof. P. Phillips Bedson.
Prof. Marston T. Bogert.
E. Carey.
Dr. John Clark.
E. Grant Hooper.
Ivan Levinstein.
Dr. R. Messel.
W. H. Nichols.
Dr. F. B. Power.
Prof. H. R. Procter.
Dr. Jos. W. Swan, F.R.S.
Thos. Tyrer.

Ordinary Members of Council:

Dr. Edw. Divers, F.R.S.
Dr. J. Grossmann.
H. Hemingway.
Prof. W. R. E. Hodgkinson, Ph.D.
David Howard.
Dr. J. Lewkowitsch.
N. H. Martin.
Max Muspratt.
B. E. R. Newlands.
Prof. W. J. Pope, F.R.S.
Frank Scudder.
Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

CANADIAN.	*Prof. W. R. Lang.*	Alfred Burton.
LIVERPOOL.	*F. H. Tate.*	W. R. Hardwick.
LONDON.	*Walter F. Reid.*	Julian L. Baker.
MANCHESTER.	J. Carter Bell.	Julius Hübner.
NEWCASTLE.	Dr. J. T. Dunn.	F. C. Garrett.
NEW YORK.	Dr. V. Coblentz.	Dr. H. Schweitzer.
NOTTINGHAM.	J. T. Wood.	S. R. Trotman.
SCOTTISH.	*T. L. Patterson.*	Dr. Thos. Gray.
SYDNEY, N.S.W.	Prof. A. Liversidge.	T. U. Walton.
YORKSHIRE.	*Jas. E. Bedford.*	Thos. Fairley.

Honorary Treasurer:
Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary:
Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

Telegraphic Address: 59, Palatable, London.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.
G. Beilby.
J. Carter Bell.
Joseph Bernays, M.I.C.E.
H. Brunner.
Edw. Divers, M.D., D.Sc., F.R.S.
Sir John Evans, K.C.B., F.R.S.
T. Fairley.
Prof. A. G. Green.
Samuel Hall.
Otto Hehner.
John Heron.
D. B. Hewitt, M.D.
Prof. W. R. E. Hodgkinson, Ph.D.
E. Grant Hooper.
David Howard.
Julius Hübner.
Prof. A. K. Huntington.
Wm. Kellner, Ph.D.
Charles A. Kohn, M.Sc., Ph.D.
Ivan Levinstein.
J. Lewkowitsch, Ph.D.
A. R. Ling.
W. Macnab.
N. H. Martin.
B. E. R. Newlands.
John Pattinson.
Prof. W. J. Pope, F.R.S.
F. B. Power, Ph.D.
Prof. H. R. Procter.
Boverton Redwood, D.Sc.
Walter F. Reid.
John Spiller.
W. S. Squire, Ph.D.
L. T. Thorne, Ph.D.
Thomas Tyrer.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who propose to attend the meeting are requested to inform the General Secretary, as soon as possible, by what steamer they will travel. Each boat will be met on arrival at New York by a representative of the Reception Committee, with a list of apartments, at various prices, which have been reserved for the Society. The same system will be observed at all the other cities visited by the special train. A revised programme appeared in the March 31st issue.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Wm. H. Nichols has been nominated to the office of President under Rule 8; Dr. Edw. Divers, Prof. W. R. Eaton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. Parker have been nominated Vice-Presidents under Rule 8; and Sir Wm. Ramsay has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the Annual General Meeting at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

MR. WALTER F. REID IN THE CHAIR.

THE VOLATILISATION OF LEAD OXIDE FROM LEAD GLAZES INTO THE ATMOSPHERE OF A CHINA GLOST SAGGAR, AND ITS EFFECT UPON THE LEADLESS GLAZE WARE IN THE SAME SAGGAR.

BY W. THOMASON, F.I.C.

Concurrently with the agitation against the use of raw lead in china and earthenware glazing operations, there have been made by most potters more or less serious attempts at the production of a suitable glaze for the above purposes containing no lead oxide whatever, and still more extensive experiments for the substitution of raw lead by fritted lead in one or other of its forms. With the composition and solubility of these glazes I do not propose to deal in this paper, but wish to direct your attention to the important part the volatilisation of lead oxide from even fritted glazes may play in the production of the smooth surface so necessary in the above wares. Most makers entering upon the manufacture of leadless glazed goods have met with initial successes, and have been encouraged to pursue the matter further, with the result in many cases that the bulk experiments have not been so successful as the earlier trials, though absolutely no changes may have been made in the composition of the glaze and body worked upon. These disappointing results have been somewhat vaguely ascribed to the fact that lead oxide in the glost oven has been transferred on firing during the earlier trials from the lead-glazed walls of the saggar, and from the stilts upon which the vessels are placed in the saggar to the surface of the leadless-glazed ware operated upon, but no measure of this transference has, up to now, been attempted. This would be a sufficient explanation if it could be shown that the actual absorption of lead oxide by a leadless glaze from a lead-glaze surface near to it, amounts to more than a few decimal points per cent., and it is with the extent to which such absorption may go on that I wish to deal in this paper.

To obtain any quantitative reading of the lead gathered in process of firing under the above conditions, it is necessary first of all to ascertain the ratio of glaze to bisque, since when fired the two cannot be separated, and consequently the analyses have to be made upon the mixture of these two bodies.

In the first experiment, china saucers were selected as being capable of accurate weighing, and yet fairly representing flat ware. These were carefully dried, weighed, dipped into a leadless glaze, and again dried and weighed, with the result as shown in Table A, which also indicates the effect of firing upon the weights. The saggars and stilts in this experiment were washed with a lead glaze containing about 30 per cent. of lead oxide, of which the whole is fritted. Referring to Table A, we find the most noticeable feature is an actual gain in weight on firing in every instance, and that the increases are fairly regular. There has therefore been an appreciable absorption of some material which might be an alkaline oxide, boric acid, or more probably lead oxide. But the actual increase is more than is apparent, for the unfired glaze in question contains as one of its constituents raw china clay, which sustains a loss of 11 per cent. due to combined water on ignition.

The glaze contains 28·7 per cent. of raw china clay, which at 11 per cent. combined water would lose 3·16 per cent. on total glaze when fired; and, therefore, the actual accumulation of lead, or other oxide, amounts by direct weighing of the ware to the apparent increase in weight plus 3·16 per cent. on the glaze alone.

Table A.

Leadless-glazed Saucers in Saggar washed with Lead Glaze.

Saucer.	Weight of Biscuit.	Biscuit dipped and dried.	Biscuit Glost fired.
No.	Grms.	Grms.	Grms.
1	114·12	121·85	122·15
2	110·13	121·60	121·86
3	103·95	113·35	113·60
4	107·02	117·40	117·67
5	103·35	112·75	112·87
6	112·98	122·60	122·87
7	108·34	119·15	119·30
8	112·79	120·50	120·62
9	107·42	Broken in Dipping House	
10	110·45	118·25	118·40
11	113·35	123·30	123·52
12	120·96	130·10	130·40
Totals (excluding No. 9)	1,217·44	1,320·85	1,323·26

Excluding No. 9 we have the following totals:—Biscuit, 1217·44 grms. Biscuit glazed but unfired, 1320·85 grms. Therefore, glaze equals 103·41 grms. Weight of glazed ware after firing equals 1323·26 grms. Therefore, increase of weight during firing equals 2·41 grms., equals 2·33 per cent. of the glaze alone.

From Table A we find on 11 saucers 103·41 grms. of dry glaze were used. The increase on weight on firing amounts to 2·41 grms. – 2·33 per cent. on glaze alone. Loss of combined water sustained by the glaze = 3·16 per cent. Total foreign matter accumulated is therefore 5·49 per cent. The saucers were now crushed, and examined for lead oxide on the average sample. Analysis showed 0·56, 0·50 = 0·53 per cent. lead oxide on glazed biscuit. Calculating from Table A, we find that on the glaze alone this increase is equal to 6·78 per cent. It is, however, practically impossible in a factory where most of the glazes contain lead to produce an entirely lead-free glaze, owing to the same frit kilns and mills being employed for glazes of both kinds. Consequently the leadless glaze was examined for lead oxide, and found to contain it to the extent of 0·25 per cent. The actual accumulation of lead oxide in kiln is therefore by analysis 6·78 per cent. – 0·25 per cent. = 6·53 per cent. The gain was found to be, by direct weighing, 5·49 per cent. The absorption may therefore attain to a sufficiently high figure to have a very appreciable effect upon the surface of the glaze.

The above figures, while substantially confirming each other, make it possible that an exchange of oxides has taken place, and a small quantity of alkaline oxides, or boric acid, has been transferred to the lead-glazed saggar. On the other hand, the variation between the results obtained by different methods may be merely experimental, and, as the quantity of glaze worked upon is necessarily small, this is a not unlikely explanation.

Having dealt with saucers representing flat, it was thought necessary to repeat the trial on cups representing hollow ware. The process was the same as before, so far as the dipping, weighing, and firing are concerned; but a blank series of experiments was carried on in which a saggar was washed out with the same glaze as that in which the ware was dipped. This was done because it appeared possible that not all of the water might be capable of removal from the dipped bisque by drying; for the borax frit used in the glaze, when finely ground, becomes partially hydrated, and the water thus held might not be completely removed at the temperature to which it was convenient to raise the ware in drying. Tables B and C represent the weights, &c., of the cups in question.

TABLE B.

Leadless-glazed Cups in Saggar washed with Lead Glaze, as in Table A.

Cup.	Weight of Biscuit.	Biscuit dipped and dried.	Biscuit Glost fired.
No.	Grms.	Grms.	Grms.
1	103·170	109·160	109·169
2	85·128	91·089	91·110
3	94·531	100·389	100·465
4	102·790	108·282	108·357
5	100·689	107·334	107·364
6	102·237	108·382	108·425
7	103·624	110·932	110·922
8	102·692	109·327	109·445
9	100·040	106·216	106·233
10	99·040	105·737	105·760
11	104·529	111·144	111·245
12	108·587	114·439	114·454
Total...	1207·057	1282·431	1282·949

Therefore, glaze on biscuit equals 75·374. Increase of weight during firing equals 0·518. Increase of weight upon glaze alone equals 0·69 per cent.

In Table B we find a similar result of firing upon the weights of the ware as in Table A, though different in degree, and No. 7 is an exception in actually losing weight—this is due, in all probability, to the accidental removal of glaze during setting. On the cups 75·374 grms. of glaze were used. Actual increase in weight, 0·518. Increase, 0·69 per cent. on the glaze alone.

TABLE C.

Leadless-glazed Cups in Saggar washed with Leadless Glaze.

Cup.	Weight of Biscuit.	Biscuit dipped and dried.	Biscuit Glost fired.
No.	Grms.	Grms.	Grms.
1	83·319	89·301	89·060
2	92·122	97·782	97·540
3	97·760	104·422	104·139
4	97·431	103·313	103·72
5	103·535	109·390	109·134
6	103·564	109·650	109·380
7	94·869	101·424	101·152
8	101·885	107·671	107·415
9	89·725	96·382	96·090
10	88·829	95·117	94·854
11	107·619	114·339	114·053
12	104·027	111·055	110·745
Total...	1164·685	1239·826	1236·634

Therefore, glaze unfired on biscuit equals 75·141 grms. Decrease during firing equals 3·192 grms. Decrease equals 4·25 per cent. on glaze alone.

In Table C 75·141 grms. of glaze were used. Actual loss in weight, 3·192 per cent. Decrease, 4·25 per cent. Total accumulation of lead, or other oxides, 0·69 + 4·25 per cent. = 4·94 per cent.

Examining the powdered cups for lead oxide, it was found to exist in the ware to the extent of 0·37 per cent. Consulting Table B, we find this to be equal to 6·33 per cent. of the glaze alone. The leadless glaze here worked upon contained 0·67 per cent. adventitious lead oxide; therefore actual gain in lead oxide equals 5·66 per cent. We thus have two sets of figures corroborating each other as before, and establishing that, under certain conditions, transmission of lead oxide does take place from the walls of the saggar to the ware in the saggar, and that such transmission goes on to an extent which may easily account for early successes experienced by many manufacturers, and their less successful results in bulk; for it is the custom to use the scrapings from the ware in washing out the saggars, and these scrapings, consisting at first of a lead glaze, as more and more leadless ware is used will become correspondingly reduced in lead oxide.

The figures quoted above scarcely establish whether there is, or is not, a corresponding transmission of alkaline oxides or boric acid from the ware to the walls of the saggar, as they are necessarily not accurate to within several decimal points per cent., by reason of the low ratio of glaze to glazed ware—but so far as they do so, they point to the probability of this being the case. For the purpose of this paper, however, it does not much matter whether an exchange does or does not take place; since in either event it is obvious that the glaze on the ware becomes very considerably modified in its composition, and that the tendency will be for it to develop some of the well-known qualities of leaded glaze. To ascertain the probable experimental error, the ware as per Table C was crushed, and an average sample examined for lead oxide.

Lead oxide in this sample, 0·05 per cent. on body and glaze; 0·82 per cent. on glaze alone. Examination of the glaze before firing showed 0·67 per cent. Consequently the errors in analysis do not amount to more than 0·15 per cent. in this case, and probably the figures for lead accumulation, as shown by analysis, are not further from the truth than this.

It has been pointed out that lead oxide can be found in the glaze of some of the leadless-glazed wares on the market; but while there may be instances of makers thus wrongly describing their goods, it is more probable that the lead oxide is derived from the frit kilns in preparation of the glaze, or by the above-mentioned transference in firing.

In advancing the 5—6 per cent. lead oxide which a leadless glaze may gather in firing as an explanation of some of the successes experienced by the manufacturers in their earlier attempts at this work, and their less marked success in bulk, I do not mean it to be inferred that this accumulation of lead oxide is necessary for the production of first-class leadless-glazed ware—in point of fact, there is not much to choose between the cups of Tables "B" and "C," but it is evident that the presence of lead vapour may have a steadying effect on a leadless glaze, and such glaze may come to the necessary brightness at a fire just not sufficient to develop the surface in leadless-washed saggars.

Leadless-glazed wares, fired in leadless-washed saggars, are being produced by many firms at present, but for the most part there is either a somewhat lower standard of selection set than if lead glazes are used, or an extra price is charged if the lead-glaze standard be maintained.

The presence of so high a percentage of 0·67 per cent. of lead oxide in a glaze intended to be leadless may appear anomalous to some, but, as I have explained earlier, it is almost impossible, in a factory where lead is largely used, to make a wholly leadless glaze without duplicating the grinding plant and frit kilns; and, recognising this difficulty, for purposes of exemption under special rules for earthenware and china trades, the Government considers a glaze leadless if not more than 1 per cent. of lead oxide be present in the dried material.

THE PREPARATION OF LEAD GLAZES OF LOW SOLUBILITY, AND SOME POINTS TO BE OBSERVED IN THE PROCESS.

BY W. THOMASON, F.I.C.

The fritting of lead in the manufacture of lead glazes is one of the oldest, and, under certain conditions, it may also be one of the best, methods of preventing plumbism amongst the workers in these glazes. So far as this country is concerned, however, up to 1898 the mere act of fritting had been looked upon as all that could be done in the matter, and no regard had been taken of the composition of the frit. The act of fritting was probably in itself not without a good effect upon the health of the workers; since the vitrified lead oxide (as monosilicate for the most part) was less dusty when dried on the ware than was the white lead for which it was substituted, and was consequently less liable to be taken into the system by breathing. Here, however, its utility ended, for when it did gain access to the stomach, through neglect of the ordinary dictates of cleanliness on the part of the workers, or through defective ventilating and cleaning of the dipping house, &c., by some of the manufacturers, its solubility in the gastric juice proceeded with almost as great rapidity as did that of white lead, and cases of plumbism have occurred in factories where none but fritted lead of this composition was employed.

Up to 1898 the use of fritted or raw glazes was optional to the manufacturers, but in that year the Home Office commissioned Drs. Oliver and Thorpe to inquire into the best means of checking the growth in the number of cases of lead poisoning which were yearly occurring in the industry, and the results of the enquiry are embodied in the Blue Book of 1899 (C. 9207). The Commission visited the principal English and Continental potteries, and the trend of the report was in favour of stricter preventive measures in the shape of age limits, medical examination of females (in which sex the disease was relatively high in this country), suspension of workers suspected of the disease, greater cleanliness in such parts of the factory as employed lead oxide, the more extensive use of ventilating fans, &c. These regulations, while beneficial in themselves, and largely suggested by the manufacturers, are not in any way chemical, and have therefore little interest for this Society.

The Commission further reported upon the form in which lead oxide was employed in various continental works, and its effect upon the percentage of plumbism amongst the workers, and found that the practice of fritting was distinctly in the direction of safety to the workers, though no official register of the cases of lead poisoning is kept on the Continent, as is the case in this country. In the Continental works, the lead when fritted was for the most part lead bisilicate—a harder and more insoluble form than any in considerable use in this country at the time; though a few months previous to the issue of the report Messrs. Doulton and Co., Lambeth, had arrived at a similar conclusion as to the low poisoning effects of glazes made with this bisilicate compared with raw lead, or monosilicate glazes, and had succeeded in making most of their glazes with this harder material. But the advisers to the Home Office did not consider the results by means of bisilicate to be, as regards solubility, so good as a further chemical study would produce, and in this opinion they were justified; for by adopting a glass proposed by Dr. Thorpe, a glaze containing 22 per cent. of lead oxide could be produced, having an almost inappreciable solubility. A low solubility is, however, not the only property which a glaze should possess. A glaze, particularly a lead glaze, must contain certain proportions of raw material, such as china clay, Cornish stone, &c., if it is to work satisfactorily in the dipping tub, and no amount of grinding will produce precisely the same effect upon a frit as does the presence of a proportion of such raw material in the prevention of settlement from the slop.

The 22 per cent. frit would have made practically all the earthenware and china glazes in use in North Staffordshire district too much fritted, or would have sent up heir melting point, whilst for majolica purposes, it was mpracticable on account of its composition, *i.e.*, its low ead content. Consequently, Dr. Thorpe did not press his formula, but proceeded to show that by maintaining a certain ratio between all the bases of the frit, calculated to lead oxide, and all the acids calculated to silica, low olubilities must result. The weakness of such a broad tatement was that no limit was put to the proportion in which the silica might be replaced by boric acid. Dr. Thorpe did not examine any frit containing more than per cent boric acid, whereas it would be possible for us t Lambeth to include this acid to the extent of over 0 per cent. in the frit, if it were thought necessary to do o, and still preserve the ratio as proposed by Dr. Thorpe. The ratio as finally proposed by Dr. Thorpe was that all ases thus calculated should not exceed 1·45 : 1·00 as compared to the acids calculated to silicic acid, yet, at a meeting of the Royal Institution previously the same observer had announced that 2·00 : 1·00 would be a safe ratio. This alteration meant much to the manufacturers, since it made a more acid and, consequently, more infusible frit necessary, and, in addition, tended to further limit the lead oxide in the frit, and therefore in the finished glaze. It meant even more than this, for, under the original figures of 2·00 : 1·00, the most regularly used Continental frit would have been available for English potters, *viz.*, lead bisilicate; but under the latter ratio this was excluded from the frits which would fall within the Home Office requirements. On the 1·45 : 1·00 ratio Dr. Thorpe recommended to the Home Office that after a certain period all glazes should have a solubility not exceeding 2 per cent. lead oxide when treated in a certain manner with hydrochloric acid, of the average acidity of gastric juice, *i.e.*, 0·25 per cent. The frits capable of producing such glazes were shown to range in lead oxide from 16 per cent. to 44 per cent.

There are, however, majolica colours which cannot be produced by so low a lead content as even the 44 per cent., and consequently by the adoption of this frit such glazes would have been excluded from use.

Probably the most serious objection to the 2 per cent. standard is, that in it are included glazes of all classes, from majolica to earthenware and china, which glazes differ fundamentally in their melting points and lead contents.

Obviously, therefore, the standard (whatever may have been practicable to makers of earthenware and china) was out of the question for majolica, and this has been partially recognised, although the proposal, if it had become law in its original form, would have included glazes of all melting points.

Negotiations proceeded between the Home Office and the potters, and the following objections were raised to the 2 per cent. standard:—(1) English potters are being asked to accept conditions never before employed by any potters in the world. (2) On the Continent, lead bisilicate has been found to prevent plumbism, so there would appear to be no good reason why English potters should accept a harder and more inconvenient frit. (3) That lead bisilicate, while producing a non-poisonous glaze would give with most earthenware and china glazes a solubility, if not over 2 per cent., at least so near to that figure as to make it unsafe for the potters to accept the standard. (4) That the solubility of the frit might vary considerably with its degree of fineness.

In connection with the objection No. 4, figures were adduced by the representatives of the potters upon work done by Messrs. Jackson and Rich to show that the same glaze might, in different degrees of subdivision, yield anything from 1·5 per cent. to 17·5 per cent. lead oxide, to 0·25 per cent. hydrochloric acid.

The negotiations, unfortunately, were productive of no good result, and the matter was referred to arbitration, the manufacturers refusing to accept any standard of solubility whatever, and withdrawing their previous offer to frit the lead in all their glazes without accepting a fixed standard, and the Home Office relying on the 2 per cent. standard as advocated by Dr. Thorpe.

The arbitration award has now been made, and by it all manufacturers who conform to a 5 per cent. standard of solubility are exempted from liability should a worker acquire lead poisoning in a factory where the proper rules of cleanliness are observed by the manufacturer; while such makers as do not accept this standard must accept liability for damage to the health of the worker on lines similar to the Workmen's Compensation Act, with liability for the first fortnight during which the worker is incapacitated.

The foregoing *résumé* of the proceedings between 1898 and the present date, while probably unnecessary for many here to-night, has been thought desirable for pointing the importance of the following figures, in which glazes made by lead bisilicate are considered.

Government Method of Testing the Solubility of a Glaze.—A portion of the dried glaze is shaken with one thousand times its weight of 0·25 per cent. hydrochloric acid at 15° C. for a period of one hour; allowed to settle for one hour and filtered. The lead in the filtrate is then estimated, and returned as the solubility of the glaze in question.

The method is open to criticism, particularly as to its temperature and the time of contact of acid and glaze, but it appears to give in practice a good ratio of solubilities of various glazes. Previous to the issue of the Government method, Messrs. Doulton and Co. had used 0·20 per cent. hydrochloric acid at 37·7° C. as representing more nearly the composition and temperature of gastric juice; but inasmuch as to work at ordinary temperatures is more convenient than at the temperature of the human body, the Government method was adopted, and this was further necessary to obtain concordant results with other workers.

The frit used at Lambeth is lead bisilicate, and the reasons for selecting this compound as the most suitable for general purposes are the following:—(1) It contains only two materials, both of which can be obtained almost chemically pure. (5) It is known to be fairly insoluble in acids, and is yet capable of being conveniently run down in a frit kiln, and will thence flow into water, leaving the bottom of the kiln clean. (3) Its theoretical composition is 65 per cent. lead oxide, and 35 per cent. silica, consequently it can be used in the preparation of glazes of high lead content. The compound is made by intimately mixing red lead, or litharge, and dry flint in the easily calculated proportions, transferring to a frit kiln, and when completely vitrified, and fluid throughout, running off into water, which breaks up the glass into small portions.

The most important points in the preparation are the intimate mixing of the materials, and their complete combination in the kiln; since, if either be defective, a high solubility will result. The resulting frit is not, strictly speaking, lead bisilicate; for analysis of the glass, as run from the kiln, shows the following proportions:—

——	By Analysis.	By Theory.
	Per Cent.	Per Cent.
Lead oxide	61·71	65·02
Alumina	1·00	..
Silica	36·88	34·98
Totals	99·56	100·00

It is therefore evident that the frit has gathered some alumina and silica from the hearth of the kiln. From the composition of the fireclay bottom of the kiln, and the amount of alumina taken up, it also follows that some lead oxide has been lost by volatilisation. The composition of the frit is about one-third of the distance between lead bisilicate and trisilicate, and the loss of lead oxide is about equally accounted for by absorption from the bed of the kiln and by volatilisation.

The above figures are confirmed by analysis of lead bisilicate from two North Staffordshire houses, and may be taken to represent very closely the average composition of commercial bisilicate. This frit is referred to as bisilicate in the following figures. The glaze is now prepared by grinding the lead frit with a borax frit and some raw material, preferably china clay or Cornish stone, which assist to prevent its settlement in the dipping tub.

One of the points raised by the manufacturers in opposing the Home Office standard was that great increases of solubility might be caused by excessive grinding of the glaze. These figures were obtained from the researches of Messrs. Jackson and Rich, who, as stated before, found that solubilities of 1·5 per cent. to 17·5 per cent. could be obtained from a frit, according to its fineness. For their purpose these gentlemen elutriated the frit and examined the finest and coarsest particles, but what they did not show, so far as I am aware, was the proportion in which these extremely fine particles would be produced in practical grinding. This is most important, since, if in very small quantities, their solubility, though high, might have very little effect on the solubility of the glaze as a whole. The following experiments show that the glaze, as wet-ground in different mills, is not capable of any such variation in solubility.

Glaze contains 14 per cent. total lead oxide.

Series A.

Mill running with one-half its normal load.

	Soluble Lead Oxide, per Cent.
Ground 9 hours	1·64*
„ 18 „	2·26

* Easily passes 160-mesh, and is in condition for dipping.

Series B.

Mill running with its full load.

	Soluble Lead Oxide, per Cent.	
Ground 9 hours	0·90	
„ 18 „	1·20	
„ 27 „	1·36 1·44	mean 1·40*
„ 36 „	1·51 1·55	mean 1·53

* Easily passes 160-mesh.

The above figures were obtained by grinding the glaze in an ordinary granite mill, and show that the first day's grinding is the most productive of soluble lead oxide, and that the subsequent days are of successively diminishing effects. Series A and B represent the effect of prolonged grinding in mills of a particular class, but, so that no error could be made, the experiment was repeated with a grinding cylinder of the Alsing pattern, and the results are stated in Series C.

Series C.

Glaze contains 14 per cent. total lead oxide. Ground in Alsing cylinder.

	Soluble Lead Oxide, per Cent.	
Ground 6 hours	0·88	
„ 12 „	1·05	
„ 18 „	1·29	
„ 24 „	1·45 1·53	mean 1·49†

† Pass 160 lawn.

Thus substantially confirming Series A and B.

The figures given above are from a glaze which has since been discarded as having an insufficient lead content for our purpose at Lambeth, but the ratios will stand. While these figures show that Messrs. Jackson and Rich's contention, however theoretically accurate it may be, has not the practical bearing which may be read into it; they, nevertheless, prove that some considerable effect is produced, and that it would not be safe to work so near the standard of solubility as a manufacturer would be doing if he used the average continental proportions, and the usual continental frit.

Dr. Thorpe contended that, though under no rules, the continental makers were conforming to the 2 per cent. standard, and while this would be mainly true, there certainly would be occasions on which they would be exceeding the limit.

Another point in the examination of the glazes for solubility, is that the first hour removes by far the greater proportion of the soluble lead oxide, and that subsequent shaking has less considerable effect, as witness the following figures:—

	Lead Oxide. Per Cent.
One hour shaken, one hour standing:—	
Glaze A	1·64
Glaze B	2·26
Two hours shaken, two hours standing:—	
Glaze A	1·91
Glaze B	2·52

Messrs. Jackson and Rich have found similar effects from continued shaking with acid, and ascribe the cessation of chemical action to a film of silica which the acid separates from the lead contained in the glaze. They find that the same frit in the presence of pebbles does not similarly lose in solubility on shaking; and that a frit which has become insoluble when washed with caustic soda, again becomes partially soluble in acid. Their point that the silica is the cause of the reduction in speed of solubility is therefore supported, but not entirely established, as the pebbles may be rubbing down the frit, thus producing more soluble particles, and the action of the caustic soda may result in surface decomposition of the frit, and not in merely removal of silica from the surface.

Dr. Thorpe has opposed their contention by assuming that the frit which they worked upon was wanting in homogeneity, and that what at first dissolved was in reality a more basic frit present in the mass worked upon. He supports his argument by showing that in seven frits which he examined, the basic oxides passing into solution do not bear the same ratio to each other as existed in the original frit worked upon, this proving what was presumed to be a simple glass, to be, in reality, a mixture of glasses of different solubility. The net result is, that starting from such a frit as commercial bisilicate, it is possible to get, within the limits of practical grinding, variations in solubility of a glaze amounting to from 25 per cent. to 35 per cent. of its normal solubility, but that such variations as anticipated by Messrs. Jackson and Rich are quite impossible. That more serious differences are possible under other conditions will be shown later on.

The bulk of the lead glazes used in the Lambeth Works are coloured, and have a low melting point. They therefore contain more lead oxide than do the earthenware and china glazes in North Staffordshire; and however possible or impossible it may be to adopt a more insoluble frit than bisilicate for earthenware and china, it is quite impossible to do so for majolica, &c.; since the more insoluble frits, in many instances, contain less lead oxide than do our finished glazes, and yet I consider that at Lambeth we are working with as little lead oxide as is compatible with good results, and reasonable losses in process. For the past three or four years we have used all our lead fritted as bisilicate in two of our departments, and during that period have produced thousands of gallons of majolica glazes ranging from 2·5 per cent. to 3·0 per cent. of soluble lead oxide. The results are satisfactory, though certain details of dipping and firing had to be mastered. Up to somewhat less than two years ago there still remained a department in which all the glazes were fritted, but of no definite solubility, *i.e.*, old glazes containing 60 to 70 per cent. of lead oxide, of which most was soluble, and of such glazes many are still in use elsewhere. To obtain exemption under the then provisional 5 per cent. standard, it was necessary for a change to be made in this department, and in doing so an unexpected source of variation in solubility came to light. The same frits were in use as in the departments already conforming to the 5 per cent. standard, and the mills for the final wet grinding were of the same pattern; there was a difference, however, in the treatment of the frits before being introduced into the mill for the final grinding. In this new department the frits were dry-ground into a fine flour in a cylinder, whereas in the other instances the dry grinding was not carried beyond a coarse meal. The glazes prepared under these conditions did not yield the customary 2·5 per cent. to 3 per cent., but as high as 7·0 per cent. to 7·5 per cent. The increase might have been due to several causes: (1) Lead oxide, accidentally present in the borax frit which is supposed to be leadless; (2) Imperfectly prepared bisilicate; (3) Different treatment of the frit in the dry state. The borax frit on analysis accounted for 0·70 per cent of soluble lead oxide. The bisilicate was normal in composition, and well fused, and, further, during the period in which high solubilities were being obtained in one department, the customary 2·5 per cent. to 3·0 per cent. was ruling in the other two, although the frits were from the same batch.

Accordingly the frit was less finely dry-ground, and the solubility at once fell to 4·40 per cent. and 4·52 per cent. in different samples.

The rougher dry grinding had occasioned a drop of more than half the difference in solubility between the glazes used in the different departments; consequently, the rough grinding was made rougher, and the frit merely reduced to pass a 12-mesh sieve. The glazes immediately fell in solubility to 2·8 per cent. and 3·02 per cent. in two different samples. This brought all departments into line, and within the 5 per cent. limit of solubility when ground to pass the 160 lawn. The glazes contain about 30 per cent. of lead oxide, but by using a very coarsely-crushed frit, and carefully watching the grinding, it has been found possible to produce a glaze containing 55 per cent. of lead oxide of solubility of about 3 per cent. to 3·5 per cent.

It appears to me that the unlooked-for effect of dry grinding considerably supports the theory of solubility being more influenced by the surface exposed to the solvent, than to irregularity of composition; nevertheless, the contention that the solubility may be much influenced by wet grinding is not supported by these results. I believe the dissimilarity between two glazes of the same composition, but prepared, one largely by dry grinding, and the other almost entirely by wet, can only be accounted for by the different shapes which the small particles of frit assume in the processes; those in the dry-ground glaze being angular, and those in the water-ground essentially rounded and consequently exposing the smallest surface to the solvent in proportion to their mass.

The experiments referred to in this paper cover a period of four years, and represent tons of material; and it is the fact that they are the result of actual manufacturing experience, and not merely laboratory trials, which has prompted me to bring them before you.

Table showing the effect of fine dry grinding of Lead Frit as a preliminary to the final wet grinding. In all cases the particles pass a lawn of 160 *meshes to the linear inch.*

State of Frit when introduced into Mill for wet grinding.	Lead Oxide contained in Glaze.	Lead Oxide soluble in 0·25 per Cent. HCl.	Percentage soluble of the Lead Oxide present.
	Per Cent.	Per Cent.	Per Cent.
Finely dry-ground	30—32	7·0—7·5	23·4
Coarsely dry-ground.......	30—32	4·40—4·52	14·4
Crushed to pass a No. 12 sieve.	30—32	2·8—3·02	9·3
Extremely coarse, having all fine dust removed by sieving.	55	3·0—3·5	5·9

There is no doubt but that for purposes such as those at Lambeth, it is possible to produce glazes, either colourless or coloured, for which a 5 per cent. standard of solubility affords margin for an occasional slight variation in the composition of frits, and of fineness of grinding. This statement is made on the evidence of about two hundred observations of solubility, none of which have exceeded the 5 per cent. limit, except under the conditions of dry grinding above alluded to. To ensure success, it is, however, essential that that the condition of the frit kiln be considered, and that a good stock of lead frit be prepared before going on to make the borax frit, or *vice versâ*. Failing this, the solubility will rise from one of two causes:—(1) Slight residues of lead frit always remain in kiln, and these are taken up by the following borax frit, and rendered soluble, making their way into the glaze through the borax frit. (2) Residues of borax frit remain, which increase the basicity of the lead frit, and make it more soluble. The use of lead bisilicate is described above, but it will occur to many chemists that lead sulphide or sulphate might have been used instead of the fritted lead with complete immunity from poisoning. As a matter of fact, lead sulphide is occasionally used in potteries, but the results are not such as to make it a sufficient substitute for white lead in high-class work—the sulphur is the difficulty, as lead sulphide in the presence of a limited amount of air may produce metallic lead. Lead sulphate is not, of course, liable to this trouble, but it is not so insoluble in dilute hydrochloric acid.

Before finally deciding upon what form of lead to use at Lambeth we had adopted provisionally the bisilicate, and realising that it was to an extent soluble, the following attempts to reduce its solubility were made:—

(1) The amount of lead soluble from the frit being known, a portion of the calcium oxide of the glaze equivalent to the amount of lead soluble, was introduced as

sulphate with the idea of rendering insoluble the small quantities of lead which would otherwise pass into solution. The results were disappointing, as no decrease in solubility was discernible.

(2) As lead sulphate is less soluble in dilute sulphuric acid than in water, in another case the whole of the calcium was introduced as sulphate. The result was again imperceptible.

Precipitated lead sulphate was now examined for solubility, and found to be at least as soluble as the bisilicate, a fact which explains the non-success of the experiments above. It would appear, therefore, that in factories where lead of a not more soluble character than bisilicate is used, there is no proper reason for the administration of dilute sulphuric acid to the workers as a safeguard against plumbism.

During the period in which the wholly fritted lead glazes have been in use at the Lambeth works there has been no case of lead poisoning, and the workers as a whole feel an improvement in health, particularly in the case of one man who is a very susceptible subject.

Some makers who have attempted to use fritted lead as a substitute for white lead, find the tendency to be towards a rise in melting point, and consequently a somewhat egg-shell surface. I believe that such effects are merely the result of silicious matter taken up in the preparation of the frit from the bed of kiln—that, in fact, the theoretical composition of the frit has been taken in calculating and not the actual composition as determined by analysis.

There are here for your inspection, examples of majolica semi-transparent enamels, opaque enamels, and under-glaze painted tiles, &c. On each is marked the solubility of the glaze employed.

Cost of Fritted as compared with Raw Lead Glazes.—There is of course more labour and time spent in the preparation of the former glazes, but, on the other hand, the cost of materials is somewhat less than where raw white lead is used. For instance, the price of white lead is at present 18*l.* 10*s.* per ton. The price of red lead is 14*l.* 15*s.* per ton. Therefore the PbO costs in white lead 4·3*s.* per unit per ton, and the PbO costs in red lead 3·0*s.* per unit per ton. Further, the fritting tends to the use of a lower percentage of lead oxide—for an excess of lead frit means settlement in the dipping tub, and this remark applies especially to soft enamels and majolica glazes. Consequently borax and lime are used to replace the lead, and are introduced in the form of a soft and easily prepared frit, thus further reducing the cost of materials.

Our experience at Lambeth is that it is possible to make fritted majolica glazes at practically the same cost as the older raw lead glazes.

DISCUSSION.

Mr. BERTRAM BLOUNT questioned whether all these regulations had been necessary. It seemed to him that great excitement and interest had been aroused by what was, after all, a small matter. The worker of course must be protected from anything which could do him harm, if it was controllable without undue expenditure, but he feared that, in the eagerness which the Government showed to safeguard the worker, they had hedged him in with needless restrictions. The manufacturers seemed to have accepted the situation loyally, and they had brought the matter to a point where they had as far as possible no restrictions such as would hamper their trade. As far as he had followed this controversy, it amounted to this, that the manufacturers had decided to accept the use of fritted lead—he thought unnecessarily; but having accepted that, they objected a little, which was not surprising, to the requirement that this fritted lead should have a certain standard solubility. Originally the solubility was very vaguely defined; it was that the material should be soluble to the extent of only 2 per cent. of lead oxide, but no definition was given as to the fineness of the frit—a point which had been brought out by many, and which Mr. Thomason had shown to be important, although not so important as some had supposed. The point on which Dr. Thorpe probably relied was that for practical purposes the glaze was always ground to a fineness suitable for dipping, so that it might go through a 160-mesh sieve. But that was not sufficient, for it was possible to have a material which could just scrape through a sieve of that fineness, which would contain numerous coarse particles as well as floury particles. The proportion of particles which would just scrape through was not important; it was the flour which was important, and, unless some more exact definition of fineness were given, no standard of solubility could be set up. Supposing the glaze were prepared of the requisite fineness and insolubility, it had yet to be shown that the workers would suffer any particular harm by absorbing moderate quantities of it, and the direction of safety to the worker lay in the greater cleanliness of the works and the workers, and the general precautions in carrying out operations rather than in any particular rule. If manufacturers decided that they could better prepare their ware with a glaze containing an amount of soluble lead precisely defined, he thought the body of opinion of chemists and technologists should be on their side. It seemed to him that until that was done, an unsatisfactory situation would exist, and manufacturers might be more or less harassed and perhaps not quite fairly treated. The knowledge which a Government inquiry certainly should have at its disposal might be actually misleading unless conference with the manufacturers was held in a more liberal spirit than appeared to have been exhibited in this case.

The CHAIRMAN said the volatilisation of lead in furnaces was well known, and a French process called "posage par volatilisation" was based on the method of lining the saggar with a paste of red lead, and putting the ware inside without any contact whatever with the glaze. The method was published by Brogniart in 1844, and some of our old Chelsea ware was made in the same way. The pieces to be glazed were burned alternately with lead-glazed ware in the same saggar. After using a lead-glazed ware the same saggar was employed for burning biscuit figures, and on the surface of the biscuit a very fine glaze was produced, which was called a "spitting"; such a glaze was almost unobtainable by the actual immersion of the figures in a solution. The author had rendered great service, however, in getting the actual figures as to what occurred; for he (the speaker) had not been able to find in the literature on the subject any definite statement of the actual amount of this volatilisation. The knowledge of the old potters was carried down from father to son; they got certain results, but as to the exact quantities of the ingredients used they had not the slightest knowledge and very often could not reproduce them. The difficulties to which Mr. Blount had alluded with regard to fixing the composition of the ingredients which some manufacturer should use were very great. On the one side there was a Government department doing its best for the workers, the manufacturers, and the public, but he thought they ough to consult manufacturers more than they did. In Germany there was quite a different state of affairs. Each trade had a guild, and the Government never introduced any important measure without consulting the guild, the consequence being that they worked hand in hand. Perhaps there was no necessity to have these restrictions, because the manufacturers did what they could do to get rid of the difficulties. Here there was the Employers' Liability Act which was most unfair to employers. Damages occasioned to the workers by the operations they carried out were no always due to a fault of the employer, but he had to pay everything, and that seriously hampered industrial enterprise. In Germany, the compensation paid to a workman injured in the course of his employment—and all employments were subject to some risk—was made good from three sources: first, a fund to which the workmen themselves had to contribute; secondly, the general taxation of the country; thirdly, the employer. This principle wa extended to all industries, and he thought it was a subjec the Society might take some action upon later on. Th pottery industry was an instance where it was particularl hard on the employers. It was a trade where the profit were not unduly great, and through the carelessness of th employees the employer might be saddled with a ver heavy liability. As every trade was carried on for th benefit of the whole community, there was no reaso why a portion of the damages should not be paid by th community as a whole. It was particularly unfair when employers were pinned hand and foot by Government restrictions which they could not fight as individuals, though they might be perfectly well aware that, as in this case, there were most complicated questions which could not be solved by a few tests made in a laboratory; the long experience of the manufacturer should be consulted. In Germany, he believed, there were very great restrictions as to the use of vessels containing lead glaze soluble in dilute acids, and the police regulations prohibited altogether the use of any vessel for culinary purposes which contained glaze or enamel in which the lead was soluble. In some enamels lead was prohibited altogether. He had not heard, however, of any regulations which prevented the German manufacturers making such ware and selling it to us. Here was another point where the Government might step in with great advantage and test the cheap enamelled goods that came from abroad and were sold very largely in this country. There again came in the trade question whether such competitors who sent over things which might be prohibited in their own country were not working much more cheaply than our manufacturers possibly could. He thought that the fact of the solubility of glaze ground dry being greater than that of the same glaze if ground wet might possibly be due to the particles being finer when ground dry, because the same particles might be ground over and over again when dry, but when suspended in water they did not come under the same amount of attrition. He quite agreed that passing through a sieve of 160-mesh was no test at all of fineness; only careful levigation would be a sufficient indication, and that was very difficult to carry out.

Mr. **Thomason** in reply said the fineness of the glaze as produced by dry grinding and subsequent wet grinding was in all probability the cause of the extreme solubility. The matter of volatilisation from the red lead of the saggar added to the unglazed article placed inside the saggar was rather different from the point he referred to in the first paper. In one instance the glaze was lead oxide, in the other a silicate or rather a silico-borate. It was the fact that volatilisation occurred even from fritted lead as distinct from raw lead which led him to prepare the first paper. There was considerable communication between the Home Office and potters before any standard of solubility was decided upon, and it was upon the margin which should be left in the hands of the potter that the atter finally came to grief. It was quite obvious that, hile in most instances 2·5 or 3 per cent. would be sufficient or most majolica purposes, there were cases in which the ame glaze would exceed that point. The German method f estimating the value of the ware by the fact of its ielding or not yielding lead oxide in an acetic acid solution as a very much less drastic one than those in which the laze was in a very fine state of subdivision, in spite of the ifference in the strength of the acid—it was, he believed, ne per cent. acetic acid. Considering the surface exposed the action, the British method was much more searching an the German.

ACTION OF CERTAIN SOLUTIONS UPON ALUMINIUM AND ZINC.

BY WATSON SMITH.

I will first give the results of some experiments as to e action of certain acids and alkalis on aluminium and nc.

Phosphoric Acid and Sulphuric Acid.—Phosphoric acid, ncentrated or dilute, attacks aluminium strongly with olution of hydrogen.

Winteler (Die Aluminium Industrie, 1903, 21) states at concentrated phosphoric acid acts like concentrated suluric acid on aluminium, in the former case phosphorus, the latter sulphur, being separated. I have observed ther separation of phosphorus nor of sulphur in such es. Dammer, Bd. III., p. 86, mentions in the case of phuric acid that sulphur dioxide is formed during the cess of solution. This I can confirm.

With zinc, phosphoric acid solution yields zinc phosphate and phosphide (Dammer, II., 458), I find, with evolution of hydrogen gas.

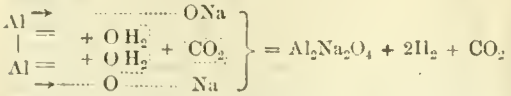
Organic Acids.—It has been stated that organic acids, dilute and cold, are without action on aluminium. Dammer (Bd. III., 86–87) states that even in presence of sodium chloride, acetic acid of 4 per cent. strength and citric acid of 1 per cent. strength showed no action after many days' contact. Only after 14 hours' boiling in a 4 per cent. acetic acid solution in presence of sodium chloride, did a sheet of aluminium of 1 square metre superficies, and 24·743 grm. weight, lose 47 mgrms. Roscoe and Schorlemmer, Vol. II., 545, state that organic acids attack aluminium only slightly, but it dissolves in them with ease in presence of chlorides, such, *e.g.*, as common salt. They draw the conclusion that it cannot therefore be used for plating cooking utensils. Winteler is silent on this subject. I tested this matter, and found that the action of acetic acid, dilute or fairly strong, is but slight, but on adding common salt and heating, greater action springs up, provided the acid be fairly strong. I should incline, according to appearances in my own experiments, to accept Dammer's figures and definition here, and hence would say that aluminium is not quite suitable for some cooking utensils, whilst it is for others.

Nitric Acid.—Winteler (p. 21) writes, "Nitric acid appears on superficial observation, to have absolutely no action on pure aluminium." Dammer (Vol. III., p. 86) says, "It is not attacked by nitric acid hot or cold," quoting Deville, Heeren and Buff. Roscoe and Schorlemmer (Vol. II., 545) write, "Concentrated as well as dilute nitric acid is almost without action on the metal." This latter statement is nearest the truth; that alone given from Dammer, *loc. cit.*, is partially false. According to my own experiments the case stands thus: Cold nitric acid, whether concentrated or dilute, is practically without action on aluminium at ordinary temperatures. But on raising the temperature to near the boiling point, fairly vigorous action is set up with liberation of nitrous fumes. If the liquid be now cooled, the action subsides and at about 50° C. or somewhat over, ceases. If aluminium dust or powder be used, the action, on heating, becomes very vigorous, and the temperature thereby rises further. Still, even then, on cooling the action greatly subsides. Besides nitrous fumes, ammonia in one case was also formed. This was proved by removing some of the clear acid liquid, and heating with caustic soda in excess.

Ammonia.—Winteler, *loc. cit.*, p. 21, says that ammonia solutions act slowly upon aluminium with formation of the hydroxide. Dammer also states that ammonia acts slowly. I find that a hot and strong ammonia solution acts on aluminium with generation of hydrogen and formation of aluminium hydrate. On raising such an ammonia solution to boiling, ammonia is evolved with appearance of effervescence, and this may have caused previous observers to overlook the possibility of admixed hydrogen. If the evolved gases be passed through water, bubbles of the hydrogen will be perceived and may be easily collected and tested.

Action on Zinc.—The action of a hot, almost boiling solution of ammonia was now tried on zinc cuttings. Slight but perceptible evolution of hydrogen was proved. If zinc dust be employed, the evolution is considerably greater. But whereas in the case of zinc the zinc hydrate formed, readily separates from the metal and falls in the solution, it was found that in the case of aluminium the hydrate adheres firmly and forms a coat, thus protecting the metal from further action.

Aluminium and Sodium Carbonate.—If aluminium dust be warmed with normal sodium carbonate solution, decomposition of the latter sets in with such violence that the contents of the vessel soon froth over. The effervescence is due to escape of a mixture of carbon dioxide and hydrogen. The action is very vigorous even with aluminium foil or sheet. In the reaction it may be said that in presence of the alkali carbonate the tendency of aluminium to unite with the hydroxyl of the water is so strong as to cause displacement and expulsion of hydrogen, and almost simultaneously—*in statu nascendi,* the alumina hydrate half-formed attacks the sodium carbonate, liberating carbon dioxide and uniting with soda to form sodium aluminate. The reaction cannot then be represented by an ordinary equation, and thus a special device is required—



$$\left.\begin{array}{l} Al \rightarrow \cdots\cdots ONa \\ \ \ | = \ \ + OH_2 + CO_2 \\ Al = \ \ + OH_2 \\ \rightarrow \cdots O \cdots Na \end{array}\right\} = Al_2Na_2O_4 + 2H_2 + CO_2$$

If now the liquid be filtered from excess of aluminium powder or foil, and carbon dioxide be passed through the clear liquid (sodium aluminate), a copious precipitate of aluminium hydrate is obtained, sodium carbonate being re-formed—

$$Al_2Na_2O_4 + CO_2 + 3H_2O = Na_2CO_3 + Al_2(OH)_6.$$

We thus see that on heating, aluminium expels the carbon dioxide from an aqueous solution of sodium carbonate, also decomposing water to form sodium aluminate, whilst in the cold, carbon dioxide decomposes sodium aluminate solution, precipitating aluminium hydrate and re-forming sodium carbonate. Thus in a hot solution the elements of aluminium hydrate in the nascent state can decompose sodium carbonate, expelling the carbon dioxide and combining with the soda. It was natural next that the attempt should be made to utilise aluminium hydrate, freshly precipitated and washed, for this same purpose. But I found that even on boiling such aluminium hydrate with sodium carbonate not the slighest reaction occurred. This clearly proves that it is only the nascent aluminium hydrate that will effect the decomposition referred to.

Zinc and Sodium Carbonate.—The contrast in the action of aluminium and zinc is shown by the fact that boiling sodium carbonate solution simply dissolves and oxidises aluminium with decomposition of water and liberation of hydrogen; also sodium carbonate is decomposed with liberation of carbon dioxide and union of soda to form sodium aluminate, which remains in solution, whilst with zinc a boiling sodium carbonate solution causes oxidation of the metal at the expense of water hydrogen being evolved, but any basic zinc carbonate or even hydrate, if formed, is decomposed in the boiling solution with formation of insoluble zinc oxide left along with residual metallic zinc. In other words, a boiling sodium carbonate solution simply converts metallic zinc into zinc oxide with escape of hydrogen.

But according to Gmelin, Wöhler showed that by the action of sodium carbonate solution on zinc a basic "zincosodic carbonate" is formed, which dissolves, and probably has the composition $Zn<\substack{NaCO_3\\ONa}$ hydrogen escaping. Wöhler states that he obtained octahedral crystals of this compound. On attempting to repeat this experiment I have entirely failed to obtain any solution containing dissolved zinc. I can confirm the evolution of hydrogen in the action of hot sodium carbonate solution on zinc, but on prolonging this action I gradually accumulated a white deposit, chiefly consisting of zinc oxide, and the filtrate from this contained no zinc. If Wöhler's compound be formed, it must be by the slow action of a cold solution; if attempted hot, and "zinc-sodic carbonate" for an instant be formed, it must be instantaneously decomposed again as follows:—$Zn<\substack{CO_3Na\\ONa} = ZnO + Na_2CO_3$. Wackenroder has shown that zinc oxide remains invulnerable when boiled with a sodium carbonate solution.

Aluminium and Ammonium Phosphate.—A weight of 4·7955 grms. of thin aluminium plate was placed in a solution composed of 100 c.c. of phosphoric acid (sp. gr. 1·275), rendered faintly alkaline by addition of ammonia. The whole was then heated till the liquid boiled, and ebullition continued till ammonia was no longer evolved. After this treatment, during which it was observed that the metal was greatly suffering, a white substance was plentifully formed. The aluminium was then gently wiped, after first washing in water, and weighed. It had lost no less than 0·9815 grm., that is 20·47 per cent. of its original weight. Evidently, then, aluminium is not the metal for vessels in which to heat ammonium phosphate solutions. The next question was, Which is the attacking constituent, the phosphoric acid or the ammonia? Ammonium phosphate solution, on boiling, suffers decomposition, ammonia being rapidly liberated. In this decomposition, of course, both phosphoric acid and ammonia at the moment of liberation may be regarded as *in statu nascendi.* It would seem tolerably certain that in the case of the hot ammonium phosphate the action on the aluminium is as follows:—Nascent ammonia in presence of steam acts as do the fixed alkalis, water being decomposed and aluminium hydrate being produced, with evolution of hydrogen. This aluminium hydrate then falls an easy prey to phosphoric acid, aluminium phosphate being formed.

Zinc with hot (boiling) ammonium phosphate solution yields hydrogen gas which comes off with the ammonia evolved.

Ammonium Arseniate and Aluminium.—The action of hot or warm ammonium arseniate solution on aluminium is very pronounced, hydrogen with arseniuretted hydrogen being copiously evolved.

Ammonium Arseniate and Zinc.—In the case of zinc a similar action to the foregoing occurs, but less freely.

Sodium Chloride and Aluminium.—The action on aluminium in the form of powder or foil, of hot and moderately strong solution of sodium chloride was now tried. The metal was attacked with evolution of hydrogen, the solution becoming alkaline. It was found that the *rationale* of this reaction is as follows:—Aluminium in the presence of sodium chloride attacks the water, setting hydrogen free. Aluminium hydrate is thus formed, and almost instantaneously attacking the sodium chloride, yields basic aluminium chloride and some free sodium hydrate. It is already known that organic acids which attack aluminium only slightly, dissolve it to quite an appreciable extent if sodium chloride and similar chlorides be present. It is clear, therefore, that aluminium is not quite suitable as a material for cooking utensils. 15·714 grms. of aluminium foil were heated for four days in a solution of sodium chloride (0·759 grm. of NaCl in 125 c.c., 6·072 grms. per litre). The loss of weight was only 0·002 grm. But the metal became also coated, and this coating protected it from further action. Such formation of an adherent protective coating is an important practical point, for it was found on removing the piece of aluminium from the solution and heating it in a fresh and even stronger sodium chloride solution, that it was but very slowly attacked. Hence, for some culinary purposes, and with suitable precautions, aluminium might prove useful. (See this J., 1899, 149.)

Sodium Chloride and Zinc.—But the action of sodium chloride on aluminium is very trifling compared with this action on zinc. 15·692 grms. of zinc foil were heated for about two weeks at about 80° C., in a dilute solution of sodium chloride (0·749 grm. in 125 c.c. or 5·992 grms. per litre). The loss of weight was 0·684, or the zinc in this period lost 4·36 per cent. of its weight. The precipitate formed on the zinc separated easily, and fell to the bottom of the containing vessel leaving the metal clean, and of course ready for renewed attack. But since solutions of sodium chloride so dilute could act as stated on aluminium and zinc, the question suggested itself that possibly water at 100° C., or thereabouts, might even act on these metals.

Distilled or Pure Water and Aluminium and Zinc.—On experiment, it was found that distilled water at 80° C. acted very slightly on aluminium after several days digestion, whereas zinc was considerably affected. Here, again, too, the hydrate formed at the surface of the zinc separated very easily and settled down in the liquid. With the aluminium a slight coating was formed, both adherent and protective. (See this J., 1899, 279.)

Hot Water and Aluminium.—As is well known, a very small quantity of an alkali hydrate in water will cause very considerable action on the metal. Having some suspicion that the soft glass of the test tubes I had been using for some of the experiments might contribute a small quantity of alkali to boiling water, I applied the following test. Distilled water was heated to incipient ebullition in a platinum dish with aluminium powder. Very slight action thus took place. But when the same powder was transferred to a test-tube and heated, quite a vigorous evolution of hydrogen was observed.

Hot Water and Zinc.—The action of boiling or almost boiling water on zinc dust in a test tube was such as to generate hydrogen enough to collect and test. The action was considerably less than on aluminium. In a platinum dish it was very slight indeed.

Sodium and Potassium Nitrate and Aluminium.—Aluminium powder with an aqueous solution of potassium or sodium nitrate heated to 100° C. in platinum, gave rise to a faint evolution of hydrogen gas, whereas the same mixture transferred to an ordinary soft glass test tube and boiled, showed vigorous action, and a considerable evolution of gas. In the experiment with the test tube about 20 c.c. of liquid were generally used. So 20 c.c. of distilled water were evaporated in the same test tube three times over (about 60 c.c. in all). Time of action on the glass, was about one hour. The alkali thus extracted from the glass was found to be equivalent to 0·0015 grm. NaOH; or 0·025 grm. per litre. (For an interesting and analogous case of the influence of the alkalinity of glass, see Lindet, this J., 1904, 330; bottom of col. 1.) A sodium nitrate solution heated to boiling (or rather, incipient ebullition) with aluminium powder in a test tube, after a time invariably and quite suddenly set up a vigorous effervescent action through evolution of hydrogen, and formation also of ammonia which was largely evolved.

As at most very slight action could be obtained in platinum, it was thought that incipient action must have been started by the alkalinity of the test tube, and this alkalinity once induced and becoming active, is continually increased, as follows—

$$NaNO_3 + \left\{\begin{array}{l} 6H_2O \\ 3H_2O + 3Al = 3Al(OH)_3 + 3H_2O + NaOH + \\ H_2O \qquad\qquad\qquad\qquad NH_3 + H;\ \text{or}, \end{array}\right.$$

$$2(NaNO_3) + 20H_2O + 3Al_2 = $$
$$3[Al_2(OH)_6] + 6H_2O + 2NaOH + 2NH_3 + H_2.$$

In this action we have two sources of alkalinity, the nitrate of soda and the walls of the test tube, and both continually increase, and so give rise to ever increased reducing action in presence of the aluminium on the sodium nitrate, and thus the way is prepared to a final tempestuous evolution of ammonia and hydrogen, with proportionately greater increments of alkali.

Sodium and Potassium Nitrate and Zinc.—Action similar to that on aluminium, only much less vigorous.

Petroleum Products and Aluminium.—It may be interesting to note here that Charitschkow has observed with regard to the action of petroleum products on aluminium, that in this respect aluminium is superior to copper and fully equal to iron. (See this J., 1896, 443.)

Practical Applications of the Foregoing Facts, &c.—I. From my experiments with nitric acid, the great value of pure aluminium as offering such resistance to the action of nitric acid, below a temperature of 50° C., or thereabouts (not over 50° C. to 55° C.) forced itself upon me, and I would suggest that for transport of nitric acid, not glass carboys or even earthenware vessels be used, but box-shaped vessels composed of pure sheet aluminium, protected by enclosure in wood (this J., 1903, 1352). It seems to me also that storage vessels in the nitric acid factory, would be most conveniently made of pure sheet aluminium. (See Guttmann, this J., 1898, 313.)

II. If aluminium could be produced cheaply enough, it were certainly better suited than zinc for cisterns in which to store water for household purposes and in the construction of receptacles to catch and run off rain water. It would last far better than zinc. Brackish water would rapidly act on zinc, whilst aluminium would prove ery resistant. (See Norton, this J., 1897, 465; 1899, 497.)

III. As a material for cooking vessels and culinary purposes, discrimination and caution are required. Aluminium kettles and teapots are largely offered for sale. I fear, however, in the latter case (teapots) when carbonate of soda" is added to get the "tea to draw" as the old people say, that the drawing power would soon extend from the tea to the teapot itself! (See this J., 1896, 118; 1899, 587.)

I have much pleasure in acknowledging here the very intelligent help received from my assistant, Mr. Albert Shonk.

Discussion.

Mr. Oscar Guttmann said that he was the first to mention the use of aluminium in that room some years ago. He believed he suggested it to the Royal Gunpowder Factory, where they now used aluminium extensively for nitric acid and nitroglycerin. He thought there would be some difficulty in constructing storage tanks of aluminium, and boxes lined with aluminium in which nitric acid could be safely carried, *e.g.*, to India. Although aluminium had been successfully soldered recently, he did not think the composition of the solder was the same as the metal, and though the aluminium might stand, the solder would not. Another difficulty has been that rivets would not always do. Centrifugal machines were made for separating the waste acids from guncotton, the baskets of which were constructed of aluminium, but it was found that the centrifugal force drove the rivets into the aluminium, the holes became oval and the basket began to leak. In order to make a vessel out of aluminium, three rows of rivets had to be provided which weakened the construction and was expensive. There were a number of mechanical and other difficulties in the way of using aluminium for such purposes as Mr. Watson Smith had suggested. On the other hand, for long lines of gutters for conveying nitroglycerin and mixed acids it was very extensively used already.

Mr. Blount said aluminium soldered very badly, but the difficulty could be overcome by autogenously soldering.

The Chairman said that there was one observation in the paper which, if not absolutely novel, was new to most of those present, namely that they could use a test-tube as one of the reagents in a test. He agreed with Mr. Guttmann about the difficulty of getting a box-shaped vessel as recommended by Mr. Watson Smith for the conveyance of nitric acid, but when the difficulty of getting a good joint was surmounted, it was not the best form of vessel for conveying liquids.

MR. JAS. E. BEDFORD IN THE CHAIR.

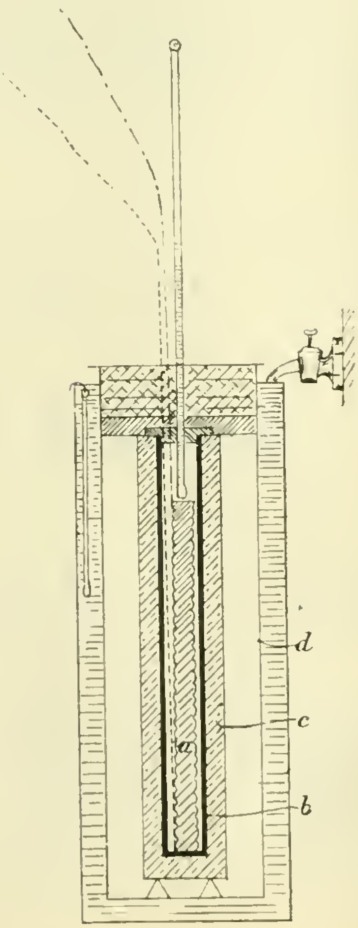
NOTE ON THE RELATIVE EFFICIENCY OF HEAT-INSULATING MEDIA.

II.—STEAM PIPE COVERINGS.

BY S. H. DAVIES, M.Sc.

This work was begun with the object of finding a suitable covering for pipes conveying highly superheated steam. A very high temperature has therefore been maintained throughout the experiments. In most cases the temperature of the steam pipe was raised to about 250° C. (482° F.). If steam of 90 lb. pressure is used, this is equivalent to a "superheat" of 150° F.

The first method of experimenting which suggested itself was to cover considerable lengths of pipe with the material, supply a regulated quantity of superheated steam, collect and weigh the quantity of water condensed in unit time. To carry this out with any degree of accuracy is, however, extremely difficult. To supply steam at a uniform pressure and superheated to a uniform temperature for a considerable period is almost impossible. If this difficulty is evaded by supplying the same steam to a number of parallel pipes covered with different materials, it is difficult to insure that the supply to each pipe is uniform. I therefore abandoned this in favour of an electrical method of heating. The loss of heat was determined by simply observing the quantity of electrical energy which must be supplied to the apparatus and transformed into heat in order to maintain a uniform temperature. I am greatly indebted to Prof. Stroud, of Yorkshire College, for his suggestions regarding this part of the work.



The heater consisted of a coil of fine platinoid wire wound round a porcelain core (*a*) (see diagram). This was placed in a wrought-iron steam pipe (*b*) 2 inches in diameter, 2 feet in length, closed at one end by a blank end of iron welded into the pipe of the same thickness as the wall of the pipe. The heater was immersed in melted paraffin wax to insure a uniform temperature throughout the length of the pipe. The sides and closed end of the pipe were then surrounded by the lagging or insulating material (*c*); the open end was covered with a wooden lid, perforated with holes for a thermometer and wires to convey the current to the heating coil. The steam pipe and its fittings were placed vertically in a wide tin cylinder (*d*), and the top covered with a closely fitting wooden lid and with several layers of hair felt. The loss of heat from the top end of the pipe was thus reduced to a negligible quantity.

The outer cylinder was immersed in running water to secure a uniform temperature, and therefore uniform conditions for radiation from the free surface of the material.

The coil of wire on the heater was connected with the factory current, regulated by the introduction of a rheostat of incandescent lamps placed parallel with each other and in series with the heater. An ammeter was included in the circuit. A current of 3 to 4 ampères was passed through the heater until the temperature rose to about 250° C., and then the current was regulated by means of the rheostat until a constant temperature was obtained in the pipe. In every case this high temperature was maintained in the steam pipe over-night, so that any moisture present in the covering might be expelled. An opportunity was thus given of observing any charring or disintegration of the material which might take place. The apparatus then remained under close observation, and when a constant temperature had been observed for half an hour, the temperature and flow of current were recorded.

The results of these experiments are shown in Table I. Round the insulating material a few coils of thin platinoid wire were wrapped, forming a resistance thermometer for recording the temperature on the outer surface (not shown in diagram). The wire formed one arm of a Wheatstone bridge, in parallel with an equal length of wire immersed in an oil bath, which was heated or cooled until equilibrium was established, and the temperature then recorded (column (*d*)).

It will be seen that the results are not directly comparable, owing to the different thicknesses of material supplied by the maker. Except in the case of plastic coverings, this is, however, a matter of theoretical interest, the practical question being, What loss of heat do we obtain from steam pipes covered by the materials just as they are supplied by the makers? The figures given in column (*g*) supply an answer, giving the loss of heat per hour calculated for a difference of 250° C. between the steam pipe and the water jacket.

For comparison an experiment carried out with the bare steam pipe is added, and it will be seen that, with the best covering, 77 to 78 per cent. of the heat transmitted by the bare pipe is retained, while with the worst covering examined only 21 per cent. is retained.

Pasquay states ("Wärmeschutz in Dampfbetrieb," 1895) that by using the best protective coating, in the most favourable case, about 80 to 85 per cent. of the loss whic occurs from a naked steam pipe may be avoided—a figur which corresponds closely with my results.

It will be noticed that there is a group of very efficien coverings, including magnesia sectional (thick), slag wool sectional, and remanit. Secondly, comes a grou of fairly efficient non-conductors, including the various mic preparations. Thirdly, there is a group which has abo half the efficiency of the first-named, including certai asbestos rope coverings, plastic slagwool and the Lero mixture. The list concludes with coverings which cannot l described as non-conductors.

TABLE I.

Experimental Data.

(*a*) Description of Covering.	(*b*) Mean Thickness.	(*c*) Temperatures. Inside Pipe.	(*d*) Surface of Lagging.	(*e*) Cold-Water Jacket.	(*f*) Current required to keep Temperature constant.	(*g*) Calories lost per Hour per 250° C. difference between the sides.*	Remarks.
	Ins.	° C.	° C.	° C.	Amps.	Cals.	
1. Magnesia sectional, *thick*	$1\frac{1}{2}$	253	51	14·5	2·05	55	
2. Slag wool sectional	$1\frac{7}{16}$	236·7	49	15·7	2·05	60	A thin layer of powdery material formed on the hot surface by disintegration of the fibre.
3. Remanit (waste silk rope)	$\frac{3}{4}$	249·5	50	13	2·1	60	The fibre is charred for $\frac{1}{8}$ in. depth. This is about the limit of temperature at which remanit can be used.
4. Mica, sectional, *double*	2	254·5	52	17·5	2·15	61	
5. Morley's composite	$1\frac{3}{4}$	220	50	21	2·0	63	It consists of slag wool surrounded by layers of hair felt and compressed fibre, covered with painted canvas.
6. Mica flexible, *thick*	2	248	53	13	2·25	68	
7. Mica sectional, *single*	$\frac{7}{8}$	251·5	61	17·5	2·35	74	
8. Mica flexible, *thin*	$1\frac{1}{2}$	247	64	14	2·35	74	
9. Magnesia sectional, *thin*	$\frac{31}{32}$	230	66	12	2·4	83	
10. Remanit and slag wool	$1\frac{1}{2}$	240·5	[67]	23	2·5	90	The cotton-fibre bag containing slag wool charred, and the contents were scattered.
11. Asbestos board and hair felt	1	233	65	17·5	2·5	91	Hair felt badly charred.
12. Asbestos rope filled with magnesia	$\frac{15}{16}$	253	71	12	3·0	118	The filling is contained in canvas surrounded by woven asbestos; the canvas is charred, and the filling escapes.
13. Asbestos cloth, ribbed	$1\frac{3}{16}$	251	75	15	3·0	120	
14. Asbestos rope filled with slag wool	$\frac{3}{4}$	248·5	75	15·2	3·0	121	Behaves like No. 12.
15. Leroy mixture, *thick*	$1\frac{1}{4}$	254	[77]	11	3·15	128	
16. Asbestos cloth containing sections filled with magnesia	$1\frac{3}{16}$	247·5	[76]	14·7	3·1	130	
17. Plastic slag wool covered with black pitch	$1\frac{1}{3}$	255	78	11·5	3·2	132	
18. Asbestos rope filled with asbestos fibre	$1\frac{1}{3}$	250	[79]	13·5	2·95	142	Owing to scarcity of material this result was obtained with 18 ins. of asbestos rope, plus 7 ins. of magnesia sectional covering, but the result has been calculated for a complete covering of asbestos rope.
19. Leroy mixture, *thin*	$\frac{17}{32}$	254	[80]	18·7	3·37	151

24. Bare pipe	..	177	..	18	3·45	242	

NOTE.—Figures in brackets are interpolated, not experimental figures.

* The last column is calculated as follows:—Calories lost $= C^2Rs\frac{0{\cdot}2387}{1000}$. The resistance of the heater = 14·6 ohms. Calories lost per hour per difference of 250° between the sides $= C^2 \times 14{\cdot}6 \times 60 \times 60 \times \frac{0{\cdot}2387}{1000} \times \frac{250}{(c)^\circ - (e)^\circ}$. The probable experimental error does not exceed 4 per cent. of the calculated heat losses.

In this connection it may be noted that while asbestos ibre may be necessary as a binding material, or asbestos loth may be used to carry a filling, asbestos itself is not good insulating material. Bergmehl also appears to have een over-estimated in this respect.

From the data recorded in Table I., it is possible to alculate, with some approach to accuracy, a coefficient of onductivity for the pipe coverings. (See Table II.) This oefficient expresses the number of calories lost per hour, er square metre of area, by transmission through 1 metre f the insulating medium, with a difference of temperature 1° C. between the sides. Let Q = loss of heat recorded alories per hour); r_1 = half the outside diameter of the pe in cm.; r_2 half the outside diameter of the lagging in n.; l = length of pipe in cm. (instead of considering e closed end of the tube separately, it is treated as an ldition to the length of the tube); t_1 = temperature inside pe; t_2 = temperature on the surface of the lagging. hen the coefficient of conductivity—

$$K = \frac{Q.\log_\epsilon\left(\frac{r_2}{r_1}\right).100}{2\pi l.(t_1 - t_2)}$$

This assumes that the conductivity of the iron pipe is infinitely great compared with the conductivity of the lagging—an assumption which does not introduce any appreciable error.

In certain classes of work the weight of the covering is important; details of the actual weight of covering on the 2-ft. length of pipe, as well as the weight per cubic foot, will be found in Table III.

I have not found it possible to prepare a table of costs, but in this connection it is obvious that an extra capital outlay on a good insulator may lead to very important economies in the fuel required for steam-raising.

In a factory with which I am acquainted, the total area of pipes employed in the distribution of steam from the boiler house to all parts of the factory is 730 square metres. At the moderate computation of 3 kilos. of steam condensed per square metre of naked pipe per hour, the condensation would amount to 2,190 kilos. of water per hour, if the pipes were uncovered, representing a loss of 2,750 tons of coal per annum. Nearly 80 per cent. of this loss may be avoided by the use of an efficient covering.

Table II.

Coefficients of Conductivity.

19. Bennett-Lawes' plastic	0·181

* See note to Table III.

With the increasing tendency to use high-pressure steam and superheated steam, the importance of selecting a good insulating medium is greatly enhanced. In the factory referred to above I have made a number of observations regarding the amount of condensed moisture present in the steam at different points. In each case steam has been travelling at a fair rate past the point at which the test has been made. A large calorimeter was used, made of tin-plate surrounded by hair-felt and wood, and provided with a lid of similar material and a disc stirrer. About 100 kilos. of cold water were used, and from 10 to 12 kilos. of steam condensed. The rise in temperature was about 60° C. Starting with superheated steam from the boiler house at about 90 lb. pressure and a temperature of about 550° F., I have recorded from 0 to 12 per cent. of condensed moisture in the steam at distances of 140 to 460 ft. A mean of 11 satisfactory experiments gave 6·2 per cent. of condensed moisture. The distributing pipes were covered, but not in a very efficient manner.

Table III.

Density of Materials.

Description of Covering.	Length.		Thickness.	Outside Diameter.	Weight in Grms. covering Sides and one End of Pipe.	Weight per Cb. Ft. in Lb.
	Ft.	In.	In.	In.		
1. Remanit	2	3	⅜	4⅛	710	11

6. Leroy mixture, thick	2	1	1¼	4⅝	1925	21
7. Asbestos rope filled with magnesia	2	1	15/16	4¼	1570	24
8. Asbestos cloth and magnesia	2	1⅝	1 5/16	5	2540	25
9. Asbestos cloth, ribbed	2	1¾	1 3/16	4⅞	2570	28
10. Slag wool, sectional	2	1⅛	1 7/16	5¼	3230	28
11. Asbestos rope filled with slag wool	2	1	¾	4¼	1870	31
12. Mica flexible, *thick*	2	1½	2	6¾	6020	32
13. Creswell's asbestos, plastic, No. 2	2	1	1	4¾	2550	36
14. Mica sectional, double	2	2	2	6⅝	7800	41
15. Creswell's asbestos, plastic, No. 1	2	1	1	4⅝	2950	42
16. Bennett-Lawes' plastic	2	1	1	4⅝	2990	42
17. Asbestos rope filled with asbestos fibre	1	6 *only*	1⅛	4½	2620	45
18. Leroy's asbestos, plastic	2	1	1	4⅞	3300	47
19. Plastic slag wool	2	0	1½	5⅜	6450	56

Note.—In cases where two different thicknesses of material have been experimented with, the results are only given with the *thicker* covering.

During a period when the steam was not superheated, other conditions remaining the same, a mean of 12 satisfactory tests gave 13·5 per cent. of condensed moisture. This may serve as a further illustration of the extraordinary loss of energy resulting from the condensation of steam during its distribution in any large factory, and the great importance of securing an adequate covering for the distributing mains.

Discussion.

Mr. G. W. Slatter inquired which was the best covering in the opinion of the author, taking into consideration the cost as well as the other qualities of the covering. Which was the best method of protecting steam pipes exposed out of doors from the weather?

Mr. Ward inquired whether the amount of air contained in the cover had not a considerable effect on its efficiency.

The Chairman stated that he had been in the habit of covering the pipes at his factory with a mixture of clay, waste flax (known locally as "Shivvy-dan,"), cow-hair, &c., worked up into a paste and applied as plastic covering, finishing with a coat of pitch. This covering was cheap and durable.

Mr. Thorp Whitaker said he had had a large experience with steam-pipe covering, and had covered many miles of piping in Bradford dyeworks with magnesia sectional covering. Unfortunately, like most covers, this was liable to be damaged when pipes were taken down and their position altered, and he had found it advisable to coat the magnesia covering with a mixture such as Mr. Bedford had described, finishing with two coatings of pitch or boiled tar. This formed a weather-proof covering, and the pipes covered in this manner could be taken down and replaced without the covering tumbling to pieces.

Mr. Davies, in reply, stated that he was not prepared to recommend one cover as being superior to all others. He had found difficulties in ascertaining the cost of material, these costs appearing to be somewhat elastic. Wherever steam pipes were covered it was advisable to finish off the cover with a coat of canvas and paint, whether for indoor or outdoor use. In reply to Mr. Ward, the amount of air present in a covering was of great importance, and the best covering consisted of a mass of minute air cells, separated by walls of non-conducting material. Unfortunately, the difficulty was to discover a material which was non-conducting, and stable at the high temperatures employed, and which would permanently retain a light, porous texture. With regard to the covering the chairman employed, he was quite unable to recommend it, and he considered that it would prove very inefficient compare with the coverings of which he had spoken.

THE AMOUNT OF COCOA BUTTER CONTAINED IN THE COCOA BEAN.

BY S. H. DAVIES, M.Sc., AND B. G. MCLELLAN, A.I.C.

The physical and chemical constants of cocoa butter hav been exhaustively dealt with by Lewkowitsch (this J 1899, 556), but so far as I am aware no communicatio regarding the percentage of cocoa butter in the bean ha been made to this Society. The matter is one of som importance to food analysts who are called upon to stat the amount of pure cocoa present in samples of commerci chocolate. It might be supposed that the amount of t chief constituent of such a well-known substance h already been determined with great accuracy, but this not the case.

On examining a section of the cotyledons, or ker (known commercially as cocoa-nibs) under the microsco it will be found to consist of cells, some of which a coloured, and others contain crystals of fat associated w very small starch granules and albuminoid substanc These cells are not permeable to fat solvents, and it necessary to disrupt them by mechanical means before t cell contents can come in contact with the solvents.

It is probably owing to this fact, that all the ol estimations of the percentage of fat in cocoa nibs a too low.

Our work is entirely concerned with the percentage of cocoa butter in the roasted nibs, this being the only value of commercial importance.

Ridenour (Amer. J. Pharm., 1895, 202) has given values which vary from 37 to 50 per cent. for different varieties of bean, which are certainly too low.

The most reliable determinations are those by Heisch (Analyst, 1, 142) and Zipperer (Untersuchungen uber Kakao, &c., 1887). They are given in Table I.

TABLE I.

Percentage of Cocoa Butter in Roasted Cocoa Nibs.

——	Heisch.	Zipperer.
Caracas	48·4	49·24
Puerto Cabello	..	48·4
Trinidad (inferior)	49·4	48·14
Surinam	54·4	49·88
Arriba	..	50·07
Guayaquil	49·8	52·09
Grenada	45·6	..
Port au Prince	..	46·9
Bahia	50·3	..
Cuba	45·3	..
Para	54·0	..
Mean	49·65	49·24

Our determinations range over two years, and represent samples taken from bulk lots on the London market, with the exception of the Jamaica cocoas; these came direct from the island.

The beans were roasted fully, but with careful precautions against burning; they were then broken and winnowed, to remove all the husk, and the nibs very finely ground on stones in a small mill. The resulting pasty mass was cooled quickly to prevent any separation of butter, and the mass of cocoa carefully sampled by taking scrapings from different parts of the block. Two grams of this sample are exhausted in a Soxhlet extractor with petroleum ether. The latter has been subjected to fractional distillation, and the fraction boiling between 40° and 50° C. is used for the extraction. The treatment with petroleum ether lasts overnight. After distilling off the ether, the residue is heated for four hours at 95° C., cooled, and weighed. Petroleum ether will be found more satisfactory than ether for this purpose. Ether extracts theobromine and some of the colouring matter of the cocoa in addition to the fat.

An experiment was made to determine the extent to which an alteration in roasting affected the proportion of fat.

TABLE II.

Roasted Cocoa-Nibs (Trinidad).

——	Moisture.	Fat.
Very high roast	3·0	54·0
„ low „	3·8	52·7

We conclude that the small variations in our roasting would not appreciably affect the comparisons given in our next table. The individual tests, and the mean for each country, are given in Table III. This gives a general mean of 54·44 per cent., or 5 per cent. higher than Heisch's and Zipperer's results.

In the case of the Jamaica cocoas, the exact history of which was known, it was possible to observe the effect of *fermentation* of the cocoa bean on the fat contents. These figures are shown in Table III. As might have been expected, prolonged fermentation results in the loss of some of the carbohydrate and albuminoid constituents of the bean, leaving a substance richer in fat.

We agree with the earlier observers that there is not sufficient variation in the percentage of fat in different kinds of bean to enable the country of origin to be established from this determination. Probably the percentage varies chiefly with the richness of the soil and with the method of curing adopted, and is not dependent upon the locality.

Discussion.

Dr. Chaplin inquired what time was necessary for the full extraction of the cocoa butter; he also wished to know whether the introduction of fats other than cocoa butter was permissible in commercial chocolates.

Mr. G. Ward asked whether cocoa butter extracted from beans from different countries was uniform in constitution.

Mr. Dixon inquired whether there was any great difference in the amount of extract obtained by using ethyl ether as compared with petroleum ether.

Mr. Davies, in reply, stated that they had usually started the extraction in the afternoon and allowed it to proceed for an hour or so; then the packet of cocoa stood in Petroleum Ether overnight, and the exhaustion was continued for two or three hours the next day. With regard to the constitution of chocolate, it was illegal to use other fat to replace cocoa butter in many European countries, but in England the constitution of chocolate has never been legally defined, and it would be possible to use any foodstuffs in the preparation of chocolate. He expected that the addition of other fats would be forbidden in the future in England. He had not elaborately examined the cocoa butters from different countries to see if they had the same chemical constitution, but the physical characteristics of the taste, odour, melting point, &c., were the same, and he had no reason to suppose that there was any difference in the chemical constitutions. Ethyl ether appeared to extract from 0·2 to 0·5 per cent. more material from the cocoa bean than petroleum ether.

Obituary.

DR. ANDREW PEEBLES AITKEN,

Professor of Chemistry and Toxicology in the Royal (Dick) Veterinary College, Edinburgh; Member of the Society of Chemical Industry.

Dr. A. P. Aitken was a native of Edinburgh, and was educated in the Edinburgh University, where he took the degree of Master of Arts in 1867, of Bachelor of Science in the department of Physical Science in 1871, and finally of Doctor of Science in the department of Chemistry in 1873. He then studied at Heidelberg, and on his return to Edinburgh was appointed assistant to Professor Crum Brown and Demonstrator of Practical Chemistry in Edinburgh University. His final appointment was to the Professorship of Chemistry in the Dick Veterinary College in 1875. He died on Sunday, April 17th, at his residence in Edinburgh.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

I.—PLANT, APPARATUS AND MACHINERY.

Superheated Steam for Petroleum Borings. W. Szaynok. Naphta, 1904, **12**, 17—19.

Most of the existing engines in use in the Boryslaw (Galicia) district have insufficient heating space in the boilers to satisfactorily deal with the task of boring the deep wells now required. By introducing superheaters in the boiler smoke boxes, however, the author finds the increased efficiency of the dry steam reduces the consumption of fuel by about 15 per cent. At the same time there is practically no condensation in the live steam pipe, and the use of superheated steam in the atomiser diminish the consumption for this purpose. The best results with superheater are obtained when the effect of this apparat is to reduce the temperature of the effluent flue gases 273° C., this being the point at which the maximum weig of gas can pass through the smoke stack.—C. S.

English Patents.

Hydro-extractors. M. de Marchéville, Paris. Eng. P 6925, March 25, 1903.

See Addition, of May 13, 1902, to Fr. Pat. 291,015 of 1 this J., 1903, 355.—T. F. B.

Filtering Apparatus. R. E. Ellis, London. From Maschinenfabrik Grevenbroich, Grevenbroich. Eng. Pat. 4575, Feb. 24, 1904.

Hollow arms are provided with perforated pipes depending from them and penetrating the filtering medium. When the latter has become clogged, water is forced through the arms, which are rotated, and the filter is thus cleansed. Means are provided for carrying off the muddy wash water and for injecting water under the porous floor of the filter. —W. H. C.

Rotary Driers. D. Grupe, Davenport. Eng. Pat. 15,955, July 18, 1903.

The horizontal rotary drier with internal steam flues, described in U.S. Pat. 659,299 of 1900, is fitted with a steam chamber at the outlet end into which the ends of the steam flues are fixed, and this steam chamber is provided with a special drain trap and outlet, as well as steam inlet; the chamber rotates with the drier. At the other end, the steam flues pass through holes in a perforated plate forming one portion of an end chamber, and are connected beyond this plate together in groups of two or more, by small steam chambers provided with cleaning doors opposite the steam flues. In this way the contraction and expansion of the steam flues does not interfere with the working. The drier is supported on rollers, and suitable feed and discharge openings are provided.—W. H. C.

Vacuum Evaporating Apparatus; Piled ——. T. Suzuki, Sunamura. Eng. Pat. 3165, Feb. 9, 1904.

Each evaporating pan is constructed of several superposed segments or "drums," with suitable heating coils. At the top there is a rotating distributing coil, and between the segments are arranged overflow valves, operated from without. The liquid to be evaporated flows from segment to segment in each pan, whereby very rapid and economical evaporation is effected.—W. H. C.

Freezing of "Liquid Gases" on the Discharge thereof from Storage Vessels; Method and Apparatus for Preventing ——. L. von Orth, Berlin. Eng. Pat. 4694, Feb. 25, 1904.

The outlet pipe from the storage vessel has a spiral opening, so that the issuing liquefied gas impinges on the walls of an outer tube of larger bore. This tube has ribs on its outer side, and is surrounded by a casing, "through which a heating liquid medium is made to flow" in a "serpentine direction." The liquefied gas is only heated after it has begun to expand.—W. H. C.

French Patents.

Forcing and Drawing off Liquids, Inflammable, or those which evolve Explosive Gases; Process for ——. C. Martini and H. Hüneke. Fr. Pat. 337,733, Feb. 28, 1903.

See Eng. Pat. 4233 of 1903; this J., 1904, 14.—T. F. B.

Furnace. J. Ritz. Fr. Pat. 337,770, Dec. 16, 1903.

See Eng. Pat. 27,613 of 1903; this J., 1904, 363.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

ron Carbonylferrocyanide; a Constituent of Spent Oxide. M. Stoecker. VII., page 488.

ulphur; Determination of —— *in Calcium Carbide.* H. Lidholm. XXIII., page 504.

English Patents.

Coke Ovens. T. von Bauer, Berlin. Eng. Pat. 17,327, Aug. 10, 1903.

y a special arrangement of flues and air channels, and by acing the return-gas channels below the gas-distributing annels, the same ovens can be operated for either "direct indirect production," and for hand or mechanical charging. pecial plugs are provided for altering the distribution of gas. Steam can be injected into the gas flues to clear them of deposits, and is also injected through the coking coal to increase the yield of tar and ammonia.—W. H. C.

Solidified Liquids [Hydrocarbons, Alcohols]; Manufacture of ——*, and of a Material therefor.* E. Raynaud, Spy. Eng. Pat. 7860, April 4, 1903.

Liquids, such as hydrocarbons or alcohols, may be solidified by the addition of 0·4 to 10 per cent. (according to the degree of hardness desired) of a mixture of sodium silicate and saponified fat, which may be made by saponifying "cocoa-butter" with caustic soda, and adding four to five times the weight of sodium silicate. This mixture should be heated with the liquid to be solidified at about 40° C., with stirring.—T. F. B.

Fuel [Briquettes]; Artificial ——. E. J. Hoffman and W. J. Clark, Chicago. Eng. Pat. 1887, Jan. 25, 1904.

The fuel is made by intimately mixing 92 per cent. of coal dust or crushed coal, 3½ per per cent. of crude petroleum, 2½ per cent. of rosin, and 2 per cent. of soda ash, the last three ingredients being first melted together; the mass is then formed into briquettes.—L. F. G.

House or other Refuse; Process of Treating —— *for Converting it into Substances of Commercial Utility [Fuel Briquettes].* T. G. Charlton. Eng. Pat. 16,304, July 24, 1903. XVIII. B., page 500.

Gas from Petroleum Oils; Generation of —— *for General Purposes, particularly for Use with Burners for Steam Generation and like purposes.* E. R. Bridson, Nottingham. Eng. Pat. 14,335, June 27, 1903.

Oil is pumped through a vaporising coil, which surrounds a burner, the latter being fed with a portion of the vapour from the coil. The supplies of oil to the coil and vapour to the burner are controlled automatically by diaphragm valves. The apparatus is put in operation by burning some spirit in a gutter surrounding the vaporising burner, and pumping oil into the coil by means of a hand pump. The main portion of the vapour generated, is led to the motor or other place of consumption.—H. B.

Coal Gas; Apparatus for the Purification of ——. R. Good, Croydon, and S. Spencer, London. Eng. Pat. 23,045, Oct. 24, 1903.

A hydraulic main, of the form described in Eng. Pat. 7258 of 1886, is fitted longitudinally and transversely with horizontal tiers of pipes, open at each end to the atmosphere, for inducing the more rapid condensation of the tar, &c., within the main. The outlet for the tar and liquor is provided with regulating and cleaning devices. A washer of the kind referred to in Eng. Pat. 2317 of 1881, is constructed with similarly arranged condensing pipes, and other modifications of details are introduced.—H. B.

Gases; Apparatus for Producing a Mixture of —— *or of Gas and Air for Illuminating Purposes.* H. H. Lake, London. From Selas Ges., Berlin. Eng. Pat. 5088, March 4, 1903.

See Fr. Pat. 333,033 of 1903; this J., 1903, 1287.—T. F. B.

Acetylene Gas; Process for the Purification of ——. A. Landriset, Gampel. Eng. Pat. 7490, March 31, 1903.

See Fr. Pat. 330,180 of 1903; this J., 1903, 1080.—T. F. B.

Carburetting Air by Means of Naphthalene, and Generating Naphthalene Vapour in connection with Lamps for Lighting Purposes. G. P. J. Lion, Paris. Eng. Pat. 11,561, May 21, 1903. Under Internat. Conv., May 21, 1902.

See Fr. Pat. 321,495 of 1902; this J., 1903, 205.—T. F. B.

Producer Gas and the like; Manufacture of ——. E. Hovine and H. Breuillé, Paris. Eng. Pat. 25,763, Nov. 25, 1903.

See Fr. Pat. 336,786 of 1903; this J., 1904, 365.—T. F. B.

Mantles; Manufacture of Incandescent ——. F. B. Grundy, Richmond. Eng. Pat. 10,852, May 13, 1903.

The filaments of which "artificial silk" is composed are twisted together in a manner similar to that in which cotton yarn is twisted to produce knitting cotton, and the two-ply or three-ply cord thus formed is knitted into fabrics as usual. The latter are then impregnated with a solution containing 10—20 per cent. of the usual oxides, dried, treated with ammonia gas or soaked in a strong solution of ammonia, dried, and burned off.—H. B.

French Patents.

Gas from Pulverised Combustibles; Process and Apparatus for Producing ——. G. Marconnet. Fr. Pat. 337,514, Dec. 8, 1903.

Pulverised fuel is allowed to fall down a vertical conduit, the lower end of which opens into an ash-box. The particles of fuel are burned during their fall, by means of suitable burners, the ash being collected in the box beneath, whilst the gas is led off to the motor or other apparatus in which it is to be used. In the apparatus described, the fuel conduit or shoot, constructed of refractory material, is of rectangular cross-section, and the walls are perforated with series of orifices serving to admit air and gas respectively, and to maintain the flames required for burning the fuel during its fall. Parallel passages supply the air and gas to the orifices, and the whole is surrounded by a body of coke. The gas, produced by the combustion of the powdered fuel, on issuing from the lower end of the shoot, is led up through the surrounding coke, whereby any accompanying dust is removed.—H. B.

Pyrophoric Alloys for Use in Igniting and Illuminating. C. Auer von Welsbach. Fr. Pat. 337,320, Oct. 31, 1903.

Pyrophoric alloys are prepared by fusing together one or more of the rare-earth metals (lanthanum, cerium, &c.) and iron, the best results having been obtained on adding 30 per cent. of iron. The iron may be wholly or partly replaced by nickel or cobalt. On rubbing such an alloy with a file or the like, brilliant sparks are emitted, which are capable of igniting, with certainty and almost immediately, a mixture of air and combustible gas. The alloys may be used for illumination, or for the ignition of gases.—H. B.

Mantles; Manufacture of Incandescence ——. F. Haan, A. Krausz, and Z. Sziklai. Fr. Pat. 337,475, Nov. 12, 1903.

Mantles are made as usual from a solution composed of water, 1,000 parts; thorium nitrate, 300—500 parts; cerium nitrate, 2—4; cobalt nitrate, 0·5; ammonium nitrate, 1; aluminium nitrate, 0·5; lead nitrate, 1; "tartar," 1; and 0·5 to 1 part of "nitrate of sepia or of mother-of-pearl, that is, of the salts formed by dissolving these substances in nitric acid."—H. B.

Mantles; Manufacture of Incandescence ——. G. H. Maisch. Fr. Pat. 337,371, Nov. 17, 1903.

See U.S. Pat. 712,562; this J., 1902, 1527.—H. B.

Incandescence Filaments for Electric Lighting; Manufacture of ——. Siemens and Halske A.-G. Fr. Pat. 337,608, Dec. 12, 1903.

Incandescence filaments are made from tantalum or niobium by drawing or rolling the metal into fine tubes, filled or not with conductors of the first or second class. —H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum Borings; Superheated Steam for ——. W. Szaynok. I., page 482.

Petroleum; Determining Impurities [Water] in Boryslaw (Galicia) ——. M. Wielezynski. XXIII., page 504.

United States Patent.

Still for Crude Bituminous Material. H. W. Ash, Cambridge, Assignor to Warren Bros. Co., Charleston. U.S. Pat. 757,387, April 12, 1904.

An upright still is heated directly by a furnace below it, and also by the furnace gases, which are led into a chamber surrounding the sides of the still. The products of combustion of the furnace pass from this chamber to a blower, whence they are forced through the material which is being distilled.—T. F. B.

French Patent.

Greases [Lubricants], Plasters, and Waterproofing Compositions [Paints]; Process of Making ——. J. Girard and P. J. Tabourin. Fr. Pat. 337,753, Dec. 15, 1903.

Ozokerite is employed in the manufacture of lubricants (*e.g.*, mixed with naphtha); in making waterproof paints (*e.g.*, mixed with paraffin wax, petroleum residue, and colouring matters); and for similar purposes.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

o-Tolidine; Constitution of ——. G. Schultz, G. Rohde, and F. Vicari. Ber., 1904, **37**, 1401—1402.

The diaminoditolyl (*o*-tolidine) prepared from *o*-nitrotoluene is generally regarded as having the constitution $[4.3](NH_2)(CH_3)C_6H_3.C_6H_3(CH_3)(NH_2)[3.4]$, both on account of its method of preparation and its behaviour, which is analogous to that of benzidine (di-*p*-diaminodiphenyl), but no complete proof of the correctness of this formula has hitherto been found. This proof is now supplied by the authors, who have found that the hydrocarbon prepared from *o*-tolidine by means of its hydrazine compound is identical with the hydrocarbon—

$$[3](CH_3).C_6H_4.C_6H_4(CH_3)[3],$$

obtained by treating *m*-iodotoluene with sodium.—A. S.

Indole from Indoxyl; Preparation of ——. D. Vorländer and O. Apelt. Ber., 1904, **37**, 1134—1135.

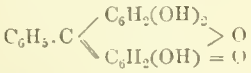
Indoxylic acid and indoxyl are readily reduced to indole by reduction in alkaline solution, either with sodium amalgam or with caustic alkali and zinc dust. The yields are satisfactory.—E. F.

Amino- and Aminohydroxy-diphenylamines. R. Gnehm and G. Weber. J. prakt. Chem., 1904, **69**, 223—244.

Dimethyl-*p*-diaminodiphenylamine is prepared either by oxidation of dimethyl-*p*-phenylenediamine with aniline and reduction of the indamine so obtained, or by condensation of dimethyl-*p*-phenylenediamine with *p*-aminophenol. It yield no dyestuff if heated alone with sulphur, but if heated wit sulphur in presence of phenol, sulphuretted hydrogen i evolved and a sulphide dyestuff is obtained which dye cotton in yellow shades. Dimethyltriaminodiphenylami is prepared by reducing the indamine obtained from th oxidation of dimethyl-*p*-phenylenediamine with 1 mol. o *m*-phenylenediamine. On melting with sulphur and pheno this substance yields a sulphide dyestuff which dyes cotto in dark greenish-black shades. Dimethyl-*p*-diamino-*m* hydroxydiphenylamine is obtained by condensing dimethy *p*-phenylenediamine with resorcinol. With nitrous acid yields a nitrosamine which is transformed by hydrochlori acid into the *p*-nitroso compound. This latter reacts wit amines and phenols to form oxazine dyestuffs. Those pr duced with diphenylamine, β-naphthol, and dimethyl-*n* aminophenol are blue in shade. With formaldehyde, dimethy *p*-amino-*m*-hydroxydiphenylamine forms either dimethyl-, amino-*m*-hydroxybenzyl alcohol or the diphenylmetha compound, $CH_2[C_6H_3(OH).NH.C_6H_4N(CH_3)_2]_2$, accordi to the proportions used. On oxidation with tertiary amin the latter gives triphenylmethane dyestuffs. On melti dimethyl-*p*-amino-*m*-hydroxydiphenylamine with sodi sulphide and sulphur, a sulphide dyestuff is formed whi dyes cotton in green to greenish-blue shades. *p*-Dimethylamino-7-hydroxynaphthalene is obtained from dimethyl-*p*-phenylenediamine and 2.7-dihydroxynaphthalene.—E. F.

Hydroxyquinone; Condensation of —— with Aldehydes. C. Liebermann and S. Lindenbaum. Ber., 1904, 37, 1171—1180.

One mol. of benzaldehyde condenses with 2 mols. of hydroxyquinone in presence of concentrated sulphuric acid to form a triphenylmethane dyestuff of the constitution—



$$C_6H_5.C\begin{cases}C_6H_2(OH)_2\\ \quad\quad\quad\quad\quad > O\\ C_6H_2(OH)=O\end{cases}$$

which dyes intensely on basic mordants, reddish-orange on alumina and greyish-violet on iron oxide, not very fast to light. An analogous dyestuff is obtained if the benzaldehyde be replaced by acetaldehyde. The properties of the product are very similar, but the dyeings produced by it are redder in shade than those from the benzaldehyde derivative. With formaldehyde no dyestuff is produced, the product obtained being hexahydroxydiphenylmethane. With pyrogallol and phloroglucinol, benzaldehyde reacts under the same conditions in equimolecular proportions, yielding colourless compounds possessing no dyeing properties.—E. F.

Benzimidazoles, and Dyestuffs derived therefrom. O. Kym. Ber., 1904, 37, 1070—1074.

A triaminobenzimidazole derivative, *p*-amino-*a*-phenyl-N-*p*-aminophenol-*m*-aminobenzimidazole, is best obtained by partially reducing *o-p*-dinitro-*p′*-aminodiphenylamine to o-*p′*-diamino-*p*-nitrodiphenylamine, heating this with *p*-nitrobenzoyl chloride, thus forming *p*-nitro-*a*-phenyl-N-*p*-nitrobenzoylaminophenyl-*m*-nitrobenzimidazole and subsequently reducing. The base, when diazotised and coupled ith other compounds, yields dyestuffs which have less ffinity for cotton and dye in redder shades than those erived from diaminobenzimidazole derivatives.—E. F.

riphenylmethane Dyestuffs; Colour Bases of ——. A. Baeyer and V. Villiger. Ber., 1904, 37, 1183—1184.

N treatment with alkali, Aniline Blue forms the corre-ponding phenylimide, $C_{37}H_{29}N_3$, which is black. On rinding with caustic soda solution, Parafuchsin yields a olymer of the corresponding imide, which can be recrystalsed from xylene and which differs from the carbinol in ing extremely insoluble and difficult to crystallise. Its mpirical formula is $C_{19}H_{17}N_3$. In the case of New Fuchsin e monomolecular quinone-imide is formed and is already own as Homolka's base.—E. F.

Hydroxyflavonol; Synthesis of ——. S. v. Kostanecki and M. L. Stoppani. Ber., 1904, 37, 1180—1182.

AEONOL is condensed with benzaldehyde to form 2′-droxy-4′-methoxychalkone, according to the equation—

$$C_6H_3(OCH_3)OH.(COCH_3)[1:3:4] + C_6H_5.CHO =$$
$$C_6H_3(OCH_3)OH(CO.CH:CH.C_6H_5) + H_2O.$$

boiling with alcohol and sulphuric acid, this is converted o 3-methoxyflavanone—

$$(CH_3O)\underbrace{C_6H_3.O.CH(C_6H_5).CH_2.CO}$$

ich is converted by amyl nitrite and hydrochloric acid o an isonitroso compound, which, on boiling with dilute phuric acid, forms 3-methoxyflavonol. This is saponified hydriodic acid to 3-hydroxyflavonol—

$$(HO)\underbrace{C_6H_3.O.C(C_6H_5):C(OH).CO}$$

ch dyes in pale yellow shades on alumina mordants. —E. F.

Orsellinic Acid; Constitution of ——. F. Henrich. Ber., 1904, 37, 1406—1415.

By treating 1 mol. of orsellinic acid ethyl ester dissolved in caustic soda solution with a solution of diazobenzene chloride prepared from 2 mols. of aniline, benzene-disazo-orsellinic acid ethyl ester, $(C_6H_5N_2)_2:C_6(CH_3)(OH)_2(COOC_2H_5)$, is produced, m. pt. 186° C., easily soluble in cold benzene and toluene and in hot petroleum naphtha (ligroïn), alcohol, and glacial acetic acid. This disazo compound was reduced with stannous chloride and hydrochloric acid, and the reduction product heated with concentrated hydrochloric acid for five hours at 160° C. The diamine obtained was identical with diamino-orcinol, $C_6H(CH_3)(OH)_2(NH_2)_2[1.3.5.2.4]$, and consequently orsellinic acid must have the constitution $C_6H_2(CH_3)(OH)_2(COOH)[1.3.5.6]$. This view was confirmed by a determination of the dissociation-constant of the acid. Ostwald has shown that the electric conductivity of an acid is increased considerably if it contain a hydroxyl group ortho to the carboxyl group, and to a much greater degree if there are two hydroxyl groups ortho to the carboxyl group. The dissociation-constant of orsellinic acid is 0·0127, but that of the so-called *p*-orsellinic acid is 4·1; hence the true formula for orsellinic acid is that given above, whilst the constitution of *p*-orsellinic acid must be $C_6H_2(CH_3)(OH)_2(COOH)[1.3.5.4]$.—A. S.

Amino-Orsellinic Acid Ethyl Ester; Derivatives of ——. Formation of Litmus Dyestuffs. F. Henrich and K. Dorschky. Ber., 1904, 37, 1416—1424.

It has been previously shown (this J., 1897, 529; 1902, 1450) that by the oxidation of β-amino-orcinol in alkaline solution, a mixture of dyestuffs is produced, of which those insoluble in alcohol greatly resemble the dyestuffs of litmus insoluble in alcohol. The authors have now subjected the amino-orsellinic acid, $C_6H(CH_3)(NH_2)(OH)_2COOH[1.6.3.5.2]$, corresponding to β-amino-orcinol, to oxidation in alkaline solution. A well-cooled solution of 1 mol. of the hydrochloride of amino-orsellinic acid ethyl ester was treated with 2 mols. of potassium hydroxide dissolved in a small quantity of water. The mixture oxidises rapidly in the air and becomes coloured red with a vivid fluorescence. After 48 hours, the mixture was acidified, and the reddish-brown precipitate filtered off. The product crystallises from acetic ester mostly in orange-coloured needles, with an intense blue lustre, but occasionally also in greenish scales. It is easily soluble in warm glacial acetic acid and alcohol and in cold benzene; its alcoholic solution is fluorescent. The dyestuff greatly resembles those discovered by Weselski, and proved to be phenoxazine derivatives (this J., 1890, 489, 600). If more than 2 mols. of alkali be used and the solution be not cooled. the carboxyl group is split off, and non-fluorescent dyestuffs are obtained similar to those obtained by the oxidation of amino-orcinol. The authors consider it probable that the two classes of dyestuffs present in litmus, *viz.*, (1) fluorescent dyestuffs soluble in alcohol, and (2) non-fluorescent dyestuffs insoluble in alcohol, are produced from erythro esters of orsellinic acid in a similar manner to the formation of the dyestuffs from orsellinic acid ethyl ester as already described.—A. S.

English Patents.

Basic Colouring Matters; Manufacture of Soluble Compounds or Salts of —— [for Soaps, Varnish, &c.]. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen. Eng. Pat. 12,681, June 5, 1903.

Soluble compounds, suitable for colouring soap, wax, varnish, or printing ink, are obtained by the action of alkalis or alkaline salts, on the insoluble compounds of basic dyestuffs and the higher fatty acids. For example. 20 parts of caustic soda lye (containing 35 per cent. of sodium hydroxide) are added to a mixture of 100 parts of oleic acid and 30 parts of the free base of Benzyl Violet, at 100° C. To prepare a coloured varnish, 500 parts of "printer's varnish" are added to the above mixture previous to the addition of the alkali.—T. F. B.

Sulphurised Colouring Matters [*Sulphide Dyestuffs*]; *Manufacture of Green* ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabrikation, Berlin. Eng. Pat. 11,003, May 14, 1903.

See Fr. Pat. 332,101 of 1903; this J., 1903, 1192.—T. F. B.

Sulphur Dyes [*Sulphide Dyestuffs*]: *Manufacture of Blue* ——. G. B. Ellis, London. From Chem. Fabr. vorm. Sandoz, Basle. Eng. Pat. 12,879, June 8, 1903.

See Fr. Pat. 332,560 of 1903; this J., 1903, 1241.—T. F. B.

[*Sulphide*] *Dyestuffs; Production of Brown* ——. Soc. pour l'Ind. Chim. à Bâle. Fr. Pat. 337,316, Oct. 26, 1903.

Dyestuffs dyeing unmordanted cotton in various shades of brown, from a dyebath containing an alkali sulphide, are obtained by heating a mixture of an alkylated *m*-aminophenol or one of its substitution products, with an aromatic amine or phenol, or their substitution products, in presence of sulphur.—A. B. S.

Aminothioalphyl Derivatives and Azo Sulphide Dyestuffs derived therefrom; Production of New ——. [*Sulphide Dyestuffs.*] Soc. pour l'Ind. Chim. à Bâle. Fr. Pat. 337,329, Nov. 5, 1903.

If dinitrophenylthiocyanate, which is obtained by heating a mixture of dichlorobenzene, alcohol, and potassium thiocyanate, be partially reduced with ammonium sulphide, a red crystalline powder is formed consisting of aminonitrothiophenyl. In a similar manner, dinitrophenylthiocarbamide and other dinitrophenyl-thio derivatives, and also those derived from trinitrochlorobenzene, dinitrochlorobenzene sulphonic acid and other similar substances, can be converted into nitroamino-thio derivatives. These derivatives can be diazotised and combined with amines, phenols, &c. to form azo dyestuffs. All these azo dyestuffs contain at least one atom of sulphur, which can be converted by an alkaline reducing agent into a sulphydric group, which causes the dyestuff to dissolve in alkalis even if it contain no carboxylic or sulphonic groups. The dyestuffs of this class which are soluble in water, dye wool and silk from an acid bath. The others dye unmordanted cotton from an alkaline bath containing an alkali sulphide, in the same manner as the usual sulphide dyestuffs.

—A. B. S.

Tetrazo Dyestuffs; Production of New Substantive —— Soc. pour l'Ind. Chim. à Bâle. Fr. Pat. 337,449, Dec. 5 1903.

See Eng. Pat. 27,630 of 1903; this J., 1904, 249.—T. F. B

Dyestuffs suitable for Sensitising Purposes; Process fo Preparing ——. Soc. Anon. Prod. F. Bayer et Cie Fr. Pat. 337,704, Nov. 16, 1903.

See U.S. Pat. 752,323 of 1904; this J., 1904, 337. Homologues of quinaldine, such as toluquinaldines or bromo quinaldine, may be used instead of quinaldine, and sulphuni esters, such as the ethyl esters of ethyl-, benzene-, o toluene-sulphonic acid, may replace the diethyl sulphate o the principal patent: other dialkyl sulphates give simila compounds to that obtained by using diethyl sulphate.

—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Aniline Black on Wool; Colour Reserves for —— Pokorny. Bull. Soc. Ind. Mulhouse, Procès-verbau 1903, 205.

Woollen tissues, after being successively washed, soape treated with sodium bisulphite, passed (in such a manne as to remain immersed for 15 seconds) through a bath com posed of 22 litres of bleaching powder solution at 4° B 18 litres of hydrochloric acid at 4° B., and 240 litres water, and then washed and dried, are padded two three times in a solution containing, in 30 litres, 4,0 grms. of aniline hydrochloride, 1,500 grms. of sodiu chlorate, and 2,600 grms. of potassium ferrocyanide. The are then dried and printed with dyestuffs, such as Pate Blue V, Uranin, Thioflavine, Rhodamine 6 G and B ext (1 part), admixed with potassium thiocyanate (2 parts zinc oxide (5 parts) made into a paste with water (5 part and starch thickening (20 parts), with or without sodiu acetate in addition. The black is developed, in the u printed parts of the tissues, by wrapping the latter damped cotton tissues and steaming them for 15 minut The tissues are finally washed and soaped.—E. B.

Discharges with Potassium Chromate and Oxalate Vat Blues. M. Prud'homme. Rev. Gen. Mat. C 1904, **8**, 97—98.

Instead of adding oxalic acid to the sulphuric acid ba a good result is obtained in many cases by adding potassi oxalate to the printing pastes and then passing thro a sulphuric acid bath containing 150 grms. of acid litre. This method does not give good results in the c of yellow discharges with Chrome Yellow. The best res are obtained by printing the yellow paste without oxalate, then passing through a solution containing 100—150 grms sulphuric acid and 10 grms. of oxalic acid per litre.

—A. B.

Prussian Blue Discharge on Turkey-red. E. Bontem Bull. Soc. Ind. Mulhouse, 1903, **73**, 349.

Potassium ferricyanide is heated on the water-bath caustic soda-lye at a temperature of 50°—56° C., the solu obtained being cooled and poured into water in w British gum and starch are suspended. The thick mixture thus produced is printed upon a tissue dyed Turkey-red, which is thereupon passed through a Mat Platt steam-ageing apparatus, the tissue being afterw treated with sulphuric acid at 6° B., to which about 50 g of ferrous sulphate per litre is added.—E. B.

Prussian Blue Discharge on Turkey-red. (Report o preceding paper.) H. Schmid. Bull. Soc. Ind. Mulh 1903, **73**, 350.

As the function of the alkali ferricyanide, employe Bontemps (see preceding article), is not to remove Alizarin from the Turkey-red colour-lake, and as this is converted by the soda lye into an alkali ferrocyani is preferable to employ the latter in the discharge-mi t the outset. Moreover, the iron salt may be omitted from ie sulphuric acid bath, all the elements essential for the roduction of the blue being introduced into the printing iixture employed. This may be accomplished by adding mixture of ferric nitrate and glycerin to caustic soda-lye nd then adding the amount of alkali ferrocyanide necessary o combine with the iron present. The solution thus prouced, after being thickened, is printed and steamed as in ie process described by Bontemps, the Prussian blue being ormed during the subsequent treatment with acid. By dding to the discharge mixture sodium plumbite, and hroming the tissues after passing them through the acid, green discharge may be obtained. It is possible thus to btain green and blue discharge colours of the same brightess and shade as those produced in the older bleaching owder and the newer alkali (indigo) discharge styles.

—E. B.

ydrosulphite NF; Employment of —— in Clearing Whites in Calico Printing. O. F. Alliston. Bull. Soc. Ind. Mulhouse, 1903, **73**, 346—348.

HE "whites" of cotton tissues printed with insoluble zo dyestuffs cannot be efficiently cleared with bleaching owder solution without injury to the dyestuffs. They may, owever, be cleared by means of "hydrosulphite N F," the ondensation product of sodium hydrosulphite and formldehyde (Eng. Pat. 5867 of 1903; this J., 1904, 369), he tissues being, to this end, passed through gum-water ontaining, per litre, 10—15 grms. of this compound, and hen being dried and steamed for 3—5 minutes. The mployment of the compound in question is especially dvantageous in the case of two-colour prints of Paraitraniline Red and an Azo Black produced from either of ie brands, S or D P, of Azophor Black, inasmuch as both lacks satisfactorily withstand the clearing operation with , while they are considerably acted upon by bleaching owder. T. Stricker, who, at the request of the Industrial ociety of Mulhouse, has made experiments on the subject, ates that the action of the hydrosulphite compound in earing "whites" stained with azo dyestuffs is very effecve. He finds ordinary sodium hydrosulphite too unstable be employed in a similar manner for the same purpose.

—E. B.

Brightening Silk and Cotton. C. Knapstein. Färber-Zeit., 1904, **15**, 101—104.

r treating silk, after dyeing, with a dilute solution of osphoric acid, a better gloss is obtained than when citric tartaric acid is used. Phosphoric acid may also be used vantageously, with pure olive oil, for brightening black s. In the softening process, the addition of a little taric acid to the alum bath, previous to adding alkali, ances the gloss of the product. Vegetable silk is ghtened, after dyeing, by immersion in a cold on lukerm soap bath (containing 5—8 per cent. of soap on the ight of material used) and subsequent treatment with ute acid; phosphoric acid is found to give better results n sulphuric acid.—T. F. B.

Titanium Salts as Laboratory Reagents. E. Knecht. XXIII., page 503.

eing, Bleaching, Mordanting, and like operations; Tubes or holding Yarns or Threads during ——. L. Détré, eims. Eng. Pat. 4596, Feb. 24, 1904. Under Internat. onv., July 10, 1903.

prevent the uneven dyeing of yarn in the form of cops obbins, the yarn is wound on a tube the central portion vhich is perforated. This tube is fitted with a diaphragm er at the middle or at one end, which causes the dye or to pass through the central part of the bobbin.

—A. B. S.

ing Raw Stock, Wool, and similar Materials; Apparaus for ——. J. A. Willard, Chattanooga. Eng. Pat. 610, Feb. 24, 1904. Under Internat. Conv., May 21, 903.

S U.S. Pat. 755,422 of 1904; this J., 1904, 439.—T. F. B.

Printing Yarns or Threads; Method of ——. W. B. Keefer, Philadelphia. Eng. Pat. 27,483, Dec. 15, 1903.

The threads from a number of spools pass through an arrangement which spreads them out in one plane and then over a rectangular "table." The latter is in the form of a square prism; it can be rotated on a horizontal axis and has a series of continuous grooves running round the four rectangular faces. The threads lie in these grooves, and whilst there are printed in the desired colours by one or more printing rollers which pass over the upper surface of the table and are supplied with colour from colour boxes, &c. When one portion is printed, the "table" makes a quarter revolution and the next portion is similarly treated, whilst the lower face of the "table" is cleaned by means of a rotating brush held in position by means of a spring. The "table" then makes another quarter revolution, and so on. After printing, the yarn is led into the steaming and colour-fixing apparatus. The printing rollers move transversely to the threads.—A. B. S.

Intaglio Printing Forms on Cylindrical Surfaces; Method of Producing ——. H. H. Lake, London. From G. F. and J. W. McIndoe, Boston. Eng. Pat. 4207, Feb. 19, 1904.

A piece of embossed fabric, &c., a representation of which is desired on the cylinder, is coated with a solution of starch or other glutinous material, and dried by heat and pressure. An acid-resisting adhesive substance is now applied to the raised parts only of the fabric, by a light treatment with a roller. A metal cylinder is then passed over the prepared fabric, etched by means of a suitable acid, and the acid resisting coating removed from the unetched portions.

—T. F. B.

Discharging; Process of ——. Soc. Anon. Prod. F. Bayer et Cie. Fr. Pat. 337,574, Dec 10, 1903.

Complete discharges, even with sulphide dyestuffs, may be obtained by the use of chromium compounds, such as chrome alum, chromic acid, &c. For example, the dyed fabric may be printed with a paste containing about 15 per cent. of tartaric acid, 5·5 per cent. of sodium ferrocyanide, 20 per cent. of sodium chlorate, and 1 per cent. of chrome alum, together with starch, kaolin, &c. Or the goods may be first immersed in a 1 per cent. chrome alum solution, and then printed with a paste containing oxidising agents.

—T. F. B.

Fabrics; Process for Printing ——. W. B. Keefer. Fr. Pat. 337,744, Dec. 15, 1903.

See Eng. Pat. 27,483 of 1903; preceding these.—T. F. B.

Finishing of Tulle and Analogous Tissues; Continuous Arrangement for ——. Soc. Bouffier et Pravaz Fils. Fr. Pat. 337,483, Nov. 23, 1903.

The material passes from an opening and stretching arrangement into one or more vats containing the finishing liquid, and then between revolving brushes, which rub the liquid into the material and remove the excess. From the last it passes into a drying chamber, and is finally passed over calendering rollers to complete the drying.—A. B. S.

Oil for Oiling Fibres; Preparation from Petroleum or other Mineral Oils of an ——. V. J. Kuess. Fr. Pat. 337,714, Dec. 11, 1903.

Petroleum or other mineral oil (100 parts) is mixed with animal fat (15 parts) and rosin oil (10 parts). 14 parts of caustic soda solution (containing 4 parts of alkali hydroxide) are added, and then 1 part of hydrochloric acid is stirred in, and the whole heated and added to a hot solution of 1 part of lichen or other cryptogamous substance in 300 parts of water.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

English Patent.

Colouring, Decorating, and Treating Paper, Fabrics, and other Materials; Apparatus for ——. G. H. Maunsell-Smyth, Exideuil sur Vienne. Eng. Pat. 7206, March 27, 1903.

The liquid or dye to be applied to the material is forced into a closed vessel, under pressure, in the form of a fine cloud or spray. The material, which may be previously moistened with a mordant if required, is passed through this vessel, and so receives the required colour, &c., on its surface, after which it is dried.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Sulphuric Acid Manufacture; Meyer's Tangential System for ——. E. Hartmann and F. Benker. Z. angew. Chem., 1904, **17**, 554—558.

In Meyer's latest publication, he gives the yield of his two-chamber system of 1,650 cb. m. as equal to that of a three-chamber oblong system of double the capacity, and as he puts the yield of his system at 5 kilos. of sulphuric acid per cb. m. per 24 hours, equivalent to 7·4 kilos. of chamber acid of sp. gr. 1·58, the corresponding figures for the older system must be 2·5 and 3·7 respectively. Such chambers are possibly found, but a modern set of chambers on the old system will give a yield of 6 to 7, or even over 7·4 kilos., of chamber acid; and where that is not the case, there is something wrong either with the chambers (which are built too low and too wide) or with the draught, the burners, the construction of the Glover or Gay Lussac, or the co-ordination of the various parts of the system. In comparing the two systems as to cheapness of production, Meyer's system requires less lead, but its construction costs more both in lead-working and in framework, and it occupies the ground it covers less economically. Repairs are effected in the old chambers much more easily and with much less stoppage to the process than in the case of Meyer's chambers; and especially the position of the outlet pipe (which, perhaps, more frequently requires repair than any other part of the apparatus) in Meyer's system renders repairs to it almost impossible without a complete stoppage of work. In regard to yield, the modern narrow and high chambers have done away with the "dead space," and the circulation of the gases according to Abraham's law, coupled with their forward progress, secures that the gases entering the Gay Lussac contain, practically, no sulphur dioxide, and are of the right composition for effective absorption. Apparently, the Abraham circulation exists in the circular chambers too, and interferes somewhat with the tangential circulation, with the result that reaction is not completed when the second chamber is reached; this would appear to be the reason for the insertion, in Meyer's latest systems, of a very complex arrangement of condensing tubes between the last chamber and the Gay Lussac. On the whole, the authors consider the old oblong form of construction—with modern dimensions—to be preferable, in point of cost, ease of working and repair, and yield, to the tangential chambers.—J. T. D.

Oxidation of Sulphurous Acid; Influence of Hydriodic Acid on the ——. A. Berg. Comptes rend., 1904, **138**, 907—909.

Hydriodic acid either retards or accelerates the oxidation of sulphurous acid in solution by air, according to its concentration, and for a particular strength of sulphurous acid, there is a certain proportion of hydriodic acid the presence of which exerts no influence on the oxidation. For solutions containing about 1 per cent. of sulphur dioxide, this critical strength of hydriodic acid is approximately 3 per cent. Manganous and ferrous chlorides, and also the soluble iodides of the metals, likewise hasten the oxidation of sulphurous acid. Potassium bromide and chloride are without action, whilst hydrochloric acid delays the oxidation, and in large proportion prevents it.—T. H. P.

Silica and Fused Alkali Carbonates; Reaction between ——. N. M. von Wittorf. Z. anorg. Chem., 1904, **39**, 187—196.

When two molecules of sodium carbonate are fused with one of silica, the latter does not expel an equivalent quantity of carbon dioxide, but the reaction is found to be reversible. If the partial pressure of gaseous carbon dioxide be kept low, *viz.*, at 0·07 atmosphere, about 20 per cent. of the carbonate remains undecomposed at 1,300°, and about 34·5 per cent. at 870° C. Similarly, with one molecule each of potassium carbonate and silica, 10 per cent. of carbonate escapes conversion at 1,300° and 19 per cent. at 870° C. On the other hand, the formation of silicate is greatly repressed by presence of much gaseous carbon dioxide; thus, on raising its partial pressure from 0·07 atm. to 1 atm., the melt (in the case of sodium carbonate) takes up 13 per cent. of carbon dioxide at the expense of silica. From a study of the five alkali metals it is shown that the affinity of the oxides for carbon dioxide at high temperatures rises with the atomic weight, whence the amount of silicate obtainable from carbonate follows the reverse order.
—W. A. C.

Sodium Sulphite; Spontaneous Oxidation of ——*, in Air.* A. and L. Lumière and Seyewetz. Phot. Mitt., 1904, **41** 101—104 and 117—120.

The authors find that dry anhydrous sodium sulphite doe not alter appreciably on keeping in air, even at a temperature of 100° C. If, however, the atmosphere is very damp a slow oxidation occurs. Comparative experiments shov that solutions oxidise the more rapidly as they are les concentrated, both in the cold and at the boiling point.
—F. H. L.

Cyanogen Compounds in Blast-Furnace Flue Dus C. Bolin. Teknisk Tidsskrift, 1904, **34**, 24. Chem. Zeit., 1904, **28**, Rep. 95.

While a large proportion of the cyanogen compound formed in the blast furnace are destroyed in the uppe portions, a certain quantity escapes decomposition and i found in the flue-dust, the colour of which is brighter a it contains more cyanogen. The solution obtained b treating the dust with water contains alkali cyan de thiocyanate, cyanate, sulphide, and chloride, and the autho gives a scheme of analysis for determining these. He ha found in flue-dusts as much as 1·43 per cent. of petassiu cyanide and 2·60 per cent. of thiocyanate.—J. T. D.

Iron Carbonylferrocyanide: a Constituent of Spent Oxid M. Stoecker. J. Gasbeleucht., 1904, **47**, 338—342.

The author has ascertained the presence, in spent oxid of small amounts of a violet-coloured compound, ferr carbonylferrocyanide, $FeFeCO(CN)_5$. The average pr portion appears to be about 0·11 per cent., and it is du included in the result when cyanogen is determined in spe oxide by Knublauch's and the other usual methods. As is readily decomposed, it is for the most part converted i simple ferrocyanide compounds in working up spent oxi in the usual way for the production of ferrocyanide; a any of it which escapes conversion may easily be tra formed into ferrocyanide. To detect its presence in sp oxide, 10 grms. of the sample are digested for 17 ho with 50 c.c. of caustic potash solution (10 per cent.); fr the filtrate the ferrocyanide is precipitated by means of h acetate, and to the filtered solution is added concentrated ferric chloride solution. After standing for several days, the liquid is filtered, when the violet compound remains on the filter.—H. B.

Liquid Oxygen; Solubility of Nitrogen in ——. A. Stock. Ber., 1904, **37**, 1432—1434.

The solubility of nitrogen in liquid oxygen mentioned by Erdmann and Bedford (this J., 1904, 441), is a simple case of the physics of two miscible liquids; and their quantitative results could all have been predicted from the figures given by Baly. No chemical relationship between the two substances can be inferred from the facts; and the analogy between the solubility of nitrogen in oxygen and that of ammonia in water is purely accidental.—J. T. D.

Separation of Gases by means of Centrifugal Force; Principles of the ——. G. Bredig and F. Haber. Z. angew. Chem., 1904, **17**, 452—464.

The authors give a mathematical discussion of the physico-chemical principles underlying the problem, and arrive at the following conclusions:—The centrifugal separation of air as proposed by V. Calzavara is impracticable, the circumferential velocity required in a single stage separator being greater than any known material of construction can withstand. A multiple stage separator is impracticable, as the chambers and shaft would have to be of enormous length in order to yield a sufficient quantity of air rich in oxygen. The energy required for the actual separation is small, but great losses are caused by friction in the bearings of the separator. All these difficulties are due to the circumstance that the difference in density of the gases to be separated is very small, and that the rate of diffusion of the two gases, on which depends the rate of production of a gas rich in oxygen, is also small.—L. F. G.

Glover Tower Process [Sulphuric Acid Manufacture]; Impt. upon the ——. H. Hegeler and N. L. Heinz, Ill., U.S.A. Eng. Pat. 2541, Feb. 2, 1904.

See U.S. Pat. 752,677, 1904; this J., 1904, 370. See also U.S. Pat. 728,914, 1903; this J., 1903, 742.—E. S.

Stones, Artificial, or Bricks; Manufacture of ——, *in which the Waste from the Leblanc or Ammonia Soda Process is used.* C. Ahrendts. Eng. Pat. 4130, Feb. 18, 1904. IX., page 490.

Slaked Lime, and Process of Preparing the same. J. J. Feely, White Plains. Eng. Pat. 4409, Feb. 22, 1904. Under Internat. Conv., March 5, 1903.

Quicklime is slaked by water containing acetic acid, and is subjected to attrition with exposure to the air for some hours. After a further period, the now dry slaked lime is ground to the desired fineness.—E. S.

Sea-Water; Apparatus for the Evaporation of ——. H. Schmidt, Hamburg-Uhlenhorst. Eng. Pat. 4597, Feb. 24, 1904.

The vertical boiler in which the sea-water is evaporated contains in its lower part a series of connected coils (for admission of high-pressure steam), the lowest of which coils is beneath a perforated plate constituting a lower chamber. This lowest coil is jacketed. The sea-water to be evaporated enters the annular space round the lowest coil, and has exit in a heated state below the perforated plate, through which it rushes in jets which play against the heated coils in the upper chamber. The water of condensation, from the steam injected into the coil, leaves by the lowest coil, where it serves to heat the incoming sea-water. In a modified form of apparatus, the sheath or jacket to the lower coil, is longitudinally constricted in parts so as to be maintained in place. The upper part of the boiler is occupied by baffle-plates, obstructing the passage of the spray through the outlet for the steam to the condenser. —E. S.

Hydrogen Gas; Apparatus and Method for the Production of Pure or Nearly Pure ——. H. G. Hills and H. Lane, Hyde. Eng. Pat. 10,356, May 7, 1903.

Hydrogen gas is produced by passing steam, preferably superheated, over iron contained in heated retorts; and the mixture of hydrogen and steam is led through coolers, from which the hydrogen passes to a gasometer. By means of reversing valves, controlling inlet and outlet passages, a reducing gas, such as water-gas, coal-gas, or the like, is then led through the retorts, to reduce the iron oxide formed, and then steam is again passed through.—E. S.

Graphite; Treatment of —— *for the Separation of Impurities therefrom.* R. Glogner, Freiburg. Eng. Pat. 14,831, July 3, 1903.

French Patents.

Catalytic Reactions; Process for Conducting —— *[Manufacture of Sulphuric Anhydride by the Contact Process].* W. Kauffmann. Fr. Pat. 337,424, Dec. 5, 1903.

The sulphur dioxide is preliminarily heated to a temperature suitable for initiating the reaction, and is passed into a vessel charged with contact material so limited in quantity as to restrict the increased temperature of the issuing gas, due to heat of reaction, to a certain range. From this first reacting vessel the gases pass through a heat exchanger, in which their excess heat is communicated to sulphur dioxide on its way to the heater; and the cooled gases enter, at a suitable temperature for initiating reaction, a larger vessel packed with contact material, in which the oxidation is completed.—E. S.

Barium Manganate; Manufacture of a Special —— *and of all the Permanganates.* A. Tixier, R. Cambier, and C. E. Adnet. Fr. Pat. 337,629, Dec. 12, 1903.

Barium manganate is formed, either in the wet way, by reacting with barium hydroxide or a soluble barium salt on solution of an alkali manganate or permanganate; or air, free from carbon dioxide, is passed over a dry mixture of manganese dioxide with caustic soda or potash, at a low red heat; the product is lixiviated, and the solution is precipitated by barium hydroxide. The barium manganate thus obtained may serve for the preparation of permanganates; as, for instance, by the action upon it of sulphuric acid in presence of a soluble sulphate.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

United States Patents.

Glass-Furnace. S. O. Richardson, Toledo. U.S. Pat. 756,409, April 5, 1904.

The furnace consists of a receiving-chamber; a closed melting-pot divided into a melting-chamber and a planing chamber by a partition, which is provided with an opening communicating with both chambers; a feed opening leading into the melting-chamber; a dam for maintaining the "metal" at a desired height in the planing-chamber; an enclosed passage-way arranged to convey the overflow from the planing-chamber into the receiving-chamber; and means, in communication with the interior of the receiving-chamber, for maintaining the metal therein in a sufficiently fluid condition. A number of continuously operating, closed melting-pots placed opposite to each other may be arranged so as to discharge into a common run-way, feed-openings being provided for continuously charging the pots from outside the heating-chamber, and means being arranged outside the pots for melting their contents, as well as a working-chamber to receive the metal from the run-way. The contents of the pots may also be melted by means of an arrangement outside them.—A. G. L.

Glass-Reheating Furnace. J. L., C. V., F. J., P. R., and F. L. Arbogast, Pittsburg. U.S. Pat. 756,557, April 5, 1904.

A VERTICAL heating chamber is arranged in conjunction with an endless chain carrier, pivoted "blank-supporting plates" being carried by this chain, and a "tripper" adapted to tilt said plates.—A. G. L.

Glassware; Method of Manufacturing ——. J. T., C. V. F. J., F. L., and P. R. Arbogast, Pittsburg. U.S. Pat. 756,558, April 5, 1904.

"BLANKS" are pressed of suitable form, and allowed to cool without annealing; a number of the "blanks" are then reheated simultaneously, and successively blown to form articles from a part of the mass of glass contained in the "blanks," after which the completed article is cracked off from the rest.—A. G. L.

[Glass-] Furnace. S. O. Richardson, Toledo. U.S. Pat. 756,894, April 12, 1904.

THE furnace is provided with a working-chamber and a casting-chamber in free communication with each other. The casting-chamber is provided with an opening leading to its exterior, the upper part of this opening being below the level of the metal-line in the working-chamber. A movable carrier moves into and out of the casting-chamber through the opening and carries moulding means which are supplied with fluid "metal" from the working-chamber. The whole is so arranged that the casting-chamber is closed by the carrier and moulding means, whilst they are within the chamber, so as to prevent a fall of temperature. —A. G. L.

Glass Articles; Process of Manufacturing ——. S. O. Richardson, Toledo. U.S. Pat. 756,895, April 12, 1904.

GLASS articles are manufactured continuously by casting a definite quantity of the refined "metal" at a high temperature, at which the "metal" is maintained in the liquid condition, cooling the "metal" so cast to a lower temperature, and then manipulating the glass to the required form.—A. G. L.

Pottery-kiln. E. S. Bacon, Detroit. U.S. Pat. 756,561, April 5, 1904.

IN the kiln are arranged, in conjunction with an external shell, a muffle located in this shell, a pipe hanging from the wall of the shell and leading through an opening in the bottom, a fuel-receptacle sleeved within this pipe, and provided with an air-inlet through the bottom of the pipe, and with air-inlets through the side walls, and with a fuel-chamber surrounding the inlet through the bottom. Means are provided for adjusting the fuel-chamber with respect to the hanging pipe, and thus varying the combustion-chamber and regluating the combustion.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Portland Cement; New Definition of ——. Tonind.-Zeit., 1904, **28**, 302.

THE Association of German Portland Cement Manufacturers has adopted the following amended definition of the term Portland cement, *viz.*, a hydraulic cementing material, with a sp. gr. not less than 3·1 in the calcined condition, and containing not less than 1·7 parts by weight of lime to each 1 part of silica + alumina + iron oxide, the material being prepared by intimately mixing the raw ingredients, calcining them to not less than clinkering temperature, and then reducing the whole to the fineness of flour.—C. S.

Sand-Cement. H. Seger and E. Cramer. Tonind.-Zeit., 1904, **28**, 331—332.

Two opinions are current respecting the cause of the good qualities of Portland cement mixed with sand. One of them is that the increased fineness of the cement after grinding along with the sand is the sole cause of the improvement, whilst in the other the credit is given to the improved condition of the sand. To determine which view is correct, the authors made comparative trials with cement alone and in admixture with 25 per cent. of glass sand, or with the same proportion of pure quartz that had been calcined in a porcelain kiln. The results showed that, so far from the soluble silica in the calcined quartz improving the tensile strength of the mixture, the contrary is the case, at least when the test blocks are stored in air. In those stored under water the difference is inappreciable. Although the initial strength of the mixtures of cement and sand or quartz is lower than that of the pure cement, the conditions are reversed at the end of 3—6 months. At the outset, the relation between tensile and crushing strengths is more favourable in the case of the mixtures, but by the end of three months the difference has disappeared. There is no advantage in using calcined sand for the mixture.—C. S.

ENGLISH PATENTS.

Waste Heat in Brick and other Kilns; Utilising ——. T. Kirkland, London, and F. H. Cooke, Peterborough. Eng. Pat. 7128, March 27, 1903.

Two or more kilns are connected with flues and dampers in such a way that the hot products of combustion of one kiln can be passed through the others.—W. H. C.

Brick Kilns. T. Crew, Tipton. Eng. Pat. 1617, Jan. 22, 1904.

THE waste heat from one brick kiln is utilised to dry and heat unburnt bricks contained in a second kiln by connecting the flues inside the first kiln with outside flues laid all round the kiln. These flues join outside flues of the other kiln, which communicate with the interior of the latter by means of branches of brickwork extending under the furnace holes.—A. G. L.

Stones, Artificial, or Bricks; Manufacture of —— *in which the Waste from the Leblanc or Ammonia-Soda Process is used.* C. Ahrendts, Strassburg. Eng. Pat. 4130, Feb. 18, 1904. Under Internat. Conv., May 5, 1903.

SAND, or ground silicious slag or the like, and slaked lime are mixed with a large amount of alkali waste, water being added to promote the mixing. Bricks or blocks are formed from the mass obtained, pressed, and placed in trucks which are pushed over a series of pipes through which steam is led. A cover is placed loosely over the bricks, which gradually attain a temperature of 30° to 40° C., at which they are kept for 10 or 12 hours. The whole vessel is then tightly covered and supplied with high-pressure steam so as to harden the bricks.—A. G. L.

Cement; Improved Process for Manufacturing ——. R. Liebold, Weimar. Eng. Pat. 4606, Feb. 24, 1904.

TEN litres of boiling water, in which are contained 245 grms. of stearine, 12 grms. of potash, and 10 grms. of colophony, are added to 100 kilos. of calcined but unground cement. The whole is then dried and ground as usual.—A. G. L.

UNITED STATES PATENTS.

Stone; Artificial ——. V. Steger, Bonham. U.S. Pat. 756,295, April 5, 1904.

A SOLUTION of 8 lb. of sodium carbonate in 100 galls. of water is added to a mixture of 93 per cent. of sand and 7 per cent. of lime. The mixture is then formed into bricks or the like and treated for about 10 hours with steam previously brought into contact with a mixture of 9 lb. of caustic potash and 8 lb. of flowers of sulphur.—A. G. L.

Slag Cement; Apparatus for the Manufacture of ——. C. Gramm. Frankfort-on-Maine, Assignor to H. Edmunds, London. U.S. Pat. 757,035, April 12, 1904.

The material is conveyed to a rotary distributor contained within a stationary casing, and from the former the material passes to a conical rotary table, provided with an adjacent stationary scraper, located below the distributor and outside the casing. Means are provided for imparting different rotary movements to the table and to the distributor. —B. N.

Magnesia Cement Composition. E. Bidtel, Milwaukee. U.S. Pat. 757,252, April 12, 1904.

A powdered substance containing magnesia is mixed with powdered magnesium sulphate and barium chloride, and the mixture treated with water. Barium sulphate and magnesium chloride are produced, and the latter at once combines with the magnesia and causes the whole to set gradually. The composition of the cement is expressed by the formula $MgCl_2.5MgO.BaSO_4.17H_2O$.—A. G. L.

French Patents.

Stone [Artificial]; Manufacture of Calcareous ——. Second Addition, of Nov. 2, 1903, by H. C. Meurer, to Fr. Pat. 291,906 of Aug. 21, 1899, by H. C. Meurer and F. T. Bormann-Zix.

In making bricks by adding hot sand to quicklime and quenching the lime by means of hot water, it has been found o be advantageous to regulate the temperature by adding a part of the hot sand only after the mixture of the lime with he remainder of the hot sand has been quenched and has been allowed to lose a part of its heat. The whole is then at once reheated by means of steam or in any other convenient way.—A. G. L.

Wood; Process for the Rapid Drying of ——. Soc. Anon. Le Trénailage. Fr. Pat. 337,378, Nov. 19, 1903.

The wood is dried by alternately subjecting it in a closed essel, to increased and diminished pressure at a temperaure which may reach 60° to 80° C., but preferably does not xceed 30° to 40° C.—A. G. L.

Surfaces [Building Materials] exposed to the Air; Process for Waterproofing and Preserving ——. E. M. Caffall. Fr. Pat. 337,773, Dec. 16, 1903.

ee Eng. Pat. 27,426 of 1903; this J., 1904, 254.—T. F. B.

X.—METALLURGY.

old-Selenium-Silver Ores; Treatment of ——*. which are finely dispersed through the Gangue and form a large amount of Slimes.* M. Merz. Oest. Zeits. Berg- u. Huttenw., 1904, **52**, 59, 70, 86, 99; Chem.-Zeit., 1904, **28**, Rep. 103.

rom a Sumatran ore (54·21 grms. of gold and 369·86 of ver per 1,000 kilos.) containing selenium, only 75 per cent. its gold and 50 per cent. of its silver could be extracted the ordinary processes. A very large amount of potasm cyanide was consumed, and a great deal of slime was rmed, which hindered the lixiviation. The ore could not roasted, because of the selenium it contains, and the use oxidisers during lixiviation did not aid the extraction. e author proposes to treat the ore by a decantation ocess, the whole of the ore being in the first place wetound to extreme fineness, concentrated, and treated by algamation.—J. T. D.

Zinc; Metallurgy of ——. H. Brandhorst. Z. angew. Chem., 1904, **17**, 505—517.

ende is the most important ore in Silesian practice; as chanically prepared ready for roasting it usually contains –70 per cent. of zinc sulphide, 10—25 of iron pyrites, –35 of dolomite, and about 5 per cent. of quartz and ena, with occasionally a little calamine. When gradually ted in air, the pyrites burns first (at low redness); at a higher temperature the zinc sulphide oxidises; this temperature is above that of complete decomposition of zinc sulphate, so that no sulphate is formed, only oxide. The roasted ore always retains 1—2 per cent. of sulphur as zinc sulphide. The loss of zinc in Silesian practice is considerable, only 65—70 per cent. of the zinc contained in the ore being actually obtained as metallic zinc; while the Belgian process yields 85—90 per cent., or even more. The loss arises from: (1) Zinc remaining in the residue in the muffle; (2) Zinc in the gaseous form permeating the muffle or becoming absorbed in its substance; (3) Zinc passing the condenser, and being lost with the furnace gases. Investigation of the residues of a number of years' production has shown that in the Silesian works by far the largest proportion of the total loss of zinc is due to the first cause. Experiments were made, with eight different varieties of ore, in which the ore was reduced in crucibles (working with 200 grms. of ore) heated in crucible furnaces just to the temperature of the ordinary zinc-muffle. The residues in the crucibles were all free from zinc, or contained at most traces, proving that no chemical reason for the retention of zinc in the muffle-residues exists, and also that a small proportion of sulphur in the roasted blende does not harmfully affect the reduction. To ascertain whether the temperature and mechanical condition of the contents of the muffle affected the question, experiments were made at a higher temperature, with the addition to the charge of sufficient clay to form a slag, fusible at the temperature of the operation. These were so successful that a trial was made on a small manufacturing scale. Instead of muffles, vertical fireclay cylinders, open at both ends, were used. The lower ends rested in and were luted to fireclay trays resting on the bed of the furnace, while the upper ends projected through the furnace roof. Through holes in the centre of the trays passed vertical fireclay tubes, ending below in horizontal or gently inclined tubes to take away the metal, and projecting into the cylinders to about one-fourth of their height. The upper ends of these tubes were protected against the entrance of solid material by caps. The cylinders were filled with broken coke to the level of the top of the tubes, and the charge was put in above this from the top. The cylinders were heated by gas, the final temperature being sufficient to melt the slag, which collected at the bottom and could afterwards be run off. A charge containing 20 parts of incompletely roasted blende, 5 of white calamine, 5 of coke, 6 of clay, and 2 of lime, thoroughly mixed, yielded 92 per cent. of its total zinc and a slag containing only 0·3 per cent. of zinc. As far as the experiments have yet gone, the apparatus promises to be durable against both chemical and mechanical injury, and works off in 24 hours from 60—120 kilos. of ore per sq. metre of surface (against 34—39 kilos. for a Silesian muffle, and 25—30 kilos. for a Belgian tube). Added to this, the mechanical arrangements for charging, &c., are very convenient, and damaged cylinders are easily removed and replaced. In Upper Silesia there exist large amounts of ores containing low percentages of zinc. From some of these the zinc can be extracted by wet treatment with ammonium carbonate and ammonia; silicates are not amenable to this treatment, but an iron-containing oxide, of formula $2ZnO.Fe_2O_3$, can be treated if the ferric oxide be previously reduced to ferrous oxide by the reducing gases from the blende-roasting. The solutions so obtained have not as yet been treated profitably by electrolysis, but when heated they give off ammonia and ammonium carbonate, and deposit a double zinc-ammonium carbonate, which, decomposed by heat, gives zinc oxide. This oxide yields by reduction a very pure metal. The ammonium compounds can be recovered and used again. Concentration of the Silesian zinc ores by removal of the associated dolomite has of late been attempted. This is effected by dissolving the carbonates in sulphurous acid, furnished by the sulphur dioxide evolved in roasting the blende. The washed gases are pumped into vessels in which the crushed ore is agitated with water, under a few feet of water-pressure, and the sulphite solutions so obtained are sold for wood-pulp manufacture. This is probably a more profitable use of the sulphur dioxide than making sulphuric acid, and it enables ores to be worked that would otherwise be too poor to use. —J. T. D.

Carbon and Silicon; Some Compounds of —— with Metals; and a generally applicable Method for the Determination of Carbon in Metals. W. Hempel. Z. angew. Chem., 1904, **17**, 296—301, 321—325.

By heating together finely-divided iron and lamp-black in the electric furnace, carbon-iron alloys containing up to 4·96 per cent. of carbon were prepared. With cobalt, products containing up to 8·45 per cent., and with nickel, up to 6·25 per cent. of carbon were obtained. In the case of iron and cobalt, the greater part of the carbon in the cooled product is chemically combined, but in the case of nickel, nearly the whole of the carbon in the final product is present as graphite. Platinum can take up 1·2 per cent. of carbon, whereby it becomes brittle; copper, up to 0·03 per cent.; silver, up to 0·04 per cent.; gold, up to 0·31 per cent.; manganese, 0·47 per cent.; chromium, 2·23 per cent.; and tungsten, 3·3 per cent. of carbon. By fusing a mixture of the reduced metal with powdered silicon crystallised from zinc, silicon-cobalt alloys containing up to 19·3 per cent. of silicon were obtained, the products being extremely hard and brittle. The corresponding nickel alloys contained up to 19·95 per cent. of silicon. With mixtures of silicon and carbon, together with cobalt and nickel respectively, amounts of silicon less than 1·4 per cent. have little influence on the quantity of carbon taken up, but if the silicon be present in excess, the amount of carbon taken up is less, the greater the quantity of silicon in the final product. Commercial zinc is stated to be quite free from carbon. For the determination of the carbon in metals, the author recommends Weyl's method of dissolving the metal by the aid of the electric current. A piece of glass tubing is made with one end in the form of a flat plate with a hole in the middle. The material is placed on this plate and the tube is immersed in dilute hydrochloric acid, so that about one-third of the material is covered. The current flows through a platinum wire in contact with the material being examined. The undissolved carbon is determined by combustion with chromic acid by Ullgren's method. In the case of metals such as platinum, the author finds that the metal is quickly dissolved by approximately the theoretical amount of *aqua regia*, if the mixture of metal and acid be heated at 130° C. in a sealed tube. The undissolved carbon may then be determined by combustion, and any carbon dioxide formed determined gasometrically.
—A. S.

Cyanogen Compounds in Blast-Furnace Flue Dust. C. Bolin. VII., page 488.

Tin; Determination of —— in Tinplate. H. Angenot. XXIII., page 504.

English Patents.

Metals [Precious]; Apparatus for Separating —— from their Crushed Ores or Material containing same. W. N. Turner, Ipswich. Eng. Pat. 12,778, June 6, 1903.

The apparatus is especially applicable to the treatment of alluvial gold-bearing substances by the "dredger process." The ore passes through the revolving screen of the ordinary apparatus into a receiving vessel having division plates with a series of gates or sluices opening from them into separate channels, which latter are provided with adjustable baffles for directing the flow upon the tables.—E. S.

Aluminium and Alloys containing Aluminium; Alloy for and Process of Soldering and Brazing ——. L. Trezel and A. J. Compte de Montby, Paris. Eng. Pat. 4973, Feb. 29, 1904.

The alloy consists approximately of 100 parts of zinc, two parts of bismuth, and one part of nickel, melted together in a plumbago crucible, cast, and rolled into thin bars. These, cleaned by dilute hydrochloric acid, are coated with mercury nitrate, and placed in a silver bath if it be desired to solder pure aluminium, or in a nickel bath if the solder be intended for an aluminium alloy, to receive a thin layer of one or other of these metals. To use the alloy, the parts to be soldered are heated to 100° C., rubbed with stearine, and, when wiped dry, are soldered or brazed in the usual way.—E. S.

Zinc; Process for the Treatment of Metallic ——. P. and A. Gührs, Berlin. Eng. Pat. 12,186, May 28, 1903.

See Fr. Pat. 332,657 of 1903; this J., 1903, 1247.—T. F. B.

United States Patents.

Crude Iron; Process of Converting —— into Malleable Iron or Steel. J. J. Deemer, Chester. U.S. Pat. 757,276, April 12, 1904.

The bath of molten crude or cast-iron is subjected to oxidising blasts directed against the surface of the metal by an annular series of jets extending downwards and obliquely, and converging to a common point centrally on the surface of the bath, and then to similar blasts from jets directed upwards and obliquely to converge as in the former case.—E. S.

Roasting or Desulphurising Furnace. F. J. Falding, New York. U.S. Pat. 756,485, April 5, 1904.

The furnace has a combustion chamber and heating flue; the roasting chamber consists of separated sets of superposed hearths above the heating flue, and is provided with stirring and conveying arrangements. The heating flue discharges into "an uptake and downtake chamber" at the rear of the lower hearths, and extends up to the level of the upper hearth, air-heating flues extending below opening into the chamber. The stirring mechanism includes a rotatory hollow column having hollow stirrer arms, a pneumatic fan for blowing air through the same, and pipes leading to the arms, and valves whereby these are individually subject to control of the air passed.—E. S.

Zinc; Furnace for Producing ——. P. Schmieder, Lipine. U.S. Pat. 757,059, April 12, 1904.

The claim is for "the combination of a vertical receptacle or shaft for the charge of ore mixed with fuel, with a device for heating the upper part of the charge through the walls of said receptacle, a number of condensers or collectors of the liquid zinc for this reduction chamber, a number of tuyères in the lower part of the shaft, which is not arranged to be heated, an oxidation chamber, a condensing chamber and openings above the tuyères and suitable channels for leading the gases from this oxidation chamber for the slag to the condensing chamber."—E. S.

Ores; Process of Smelling ——. A. R. Partridge, Assign to F. W. Page, both of San Francisco. U.S. Pat. 757,22 April 12, 1904.

Air at atmospheric pressure is freely admitted to t bottom of the smelting furnace, in which a suction induced by injecting steam or air through a narrow passag across an outlet at the top of the furnace, into a wid passage beyond the outlet.—E. S.

Smelting Furnace. A. R. Partridge, Assignor to F. Page, both of San Francisco. U.S. Pat. 757,221, April 1904.

The smelting furnace is provided, near its closed top, wi a side horizontal flue opening into a vertical flue, of whi the upper part leads to the chimney, its lower part havi a tube closed at its lower, contracted end, which end recei an injector pipe, the tube having a widened opening imm diately below the outlet, so that when a "fluid" (as stea or air) is injected, suction is induced in the furnace.—E.

Smelting Furnaces; Hearth for ——. A. R. Partrid Assignor to F. W. Page, both of San Francis U.S. Pat. 757,222, April 12, 1904.

The hearth or crucible of the furnace is provided wit double wall entirely around it, forming a water-sp outside which a water-pipe extends, having branched val pipes opening into the water-space. A water-supply p leads into the surrounding water-pipe, and there is a wa discharge from the water-space.—E. S.

French Patents.

Steel; Hearth Furnace for the Manufacture of ——. V. Defays. Fr. Pat. 337,589, Dec. 11, 1903.

At each end of the longer axis of the hearth are three channels, inclined from above downwards, each independently connected to a system of regenerative chambers. The central channel serves for the passage of gas, and the two channels, one on each side, converge so that the air-blast carried by each meets and mingles with the gas from the central channel, in a movable chamber of combustion contiguous to and inclined towards the bath of molten metal. At the opposite end of the bath the arrangement of flues, &c., is the same. Means for controlling the air-blasts are provided.—E. S.

Oil Furnace [for Soldering Pipes, &c.]. G. L. Bourne. Fr. Pat. 337,477, Nov. 16, 1903.

The furnace contains a primary combustion chamber, at the bottom of which is placed an oil burner, and at the top of which rests a secondary combustion chamber, provided laterally with an air pipe, which draws its supply from a pipe feeding the burner. From the secondary combustion chamber, and connected with it, extends a horizontal heating chamber with narrowing brickwork passages and closed end, the products of combustion escaping through a central transverse channel in which the pipes to be soldered are placed. Combustion is complete, and the absence of carbon or oxygen in the waste gases is of special advantage in soldering. The furnace can also be used for smelting, tempering, for heating stampings, forgings, and rivets, and for general forge work.—L. F. G.

Aluminium and Similar Metals; Soldering of ——. C. Ellis and O. J. Flanigan. Fr. Pat. 337,500, Dec. 7, 1903.

See U.S. Pat. 746,802 of 1903; this J., 1904, 66.—T. F. B.

Pyrophoric Alloys for Use in Igniting and Illuminating. C. Auer von Welsbach. Fr. Pat. 337,320, Oct. 31, 1903. II., page 484.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*A.*)—ELECTRO-CHEMISTRY.

Silver; Double Salts of ——. Bodländer and Eberlein. Z. anorg. Chem., 1904, **39**, 197—239.

The authors have investigated, by electro-chemical methods, the ionic conditions under which the double silver salts which are formed by solution of a silver salt in the corresponding potassium salt, exist in aqueous solution. They find that the tendency to form double salts increases with the negative radicles Cl, Br, CNS, I, CN, in the order given. In a solution of potassium cyanide, silver, like gold, is quite insoluble in the absence of oxygen, and for silver voltameters the use of a cyanide bath is recommended, with the addition of a piece of silver foil surrounding the cathode. To deposit it from cyanide solutions, a higher E.M.F. is required for silver than for gold, and a still higher for mercury.—W. A. C.

Potassium Double Cyanides; Electrolysis of ——. H. von Hayek. Z. anorg. Chem., 1904, **39**, 240—256.

The electrolytic oxidation of potassium ferrocyanide to ferricyanide is brought about by the combination of one anion, $Fe(CN)_6$, with three molecules of $K_4Fe(CN)_6$. At he same time the anion $Fe(CN)_6$ may react thus: $Fe(CN)_6 + 2H_2O = H_4Fe(CN)_6 + O_2$, but if the liquid be kept alkaline there is no loss, since the nascent oxygen oxidises he ferrocyanide to ferricyanide. The secondary electrolysis of ferricyanide and of alkali, however, leads to loss, as ndicated by evolution of gaseous oxygen. To secure the best results the liquid should be kept alkaline; the anode, which may be of nickel, should be rotated; and the volume of anode-liquid should be twice that of the cathode-liquid, from which it is separated by a porous cell. The current efficiency remains about 100 per cent. until the concentration of ferrocyanide falls so far (about 1·75 grm. per 100 c.c.) that oxygen is evolved.—W. A. C.

Sodium Thiosulphate; Electrolytic Oxidation of ——. C. J. Thatcher. Z. physik. Chem., 1904, **47**, 641—720.

By the aid of platinised electrodes, sodium thiosulphate can be oxidised to tetrathionate, which, in neutral or acid solutions, is not further oxidised. Sodium thiosulphate solutions are faintly alkaline, and so long as this slight degree of alkalinity is maintained, the oxidation of S_2O_3 ions to S_4O_6 ions is the only reaction which takes place. The formation of sulphur, sulphite, or sulphate, is the result of secondary reactions, which only occur in more strongly alkaline or in acid solutions. The chief reaction, *viz.*, the conversion of S_2O_3 ions into S_4O_6 ions, is not a direct electrolytic one, but is due to a secondary chemical oxidation by an oxidising agent, probably oxygen, which is produced primarily by the electrolysis. In this chemical oxidation the platinised platinum exerts a catalytic influence. Sodium tetrathionate is unstable in alkaline solution, undergoing hydrolysis, with formation of thiosulphate and trithionate. It is probable that tetrathionic acid is a hydrogen peroxide derivative of thiosulphuric acid, and this opens out an interesting field for research.—A. S.

Tetra-ethylammonium Iodide; Electrolysis of ——. E. Goecke. Z. Elektrochem., 1904, **10**, 249.

By the electrolysis, at the ordinary temperature, with a current of 0·5 ampère, of a solution of 10 grms. of tetra-ethylammonium iodide in 100 c.c. of water, between platinum electrodes without a diaphragm, from 3·5 to 4 grms. of tetra-ethylammonium tri-iodide, $N(C_2H_5)_4I.I_2$, and a smaller quantity of iodoform were produced. The tetra-ethylammonium tri-iodide is deposited on the anode and on the bottom of the containing vessel as a reddish-brown product, which is insoluble in ether, but soluble in acetone. The yield of iodoform increases with rise of temperature and strength of current.—A. S.

English Patents.

Electrolytic Meters. E. A. Carolan, London. From the General Electric Co., New York. Eng. Pat. 7587, April 1, 1903.

A glass float carries one of the electrodes in a pierced bulb at its lower end and a scale in its upper portion, the reading index being also supported by a second float. The change in weight of the electrode produces a relative movement between the two floats, which is irrespective of the level of the electrolyte, and thus indicates the amount of current passed through the meter. The second electrode is placed in a trough attached to the outer vessel, or may be carried by the float which supports the reading index, so as to obtain a greater relative movement between the scale and reading index. Mercury is used for the electrodes, and a solution of mercurous nitrate as the electrolyte.
—B. N.

Anodes for Electrolytic Operations. F. Greenfield, Birmingham. Eng. Pat. 11,579, May 21, 1903.

The anode consists of two or more concentric rings connected together by radial arms, and is suspended by means of a conducting-rod covered with insulating material, the latter pressing against insulating washers so as to prevent the portion of the rod immersed from coming into contact with the electrolyte. The rod may be threaded and screwed into a tapped hole in the anode so as to adjust the height of the latter in the liquid, or the rod may be screwed into a socket wormed internally which is sunk into the anode so as to make contact at its lower end, and the remainder of the socket is covered with insulating material. In a third form the anode has a lug threaded externally, and the suspender rod is provided with a socket wormed internally at its lower end to screw on to the lug, both rod and socket being covered with a sleeve of insulating material.—B. N.

Water; Apparatus for [Electrically] Separating Oily and Similar Impurities from ——. Davis-Perrett, Ltd., H. T. Davis, and E. Perrett, London. Eng. Pat. 8175, April 8, 1903.

See U.S. Pat. 744,171 of 1903; this J., 1903, 1362.—T. F. B.

United States Patent.

Chemical Compounds; [Electrolytic] Process of Producing ——. J. J. Griffin, Washington. U.S. Pat. 757,036, April 12, 1904.

An electric current is passed from an anode of carbide to a cathode of carbide, one or both of which may consist of calcium carbide, through an electrolyte, such as sulphuric acid, which reacts chemically with the carbide, and which yields an electrolytic product reacting with the products of the chemical action, or with the carbide, to give the desired compound. Instead of using carbide for both electrodes, one only may be made of carbide, and an insoluble substance, which will react with the electro-chemical product, may be maintained in suspension in the electrolyte. —B. N.

French Patent.

Ozone; Production of —— for Application as a Disinfectant. A. D'Arsonval, G. E. Gaiffe, and G. Gallot. Fr. Pat. 337,531, Dec. 8, 1903. XVIII. C., page 500.

(*B.*)—ELECTRO-METALLURGY.

English Patent.

Electric Furnaces. C. A. Keller, Paris. Eng. Pat. 3790, Feb. 15, 1904.

See Fr. Pat. 336,403 of 1903; this J., 1904, 377.—T. F. B.

United States Patents.

Metals; Precipitating —— from [Cyanide] Solutions. C. Butters, Berkeley. U.S. Pat. 756,211, April 5, 1904.

Metals are precipitated from solutions (chiefly from cyanide solutions) by the use of cathodes having smooth tin surfaces and anodes of lead peroxide, operating with an electric current of high density.—E. S.

Ores and Tailings [Precious Metals]; Process of Treating Low-Grade —— by Electrolysis. E. Fahrig, Philadelphia. U.S. Pat. 756,223, April 5, 1904.

The low-grade ore or tailings is made into a pulp with water and a suitable electrolyte, and the pulp is passed by gravity between a series of pairs of anode and cathode plates, inclined alternately and arranged in a tower fashion one below the other in an oxidising atmosphere at a pressure equal to the height of the tower. The precious metal is deposited, and the partially extracted pulp is subjected to an oxidising action, then to a leaching action for some time, and then to successive electrolytic, oxidising, and leaching actions until the precious metal in the partially extracted pulp has been almost completely dissolved. The solution is subjected to defecation, the defecated liquor is heated, and the latter is finally submitted to electrolytic action so as to obtain the last traces of precious metal.—B. N.

Gold and Silver; Recovery of [Electrolytically] —— from Cyanide Solutions. S. B. Christy, Berkeley. U.S. Pat. 756,328, April 5, 1904.

Continuous circulation is induced between a large volume of dilute cyanide solution of precious metals contained in a storage tank, and an electrolytic cell having "primary cathodes" of large area alternating with suitable anodes, and the circulation is maintained at a stated rate until the gold and silver are sufficiently deposited on the cathodes. Secondly, a small volume of a cyanide solution is similarly circulated through an electrolytic cell containing the primary cathodes from the first-named solution, which primary cathodes are now made secondary anodes in alternation with suitable secondary cathodes of smaller area, so that the gold and silver deposited upon the original cathodes are concentrated upon those of smaller area. Zinc anodes, as grains or shavings, are used, coated with a "previous cathode coating of an electro-negative metal." Residual zinc is removed from the precious metals precipitated on the zinc grains or shavings, by constituting such zinc residues anode in a circulating solution of an electro-negative metal until the zinc is dissolved.—E. S.

French Patents.

Electric Furnace worked by Induced Currents. A. Fauchon Villeplée. First Addition, dated Dec. 2, 1903, to Fr. Pat. 336,313 of Oct. 30, 1903.

The furnace is adapted for use as a reverberatory furnace, and can be used for smelting, for the manufacture of steels, for annealing, carbonising, and for the maintaining of substances at a uniform temperature.—L. F. G.

Tantalum or other Slightly Fusible Metals; Production of Homogeneous Bodies of ——. Siemens and Halske A.-G. Fr. Pat. 337,607, Dec. 12, 1903.

To facilitate the working of tantalum and other metals of high fusing points, the metal, in the form of powder, is compressed into a sufficiently coherent form, and is then fused *in vacuo* by means of an electric arc. The arc may be formed between two compressed electrodes of the metal to be fused, and, to prevent loss by volatilisation, a large mass of another metal (*e.g.*, silver) is placed in proximity to the arc. This seems to cool the arc, and permits the fusion of the metal into large drops without sensible loss by volatilisation. Preferably the metal to be fused forms the positive electrode, whilst the large mass of metal itself forms the negative electrode.—H. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Almond and Allied Oils; Characteristics of ——. J. Lewkowitsch. Analyst, 1904, **29**, 105—110.

The analytical constants of genuine almond, peach-kernel, and apricot-kernel oils are given, and it is shown that these cannot be relied upon as differentiating tests. Bieber's test (in which 5 parts of oil are treated with 1 part of a mixture of equal parts of sulphuric acid, fuming nitric acid, and water) is as yet the best test. The reagent should be freshly prepared, and it should be noted that fresh peach-kernel oil gives a more pronounced coloration than that which has been kept for six months or more. It is unsafe to base a judgment of the adulteration of a given sample of almond oil with either peach- or apricot-kernel oil on the results of this test. He has also found Maben's elaïdin and zinc chloride tests quite useless for the purpose. The results obtained in the determination of the neutralisation and saponification values of the fatty acids of the different oils examined did not confirm the statement of Tortelli and Pergami that most fatty acids contain small quantities of lactonic substances (this J., 1902, 1187).—C. A. M.

Chinese Tallow-Seed Oil [Stillingia Oil]. L. M. Nash. Analyst, 1904, **29**, 110—112.

The specimen examined was dark brown and had an odour recalling that of tung oil. It had about three-fifths the viscosity of rape oil at 15° C., and had good drying properties, yielding a hard film when exposed on glass for six days. It did not give any deposit of stearine when cooled to 0° C.; but the fatty acids separated on standing into a solid and a liquid portion. The following values were determined:—Sp. gr. at 15·5°/15·5° C., 0·9395; free fatty acids (as oleic acid), 3·1 per cent.; unsaponifiable matter, 0·44 per cent.; saponification equivalent, 277; iodine value (Hübl), 160·7; iodine value of fatty acids, 165; Hehner value, 94·4; insoluble fatty acids, 93·96 per cent.; molecular equivalent of fatty acids, 272; rotation in 100 mm. tube, about $a_D = -4°$; Butyro-refractometer reading at 20° C., 89·1; and refractive index, n_D at 20° C., 1·4835. On treating the liquid fatty acids of this oil with bromine Lewkowitsch obtained 25·78 per cent. of hexa-bromides; linseed oil yielding upwards of 40 per cent.—C. A. M.

Castor Oil Product, "Floricin," which is miscible with Mineral Oils. G. Fendler. Deutsch. pharm. Ges. Ber., 1904, **14**, 135. Chem.-Zeit., 1904, **28**, Rep. 101.

When castor oil is distilled at 300° C. till it has lost between 5 and 10 per cent. of its weight, the residue (to which the name *floricin* has been given) is miscible with mineral oils, ceresin, or vaseline, though not with alcohol or acetic acid. "Floricin" is yellowish-brown, with a green fluorescence. An examination seems to indicate that it contains a considerable quantity of the glyceride of undecylenic acid.
—J. T. D.

Fucol: a Cod-liver Oil Substitute. H. Norrenburg. XX., page 501.

English Patents.

Soaps; Manufacture of Hard Alcoholic ——. R. Falck, Breslau. Eng. Pat. 2343, Jan. 30, 1904.

Soda soaps are mixed with water and dissolved in alcohol of high strength (*e.g.*, 80 per cent.), or intimate combination between the anhydrous soda soap and the alcohol may be effected by the addition of potash soap. Owing to the large amount of alcohol, antiseptic or medicinal substances can be readily introduced into the soap.—C. A. M.

Basic Colouring Matters; Manufacture of Soluble Compounds or Salts of —— [for Soaps, Varnish, &c.]. J. Y. Johnson. From Badische Anilin u. Soda Fabr. Eng. Pat. 12,681, June 5, 1903. IV., page 485.

French Patent.

Soap; Preparation of Insoluble —— so as to readily separate the Glycerin. P. Krebitz. Fr. Pat. 337,509, Dec. 8, 1903.

The fats are boiled with a metallic hydroxide, such as milk of lime, the insoluble soap allowed to settle, and washed with hot water, and the glycerin recovered from the aqueous layer and washings.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

French Patents.

Oil Colour. M. Hérisson. Fr. Pat. 337,440, Dec. 5, 1903.

Claim is made for an oil colour containing aluminium silicate, zinc oxide, linseed oil, and barium chloride.
—C. A. M.

Pigment; Composition for ——. W. A. Hall. Fr. Pat. 337,723, Dec. 14, 1903.

See Eng. Pat. 26,903 of 1903; this J., 1904, 328.—T. F. B.

Greases [Lubricants], Plasters, and Waterproofing Compositions [Paints]; Process of Making ——. J. Girard and P. J. Tabourin. Fr. Pat. 337,753, Dec. 15, 1903. III., page 484.

(*B.*)—RESINS, VARNISHES.

English Patent.

Basic Colouring Matters; Manufacture of Soluble Compounds or Salts of —— [for Soaps, Varnish, &c.]. J. Y. Johnson. From Badische Anilin u. Soda Fabr. Eng. Pat. 12,681, June 5, 1903. IV., page 485.

United States Patent.

Varnish. A. Müller-Jacobs, Richmond Hill, Assignor to Cosmos Chemical Co., New York. U.S. Pat. 756,975, April 12, 1904.

Solutions of an amide of one of the higher fatty acids, in which some of the hydrogen has been replaced by an alkyl group ("stear-amid"), are mixed with varnish or varnish constituents.—R. L. J.

XIV.—TANNING; LEATHER, GLUE, SIZE.

United States Patents.

Tanning Wheel. B. Allen, jun., Buford. U.S. Pat. 756,553, April 5, 1904.

Mechanical details are given of a tanning plant consisting of vats arranged in pairs, with storage tanks, and troughs for transferring the liquor from one vat to another. Tanning wheels mounted on horizontal shafts revolve in the vats, being turned by suitable machinery either in unison or independently of one another.—R. L. J.

Tanning Drum. B. Allen, jun., Buford. U.S. Pat. 756,554, April 5, 1904.

Mechanical details are given of a drum provided (1) with a hinged door and special mode of closing it; (2) with parallel guides at the ends of the drum, and movable slides to be placed in same and spaced according to requirements; and (3) means for supporting and revolving the drum.
—R. L. J.

XV.—MANURES, Etc.

English Patent.

Distillery Effluents or other Polluting Liquids, Sewage or other Putrescible Material, Soils for Filtering Purposes, and Agricultural Land; Treatment of ——. J. Hunter. Eng. Pat. 15,555, July 14, 1903. XVIII. B., page 500.

XVI.—SUGAR, STARCH, GUM, Etc.

Cane Sugar; Alteration of —— on Storing. F. Strohmer. Oesterr.-ung. Zeits. Zucker-Ind. u. Landw., **32**, 710—712. Chem. Centr., 1904, **1**, 1111—1112.

In the interior of a heap of raw sugar, 5 m. high, was found, after four months' storing, about 50—60 double centners of a dark-coloured product of composition differing considerably from that of the outer portions of the heap. The author found that the alteration of the sugar was due to bacterial action, invert sugar and other optically-active and reducing substances being formed. The dark-coloured product contained considerably more bacteria (*cocci*) than the normal product. It is probable the sugar was placed on the heap whilst still warm, and that consequently the sugar in the interior of the heap could only cool slowly, and thus it became a favourable medium for bacterial action.—A. S.

Diffusion Juice [Sugar]; Preservation of ——. Herrmann. Zentralbl. Zuckerind., 1904, **12**, 701. Chem.-Zeit., 1904, **28**, Rep. 108—109.

The author states that with normal beets and with a proper method of working and the use of perfectly clean vessels for holding the samples and taps for drawing off the same, samples of diffusion juice can be obtained, which, in closed vessels, will not undergo alteration within two hours; the amount of "apparent dry substance" remains unaltered for at least four hours. The following method of control for diffusion juice is recommended. Samples of the juice are withdrawn every two or four hours from several vessels in each battery, the density and polarisation are immediately determined, and the figures compared with the corresponding ones obtained from an average sample of the juice from the whole plant. Of the preservatives generally used, 1/20 vol. of lead acetate preserves the juice unaltered for at least 36 hours.—A. S.

Green Syrups; Treatment of —— by the Karlík-Czapikowski Method. K. Andrlík and V. Staněk. Z. Zuckerind. Böhmen, 1904, **28**, 283—291.

The authors give a further account (see this J., 1903, 564) of the working of this method at Nymburg, and of various improvements introduced into the process. During the past campaign about 55 per cent. of fine, light sugar and 1·3 per cent. of molasses were obtained from the second "Füllmasse."—T. H. P.

Sugar Works; Use of Sulphurous Acid in ——. J. Weisberg. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 972—986.

The process of "sulphicarbonation," patented by Steffen in 1893, consists in cooling the filtered juice from the first carbonation to 30°—40° C., then passing in sulphur dioxide until the acidity reaches 1 grm. or 1·5 grm. per litre, with or without subsequent treatment with finely-powdered bone-black; the acid juices, filtered from the bone-black, are rendered slightly alkaline with milk of lime, reheated to 80°—85° C., filtered, and sent to the evaporators. The disadvantages of this method are overcome in the author's modification of it, in which the carefully filtered juice from the first carbonation, which has an alkalinity to phenolphthaleïn of 0·7 to 1·2 grm. per litre and a temperature of 60°—80° C., is run directly into the boilers and at once sulphited to reduce the alkalinity exactly to the necessary minimum, depending on the initial alkalinity of the juice. From 1 to 2 litres of milk of lime are then added per hectolitre of juice and the temperature is raised to 80°—85° C., at which point carbonation is commenced; this is continued to the extent usual in the second carbonation, the juice being at the same time heated to brisk boiling, which is kept up for one or two minutes. The liquid is then filtered and treated in the ordinary way. The addition of barium carbonate with the milk of lime, precipitates any calcium sulphate formed by the use of the sulphurous acid. Other processes involving the employment of sulphurous acid as a defecating agent are described.—T. H. P.

Sugar; Tin in ——. M. Pitsch. Zeits. Ver. Deutsch. Zucker-Ind., 1904, **54**, 353—357.

Examination of many samples of beet-sugar showed them to be quite free from tin, whilst four samples of Demerara sugar were found to contain appreciable quantities of this metal, probably owing to the use of a tin salt for the production of "bloom." The following are the percentages of ash and, approximately, those of tin (calculated as chloride) in the four samples:—

Description.	Ash.	Stannic Chloride.
"Yellow Post"	0·76	0·0112
"White Post"	0·32	0·0014
Molasses sugar for direct consumption	2·90	0·042
Dark crystals for the American market	0·47	0·01

—T. H. P.

Cane-Sugar; Inversion of —— *by Platinum Metals.* F. Plzák and B. Hušek. Z. physik. Chem., 1904, **47**, 733—739.

Ráyman and Šulc in 1896 (Z. physik. Chem., 1896, **21**, 481) found that the hydrolysis of cane-sugar is accelerated by the platinum metals, with the exception of iridium. Later, Sulc found (this J., 1900, 698) that the hydrolysis of cane-sugar by very dilute hydrochloric and sulphuric acids is considerably retarded by palladium. The authors' experiments with commercial powdered palladium led to conflicting results. After ignition in air the palladium almost completely prevented the inversion of cane-sugar by N/500 hydrochloric acid at 80° C.; after being boiled with dilute hydrochloric acid and then ignited in air, it retarded the inversion only to a much smaller degree; whilst after being ignited in hydrogen, it was practically without influence on the inversion. The palladium was found to contain a small amount of iron and a considerable quantity of zinc, and it is to the presence of the latter the authors consider the retardation of the inversion is chiefly due. That the presence of a small amount of a foreign metal in the palladium can considerably retard the inversion of the sugar, was proved by an experiment, in which 0·2 per cent. of manganese was added to the palladium. Pure palladium, prepared by reduction of the chloride with formaldehyde, had a very considerable accelerating influence on the inversion of cane-sugar by water at 99° C., and also slightly accelerated the inversion of the sugar by N/500 hydrochloric acid at 80° C. After being ignited in the air, the palladium had practically no effect on the inversion of the sugar by water at 99° C. during the first three hours, but after that time the inversion was accelerated to almost the same degree as before. Experiments with pure platinum gave similar results, but the accelerating influence of the latter is much greater than that of palladium. The accelerating effect of iridium is somewhat slighter than that of palladium. The authors consider the action of the platinum metals to be due to oxides produced during the drying of the finely-divided metals in air; and as a confirmation of this view, they state that the accelerating action of palladium on the inversion of cane-sugar is increased by prolonging the drying.—A. S.

Cane-Sugar, Dextrose and Lævulose; Analysis of a Mixture of ——. E. Remy. XXIII., page 504.

l-Arabinose; Action of Lime on ——. H. Kiliani and F. Koehler. Ber., 1904, **37**, 1210—1215.

l-Arabinose, prepared by the hydrolysis of cherry gum, was treated with milk of lime in the proportions: arabinose, 1 part; water, 10 parts; and quicklime, 0·2 part, for 14 days. At the end of that time it was found that 0·37 mol. of lime per 1 mol. of arabinose had been neutralised. Attempts to isolate the free organic acids produced (other than acetic and lactic acids), having failed, the neutralised solution of calcium salts was submitted to fractional precipitation by alcohol. Five fractions were thus obtained; the analysis of the two main groups of products indicated salts corresponding to the formulæ $(C_5H_9O_5)_2Ca$ for the less soluble, and $(C_6H_{11}O_6)_2Ca$ for the more soluble. The last fraction but one contained still less calcium than the above, and the last liquor contained cupric reducing substances. As in the case of the saccharinic acids, the ratio of C to O in the above salts = 1. The production of molecules containing six (and probably even more) carbon atoms from a sugar containing only five, tends to confirm the theory previously put forward, that, under the influence of lime, the sugar molecule is partially broken up, and that the fragments are utilised for the synthetical building up of higher molecules.—J. F. B.

United States Patents.

Sucrose; Process of Extracting ——. W. J. Gibbens, New Orleans, and E. W. Christie, New York, Assignors to the Christie Engineering Co., Ltd., New Orleans, U.S. Pat. 757,295, April 12, 1904.

Sugar cane is crushed by an ordinary cane-mill; the bagasse is then subjected to a series of immersions in an extracting liquid, and is pressed between each pair of immersions, being finally conveyed to a second heavy cane-mill, which removes most of the liquid contained in the bagasse. The liquid from the last mill is injected, together with water, into the last member of the series of immersion tanks, and passed onwards through the whole series in a direction contrary to that of the travel of the bagasse, the strongest liquor overflowing from the first immersion tank. —J. F. B.

Sugar Cane; Apparatus for Extracting Sucrose from ——. W. J. Gibbens, New Orleans, and E. W. Christie, New York, Assignors to the Christie Engineering Co., Ltd., New Orleans. U.S. Pat. 757,296, April 12, 1904.

The apparatus for carrying out the extraction of sugar from sugar cane (see preceding abstract) comprises two cane-mills, a series of immersion tanks, means for conveying the bagasse from one mill into the series of immersion tanks, rotary pushers armed with V-shaped pusher-teeth situated in each of the tanks, scrapers for cleaning the pushers, a pair of press-rolls between each pair of tanks, means for conveying the bagasse to the second cane-mill, and means for circulating the liquid in a contrary direction to the bagasse.—J. F. B.

French Patents.

[*Sugar*] *Juice Heater situated between the Vacuum Pan and Condenser.* L. Bernot and F. Massicot. Fr. Pat. 337,313, Oct. 24, 1903.

The heat contained in the vapours discharged from the vacuum pan during boiling is utilised for heating juices or syrups. A juice-heater, consisting of a large number of tubes enclosed in a casing, is inserted between the vacuum pan and the condenser, and whilst the juice is circulated through the tubes it is heated by the vapours drawn through the casing by the air-pump.—J. F. B.

Charcoal for Clarification. Soc. Brunon and Rothé. Fr. Pat. 337,321, Oct, 31, 1903.

A form of animal charcoal is obtained by heating ossein in closed vessels. The ossein is obtained as a residue from the extraction of bones with hydrochloric acid: it is freed from chlorine and arsenic compounds by neutralisation with slaked lime before calcination.—J. F. B.

Crystallisation of Massecuites; Process of Rapid ——. M. Lambert. Second Addition, dated Nov. 21, 1903, to Fr. Pat. 301,258, June 14, 1900.

A non-conducting screen is interposed between each of the crystallising vessels in such a way that these are only heated or cooled by the air circulating around them. Various sets of crystallisers are placed in rows in different rooms, which may be maintained at temperatures suitable for the different stages of the manufacture.—J. F. B.

Syrup from Beetroot, Cane, Grain, Roots, or other Bodies containing Saccharine Substances; Process for Producing ——. W. C. Salisbury and A. J. Kramper. Fr. Pat. 337,573, Dec. 10, 1903.

See U.S. Pats. 748,313 and 748,314 of 1903; this J., 1904, 124.—T. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Cane-Sugar Yeast from Nicaragua. M. E. Pozzi-Escot. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1007—1008.

The author describes a yeast isolated from a sample of Nicaraguan molasses. When grown in malt wort, the young cells are round, but become elongated like a sugar oaf; it imparts a strong odour of sugar-cane juice to the wort. It is most active at a temperature of 30°—35° C., and it ferments cane-sugar, dextrose, and maltose, but not actose or galactose. It grows readily in musts of high density, and without preliminary acclimatisation yields wines ontaining 14—15 per cent. of alcohol.—T. H. P.

Pressed Yeast; Detection of Bottom-Fermentation Beer Yeast in ——. P. Lindner. Z. Spiritusind., 1904, **27**, 156—157. (See also this J., 1904, 762.)

HE author proposes a method for the differentiation of op-fermentation and bottom-fermentation yeasts, based on he different manner in which the two types multiply. The east to be tested is suspended in wort at such a dilution hat, when preparations are made by the "droplet" method, ach droplet shall contain not more than 2 or 3 cells. A umber of hemispherical pearl-shaped droplets are made with a pen on the underside of a cover glass. These are lowed to hang freely, and are examined after an interval ot exceeding 24 hours. In this way, with about 30 droplets, nd the degree of dilution described, about 100 cells are btained for the analysis, and the result can be read off n the following morning. All the top-fermentation easts which the author has examined multiply with the roduction of squarrose budding chains in a manner hich may be described as a monopodial ramification, e original axis continuing as such. On the other nd, the bottom-fermentation yeasts, even when they are having temporarily as top yeasts, grow with a sympodial mification, the main axis suddenly ceasing, whilst a side anch takes up the functions of the main axis. In other ords, if the yeast aggregates could grow freely like trees, e top yeast would resemble a fir tree and the bottom yeast a birch tree. This difference is put forward as being perfectly characteristic, whilst a simultaneous observation of the purity of the yeast can be carried out on the same set of preparations. In cases of doubt, a dilute streak culture may be made with a brush on a gelatin plate, and the colonies which develop may be picked off with a needle and stirred in a drop of water. The top-fermentation yeasts will then be found to make a uniform emulsion, whilst the bottom yeasts clot together in flaky aggregates.—J. F. B.

Yeast; Observations on the Period of Vitality of Dried ——. H. Will. Z. ges. Brauw., 1904, **27**, 269—271.

In concluding the present series of experiments, the author remarks that the asbestos conserve (see this J., 1903, 1097) still contained living cells after more than 17 years; these cells were, however, exclusively those of wild yeasts. The vitality of wild yeasts considerably exceeds that of the culture yeasts, especially when it is considered that the proportion of the former in the original samples was very small. Of the culture yeasts the top-fermentation varieties are less resistant than the bottom yeasts. None of the top-fermentation yeasts survived for 10 years, whilst a conserve of bottom-fermentation yeast in wood-charcoal contained a large number of living cells after 13 years. In considering the period of vitality of different types and races of yeast preserved in the same manner, the physiological condition of the yeast at the time of drying must be taken into account. Substances which absorb moisture strongly, such as gypsum and kieselguhr, are not so advantageous as wood-meal, asbestos, and, above all, wood-charcoal for making the conserves. Preservation in sealed vessels at low temperatures is advantageous. The most favourable proportion of moisture in the prepared conserve is probably between 3 and 6 per cent. (15—20 per cent. in the yeast). A comparatively rapid drying, preferably by a strong current of dry air, with a gradual rise of temperature not higher than 40° C., is recommended.—J. F. B.

Barleys; Germination and Kiln-drying of ——. *I.* A. J. Murphy. J. Fed. Inst. Brewing, 1904, **10**, 99—148.

Chemical analysis, so far, is of little use for determining the age and germinating power of barley. In case of necessity the moisture in matured barleys may be reduced to 8 per cent., or perhaps lower, without detriment to the vitality. Excessive steeping is often responsible for irregular growth. Aeration during steeping is advantageous. Kiln-drying is not only of value for the maturing of barleys when maturation is defective, but the reduction of the moisture also assists the uniform soaking of the grain in the steep. It is recommended that the temperature of kiln-drying should be recorded by a thermometer which is not in contact with the grain, but which is freely bathed by a current of the hot gases employed. Drying at low temperatures is to be avoided because it favours the development of moulds, especially when the drying process is long-continued and when a large proportion of damaged corns is present. A fairly high temperature (160° F., measured by a protected thermometer in the grain) may be employed without injury. If maturation only be desired, the temperature of hot sunshine, 140° F., is perhaps the best. Long-continued drying causes such an accumulation of heat in the grain and expels so large a proportion of water that a "resting period" is necessary before steeping, in order that the grain may cool down and recover its normal content of moisture. Kiln-drying can, however, be regulated in such a way that no "resting period" is necessary. Barleys stored at ordinary temperatures should retain their germinative power, possibly indefinitely, provided they contain a minimum proportion of moisture (*e.g.*, 8 per cent.), together with practical freedom from adherent germs and absence of broken or snipped corns damaged by threshing. Absence of these conditions facilitates the growth of moulds, which is regarded as the chief cause of loss of germinative power.—J. F. B.

Malt; Soluble and Coagulable Nitrogenous Matters of ——. K. Dinklage. Z. ges. Brauw., 1904, **27**, 249—251.

In continuation of a previous paper (this J., 1903, 1370) the author discusses the results of further analyses carried out upon 21 samples of malt by the method proposed (*loc. cit.*). With the exception of three abnormal samples, the total nitrogen of the malts lay between the limits of 1·5 and 1·8 per cent. on dry substance. With the above exceptions the proportions of soluble and coagulable nitrogen were quite independent of that of the total nitrogen. The proportions of soluble and coagulable nitrogen varied together in a perfectly parallel manner. The paler types of malt were always richer in soluble and coagulable nitrogen than the darker types. The proportions of soluble and coagulable nitrogen were in close relationship to the method and temperature of kilning. With higher kilning (increasing colour) the soluble nitrogenous matter is increasingly converted into insoluble matters; the same conversion also takes place to a still greater extent in the case of the coagulable nitrogenous matter. The author lays down the rule that, in the case of malts containing a normal proportion of total protein, *i.e.*, 9—11 per cent. on the dry substance, the soluble and coagulable nitrogenous matters should lie within the following limits:—

Type of Malt.	Per Cent. on Malt. Dry Substance.	
	Soluble Nitrogen.	Coagulable Nitrogen.
Pale to gold-coloured ..	0·48—0·54	0·11—0·13
Dark-coloured.........	0·39—0·48	0·08—0·11
Very dark coloured....		0·07—0·08

If the above relations be not fulfilled, it may be concluded with great probability that the malt has been kilned by a treatment which is not in accordance with its type, or else that the composition of the malt or barley is abnormal.

—J. F. B.

Malt; Determination of the Proteolytic Capacity of ——. P. Schidrowitz. J. Fed. Inst. Brewing, 1904, **10**, 166—172.

In carrying out the determination of the proteolytic capacity of malt by the method described in this J., 1903, 958, the author has found that the results may vary enormously according to the nature of the gelatin employed and to its acid or alkaline reaction. Only fine qualities of gelatin are to be used, and these should be either neutral or slightly acid. The solution of gelatin is made up as follows:—64 grms. of gelatin are dissolved in 500 c.c. of hot water (measured at 15° C.), and a volume of N/10 caustic soda solution, calculated from a preliminary titration of the acidity towards phenolphthalein, is added. Sufficient water is then added to bring the total volume of liquid (water + N/10 alkali) used for dissolving the gelatin, up to 736 c.c. The solution is cooled to 45° C., the white of an egg, previously beaten, is mixed in, and the whole is heated gradually to 80°—90° C. on the water-bath, and maintained at that temperature for 10 minutes. The solution is filtered hot through paper, and when the filtrate has cooled to about 50° C., 4 grms. of powdered thymol are added. The above quantities of water are used for a gelatin containing 16·8 per cent. of moisture, and are to be varied proportionately with any variation from that percentage.—J. F. B.

Barley, Malt, and Unhopped Wort; Tannin Constituents of ——. A. Reichard. Z. ges. Brauw., 1904, **27**, 229—235, 253—258, 271—275.

When a section of a barley or malt corn is treated with ferric chloride or gold chloride reagent, a sharply defined blue-black or violet stain appears in the form of a peripheral ring beneath the husk, owing to the presence of tannin. The tannin appears to be confined solely to the cells of the integuments of the seed, and the stain shows very little tendency to spread. The constituent in question is not free tannin, but most probably a tannin-albuminoid compound. This constituent is almost insoluble in cold water, but it is readily extracted from the cells by means of hot water (from which it separates to a large extent on cooling), or by means of alcohol, in which it is freely soluble. During the malting process, the subsequent solubility of the tannin compound in cold water is considerably increased by the action of the alcohol produced by the germinating grain. This tannin compound is found in unhopped worts, its proportion being greater, relatively to the extract, in the last sparging liquors than in the main wort. In unhopped worts and beers the tannin constituents occur in four different forms:—(1) coarse flocks, films, or corpuscles, which settle out, and are readily stained with reagents; (2) turbidities, which make the obtainment of bright liquors by filtration very difficult; (3) an emulsified form, which is not in true solution, but which occurs in perfectly bright and settled liquors; (4) the truly dissolved form, which is more abundant in beer than in wort, owing to the influence of the alcohol present in the former. The forms (2) and (3) tend to clog the pores of filters; they also have a tendency to be co-precipitated with turbidities, such as those due to gluten. Moreover, these forms penetrate the pores and attach themselves very readily to the walls of the vessels in which the beer is kept; they thus form the basis of "beer-scale," from which they can be extracted by alcohol. The action of the yeast cells in removing the finely-divided forms of the tannin compounds is probably greatest after the active fermentation has ceased. Whilst fermentation is in progress, the alcohol diffusing from the cells would preserve their membranes free from tannin deposits. It has been found, however, that the addition of lactic acid to unhopped worts and beers, causes the precipitation of the tannin compounds in a form which is insoluble in alcohol. Hence it is inferred that infection with bacteria which produce lactic acid, would lead to a speedy clogging of the yeast by tannin compounds in this form.—J. F. B.

Distillery Fermentation Tuns; Suggestions for Treatment of ——. G. Heinzelmann. Z. Spiritusind., 1904, **27**, 157.

The tuns should be constructed only of sound, non-resinous pine wood (pitch-pine), free from knots. At the time of the non-working season, the tuns should not be left full of water, since development of putrefactive organisms will cause the wood to rot. Before going out of use, the tuns should be cleansed, freed from scale, and allowed to dry; they should then be painted inside and out with "carbolineum"; the hoops should be tightened as the wood shrinks. Internal coating with paint, tar, or lacquer is not to be recommended. Before re-starting, the tuns are to be scrubbed and thoroughly soaked with water. During the working season, the tuns are to be cleaned each time before filling, by scrubbing thoroughly with brushes and hot water. A coat of strong, freshly prepared milk of lime is then to be given inside and on the edges; it should remain on for about one hour. The lime is then removed by scrubbing with sand and washed away with hot water. Any calcareous scale which tends to accumulate may easily give rise to infections, and it should be loosened from time to time by the application of dilute hydrochloric acid and subsequent scrubbing. For the purification of badly infected tuns, which have been causing excessive acidities, the following directions are given:—Wash out all traces of fermented wort with hot water, using the brush; apply a wash of dilute caustic soda to all parts of the tun, including edges and crevices; leave for at least an hour, then wash off with hot water. The tun should then be steamed with moderation, since frequent steaming tends to soften the fibres of the wood. Before use, paint the tun with dilute sulphuric acid, which need not be washed off.

—J. F. B.

Fermentations; Action of Oxidising Agents on the Purity of ——. H. Alliot and G. Gimel. Comptes rend., 1904, **138**, 911—913.

The authors have investigated the influence exerted on the amount of acid produced in a malt wort (acidity, 0·5 grm. of sulphuric acid per litre) by butyric bacteria, by 1 grm. per litre of the following oxidising agents:—Sodium and calcium hypochlorites, ferric chloride, potassium chlorate, perchlorate, and bichromate, manganese dioxide and hydrogen dioxide. The last-named exhibits the greatest bactericidal action, but is only slightly more effective than calcium hypochlorite and manganese dioxide, the use of which in practice is recommended by the authors.

These agents also accelerate the multiplication of the yeast cells and destroy any sulphurous acid—either free or as potassium hydrogen sulphite (bisulphite)—present in the wort.—T. H. P.

Beer Filtration and Permanence of "Head." W. Windisch. Woch. Brau., 1904, **21**, 194—198.

The author discusses the theory that the "head"-retaining properties of beer are dependent on the presence of minute suspended particles of colloidal bodies which are not in a state of true solution. The effect of filtration, if very efficient, may be to remove these bodies and thus impair the "head"-retaining properties. Cases are quoted in which the introduction of the filter into certain breweries has resulted in a marked falling-off in the quality of the beer. The removal of the colloidal bodies in quasi solution by filtration, besides affecting the permanence of the "head," may deteriorate the flavour (*a*) by reducing the palate-fulness which is probably dependent on these colloids, and (*b*) by imparting an after-flavour characteristic of the filter, derived from the filtering medium and the metallic surfaces. The author contends that the competition to create and to satisfy a public demand for the brightest beers has led to the result that modern filters are too perfect. In the early days of the beer-filter, owing to a lower filtering efficiency, a small filter could deal with a relatively large volume of beer. But in recent years the increase in the density of the medium, in order to obtain the brightest possible effluent, has resulted in the removal of the colloidal bodies above referred to, and has necessitated an enormous increase in the ratio of filtering medium and metallic surface to the volume of beer treated. —J. F. B.

Beer Filtration. E. Ludwig. Woch. Brau., 1904, 214—215.

The author agrees with the views expressed by Windisch (see preceding abstract) that modern beer filters are too efficient from a filtration point of view, and that the quality of the beer suffers in consequence. He considers that the evil effects are due to the ever-increasing density of the filtering medium, involving an increased pressure. In modern filters the beer is forced through what are practically solid cakes of pulp, instead of through a mass of loose pulp as formerly. Consequently a thick slimy layer of impurities collects on the surface of the cakes. Under the influence of very high pressures the impurities in this layer of sludge are far more soluble in the beer than under moderate pressures; hence the appearance of an unpleasant flavour. The ideal system of filtration would be a "mass" filtration, as opposed to a "surface" filtration, in which the final degree of purity should be attained in several progressive stages under a low pressure.—J. F. B.

Beer; Metallic Turbidities in ——. F. Schönfeld. Woch. Brau., 1904, 209—210.

The author has confirmed the general accuracy of his observations (this J., 1904, 332) on the action of metals on beer. He has repeated his experiments with metals of undoubted purity, and states that there was no doubt as to the galvanic efficiency of his couples. It is not contended that those metals which give a negative result are absolutely without action on beer. On the contrary, changes in the colour of the beer are frequently to be noticed, owing to the metal entering into solution, but only tin (even the purest Banca tin) gave the characteristic heavy albuminoid turbidity. The contentions of Sellenscheidt (this J., 1904, 333) as to the indifference of tin, when pure, and the harmful effects of zinc and lead, are not confirmed. After tin, iron is the next most harmful metal in producing turbidities in beer.—J. F. B.

English Patents.

Malt Furnaces and other Kilns and Drying Apparatus. E. S. Beaven, Warminster. Eng. Pat. 8847, April 18, 1903.

In malt kilns and other drying furnaces in which the products of combustion come into direct contact with the material to be dried, the arch, posterior end, or walls of the furnace structure are perforated so as to be capable of supporting blocks of lime, limestone, or other basic filtering material, thus forming a chamber in which the gases of combustion are freed from arsenical and other deleterious constituents before they reach the drying chamber. Arrangements are made for heating the air in channels, constructed in the furnace, before it enters the combustion chamber. The filtering chamber is constructed with a sloping floor, and the contaminated material is removed from the bottom, fresh blocks being introduced from above.—J. F. B.

"Whizzer" or Hydro-extractor for Drying Grain and the like. H. Simon and G. Huxley, Manchester. Eng. Pat. 11,064, May 15, 1903.

A perforated vertical cylindrical casing, of one or more segments, joined by flanges which are attached to an outer casing, is provided with solid end pieces. A rotating barrel having slightly inclined lifting blades, is arranged within the casing so as to lift the grain upwards to the outlet. The barrel is perforated about the centre, and has fans or blades at the ends to draw air from the end openings and deliver it through the central perforations. Tangental blades are arranged in the upper end piece, which may be rotated to sweep the grain outwards to the delivery spout. Means are provided for feeding the grain tangentally at the bottom of the casing.—W. H. C.

Fermentation of Liquids. G. Johnson and P. R. Hare, Bromley. Eng. Pat. 10,093, May 4, 1903.

A species of yeast called *S. thermantitonum* is claimed for fermenting saccharine worts. This yeast is isolated from eucalyptus leaves, and the cells, which are somewhat smaller and more oval than those of ordinary yeast, are generally observed in compact masses hanging together by means of a membranous substance or web. This yeast possesses the peculiarity of resisting the action of high temperatures; it can be freed from foreign organisms by pasteurisation, and will resist a temperature of 170° F. for a short time. It ferments best at temperatures between 80° and 110° F. Its industrial value lies in the fact that it can be sown in sterilised hot worts at a temperature of 175° F., the worts being then rapidly cooled in closed vessels to 105° F. When fermentation subsides, this yeast, owing to its peculiar agglutinating properties, is found at the bottom of the vessel in a compact mass, whilst the liquid is run off perfectly clear.—J. F. B.

Distillery Effluents or other Polluting Liquids, Sewage, or other Putrescible Material, Soils for Filtering Purposes, and Agricultural Land; Treatment of ——. J. Hunter. Eng. Pat. 15,555, July 14, 1903. XVIII. B., page 500.

United States Patent.

Whisky, Gin, or other Spirits; Manufacture of ——. J. M. Sanguineti, Lille. U.S. Pat. 757,352, April 12, 1904.

See Eng. Pat. 27,068 of 1902; this J., 1903, 815.—T. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A.*)—FOODS.

English Patents.

Nutritive Substance [from Blood]. W. P. Thompson. From Actienges. für Chem. Ind., Vienna. Eng. Pat. 15,606, July 14, 1903.

One kilo. of blood or a 20 per cent. hæmoglobin solution, is mixed with 50 c.c. of sodium hydroxide solution (35° to 40° B.) and after 24 hours the mixture is heated to a temperature of 80° to 85° C. for two hours. The solution is then acidified with hydrochloric acid, and the precipitated albuminoids separated and dried at a low temperature. The product so obtained is then digested with artificial gastric juice.—W. P. S.

Furze; Treatment of ——, for Obtaining a Food for Cattle, Paper Pulp, and an Ammonium Salt which may be used as a Manure. G. P. Horteloup, Paris. Eng. Pat. 26,150, Nov. 30, 1903. Under Internat. Conv., April 14, 1903.

See Fr. Pat. 331,176 of 1903; this J., 1903, 1145.—T. F. B.

(*B.*)—SANITATION; WATER PURIFICATION.

English Patents.

Sewage; Process for the Purification of ——. F. Eichen, Wiesbaden. Eng. Pat. 14,258, June 27, 1903.

See Fr. Pat. 335,406 of 1903; this J., 1903, 1362.—T. F. B.

Distillery Effluents or other Polluting Liquids, Sewage or other Putrescible Material, Soils for Filtering Purposes, and Agricultural Land; Treatment of ——. J. Hunter, Edinburgh. Eng. Pat. 15,555, July 14, 1903.

The effluent is heated and treated with slaked lime or other alkaline substance, either during or after the heating. Calcium phosphate or phosphoric acid is then added and the heating continued until thorough precipitation has taken place. The liquid portion is then passed on to bacterial beds, or used for irrigation purposes. Calcium and magnesium carbonates are added to the filter-beds or to the soil to favour the action of the nitrifying bacteria. Claim is also made for the use of calcium sulphate, alone or mixed with carbonates, in evaporation processes employed in the purification of distillery effluents.—W. P. S.

House or other Refuse; Process of Treating ——, for Converting it into Substances of Commercial Utility. T. G. Charlton, Loughton. Eng. Pat. 16,304, July 24, 1903.

The sorted refuse is heated in closed retorts until completely carbonised, the volatile products being led off and dealt with as in gas-works. The residue left in the retorts is then quenched with water, sifted and again sorted, mixed with a quantity of tar obtained in the distillation, and pressed into briquettes. From 12 to 14 galls. of tar per ton of carbon is a suitable quantity. About 4 per cent. of pitch may also be added to make the briquettes weatherproof.—W. P. S.

French Patents.

Water; Installation for the Oxidation or Biological Treatment of ——. W. P. Dunbar. Fr. Pat. 337,301, Oct 20, 1903.

The water is allowed to run over a bed constructed of fine material at the top and coarse pieces at the bottom. Various forms of these beds are described and they can be used singly or in series. The water after treatment is collected in gutters at the bottom of the bed.—W. P. S.

Water and other Liquids; Sterilisation of ——, by Filtration through an Oxidising Bed of Barium Manganate. R. Cambier, A. Tixier, and C. E. Adnet. Fr. Pat. 337,630, Dec. 12, 1903.

Water is sterilised by passage through an oxidising bed of specially active barium manganate, such as that produced by one of the processes described in Fr. Pat. 337,629 (see page 489).—E. S.

(*C.*)—DISINFECTANTS.

English Patent.

Liquid Compounds of Phenol or Cresol and Soap which are Soluble in Water and form Emulsions, Intensifying at the same time their Antiseptic Properties; Process for Solidifying such ——. E. M. Raetz, Cöln-Merheim. Eng. Pat. 27,889, Dec. 19, 1903.

Solutions containing from 30 to 60 per cent. of cresol or phenol and soap are mixed in an autoclave with from 5 to 10 per cent. of an aldehyde (formaldehyde) or a ketone and a small quantity of an alkali. The mixture is heated to 150° C. and then cooled. A solid product is obtained which is soluble in water.—W. P. S.

French Patent.

Ozone; Production of ——, for application as a Disinfectant. A. D'Arsonval, G. E. Gaiffe, and G. Gallot. Fr. Pat. 337,531, Dec. 8, 1903.

The air to be disinfected is "cooled and moistened" by being caused to traverse an ozonising apparatus, entering at the lower part of an attached chamber in which ice is supported on a horizontal perforated partition separating the chamber into two compartments; or the lower compartment may be occupied by perforated vessels containing a refrigerating mixture. In a third form of apparatus, air enters the ozoniser through a chamber cooled by a coil through which a flow of liquid carbon dioxide is maintained. Or the apartment to be disinfected may be sprayed with liquid air whilst the air is being passed through the ozoniser, the apartment being meanwhile "hermetically" closed. —E. S.

XIX.—PAPER, PASTEBOARD, Etc.

Normal Papers [German]; Transparency of ——. W. Herzberg. Mitt. K. tech. Versuchsanst., 1903, **21**, 176—188.

The German Government having complained of the excessive transparency of normal papers of the highest classes, owing to which the writing shows through on the back of the paper, the Charlottenburg Institute has addressed a circular to the chief manufacturers of these papers inviting suggestions on this subject. The replies of 25 mills are recorded. It is contended that increased opacity can only be obtained by the relaxation of some of the most stringent demands as to the quality of the paper. The transparency of normal papers is due to the fact that the normal standards of breaking length and elongation can only be reached by the use of linen rags almost exclusively, and these have to be beaten to a "wet" pulp for a very long time. The cotton fibre is considerably more opaque than the linen fibre, but the addition of a sufficient proportion of the former would necessitate a lower standard of strength. Some writers suggest that a larger proportion of cotton rags could be used, whilst maintaining the strength, if the stringent demands for purity, whiteness, and freedom from specks were relaxed so as to permit of the use of stronger linen rags unweakened by extreme bleaching. The yellow tone of less highly bleached linen is, moreover, more favourable to opacity than the milk-white colour now required; the tone might even be increased by ochre. The Institute cannot, however, assent to any such relaxation as regards the appearance of the paper. The attainment of the high elongation on breaking is very difficult and necessitates a very "wet" pulp; the Institute is therefore prepared to meet this cause of transparency by lowering the standard elongation on breaking from 4·5 to 4·0 per cent. in class 1 and from 4·0 to 3·5 per cent. in class 2, whilst maintaining the standard breaking length and resistance to creasing unaltered. There remain two other means of increasing the opacity, viz., increase in thickness of the paper and the addition of mineral loading. Some of the manufacturers suggest that to increase the thickness of such strong papers would introduce difficulties in the making and in the production of a legible water-mark. The price of the paper and the cost of postage would also be increased. For special purposes, however, where cost is subordinate to increased opacity, the Institute proposes to permit the use of heavier papers to the extent of 15 per cent. above the present weights. It is generally admitted that the addition of mineral loading in the proportion of 10 per cent. would tend to increase the opacity of the paper, but at the same time the mechanical properties would only be maintained with difficulty, and the paper would be thinner for the same weight. Nevertheless, the Institute has determined to recommend that the restrictions as to ash be abolished and that the manufacturer be permitted to improve the appearance, writing surface, and (possibly) opacity of his paper by the addition of mineral loading, so far as he can do so without lowering the normal standards of the mechanical properties.—J. F. B.

English Patents.

Cellulose Compounds; Process for the Manufacture of Variously-Shaped Industrial Objects from ——. L. Lederer, Sulzbach. Eng. Pat. 7341, March 30, 1903.

See Fr. Pat. 330,714 of 1903; this J., 1903, 1100.—T. F. B.

United States Patents.

Paper; Utilisation of Waste Products from the Manufacture of ——. W. N. Cornell, Massena. U.S. Pat. 756,214, April 5, 1904.

The waste product known as "screenings" is reduced to pulp by a combined process of crushing and rubbing the material, stirring the crushed screenings in a suitable liquid, and then repeating the grinding or rubbing process, the latter operations being repeated until the particles are of the desired size.—J. F. B.

French Patents.

Papier-mâché; Manufacture of Articles of ——. C. Gaertner. Fr. Pat. 337,480, Nov. 19, 1903.

See Eng. Pat. 27,339 of 1903; this J., 1904, 453.—T. F. B.

Cellulose Xanthate; Purification of ——, for the Preparation of Viscose. Soc. Franç. de la Viscose. Addition, dated Nov. 25, 1903, to Fr. Pat. 334,636, Aug. 14, 1903. See this J., 1904, 75.

After coagulation, the crude cellulose xanthate is treated, at a temperature not above 50° C., with a solution of an lkali or alkaline earth sulphite, either alone or in conunction with aluminium sulphate, alum, sodium bicarbonate, tc.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Potassium Platinous Chloride. P. Klason. Ber., 1904, **37**, 1360—1361.

his substance is made commercially by reducing chloroatinic acid by means of sulphur dioxide, and then adding ice the calculated quantity of potassium chloride to the t solution. The salt separates out, is drained on the mp, washed with alcohol, and dried at the ordinary temrature in the dark. This method is preferable to that rting from potassium chloroplatinate. Vézes' method heating together potassium chloroplatinate and potassium alate in equimolecular proportions cannot be carried out h pure platinum compounds. It is a catalytic action, l depends upon the presence of iridium.—J. T. D.

hujone; Certain Derivatives of ——. L. Tschugaeff. ., 1904, **37**, 1481—1486. (Compare this J., 1901, 65.)

hen the methyl ester of thujylxanthogenic acid, $H_{17}O.CS.SCH_3$, is distilled, two isomeric thujenes are ained, *viz.*, α-thujene produced from the less stable tion of the xanthogenic ester, and β-thujene from the t stable portion. These two hydrocarbons boil almost a he same temperature, but α-thujene yields a crystalline d ntenedihydrobromide with hydrobromic acid, melting at 5 –59° C., whereas β-thujene does not. Probably these t thujenes are derived from two stereo-isomeric thujyl a hols produced by the reduction of thujone; they differ o in the position of the ethylenic bond in the nucleus. α- ujene yields on oxidation α-tanacetonedicarboxylic acid, a β-thujene yields homotanacetone dicarboxylic acid. By tr ment of thujamenthol, the alcohol corresponding with is njone, by the xanthogenic method, the author obtained a lrocarbon, $C_{10}H_{18}$, b.pt. 157°—159° C., which he terms *th menthene*.—J. F. B.

Menthol; Dehydration of —— by Organic Acids. J. Zelikow. Ber., 1904, **37**, 1374—1383.

Th production of unsaturated hydrocarbons by heating the aturated alcohols with oxalic acid (this J., 1901, 12 can also be effected with other polybasic organic aci Positive results have been obtained with succinic, citric, phthalic, terephthalic, and camphoric acids, but not with tartaric acid. A menthene is thus obtained by heating together camphoric acid and menthol, and it has an exceptionally high rotatory power. The presence of an excess of the free acid exerts an important influence in increasing the yields of hydrocarbon, since it neutralises the tendency, manifested when the acid esters are heated by themselves, to the production of free alcohols and neutral esters, together with the hydrocarbons. This tendency can be checked also by employing the salts of the acid esters.—J. F. B.

Cineol; Reduction of ——. H. Thoms and B. Molle. Arch. Pharm., 1904, **242**, 181—194.

Cineol has been reduced by the action of hydriodic acid in the presence of mercury, the reduction products being a new hydrocarbon, *cineolene*, $C_{10}H_{18}$, and a polymerised hydrocarbon $(C_{10}H_{16})x$. Cineolene boils at 165°—167° C., is optically inactive and has the sp. gr. 0·8240 at 18° C. By the action of bromine on it, hydrobromic acid is formed. By the action of concentrated sulphuric acid, α-2-cymenesulphonic acid was produced.—J. O. B.

"Fucol": a Cod-Liver Oil Substitute. H. Norrenberg. Pharm. Centralh., 1904, **45**, 34.

Dried seaweeds containing iodine are submitted to a roasting process, whereby an empyreumatic greenish oil rich in iodine is formed. The roasted material is then extracted with an edible fatty oil.—J. O. B.

Cinchona Alkaloids; Dibromo-addition Compounds of ——, and Compounds of their Hydrochlorides with Metallic Perchlorides. A. Christensen. Videnskabernes Selskab's Skrifter, 1904, **6**, 329; Chem.-Zeit., 1904, **28**, Rep. 93.

Like the corresponding cinchonine compound, cinchonidine dibromide is a mixture of two isomerides; when a molecule of HBr is split off from either of them, the same mono-bromo-substitution derivative remains. The two isomerides differ in the solubilities of their sulphates and of some of their other derivatives. Lead tetrachloride gives with the hydrochlorides of the cinchona alkaloids, in strong hydrochloric acid solution, compounds which fall as yellow crystalline precipitates. Similar compounds (hygroscopic and unstable, quickly turning brown in the air) are formed when hydrochloric acid gas is passed through glacial acetic solutions of the alkaloids, in which finely-divided manganese dioxide is suspended. Ferric chloride, added to solutions of the dibromo-addition compounds, forms compounds which are precipitated by hydrochloric acid as yellow amorphous substances.—J. T. D.

Colchicine Content of Colchicum Seeds. H. Blau. Pharm. Centralh., 1904, **45**, 39.

The amount of total colchicine in the seeds examined was 0·379 per cent.; the brown seed-coats contained 0·377 per cent. Seeds one year old gave 0·504 per cent.; some 20 years old, not carefully stored, yielded 0·180 per cent.; another sample, over 30 years old, kept in a well-closed vessel, gave 0·202 per cent.; seeds kept more than 20 years in a metal-lined drawer, 0·2108 per cent. It is evident therefore that the seeds deteriorate in the amount of active principle by storing, and that the seed-coat should not be removed from the drug, since it contains practically as much colchicine as the seed.—J. O. B.

Essential Oils obtained by Extraction of Fresh Blossoms with Volatile Solvents. ("Essential Blossom-extract Oils.") H. v. Soden. J. prakt. Chem., 1904, **69**, 256—271.

To obtain these oils, fresh blossoms are repeatedly treated with light petroleum spirit in the cold. The solvent is then removed from the extract by a careful distillation, often *in vacuo*. According to the author, the perfumes so obtained are distinguished by the delicacy of their aroma. They were purified for investigation by extraction with cold alcohol and distillation in a current of steam. A description of the properties of the extracts so obtained from violets, orange-blossoms, mignonette, rose-blossoms, jasmine, and cassia-blossoms is given. The extracted essential oil from violets contains a number of odoriferous substances, of which a "violet-ketone" is probably the most important. Essential orange-blossom extract contains 6·9 per cent. of methyl anthranilate and 26·7 per cent. of linalyl acetate. Essential oil of mignonette-blossom extract contains considerable amounts of aldehydes. The extract from French rose-blossoms contains 60 per cent. of phenylethyl alcohol and 20 per cent. of a mixture of geraniol, nerol, and citronellol. The oil from German rose-blossoms contains 75 per cent. of phenylethyl alcohol and 15 per cent. of primary terpene alcohols. The extract-oil from jasmine-blossoms contains 43—51 per cent. of benzyl acetate and considerable quantities of indole. Cassia-blossom oil contains about 31 per cent. of methyl salicylate, also benzyl alcohol, decyl aldehyde, a ketone with an odour of violets, cumin aldehyde, farnesol (a sesquiterpene alcohol), and probably linalool and geraniol.—E. F.

Jasmine Flowers; Essential Oil of ——. *VII.* A. Hesse. Ber., 1904, **37**, 1457—1463. (See also this J., 1899, 396, 513, 1153; 1900, 770; 1901, 275, 1137.)

The oil obtained by extracting freshly picked jasmine flowers with petroleum spirit, and distilling the extract, was dissolved in ether, and a mixture of 1 vol. of concentrated sulphuric acid and 5 vols. of ether added. This liquid was shaken with sodium bicarbonate solution and distilled with steam; a quantity of oil distilled over (equivalent to 447 grms. per 1,000 kilos. of flowers), of sp. gr. 1·015 at 15° C., $\alpha_D = +1° 45'$; saponification value 222·0; and containing 0·42 per cent. of methyl anthranilate and 2·1 per cent. of indole. An experiment on a larger quantity of flowers gave an oil of sp. gr. 1·001, containing 0·38 per cent. of methyl anthranilate and 2·0 per cent. of indole. Before the steam distillation no methyl anthranilate or indole could be detected in the oil. By extracting the flowers in a similar manner with ether, and distilling the extract with steam, an oil was obtained equivalent to 385 grms. per 1,000 kilos. of flowers; sp. gr. (15° C.) 0·9935; $\alpha_D = +2° 36'$. No methyl anthranilate or indole could be detected in this oil. The flowers, after extraction with ether or petroleum spirit, yielded, on distillation in steam, a small quantity (about 50 grms. per 1,000 kilos. of flowers) of an oil, which contained about 4·5 per cent. of methyl anthranilate, and also a base, which on diazotisation and coupling with β-naphthol, gave a strong coloration. Jasmine flowers which had been subjected to *enfleurage* were extracted with petroleum spirit; the oil obtained, contained no indole or methyl anthranilate. It thus appears that neither indole nor methyl anthranilate exists in the free state in jasmine flowers; the indole compound is decomposed by steam distillation, but not by dry distillation (this J., 1901, 1137). The methyl anthranilate compound is easily decomposed by steam, and also by dry distillation. The author points out, in conclusion, that the figures previously given (this J., 1901, 1137) for the amount of oil obtainable from fresh flowers by extraction should be doubled, according to his later experiments; thus the statement that "nine times as much oil is obtained by *enfleurage* as by extraction," must be modified to "four or five times."—T. F. B.

Laurel Leaves; Essential Oil of ——. H. Thoms and B. Molle. Arch. Pharm., 1904, **242**, 161—181.

The leaves of *Laurus nobilis* yielded from 1 to 3 per cent. of a light yellow oil with an agreeable powerful odour and sharp, somewhat bitter taste. It had a distinctly acid reaction, and the $\alpha_D - 15·95°$ at 17° C.; sp. gr. 0·9215 at 17° C. A specimen about a year old had the sp. gr. 0·9257 at 17° C. Its acid value was 2·74; ester value 47·10. The presence of methyl-chavicol in the fractions boiling above 180° C., as suggested by Wallach, was not confirmed. The acid reaction was found to be due to the presence of free acetic, iso-butyric, and iso-valeric acids. The oil contained 1·7 per cent. of free eugenol, and 0·4 per cent. as ester. The chief ester present was an acetate, but esters of caproic and valeric acids were also present. Besides these, a small quantity, 0·07 per cent., of another unidentified acid, having the formula $C_{10}H_{14}O_2$ was isolated in the form of partially aggregated, glittering scales; m.pt. 146°—147° C. It was strongly attacked by permanganate, and combined with two atoms of bromine. Pinene was found in the oil which had not been treated with alkali. Cineol was present to the extent of about 50 per cent. Geraniol was detected in the fraction boiling between 212°—230° C. The higher boiling fractions are oxygenated, and probably contain, besides a sesquiterpene, a sesquiterpene alcohol. The original oil, and in particular the high boiling fractions thereof, gave an intense blue colour reaction when the solution in glacial acetic acid was treated with bromine vapour, or a trace of nitric acid.—J. O. B.

Entada scandens; Saponins of ——. L. Rosenthaler. Arch. Pharm., 1903, **241**, 614.

Crude saponin was extracted from the seeds after removal of the fat, by means of 90 per cent. alcohol, and precipitated by ether from the cold alcoholic extract. By precipitation with barium hydroxide solution, a saponin, named "Saponin A" was removed from the aqueous solution of this crude saponin. The solution thus freed from "saponin A" was evaporated to dryness, after removing the excess of barium hydroxide, the dry residue extracted with hot 90 per cent. alcohol, and the alcoholic solution fractionally precipitated with chloroform and ether. The aqueous solution of the ether precipitate was dialysed, and the residue evaporated to dryness *in vacuo* over sulphuric acid "Saponin B" $C_{15}H_{22}O_{10}$ was thus obtained as a whitish hygroscopic powder, which became brownish on heating to 110° C. It was precipitated from strong aqueous solution by basic, but not by normal lead acetate. It gave a darl reddish-violet colour with strong sulphuric acid, eventuall turning brown. On hydrolysis, a sugar identical wit galactose, a sapogenin soluble in ether and in alcohol, an another body insoluble in those solvents and in ammoni were formed.—J. O. B.

Dipteryx Odorata, Presence of a Copal in the Fruit, an a Kino in the Bark of ——. E. Heckel, H. S. de Co demoy, and F. Schlagdenhauffen. Rép. Pharm., 190 **16**, 97—104 and 151—161.

The entire fruit of the Tonka bean. *Dipteryx odorota*, fro French Guiana, where it is known as "Gayne," contai 16·4 per cent. of a resin which in characters compares wi the best grades of commercial copal. It is best extract from the integoments of the fruit by means of chlorofor Incision into the bark of the tree yields a kino which rich in tannin, and gives reactions similar to other medicin kinos.—J. O. B.

See Eng. Pat. 3173 of 1903; this J., 1904, 203.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Gold and Platinum Toning Baths; Presence of Chlorides in ——. R. Namias. Rev. Suisse; through Phot. Mitt., 1904, **41**, 97—98.

It is highly desirable that photographic toning baths of gold and platinum should contain a soluble chloride. After exposure ordinary printing-out paper contains silver nitrate and citrate, only a little of which is removed by the preliminary washing. When the paper, therefore, is immersed in the toning bath, these salts react with the gold chloride; but since the nitrate and citrate of gold, even if capable of existence, are very unstable, the gold is precipitated instead of being deposited on the image. It is customary to tone from 8 to 10 sheets of paper 50 × 60 cm. in size with the aid of 1 grm. of gold chloride; but since each sheet contains at least 0·5 grm. of combined silver, which is equivalent to 0·16 grm. of chlorine, the gold may be thrown out of the bath entirely by the time two or three sheets have been finished. The gold toning bath should therefore be made up with a soluble chloride in it, a suitable formula being 5 grms. of sodium chloride per 1 litre of bath containing 1 grm. of gold chloride. Presence of a chloride is still more desirable in platinum toning. The ordinary bath, composed of potassium platinous chloride and phosphoric acid, often exhibits a yellow precipitate after a few prints have been immersed, and frequently the substance attaches itself to the pictures. The phosphoric acid should be replaced by oxalic acid, and the bath itself should be prepared as follows:—Platinum salt, 1 grm.; hydrochloric acid, 5 grms.; oxalic acid, 10 grms.; water, 1 litre. —F. H. L.

See Eng. Pat. 25,025 of 1902; this J., 1903, 1208.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUALITATIVE.

Titanium Salts as Laboratory Reagents. E. Knecht. J. Soc. Dyers and Colourists, 1904, **20**, 97—100.

Titanium oxalate may be used instead of nitrate of iron for the valuation of tannins by means of dye-trials on cotton.

By the action of titanous sulphate on a sulphuric acid solution of a copper salt, the latter is reduced quantitatively to copper, and the reaction is so delicate that 1 part of copper in 1,000,000 parts of water can be detected. The reaction is suitable for detecting copper in dyed fabrics. The material is boiled for one minute with dilute sulphuric acid, and the cold solution treated with a few drops of titanous sulphate solution and allowed to stand for 10 minutes. If copper be present a precipitate is produced readily discernable by reflected light, but not by transmitted light. (See also this J., 1903, 232, 762, 825.)—A. B. S.

INORGANIC—QUANTITATIVE.

Sulphur; Determination of ——, in Calcium Carbide. H. Lidholm. Z. angew. Chem., 1904, **17**, 558—560.

About 3 grms. of the sample are mixed with 15 grms. of potassium sodium carbonate and 6 grms. of ammonium chloride, and the mass is fused in a porcelain crucible over a spirit flame. After five minutes the fusion is poured out on to a marble slab, and when cold the solidified mass and the crucible are placed in a flask of about 500 c.c. capacity, connected on one hand with a carbon dioxide supply, and on the other through a reflux condenser with a couple of absorption tubes containing cadmium acetate solution (25 grms., or 5 grms. with 20 grms. of zinc acetate, dissolved, warm, in 200 c.c. of glacial acetic acid and some distilled water, and made up to a litre with distilled water). When the apparatus is full of carbon dioxide, 100 c.c. of water are added through a stoppered funnel, followed by 25 c.c. of hydrochloric acid (sp. gr. 1·19) slowly dropped in. When gas ceases to be evolved, the liquid is heated to ebullition for a few minutes while carbon dioxide is slowly passed, so that all hydrogen sulphide is expelled from the apparatus and caught by the cadmium solution. The latter is washed into a beaker, 10 c.c. of copper sulphate solution are added (120 grms. of the crystallised salt, 120 c.c. of concentrated sulphuric acid, water to make 1 litre), the copper sulphide is filtered, washed, dried, converted into oxide by ignition in air, and weighed.—J. T. D.

Tin; Determination of ——, in Tinplate. H. Angenot. Z. angew. Chem., 1904, **17**, 521—523.

The sample is cut up into fragments with sides not more than 1 c.m. in length, and about 3—4 grms. are weighed off. This quantity is mixed in an iron crucible with twice its weight of sodium peroxide, so as to be well covered, and the covered crucible is very gradually heated till the peroxide is completely fused. After 10 minutes more it can be seen that the tin is entirely removed from the fragments; the crucible is allowed to cool, placed in a covered beaker, 100 c.c. of water added, and the crucible tipped over so as to give the water access to the contents. When action is over the contents of the crucible are washed into the beaker. The liquid is made up to 250 c.c., well shaken, and filtered through a dry filter. To 200 c.c. of the filtrate sulphuric acid (1 vol. of strong acid, 2 vols. of water) is added just to acid reaction, the liquid is boiled for five minutes, filtered, and the precipitate washed free from sulphuric acid, dried, ignited, and weighed as tin oxide. If the tin contained lead (seen by testing a few drops of the alkaline filtrate with sodium sulphide) the precipitate on acidifying will be brownish, and will contain lead. The washed precipitate and filter must in this case "be digested at a gentle heat in a small beaker till the precipitate is white"; water is then added, the liquid boiled and filtered, the precipitate washed, dried, and ignited as before.

—J. T. D.

Carbon and Silicon; Some Compounds of —— with Metals; and a generally applicable Method for the Determination of Carbon in Metals. W. Hempel. X., page 492.

ORGANIC—QUALITATIVE.

Petroleum; Determining Impurities [Water] in Boryslaw (Galicia) ——. M. Wielczynski. Naphta, 1904, **12**, 23—25.

The chief impurity in Boryslaw crude oil being water, the author recommends the use of calcium carbide as a reagent for its quantitative determination. The oil is shaken with an excess of carbide, and the acetylene disengaged is collected and measured.—C. S.

ORGANIC—QUANTITATIVE.

Nitrogen [in Organic Compounds]; Determination of ——. L. Déboordeaux. Comptes rend., 1904, **138**, 905—907.

The process devised by the author for the determination of nitrogen in organic compounds, yields pure ammonia without any admixture of amines, which are obtained in other methods, and is applicable to the following classes of compounds:—(1) Oxygenated compounds. (2) Hydroxylamine. (3) Nitro-derivatives in which the nitro-group has a phenolic function. (4) Nitriles, cyanides, and double cyanides. (5) Cyanates and thiocyanates. (6) Amides and imides "in which the nitrogen is not again substituted by a carbon radicle." (7) Amines in which the radicle possesses an acid function. The method consists of two successive distillations in a cast-iron flask communicating with a modified form of Schloesing's apparatus constructed of glass. In the first case, the substance is distilled until dry with 50 grms. of crystallised potassium thiosulphate and 200 c.c. of a solution of potassium monosulphide prepared by saturating a certain volume of potassium hydroxide solution of sp. gr. 36° B. with hydrogen sulphide and then adding an equal volume of the same alkali solution. For the second distillation, which removes the last traces of ammonia formed, 25 c.c. of the potassium hydroxide solution are added, and 250 c.c. of water, about 150 c.c. of distillate being collected. The ammonia is absorbed in excess of pure hydrochloric acid and can then be determined exactly by weighing as ammonium chloride.—T. H. P.

Organic Substances; Analysis of ——, with the help of Sodium Peroxide. H. H. Pringsheim. Amer. Chem. J., 1904, **31**, 386—395.

The method described for the determination of halogens in solid organic compounds (this J., 1904, 76), is modified for liquids as follows: The substance is poured on to sodium peroxide contained in a cylindrical flat-bottomed crucible (the quantities used being the same as described before, *loc. cit.*) and thoroughly mixed; a thick lid, into which is sealed a glass capillary tube containing a copper wire (the end of which is formed into a loop), is screwed on to the crucible, a washer of some soft metal (*e.g.*, copper) being used. A piece of platinum wire, just long enough to reach to the bottom of the crucible, is attached to the loop of the copper wire. The mixture is ignited by connecting the copper wire and the crucible with the poles of an electric battery. When the crucible is cool, its contents are treated as before (*loc. cit.*).

Phosphorus and arsenic may be determined by a similar method, a silver crucible and a copper wire being used instead of iron, and about 50 per cent. more sodium peroxide being employed than for the halogen determinations. In phosphorus determinations, the resulting solution should be acidified with hydrochloric acid, neutralised with ammonia, and precipitated by means of magnesia mixture. Arsenic is determined by using the method of Friedheim and Michaelis (this J., 1895, 887).—T. F. B.

Cane-sugar, Dextrose and Levulose; Analysis of a Mixture of ——. E. Remy. Bull. Assoc. Chim. Sucr et Dist., 1904, **21**, 1002—1006.

The author points out that the formula generally employed for determining the cane-sugar by Clerget's inversion method in a mixture containing levulose, takes no account of the fact that the rotation of levulose is not the same in a strongly acid solution as it is in aqueous solution; if the levulose constitutes a considerable proportion of the mixture this difference in rotation introduces a very appreciable error. For a mixture of cane-sugar, dextrose and levulose the following formula is deduced—

$$M = \frac{(288 - t)\ Ri - 200\,Ai + 200\,aPd}{(288 - t)\ i + 200\,d}$$

where M represents the rotation due to the two reducing sugars, R the direct rotation of the mixture, *t* the temperature, P the weight of reducing sugars determined by means of Fehling's solution ; $i = a + b$ and $d = b' - b$, *a* being the ratio of the specific rotation of dextrose to that of cane-sugar, *b* the same ratio for levulose (in neutral solution) and cane-sugar and *b′* that for levulose (in acid solution) and cane-sugar. Having obtained M from the above formula, the rotation due to the cane-sugar is given by R – M. The levulose is calculated from the formula $L = (aP - M) / (a + b)$ and the dextrose from $D = (M + bP) / (a + b)$. The factor *a* has the value 0·797, and the other factors employed in the above formula are given in the following table:—

Temperature.	Rotatory Power of Levulose. In Aqueous Solution.	Rotatory Power of Levulose. In Acid Solution.	*b*.	*b′*.	*d* or (*b′* – *b*).	*i* or (*a* + *b*).

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Acid Nitrates. E. Groschuff. Ber., 1904, **37**, 1486—1493.

Ammonium trinitrate, $NH_4NO_3.2HNO_3$, is obtained in needles by dissolving 80 grms. of ammonium nitrate in 126 grms. of nitric acid (sp. gr. 1·514) redistilled from sulphuric acid, and cooling in ice. It melts at 29°—30° C. and is soluble in water without decomposition. If to the melted salt be added 80 grms. of ammonium nitrate, and he solution be cooled rapidly to 10° C., and then very radually to 6° C., plates of *ammonium dinitrate*, NH_4NO_3. HNO_3, separate, decomposing at 11·5° C., or on the addiion of water. *Potassium trinitrate*, $KNO_3.2HNO_3$, is repared like the corresponding ammonium compound. It nelts at 22° C., and the solution with another molecule of otassium nitrate forms a eutectic mixture, from which can e obtained *potassium dinitrate*, $KNO_3.HNO_3$, by cooling a carbon dioxide and ether, quickly heating to 23° C., and eeping at this temperature for some time. It is rapidly ecomposed by water, whilst the trinitrate is unaffected by nall quantities of water, though a great excess decomposes . The solubilities of all these salts in nitric acid are given nd illustrated by curves.—J. T. D.

ilver Nitrite ; Action of Iodine on ——. W. Neelmeier. Ber., 1904, **37**, 1386—1388.

y the action of iodine upon silver nitrite in carbon tetraloride solution, a quantitative yield of nitrogen peroxide as obtained.—J. T. D.

uinonoid Hydrocarbon ; A ——. J. Thiele and H. Balhorn. Ber., 1904, **37**, 1463—1470.

treating a boiling ethereal solution of phenyl-magnesium omide with a solution of terephthalic acid dimethyl ester benzene, the dimethyl ether of tetraphenyl-*p*-xylyleneglycol $(C_6H_5)_2:C(OCH_3).C_6H_4.(OCH_3).C:(C_6H_5)_2$, is produced, which on treatment with a solution of hydrobromic acid in glacial acetic acid, yields tetraphenyl-*p* xylylene bromide. From the latter the bromine can be separated by means of silver, whereby tetraphenyl-*p*-xylylene or 1.1-bisdiphenylmethylenecyclohexadiëne (2.5), $(C_6H_5)_2:C:C_6H_4.C:(C_6H_5)_2$, is produced. This quinonoid hydrocarbon crystallises from ligroïn (petroleum spirit) in orange-coloured needles, melting at 239°—242° C. with decomposition. It is soluble with difficulty in the usual solvents, the solutions having an intense yellow to orange colour, with strong golden-yellow fluorescence ; on exposure to light, the solutions are rapidly decolorised. On treatment with bromine it is converted back into the dibromide.—A. S.

Peroxides ; Function of —— in the Chemistry of Living Cells. VIII. The Nature of the Action of Peroxydases. A. Bach and R. Chodat. Ber., 1904, 1342—1348.

By the method described in the fourth paper (this J., 1903, 384), a preparation of peroxydase was made from horseradish, which was perfectly free from all other enzymes. This preparation was used for a study of the mechanism of the "activifying" influence of peroxydase upon hydrogen peroxide. Pyrogallol was selected as the oxidisable substance, since it is not sensibly oxidised, either by peroxydase or hydrogen peroxide separately. Moreover, the oxidation product, purpurogallin, being insoluble, any secondary influence of the product of reaction is avoided. The results showed that with constant amounts (excess) of either peroxydase or hydrogen peroxide, the quantity of purpurogallin produced was proportional to the variable quantity of hydrogen peroxide or peroxydase respectively employed. Increase of the concentration of the pyrogallol (in excess) had no influence on the results. Hence it is concluded that, in the "activification" of hydrogen peroxide, the peroxydase behaves as a definite chemical compound, and that the peroxydase and hydrogen peroxide participate in the oxidation of pyrogallol in constant equivalent proportions, both being used up in the course of the reaction. When peroxydase and hydrogen peroxide are mixed in equivalent quantities, the peroxydase is completely destroyed after 24 hours at the ordinary temperature. On the subsequent addition of pyrogallol and excess of peroxydase to the mixture, it was found, however, that 85 per cent. of the original hydrogen peroxide was still unaltered, the balance having presumably been used up in the oxidation of the substratum of the original peroxydase.—J. F. B.

New Books.

A Method for the Identification of Pure Organic Compounds by a Systematic Analytical Procedure based on Physical Properties and Chemical Reactions. Vol. I. Containing Classified Descriptions of about 2,300 of the more important Compounds of Carbon with Hydrogen and with Hydrogen and Oxygen. By Samuel P. Mulliken, Ph.D., of the Massachusetts Institute of Technology. John Wiley and Sons, New York ; Chapman and Hall, Ltd., London. Price 21*s*.

Large 8vo volume, containing 237 pages of subject-matter, with 11 illustrations. Besides the preface and tables of Contents and Abbreviations at the beginning, there are at the end Alphabetical Indexes of Subjects and Formulæ, with three cards giving colour standards for definition and comparison. The leading subjects treated of in the 13 chapters of this volume are as follows :—I. Classification of Compounds and the Analytical Procedure. II. Ordinal Tests. III. Aldehydes. IV. Carbohydrates. V. Acids. VI. Phenolic Compounds. VII. Esters. VIII. Acid Anhydrides and Lactones. IX. Ketones. X. Alcohols. XI. Hydrocarbons. XII. Coloured Compounds of Order I. XIII. Special Methods, Apparatus, and Reagents. In most of these chapters the treatment of the subject is similar, falling under the following three groups in Chapters III. to XII. : (i) Generic Characterisation ; (ii) Analytical Tables ; (iii) Numbered Specific or Semi-specific Tests.

The Experimental Bacterial Treatment of London Sewage. Being an Account of the Experiments carried out by the London County Council between the Years 1892 and 1903. By Prof. Frank Clowes D.Sc., and A. C. Houston, M.B., D.Sc. P. S. King and Son, 2 and 4, Great Smith Street, Victoria Street, Westminster, London, S.W., 1904. Price 10*s*.

8vo volume, containing 225 pages of subject-matter, with 63 illustrations and 14 diagrams, and an alphabetical index. The work is classified under three Divisions:—I. Chemical and General. II. Bacteriological. And III. Particulars of Bacterial Works at Various Centres. Next follows an Appendix, under the following headings:—(i) Reduction in the number of Bacteria in Sewage by Bacterial Treatment. (ii) Bacterial Examination of Average Samples from the Sewage Treatment Plant at Christ's Hospital, Horsham. (iii) Bacterial Examination of the Feed and of the Effluent of the One-acre Bacterial-bed at the Northern Outfall Works (Barking). (iv) The Number of Bacteria in Sewage Sludge produced at the Northern Outfall Works (Barking). (v) Reduction in the Number of Bacteria present in River Water by passage down the Stream. (vi) Bacterial Examination of the Water of the North Sea and of the Water, Mud, and Sands of the Thames Estuary in the vicinity of the Barrow Deep. (vii) Comparison of the Effect of Sea-water and of Fresh-water upon Bacterial Life. (viii) Determination of Maximum Solubility of Atmospheric Oxygen in Water of different Degrees of Salinity. Division I. Chemical, &c., is sub-divided into 14 groups, the first six relating to the Sewage-treatment at the Northern Outfall (Barking), and the latter four, to that at the Southern Outfall (Crossness. Chapters or Groups xi to xiv give the Conclusions arrived at by the experimental treatment; tabulation of results of Chemical examination of the crude and settled sewage and of the effluents at the Outfall Works. Methods employed in chemically examining the sewage and effluents, and also an alteration of method of treatment suggested by the experiments.

Die Elektrolytische Raffination des Kupfers. Von Titus Ulke, M.E. Ins Deutsche übertragen von Viktor Engelhardt. Wilhelm Knapp's Verlag, Halle a/S. 1904. Price M. 8.

This forms Bd. X. of the series of "Monographien über angewandte Elektrochemie," and is an 8vo volume containing 150 pages of subject-matter, with alphabetical index and series of 10 sheets of plans of plant and apparatus. The text itself is illustrated with 86 engravings, and is subdivided into three branches, *viz.*:—I. Development, Processes, and Arrangement for the Electrolytic Refining of Copper. II. Description of Electrolytic Copper Works in the United States, Great Britain, Germany, Austro-Hungary, France, and Russia. III. Estimate of Establishment and Working Costs of an Electrolytic Copper and Nickel Factory on the American System with Details and Plans. IV. Appendix with Chronological List of most important Patents, Books, and Publications on the Processes and Apparatus for the Electrolytic Refinement of Copper.

The Vegetable Alkaloids, with Particular Reference to their Chemical Constitution. By Dr. Amé Pictet. From the Second French Edition. Rendered into English, Revised, and Enlarged, with the Author's Sanction, by H. C. Biddle, Ph.D. First Edition. John Wiley and Sons, New York. Chapman and Hall, Ltd., London. 1904. Price 21*s*. nett.

8vo volume, containing 494 pages of subject-matter and an alphabetical index. The following are the Group Headings under which the complete subject is arranged:—I. Artificial Bases closely related to the Natural Alkaloids, *viz.*, (i) Pyridine and its Homologues. (ii) Pyridine Carboxylic Acids. (iii) Dipyridyls. (iv) Quinoline and Derivatives. II. The Natural Alkaloids: (i) Distribution and General Properties. (ii) Hemlock Alkaloids. (iii) Piperine. (iv) Trigonelline. (v) Alkaloids of the Betel-nut Palm (*Areca Catechuo*). (vi) Citrazinic Acid. (vii) Tobacco Alkaloids. (viii) Jaborandi Alkaloids. (ix) Cytisine. (x) Sparteine. (xi) Alaloids of the Lupine; (xii) of Solanum; (xiii) of Coca; (xiv) of Pomegranate; (xv) of Opium; (xvi) from Hydrastes Canadensis. (xvii) Corydalis Cava. (xviii) Cinchona. (xix) Strychnos. (xx) Peganum Harmala. (xxi) Aconite. (xxii) Veratrum. (xxiii) Colchicine. (xxiv) Xanthine Group. (xxv) Allantoïn. (xxvi) Asparagine Group. (xxvii) Choline Group. (xxviii) Mustard-Seed Alkaloids. (xxix) Trimethylamine. (xxxix) Alkaloids of Unknown Constitution.

The Elements of Chemistry. By M. M. Pattison Muir, M.A., Fellow and Praelector in Chemistry of Gonville and Caius College, Cambridge. J. & A. Churchill, 7, Great Marlborough Street, London. 1904. Price 10*s*. 6*d*. nett.

8vo volume, containing 542 pages of subject-matter, with 26 illustrations. The text is subdivided as 26 chapters, and an Appendix. The work closes with an alphabetical index. The object of the book is "to present some of the fundamental facts, generalisations, principles, and theories of chemistry, lucidly, methodically, and suggestively."

A Text-Book on Ceramic Calculations, with Examples. By W. Jackson, Lecturer in Pottery and Porcelain Manufacture for the Staffordshire and Hanley Education Committees. Longmans, Green, and Co., 39, Paternoster Row, London; New York and Bombay. 1904. Price 3*s*. 6*d*. nett.

Small 8vo volume, containing 67 pages of subject-matter. The text is divided into 10 groups; the principal are as follows:—(I) Loss of weight of potters' materials on drying and firing. — Contraction; Porosity; Specific Gravity. (II) Relation between Specific Gravity, Dry contents, and slop weights of slips, &c. (III) Fineness of ground materials. (IV) From a potter's recipe, to calculate the formula of a glaze or fritt. (V) Rational analysis of clays, and the methods of calculation based upon it, &c.

Trade Report.

I.—GENERAL.

Argentine Republic; Trade of the —— in 1903.

Bd. of Trade J., April 21, 1904.

According to official figures from the Argentine Director General of Statistics, the value of the imports of merchandise into Argentina in 1903 was 131,206,600 dols gold, as compared with 103,039,256 dols. in 1902. The exports of merchandise were valued at 220,984,524 dols gold, as compared with 179,486,727 dols.

Of the total import trade during 1903, the share of the United Kingdom was 34·2 per cent., that of the United States 12·7 per cent., Germany 13 per cent., Italy 11·2 per cent., and France 9·8 per cent. Of the total export trade in 1902 the United Kingdom took 16·1 per cent., France 15·5 per cent., Germany 12·1 per cent., and the United States 3·6 per cent.

The following table shows the value of certain of the articles of import in the years 1902 and 1903:—

——	1902.	1903.
	Dols.	Dols.
Manufactures of stones, earths, &c. ...	10,908,694	11,859,788
Iron and iron manufactures*.........	17,916,082	26,844,523
Oils	8,982,800	4,110,6
Chemicals and drugs..................	3,697,800	4,491,15
Paper and manufactures of	2,557,019	2,975,391

* Includes machinery and implements.

The values of exports of chemical interest from Argentina during the past two years were as follows :—

——	1902.	1903.
	Dols.	Dols.
Maize	22,094,060	33,147,249
Linseed	17,540,952	21,239,894
Quebracho logs	2,457,233	2,002,010
Quebracho extract	919,904	1,204,049

II.—FUEL, GAS, AND LIGHT.

ANTHRACITE COAL IN BRITISH COLUMBIA.

Bd. of Trade J., April 21, 1904.

The United States Consul at Vancouver states that anthracite coal has been discovered in the vicinity of Cumberland, British Columbia, and the mine is being developed. Samples contain 83 per cent. of carbon and 5·75 per cent. of ash. The coal is compact and quite lustrous in appearance. It has been tried in the open grate and in heaters, and gives satisfaction, giving off little smoke, very little flame, and much heat. It should, therefore, with a suitable fire-box and draft, make excellent steam coal. It will take at least six months to so develop the mine that regular shipments can be made in quantity.

CALCIUM CARBIDE; BYELAWS REGULATING THE CONVEYANCE OF —— ON THE THAMES.

The following byelaws have been confirmed by the Board of Trade, and came into force on March 31 last :—

1. The byelaws for regulating the conveyance of carbide of calcium on the River Thames made by the Conservators in 1899 are repealed.

2. Consists of definitions.

3. The owner or master of every ship carrying a cargo any part of which consists of carbide of calcium shall on entering the Thames immediately give notice of the nature and quantity of such cargo to the harbour master at his office at Gravesend.

4. The hold of every ship carrying carbide of calcium shall be efficiently ventilated from the time of entering the Thames until all the carbide of calcium has been discharged, or until the ship has left the Thames.

5. All carbide of calcium discharged from any ship shall be removed without unnecessary delay to some duly licensed place of storage, or beyond the limits of the jurisdiction of the Conservators.

6. The master of every ship carrying a cargo, any part of which consists of carbide of calcium, shall only discharge such carbide of calcium at a wharf, jetty, or place approved by the Conservators, and no carbide of calcium shall be conveyed on the Thames from any such wharf, jetty, or place except in a licensed barge.

7. A licensed barge, having taken on board carbide of calcium, shall forthwith proceed to its destination, so that there shall be no delay in the removal of such cargo to some duly licensed place of storage, or beyond the jurisdiction of the Conservators.

8. Carbide of calcium shall only be brought into or carried on the Thames in hermetically closed metal vessels containing, each, not more than 224 lb., of such strength and construction or so protected as not to be liable to be broken or to become defective or insecure in conveyance otherwise than by gross negligence or extraordinary ccident.

9. No vessel containing carbide of calcium shall be pened within the jurisdiction of the Conservators except n some duly licensed place of storage.

10. Every reasonable precaution shall be taken to prevent the contact of water or moisture with the carbide of alcium, and where such contact may have occurred, to revent the gas evolved from being ignited.

11. Every vessel containing carbide of calcium shall be belled, which label shall bear in conspicuous characters he words "Carbide of calcium. Dangerous if not kept ry," and with the following caution :—"The contents of this package are liable, if brought into contact with moisture, to give off a highly inflammable gas," and with the addition of the name and address of the sender.

12. Every ship having carbide of calcium on board shall, whilst anchored or moored in the Thames, be watched by a competent person on board such ship, to be appointed for that purpose by the master or other person in charge of such ship.

13. The owner or master of the ship, or the owner of the carbide of calcium, shall, when so required by the harbour master or other officer duly appointed by the Conservators, or by any police constable, show to such officer or constable all carbide of calcium under his control or upon his ship, and shall afford every reasonable facility to enable such officer or constable to inspect and examine such carbide of calcium so as to ascertain whether these byelaws are duly observed.

14. The names and expressions used in the foregoing byelaws, where not herein specially defined, shall have the same meaning as is assigned to the same names and expressions in the Petroleum Act, 1871.

15. The penalties for offences against these byelaws are those provided by the Petroleum Acts.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PETROLEUM IN BORNEO.

Eng. and Mining J., April 14, 1904.

According to A. Gurgenianz, the oil-fields of Borneo are of great promise. Development has been in progress five years, and now there are from 50 to 60 wells in the north-east part of the island with a total daily production of 600 tons

IV.—COLOURING MATTERS, Etc.

INDIGO; GERMAN ——.

Chem. and Druggist, April 23, 1904.

In 1897 the German export of indigo did not attain the value of 5,000,000 m.; in 1903, however, thanks to the success of artificial indigo, it amounted to more than 25,000,000 m. In the three preceding years the exports more than doubled in value. The chief buyers in 1903 were the United States, to the value of 6,000,000 m.; Great Britain, about 4,000,000 m.; Austria-Hungary, 1,500,000 m.; and China, 2,500,000 m.

COAL-TAR DYESTUFFS: U.S. CUSTOMS DECISIONS.

March 28 *and* 30, 1904.

The following dyes are dutiable at 30 per cent. *ad valorem* as "coal-tar colours," under paragraph 15 of the present tariff act:—Sulphur Black G T, N B, G R, Sulphur Brown G R M, Sulphur Bronze G, Sulphur Blue B, Thiogen Brown R, Melanogen Blue B, Melanogen Tg. B, Thiogen Dark Blue R, Melanogen G and T, Thiogen Brown, Thiogen Brown G and R, Thiogen Blue B, Sulphur Black 1.

—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

PHOSPHATE TRADE; AFRICAN ——.

Eng. and Mining J., April 7, 1904.

Shipments of phosphates from North Africa in the past year were large, chiefly the result of great activity in Tunis, where the Compagnie des Phosphates de Gafsa increased its exports from 65,209 metric tons in 1899 to 358,471 tons in 1903. An increased export trade was also done through the port of Boné in Algeria, and, adding the smaller shipments from Bougies, the total increased 113,719 tons, or over 21 per cent. Prices were higher, namely: 63 to 70 per cent. rock, 4·5 to 6·25*d.* per unit (5·98 dols. to 8·31 dols. per ton); 58 to 63 per cent., 4·25 to 6*d.* (5·10 dols. to 7·20 dols.); 53 to 58 per cent., 4·125 to 5·875*d.* (4·62 dols. to 6·58 dols.). Ocean freights to European ports were 6*s.* to 8*s.* 6*d.* (1·44 dols. to 2·04 dols.) from Boné, and 7*s.* to 10*s.* 6*d.* (1·68 dols. to 2·52 dols.) from Sfax, Tunis.

In detail, the African exports in 1902 and 1903 were as below, in metric tons :—

Destination.	1902.	1903
Austria	7,650	11,500
Belgium	3,850	20,080
France	172,739	190,660
Germany	78,986	79,283
Great Britain	106,290	160,229
Holland	28,230	34,676
Italy	80,396	99,584
Russia	5,400	12,080
Spain	7,530	13,820
Other countries	25,336	14,090
Total, Boné and Sfax	516,407	636,002
Bougies exports	17,720	11,844
Grand total	534,127	647,846

These phosphates, both from Algeria and from Tunis, pay an export tax to the local governments.

ARSENIC MINE IN VIRGINIA, U.S.A.

Foreign Office Annual Series, No. 3133.

In his recent report, H.M. Consul at Baltimore remarks that what is said to be the largest arsenic mine in the world, and stated to be at present turning out 70 tons per month, is situated in Floyd County, Virginia, 17 miles from Christiansburg, the nearest railroad point. The number of persons employed at the mine is about 125, who are housed and supplied with the necessaries of life by the company owning the mine. The camp is provided with electric lights, and the plant, which is considered the most modern in existence for the treatment of the ore, is driven by electric power.

GRAPHITE, ANTIMONY, AND COPPER IN THE HIMALAYAS.

Civil and Military Gazette, March 1904.

There is good and pure graphite in Lahoul, but the cost of mining and carriage about balances the selling cost in England. The abundant deposits of antimony, also in Lahoul, have been rendered unworkable by the drop in price. The Ropa Copper Mine in Busahir, situated high up on one of the tributaries of the Sutlej, is a regular mountain of copper ore, assaying 33 per cent. of metallic copper, but is very inaccessible, and little fuel is available on the spot.

MINERAL SALTS; PRODUCTION OF —— IN GERMANY IN 1903.

Chem. Trade J., April 16, 1904.

The German Imperial Statistical Office has just issued the provisional returns relating to the production of the mines during 1903. Among others, the following may be mentioned: Mineral salt, 1,095,541 tons; kainite, 1,557,243 tons; various potassium salts, 2,073,721 tons; table salt, 599,385 tons; potassium chloride, 280,248 tons. The quantity of sulphuric acid produced amounted to 928,190 tons, as compared with 891,025 tons in 1902, the values being estimated at 1,282,500*l.* and 1,209,700*l.* respectively.

X.—METALLURGY.

GOLD IN AUSTRALIA IN 1903.

Australian Mining Standard.

A return of the Australasian gold yield for 1903 shows the total of 4,997,708 crude ounces, equal to 4,225,538 ounces fine. As the yield from metallurgical works in Queensland is not included, and the Tasmanian yield is omitted, the completed statistics will show a total Australasian output of over 5,000,000 crude ounces, against 3,844,241 ounces for the previous year.

West Australia continues to make rapid advance in production; its annual output now exceeds 2,000,000 ounces fine. Queensland again occupies second place on the crude-ounce return, but has to give place to Victoria on the actual value of the gold produced. The completed returns from Queensland for the past year show the total output of Queensland for the 12 months to have been 921,363 crude (equal to 668,546 fine) ounces, or an increase of 60,910 crude (equal to 28,083 fine) ounces, as compared with the yield for 1902.

MINING INDUSTRY OF NEW SOUTH WALES.

U.S. Cons. Rep., No. 1929, *April* 16, 1904.

From an advance report of the Under-Secretary for Mines the following facts are gathered respecting the mining interests of New South Wales during 1903:—

The aggregate value of the mineral wealth to the end of 1903 produced in this State is estimated at 154,112,125*l.* The value of the production for 1903 is 5,897,698*l.*, a net increase of 417,291*l.* over that of the previous year.

The total number of persons employed in and about the mines of the State during the year was 37,739, an increase of 4,044 over the previous year. The total value of the machinery erected at the mines (other than coal and shale mines), inclusive of dredging plants, is 2,041,701*l.* This does not include the value of the various smelting plants.

Estimated Production of Minerals in 1903.

	£		£
Gold	1,051,192	Diamonds	9,720
Silver, silver lead, and concentrates	1,461,315	Cobalt	1,528
Lead	37,556	Ironstone flux	15,411
Zinc	84,275	Iron oxide	1,149
Copper	419,673	Limestone flux	13,511
Tin	121,558	Lime	16,753
Alunite	6,046	Hydraulic cement	54,252
Antimony	131	Opal	97,330
Bismuth	9,282	Platinum	1,033
Chrome	7,146	Molybdenite	4,339
		Other minerals	9,226

BESSEMER STEEL PRODUCTION OF U.S. IN 1903.

Eng. and Mining J., April 14, 1904.

The American Iron and Steel Association has just published complete statistics, received direct from the manufacturers, of the production of Bessemer steel ingots and castings in the United States in 1903; also of Bessemer steel rails by the producers of Bessemer steel ingots.

The total production of Bessemer steel ingots and castings in 1903 was 8,577,228 gross tons, against 9,138,363 tons in 1902, a decrease of 561,135 tons, or over 6 per cent. The production of 1902 was much the largest recorded.

There were no Clapp-Griffiths works in operation in 1903 and only two Robert-Bessemer plants were active. Seven Tropenas plants were at work, as compared with five in 1902. In addition one plant made steel by the Bookwalter process, and one plant on the Pacific coast made a small quantity of steel in a special surface-blown converter. One plant also made steel by the Evans-Wills process. All these active works produced steel castings only.

The production of all kinds of Bessemer steel rails by the producers of Bessemer steel ingots in 1903 was 2,813,583 gross tons, against a similar production in 1902 of 2,876,293 tons.

There was a large increase in 1903 in the production of Bessemer steel rails weighing 85 lb. and over as compared with 1902 and a considerable decrease in rails weighing 45 lb. and over and less than 85 lb. The production in 1903 of rails weighing less than 45 lb. also shows a decrease.

The total production of rails in 1903 will include rails made from open-hearth steel, rails rolled from purchased Bessemer blooms, rails re-rolled by non-producers of Bessemer steel ingots, and iron rails. The total from all these sources in 1902 amounted to 71,640 tons.

Tin Deposits of Alaska: U.S. Geological Survey.

Bd. of Trade J., April 28, 1904.

The known occurrences of tin in Alaska are in what is called the York region of the Seward Peninsula. It extends westward from Cape York and includes Cape Prince of Wales, the most western point of the continent. The region has the form of an isosceles triangle, with its apex at Cape Prince of Wales, and its two sides formed by the shore lines of the Arctic Ocean and Behring Sea.

The occurrence of tin-bearing lodes in the bed rock has been verified by the Geological Survey at points known as Lost River and Cape Mountain. The occurrence of tin in placer deposits has been confirmed on Anikovik River, Buhner Creek, a tributary of the Anikovik, and on Buck Creek, a tributary of Grouse Creek, which flows through Mint River into the Lopp Lagoon. Tin ore has also been reported from a great many other localities which have not been thoroughly examined by geologists. The tin deposits, so far as is known, do not follow any definite system, and are confined to no particular belt or zone. The known occurrences of tin ore are described under the headings "Lost River," "Cape Mountain," "Buck Creek," "Buhner Creek," and "Anikovik River."

Mineral Resources of the Dutch East Indies.

Eng. and Mining J., April 14, 1904.

In Sumatra and in Borneo there are many deposits of tertiary coal. The principal mines are at Ombilien, Pengarou, and Poeloe-Laoet. The Ombilien mines, which are worked by the State, produce about 200,000 tons of coal yearly.

The most profitable production is that of petroleum, of which the yearly output approaches 430,000 metric tons. The principal deposits of oil in Sumatra are in the districts of Perlak, Langat, and Palembang; in Java, at Rembang, Soerabaya, and Madoera; in Borneo, in the Roetei district. There are refineries in the islands having a capacity sufficient to treat all the oil produced. The refined oil is chiefly exported, while the residuum is used for fuel, a great part of it being consumed by the steamers trading in the islands.

Tin is found in alluvial deposits in the small islands of Banka, Billiton, and Singkep. There are deposits in Sumatra and Borneo, but they are of low grade The Banka mines are worked by the State, and produce about 12,000 tons yearly. The others are worked by private companies, the output from Billiton being about 5,000 tons yearly, while that from Singkep is less than 1,000 tons. The mining or washing is done entirely by Chinese miners; but natives of the island are employed to remove the waste or overburden.

Gold is found in Borneo, Sumatra, and Celebes, both in alluvial deposits and in veins. There are several vein mines being operated, the principal ones being at Redjang-Lebong and Soemalato. Both these mines are rich, but the ores are complex, and difficult to treat.

Deposits of galena and zinc-blende exist in Borneo, and of copper in Celebes. Several of these deposits are now being explored. A peculiar industry exists in the Soerabaya district in Java, where iodide of copper is obtained from the waters of a group of mineral springs.

In Java there are quarries of very fine marble. Diamonds ave been found in Borneo, on the west coast. They are btained from the beds of certain streams by the natives. he production, however, is small, having been between 00 and 800 carats yearly for several years past.

XII.—FATS, FATTY OILS, Etc.

Cottonseed Meal: U.S. Customs Decision.

March 31, 1904.

Cottonseed meal is dutiable at 20 per cent. *ad valorem* nder section 6 of the present Tariff Act, as a "manufac-red article unenumerated." The claim of the importer at it was free of duty as "oil cake" under paragraph 625 as overruled on the ground that it was an article produced om oil cake rather than oil cake itself.—R. W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

Denatured Alcohol; Exemption of —— from Internal Tax in Argentina.

Bd. of Trade J., April 21, 1904.

The Argentine "Boletin Oficial" for the 10th February contains the text of a law exempting from internal taxation denatured alcohol of national production for heating or lighting purposes, or for use as a motive power, or in the manufacture of varnishes.

XVIII. A.—FOODS.

Dried Fruit; Sulphurous Acid in ——.

Under date of January 12, 1904, the Prussian Minister of Commerce and Industry, in conjunction with the Minister of Religion, Instruction, and Medical Affairs, issued the following order:—

"In the interest of an equable mode of procedure we will, following the precedence of other Federal States, but with the understanding that such cases as are now pending before the courts are not being reflected upon, until further notice, through the officials connected with the control of food products, make no objection to a maximum of 0·125 per cent. sulphurous acid in evaporated fruits. In all cases where a higher percentage of sulphurous acid is found criminal proceedings should be instituted in accordance with the requirements of the law of May 14, 1879."

XX.—FINE CHEMICALS, Etc.

Camphor Flowers: U.S. Customs Decision.

April 5, 1904.

The Board of General Appraisers affirmed the assessment of duty at 6 cents per lb. as "refined camphor," under paragraph 12 of the present Tariff Act, on flowers of camphor. The claims of the importer for free entry as "camphor, crude," under paragraph 515, or at $\frac{1}{4}$ cent per lb. and 10 per cent. *ad valorem*, as "gum advanced in value," under paragraph 20, were overruled.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 8978. Don. *See under* IX.

„ 9187. Candy and Candy. Filters. April 21.

„ 9445. Orbison. Melting furnaces.* April 25.

„ 9516. Lennox. Evaporator for the liquid in brewers' wash, sewage, waste or spent dyes, or the like, and concentrating the solids in the same. April 26.

„ 9635. Rider. Apparatus for dissolving, filtering, condensing, evaporating, and separating organic and inorganic substances.* April 27.

„ 9729. Gutensohn. *See under* VII.

„ 9730. Gutensohn. *See under* X.

„ 9751. Cook. Apparatus for obtaining combustion products under great pressure. April 28.

„ 9835. Mathieson. Condensers. April 29.

[A.] 9853. Espenhayn. Chemical heating device.* April 29.

„ 9904. Young. Centrifugal apparatus for separating dust from blast-furnace gases or other vapours. April 30.

[C.S.] 9308 (1903). Glass and Glass. Vacuum drying and evaporating apparatus. April 27.

„ 10,866 (1903). Henderson. Regenerative steel furnaces, glass and heating furnaces, &c. April 27.

„ 13,907 (1903). Hatmaker (Merrett). Cylindrical drying machines. April 27.

„ 15,948 (1903). Marshall. Filters. May 1.

„ 5370 (1904). Knight. Filters. May 4.

„ 6855 (1904). Jensen (White-Mylin Furnace Co.). Furnaces. April 27.

II.—FUEL, GAS, AND LIGHT.

[A.] 8880. Graham. Coke ovens. April 18.

„ 8993. Poetter. Gas-producing plant.* April 19.

„ 9071. Rouse and Cohn. Manufacture of briquette fuel from coal-mine waste or dust coal. April 20.

„ 9149. Parsons. Gas washers. April 21.

„ 9190. Weldon. Arc-lamp electrodes. [U.S. Appl., April 21, 1903.]* April 21.

„ 9206. Bernheim and Wagner. Purification of illuminating gas. [Fr. Appl., April 22, 1903.]* April 21.

„ 9382. Debauche. Manufacture of fuel blocks, briquettes, and the like.* April 23.

„ 9396. Reese. Gas producer. April 25.

„ 9443. Wright. *See under* XI.

„ 9464. Akester and Paterson. Manufacture of mantles for incandescent gas burners. April 25.

„ 9512. Helps. Gas manufacture, the recovery of by-products, and retort settings and apparatus therefor. April 26.

„ 9514. Redman. Purification of gas. April 26.

„ 9573. Edelmann. Artificial fuel, and a process for its production. April 26.

„ 9608. Whitfield. Gas-producer plant. April 27.

„ 9668. Lymn. Gas producers. April 27.

„ 9693. Mason. Process for increasing the explosive force of petrol, paraffin, and other hydrocarbons. April 28.

„ 9935. Weeple. Smokeless fuel. April 30.

„ 9942. Boutillier. Gas-generating apparatus for producing poor gas free from tarry matters. [Fr. Appl., Aug. 18, 1903.]* April 30.

[C.S.] 9396 (1903). Gutknecht. Recovery of the residual products obtained in the purification of coal-gas. April 27.

„ 13,476 (1903). Dowson. Gas generators. April 27.

„ 22,946 (1903). Deegen. Gas-retort furnace. April 27.

„ 3781 (1904). Marks (International Fuel Co.). Artificial or composite fuels. May 4.

„ 6302 (1904). Loomis and Pettibone. Manufacturing wood gas. April 27.

„ 6303 (1904). Loomis and Pettibone. Manufacturing producer gas. April 27.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 9751. Cook. *See under* I.

„ 9953. Newton (Bayer and Co.). Manufacture of new phenol compounds, and the separation of phenols from phenol mixtures. April 30.

[C.S.] 6302 (1904). Loomis and Pettibone. *See under* II.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 9439. Read Holliday and Sons, Ltd., Turner and Whittaker. Preparing and dyeing colours for wool and silk fast to milling. April 25.

„ 9456. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of cyanine dyestuffs. April 25.

„ 9460. Johnson (Chem. Fabr. Griesheim Elektron). Process for chlorinating toluene and its homologues in the side chain. April 25.

„ 9675. Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds suitable for use in the preparation of colouring matters. April 27.

„ 9932. Oakes. Processes for extracting from vegetable matters glucosides possessing colouring or tanning properties, and also the products resulting from such processes.* April 30.

[C.S.] 10,536 (1903). Johnson (Badische Anilin und Soda Fabrik). Manufacture of disazo colouring matters. May 4.

„ 11,882 (1903). Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Basic dyestuffs. April 27.

„ 14,676 (1903). Johnson (Badische Anilin und Soda Fabrik). Manufacture of phenylglycin carboxylic acid nitrile and intermediate products relating thereto. April 27.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 8851. Graham and Cope. Means for and method of bleaching animal fibres. April 18.

„ 9311. Stohr. Apparatus for dyeing hanks of yarn.* April 22.

„ 9341. Morton. Method of and apparatus for printing warps. April 23.

„ 9439. Read Holliday and Sons, Ltd., Turner and Whittaker. *See under* IV.

„ 9516. Lennox. *See under* I.

„ 9787. Ellis. Machine for washing, bleaching, dyeing, or similarly treating hanks of yarn, slubbing, warps, &c. April 29.

[C.S.] 7054 (1903). Medley. Conditioning, colouring, or loading yarns during spinning and the like. April 27.

„ 10,802 (1903). Schoening and Eisengiesserei und Werkzeug-Maschinenfabr. Act.-Ges. Printing of patterns on piece goods, paper, &c. May 4.

„ 13,827 (1903). Imray (Meister, Lucius und Brüning). Process for producing white discharges in printing fabrics, and discharges therefor. April 27.

„ 16,588 (1903). Thiele. Manufacture of artificial silk. May 4.

„ 17,857 (1903). Lichtenstadt. Machines for treating fabrics to render them waterproof. April 27.

„ 25,555 (1903). Détré. Apparatus for dyeing under pressure. May 4.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

[A.] 9175. Kron. *See under* IX.

„ 9455. Abel (Act.-Ges. f. Anilinfabr.). Process for dyeing furs, hairs, and feathers. April 25.

[C.S.] 10,802 (1903). Schoening. *See under* V.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 8877. Burleigh and King. *See under* XV.

„ 9265. Paul. Preparation of lime water and milk o lime. April 22.

[A.] 9619. Parker. Production of Glauber salts and ferrous sulphate from nitre cake or acid sodium sulphate.* April 27.
„ 9634. Lyle. Process and apparatus for separating and recovering oxygen and nitrogen from air. April 27.
„ 9729. Gutensohn. Means for forming sulphate or carbonate of lead into blocks to facilitate transport. April 28.
„ 9765. Denaeyer. *See under* IX.
„ 9930. Fairweather (Levy). Industrial treatment of aluminium silicates of the leucite group. April 30.
[C.S.] 9360 (1903). Bollé (Chem. Fabr. Grünau, Landshoff und Meyer). Production of solid zinc hydrosulphite difficultly soluble in water. May 4.
„ 13,412 (1903). Grossmann's Cyanide Patents Synd., Ltd., and Grossmann. Manufacture of hydrocyanic acid and cyanides. April 27.
„ 16,298 (1903). Claude. Manufacture of oxygen by means of liquid air. May 4.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 8884. Richards. Manufacture of coloured tiles. April 18.
„ 9544. Hall. Porcelain plate. April 26.
„ 9776. Richardson. Process of and apparatus for the manufacture of glass.* April 28.
[C.S.] 10,866 (1903). Henderson. *See under* I.
„ 13,110 (1903). Orrock. Furnaces for the manufacture of glass. May 4.
„ 13,354 (1903). Cox. Printing of earthenware, &c. April 27.
„ 14,219 (1903). Kenyon and Hobson. Method of enamelling metallic articles. May 4.
„ 20,679 (1903). Arbogast. Method of manufacturing glassware. April 27.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 8892. Gerrard and Heesom. Cement, artificial stone, building materials, tiles, paving stones, and the like. April 18.
„ 8978. Don. Rotary kilns. April 19.
„ 9175. Kron. Apparatus for impregnating and dyeing wood. April 21.
„ 9318. Scammell and Muskett. Insulating and waterproofing compositions. April 23.
„ 9444. Jacobs. Compound for coating bricks, plastering, &c.* April 25.
„ 9680. Lake (Jenequel and Hayn). Manufacture of building materials, insulating materials, &c. April 27.
„ 9765. Denaeyer. Cements and limes.* April 28.
„ 9769. Lefranc. Manufacture of artificial stone in imitation of marble or granite. April 28.
„ 9944. Ducastel. Agglutinant or cement, and method of manufacturing the same.* April 30.
„ 9963. Imray (The Carborundum Co.). Manufacture of carborundum articles.* April 30.
[C.S.] 6923 (1904). Reineke. Manufacture of cement asphalt plates or slabs. May 4.
„ 7028 (1904). Levie Frères (Soc. en nom Collectif). Process of preparing and burning cement and other analogous materials. May 4.

X.—METALLURGY.

[A.] 8994. Wedge. Preparing iron pyrites for desulphurisation.* April 19.
„ 9110. Talbot. Manufacture of iron and steel. April 20.
[A.] 9152. Jousset. Metallic alloys for solders, &c. April 21.
„ 9202. Daelen. Manufacture of iron and steel. April 21.
„ 9384. Haddan (Electrodon Ges. m. b. H.). Process for obtaining metals in a pure state, and apparatus therefor. April 23.
„ 9482. Nau. Process of refining metals. April 25.
„ 9584. Routin and Mourraille. Metallic alloy. [Fr. Appl., May 25, 1903.]* April 26.
„ 9730. Gutensohn. Means for forming manganese ore into blocks to facilitate transport. April 28.
„ 9836. Lévy. Production of metallic deposits to prevent oxidation. [Fr. Appl., May 1, 1903.]* April 29.
[C.S.] 1966 (1903). Vernon. Manufacture of steel. May 4.
„ 10,866 (1903). Henderson. *See under* I.
„ 14,219 (1903). Kenyon and Hobson. *See under* VIII.
„ 14,361 (1903). Massenez. Manufacture of iron and steel from chromic pig iron, &c. May 4.
„ 27,132 (1903). Marks (Delprat). Extracting zinc and other sulphides from their ores. May 4.
„ 1695 (1904). Morgan Crucible Co., Ltd., and Fox. Manufacture of cupels. April 27.
„ 2187 (1904). Atha. Treating scrap sheet steel and recarbonising the same. May 4.
„ 6775 (1904). Parker. Production of black magnetic oxide of iron. April 27.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 8984. Delafon. Manufacture of positive electrodes for galvanic batteries. April 19.
„ 9443. Wright. Vacuum electrodes for the production of X-rays with currents of high frequency. April 25.
„ 9468. Neuburger. Method of and apparatus for heating the charge of electric furnaces.* April 25.
„ 9547. Levis (Gen. Electric Co.). Electrodes. April 26.
[C.S.] 3913 (1903). Keÿzer. Process and apparatus for the generation of electric energy. April 27.
„ 20,313 (1903). Wedekind and Porscke. Production of a porous, hard electrode mass, insoluble in alkalies, from metallic oxides or powders. April 27.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 9018. Van Meerdervoort. Process and apparatus for the continuous manufacture of sterilised fish oil and fish guano.* April 19.
„ 9620. Claus and Rée. Production of new compounds of glycerine. April 27.
„ 9638. Nusch (Chem. Werke vorm. Dr. C. Zerbe). Manufacture of a soap preparation as a protection against lead poisoning.* April 27.
„ 9696. Blackadder. Soft soap. April 28.
[C.S.] 8897 (1903). Schneider. Apparatus for extracting fat and other substances by means of vapours or volatile solvents. April 27.
„ 13,747 (1903). Lewy. Manufacture of a wax-like composition. April 27.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—Pigments, Paints.

[A.] 9537. Carpenter. Paints or enamels, and method of applying same. April 26.
„ 9674. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring-matter lakes. April 27.

[A.] 9689. Craven and Craven. Ingrain ink. April 28.

„ 9861. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring-matter lakes. April 29.

[C.S.] 12,713 (1903). Lake (Synd. pour l'Exploitation des Inventions du Prof. Oettli). Manufacture of white lead. April 27.

(*B.*)—Resins, Varnishes.

[A.] 9975. Godfrey. Manufacture of linoleum. April 30.

„ 9976. Godfrey. Manufacture of linoleum. April 30.

[C.S.] 14,987 (1903). Blume. Manufacture of an improved varnish substitute from rosin oil. May 4.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

[A.] 9932. Oakes. *See under* IV.

XV.—MANURES, Etc.

[A.] 8877. Burleigh and King. Production of monocalcium ortho-phosphate for use as a fertiliser, &c. April 18.

„ 8949. Bell. Fertiliser and insecticide.* April 19.

„ 9018. Van Meerdervoort. *See under* XII.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 9810. Walker. Fireproofing starch. April 29.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 9516. Lennox. *See under* I.

[C.S.] 9106 (1903). Aspinall. Preparation of wort for brewing or distilling purposes. April 27.

„ 1797 (1904). Sulzen. Apparatus for making malt and for treating similar materials. April 27.

„ 6975 (1904). Imray (Brauerei Gross-Crostitz Act.-Ges.). Process and apparatus for drying, desiccating, and roasting germinated and non-germinated grain. May 4.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—Foods.

[A.] 9550. Mason. Foodstuffs. April 26.

„ 9684. Maggi. Manufacture of milk powder. [Fr. Appl., April 1, 1904.]* April 27.

„ 9703. Shackleton. Treatment of flour. April 28.

(*B.*)—Sanitation; Water Purification.

[A.] 8857. Wanklyn and Cooper. Treatment of sewage. April 18.

„ 8979. Dewhurst. Treatment of clinker from refuse destructors, and apparatus connected therewith. April 19.

[A.] 9219. Filby. Process for the purification of sewage. April 22.

„ 9297. Haller. Treatment of residuary liquors containing viscous organic matter. April 22.

„ 9516. Lennox. *See under* I.

(*C.*)—Disinfectants.

[A.] 8949. Bell. *See under* XV.

„ 9218. Proctor. Antiseptic and disinfectant. April 22.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 8885. Von Schmaedel. Manufacture or treatment of paper for printing. April 18.

„ 9277. Woodward and Maclean. Production of non-inflammable celluloid. [Ger. Appl., April 6, 1904.]* April 22.

„ 9487. Boult (Fabr. Gebrauchsfertiger Holz- und Marmorimitationen Fried. Schwartz und Co.). Wall and like paper.* April 25.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[C.S.] 15,401 (1903). Johnson (Kalle and Co.). Manufacture of a new serum for curative purposes. May 4.

„ 6428 (1904). Lepetit. Manufacture of a condensation product from hæmatoxylin and formaldehyde. April 27.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 9962. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of coherent and opaque films, sheets, or masses of pyroxyline, collodion, celluloid, or the like. April 30.

[C.S.] 11,219 (1903). Fulton and Gillard. Production of photographs on linen or other fabrics or substances. May 4.

„ 3855 (1904). Hoffsümmer. Process of preparing photographic printing paper or the like. April 27.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 8985. Clark (Badische Maschinenfabr. und Eisengiesserei vorm. Sebold, and Sebold and Neff). Match-making machines. April 19.

[C.S.] 13,531 (1903). Wetter (Westfälisch-Anhalt. Sprengstoff Akt.-Ges.). Explosives or blasting compositions. April 27.

JOURNAL OF THE

Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.
ISSUED TWICE A MONTH.

No. 10.—Vol. XXIII. **MAY 31, 1904.** No. 10.—Vol. XXIII.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum:
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each; 1902 *et seq.*, 1/9 each.

he Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D. F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
F. Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.

OUNCIL FOR YEAR ENDING JULY 1904.

President: Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.

Vice-Presidents:

rof. P. Phillips Bedson.
rof. Marston T. Bogert.
. Carey.

F. W. Richardson.
Geo. Ward.
H. A. Watson.
Thorp Whitaker.
J. B. Wilkinson.

Hon. Local Secretary and Treasurer:
T. Fairley, 17, East Parade, Leeds.

The following take office in Sept. next:—*Chairman:* H. Procter. *Committee:* W. Ackroyd, J. E. Bedford, F. Bran B. A. Burrell, and A. Smithells.

N.B.—The names in *italics* are those of members of Committee who retire from their respective offices at the end of the current sess

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who propose to attend the meeting are requested to inform he General Secretary, as soon as possible, by what steamer hey will travel. Each boat will be met on arrival at New York by a representative of the Reception Committee, with a list of apartments, at various prices, which have been eserved for the Society. The same system will be observed at all the other cities visited by the special train. A revised programme appeared in the March 31st issue.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire rom their respective offices at the forthcoming Annual Meeting.

Mr. Wm. H. Nichols has been nominated to the office of President under Rule 8; Dr. Edw. Divers, Prof. W. R. Eaton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. Parker have been nominated Vice-Presidents under Rule 8; and Sir Wm. Ramsay has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the Annual General Meeting at which the election to which it efers takes place. Nor shall any such nomination be valid the person nominated be ineligible for election under Rules 2 or 15. No member shall sign more than one nomination orm."

COMMUNICATIONS.

Authors of communications read before the Society, or ny of its Local Sections, are requested to take notice that nder Rule 43 of the Bye-laws the Society has the right of iority of publication for three months of all such papers. fringement of this Bye-law renders papers liable to be jected by the Publication Committee, or ordered to be stracted for the Journal, in which case no reprints can furnished to the author.

DUTY-FREE ALCOHOL.

At a meeting of the Joint Committee of the Chemical de Section of the London Chamber of Commerce and the Society of Chemical Industry, held May 3rd, 1904, . John C. Umney in the chair, it was resolved:—

"That, having regard to the development of the question the use of alcohol for industrial purposes, and the stence already of the Joint Committee of the London Chamber of Commerce and the Society of Chemical Industry, is desirable to secure the co-operation of other interested sympathetic bodies or persons in order to take joint on for obtaining untaxed alcohol, denatured or otherwise, legislative means."

The Secretary of the Chamber, subject to the sanction o he Council, is hereby instructed to communicate with t e indicated by the Chairman of the Section and the c vener of the Society of Chemical Industry Spirit Com- n ee."

t a meeting of the Council of the London Chamber of Commerce held on May 12th, 1904, the above resolution was u nimously confirmed.

List of Members Elected

24th MAY 1904.

Buchanan, Joshua D., c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Chemical Analyst.

Cameron, Walter Scott, 239, West 136th Street, New York City, U.S.A., Manufacturing Perfumer.

Cargill, John T., 175, West George Street, Glasgow, East India Merchant.

Coysh, Basil R., 23, Woodville Gardens, Ealing, W., Manufacturing Chemist.

Crossley, T. Liosey, Hawkesbury, Ont., Canada, Analytical Chemist.

Erdmann, Prof. Dr. H., Bismarck Strasse 12, II, Charlottenburg, Berlin, Germany, Professor of Inorganic Chemistry.

Ewing, Dr. A. Ramsay, Rose Cottage, Lennoxtown, Stirlingshire, Technical Chemist.

Forrest, Charles N., New York Testing Laboratory, Long Island City, N.Y., U.S.A., Chemist.

Fraser, James Dick, 3, Melbourne Road, Waltham Cross, Essex, Chemist.

Gross, Henry B., Royal Societies Club, St. James' Street, London, S.W., Chemical Manufacturer.

Hacking, D. H., Henfield House, Clayton-le-Moors, near Accrington, Lancs., Soap Manufacturer.

Joy, Dr. J. Holmes, Manor House, Tamworth, Staffordshire, Physician.

Kaus, Dr. Emil, c/o Roessler and Hasslacher Chemical Co., Perth Amboy, N.J., U.S.A., Chemist.

Lasher, F. G., The Lake Pigment Co, Dunellen, N.J., U.S.A., Chemist.

Lichtenthaeler, Robt. A., University of Florida, Lake City, Fla., U.S.A., Chemist.

Lieber, Hugo, 25, West Broadway, New York City, U.S.A., Chemist.

McMullen, Alan, 108, James Street, Dublin, Ireland, Brewer.

Mair, William, 7, Comiston Road, Edinburgh. Chemist.

Martin, W. C., College Station, Texas, U.S.A., Instructor in Industrial Chemistry.

Murdoch, Alexander, Park Terrace, Brightons, Polmont Station, N.B., Analytical Chemist.

Olney, L. A., 118, Riverside Street, Lowell. Mass., U.S.A., Professor of Chemistry and Dyeing (Lowell Textile School).

Olshausen, B. A., Columbia University, New York City, U.S.A., Student.

Page, Edwin P., Heath Street, Stourbridge, Worcestershire, Chemist.

Prideaux, E. B. R., 17, Barnmead Road, Beckenham, Kent, Student.

Ratcliffe, Mrs. F. A., 111, Croxted Road, West Dulwich, S.E.

Rhett, Edmund, American Ether Co., Richmond, Va., U.S.A., Superindent.

Riley, Oliver, Arden Hall, Accrington, Lancs., Chemical Manufacturer.

Rodger, Robert, Government Laboratory, Clement's Inn. Passage, Strand, W.C., Analytical Chemist.

St. Clair-Fewings, L., 3, Bolingbroke Grove, Wandsworth Common, S.W., Incandescent Mantle Chemist.

Sanger, Charles Robert, Harvard College, Cambridge, Mass., U.S.A., Professor of Chemistry.

Schenck, Henry, 80, Washington Square, New York City, U.S.A.

Schultze, Dr. H. S., Griesheim a/Main, Germany.

Sharples, G. H., Holly Villas, Sutton Lane, Middlewich, Cheshire, Works Chemist.

Vernon, Richard Henry, Villa Verdeil, Lausanne, Switzerland, Student.

Walker, John P., c/o B. and M. Smelter, Great Falls, Montana, U.S.A., Metallurgical Chemist.

Weil, Jacob A., 39, Victoria Street, Westminster, S.W., Chemist.

Wheawill, Cornelius, 11, Westbourne Road, Huddersfield, Chartered Accountant.

Wilkinson, Prof. J. A., Transvaal Technical Institute, P.O. Box 3572, Johannesburg, Transvaal, Professor of Chemistry.

Wright, A. M., 62, Harman Street, Addington, Christchurch, N.Z., Works Chemist (Christchurch Meat Co.).

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Bechi, G. de, l/o Church; 11, Walton's Parade, Preston, Lancs.

Bek, Lars P., l/o Sydney; Goondi, Johnston River, North Queensland, Australia.

Bowden, Thos., l/o Rochdale; Starring Grove, Stubley, Littleborough, Lancashire.

Brookman, F., l/o 8; 6, West Street, Rochdale.

Cady, Wm. H., l/o Philadelphia; 127, Power Street, Providence, R.I., U.S.A.

Chorley, Jno. C., l/o Warrington; Bewsey, Oxford Road, Birkdale, Lancs.

Connah, J., l/o Sidcup; 31, Rudall Crescent, Hampstead, N.W.

Davis, Chas. B.; communications to c/o Dr. F. Wyatt, S.W. corner of 23rd Street and 9th Avenue, New York City, U.S.A.

Dunlop, Robt., l/o Shettleston; 5, Morrison Terrace, North Road, Bellshill, N.B.

Ellis, E. Victor, l/o Castle Street; 7, Hillside Crescent, Edinburgh.

Gas, Jas. K., l/o Camden; Haddon Heights, N.J., U.S.A.

Gate, T. Erskine; Journals to The Santubong Cutch and Tanning Extract Co., Ltd., Santubong, Sarawak, *viâ* Singapore.

Jacobs, C. B., l/o Broad Street; c/o American Lithographic Co., 19th Street and 4th Avenue, New York City, U.S.A.

Johnson, Thos., l/o 149; Caixa 91, Pernambuco, Brazil.

Kawai, I., l/o Tokyo; Camphor Monopoly Bureau, Fukuoka, Japan.

Lacey, T. S.; l/o King's Cross; The Gasworks, Bromley-by-Bow, E.

Leman, W. T., l/o Coraopolis; c/o The Texas Co., Beaumont, Tex., U.S.A.

Lippincott, W. B.; all communications to c/o United Zinc and Chemical Co., Argentine, Kansas, U.S.A.

Mills, Prof. E. J., F.R.S., l/o Harrow; 64, Twyford Avenue, West Acton, London, W.

Mitsugi, R., l/o Kobé: Engineering College, Imperial University, Tokyo, Japan.

Morson, T., l/o Southampton Row; 14, Elm Street, Gray's Inn Road, W.C.

Ogden, R. L., l/o Bethlehem; Room 21, P.O. Building, Harrisburg, Pa., U.S.A.

Pauli, Dr. H., l/o Frankfurt; Gersthofen bei Augsburg, Germany.

Pettitt, Alf., l/o Brooklyn; 3121, Avenue G., Flatbush, N.Y., U.S.A.

Phillips, Harcourt, l/o Bolton; Lynwood, Turton, Lancashire.

Pringsheim, Dr. H. H.; Journals to Gartenstrasse 68, Breslau, Germany (temporary).

Proctor, W. W., l/o 33; 8 & 10, The Side, Newcastle-on-Tyne.

Rawson, Christopher, l/o Bedford; c/o Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany.

Riederer, Dr. H. S.; all communications to 251, West 95th Street, New York City, U.S.A.

Russell, Thos. A.; Journals to 3, Queen's Park, Toronto, Canada.

Scrutton, W. J. C.; all communications to Grindley Lane, Blyth Bridge, Staffs.

Smith, Ewing, l/o Glasgow; c/o The Borneo Co., Ltd., Kutching, Sarawak, Borneo.

Smith, Francis P., l/o London; c/o C. W. Smith, 119-121, Elizabeth Street, New York City, U.S.A.

Smith, Jno., l/o Hartley Street; Calder Wharf Dyeworks, Ravensthorpe, Dewsbury.

Thiry, J., l/o Chislehurst; 95, Rue St. Lazare, Paris.

Thomson, Jno., l/o Alexandria; Devon Lodge, Helensburgh, N.B.

Townsend, Oliver C., l/o Horton Crescent; New Bilton, Rugby.

Trantom, Dr. Wm.; all communications to Haselmere, Maltman's Road, Lymm, near Warrington.

Uhlig, E. C., l/o New York; c/o Brooklyn Union Gas Co., Nevins and Degraw Streets, Brooklyn, N.Y., U.S.A., Gas Works Chemist.

Wade, F., l/o Shirley Road; 44, Beech Farm Road, Southsea.

MEMBER OMITTED FROM LIST.

Johnson, Saml. H., jun., Hempstead House, Woodford Wells, Essex, Chemical Engineer.

Deaths.

Hands, Jas., 127, Gosford Street, Coventry.

MacKinlay, R. W., Ameliaville, Aytoun Road, Pollokshields, Glasgow.

Canadian Section.

Meeting held at Toronto, on March 24th, 1904.

PROF. W. R. LANG IN THE CHAIR.

THE IMPROVEMENT OF BOILER FEED WATER.

BY A. McGILL, B.A., ETC.

Part IV.—Experimental Investigation of Certain Problems in Water Treatment.

Problem I.—Conditions of working, and limits of error, in the use of "Soda Reagent" in Water Assay.—"Soda Reagent" is a decinormal solution of soda, in which half the soda exists in the caustic and half in the carbonated state. It is used with Methyl Orange as indicator. For the explanation of its action see this J., 1904 (April 15th), p. 355. It is necessary to use "Soda Reagent" in distinct excess of the amount required by theory, and the following may be taken as minimum quantities, when work is done on 100 c.c. of the sample. For each one part per million in solution:—(1) Lime (in any combination) use 0·10 c.c. "Soda Reagent"; (2) Magnesia (as $MgSO_4$ or $MgCl_2$) use 0·15 c.c. "Soda Reagent"; (3) Magnesia (as bicarbonate) use 0·30 c.c. "Soda Reagent." The actual volume to be employed in the determination of total hardness is calculated from that base which predominates. Since in the case of magnesia it is the caustic moiety of "Soda Reagent" which alone enters into reaction, while in the case of lime it is the carbonated moiety only, it is not necessary to consider both magnesia and lime in the calculation. It is important to note that, after determinatio of "Alkalinity" (*loc. cit.*), free carbon dioxide must b boiled off before adding "Soda Reagent" for the precipitation of magnesia, since otherwise the caustic moiety o the reagent will be more or less carbonated, and incomplete precipitation of magnesia may result. This reagent i employed for two distinct purposes, *viz.*:—(1) To determine permanent hardness (Hp): (2) To determine tota hardness (H). Temporary hardness is, of course, the difference between these numbers. In such cases, where it is known that alkali carbonates do not exist in the water under examination, the "Alkalinity" number is at the same time a measure of the temporary hardness, and the permanent hardness may, in these cases, be obtained by a method of difference, since Total Hardness = Temporary H. (Alkalinity) + Permanent H.

In the direct determination of permanent hardness, a measured volume of "Soda Reagent" $(=Q^2)$ is added to 100 c.c. of the sample (from which free carbon dioxide has been expelled, if necessary), which is then boiled for a few minutes, cooled, diluted to 200 c.c., filtered (or otherwise clarified), and 100 c.c. of this filtrate is titrated with N/10 hydrochloric acid (volume used $= r^2$). Permanent hardness, in terms of lime per million, is calculated by formula 4 (p. 357)—$Hp = 28\ (Q^2 - 2\ r^2)$.

In the determination of total hardness by "Soda Reagent" it is necessary first to convert all carbonates into salts of the stronger acids. It is therefore usual to work on the solution in which alkalinity has been determined. This solution contains the bases in the form of chlorides, excepting such as originally existed as sulphates. The solution contains more or less free carbon dioxide, which must be boiled off before adding "Soda Reagent." The reagent is now added in distinct excess (Q^1), and the solution boiled a few minutes, cooled, made to 200 c.c., filtered (or otherwise clarified), and 100 c.c. of the filtrate titrated with N/10 hydrochloric acid (volume used $= r^1$). The total hardness (H) is calculated by formula 3 (p. 355)—$H = 28\ (Q^1 - 2r^1)$.

The precipitation of lime and magnesia in these operations is so close that the filtrates give but very faint reactions for these bases when tested, under most rigorous conditions, by oxalate and phosphate, provided that the filtrates in question are perfectly clear. Nevertheless an experience, based upon many hundreds of tests, convinces me that an error which may amount to 50 parts per million invariably occurs in this method of assay. The whole of the sources of this constantly occurring error are not known, but the following list comprises the most important :—

Source of Error.	Effect of Error.
1. Personal error in reading to tint with Methyl Orange.	Increases the value of (r); hence reduces that of H, making hardness too low.
2. The solubility of calcium carbonate is 10—20 parts of lime per million. (Comey's Dict. of Solubilities, p. 82.)	Same as above.
3. The solubity of magnesium hydroxide is about 20 per million (*op. cit.*, p. 216).	Same as above.
4. Presence of alkali chlorides increases the solubility of magnesium hydroxide.	Same as above.
5. Turbidity of the filtrate, due to floating particles of calcium carbonate or magnesium hydroxide which have passed through the pores of the filter.	Same as above.

Error 1 will naturally vary in amount with different ndividuals, being, to some extent, a personal one. So far s cases coming under my observation are concerned, may be taken as varying from 0·1 c.c. to 0·2 c.c. N/10, us introducing an error of from 5 to 10 parts per million to the final result.

This error may be compensated by the use of a constant, scertained once for all by each analyst.

Errors 2, 3, and 4 will vary more or less with different pes of water. The first two are fairly constant, and may considered as inevitable, and inherent in the method; hich may therefore be taken as showing a hardness of out 10 to 30 per million below the truth, under the most vourable conditions. It is probable that an addition of per million to the indicated hardness would be an improvement, so far as these errors are concerned; and I n inclined to recommend the adoption of this constant for e correction of total hardness, and for permanent hardness en directly determined.

Error 5 is a very variable one, since the precipitates are always thrown down in a finely divided state, and sometimes the obtaining of a clear filtrate is next to impossible. I have ascertained the possible magnitude of this error by substituting clarification with a centrifuge for filtration; and may put on record the following results :—

Substances in Solution.	CaO Actual.	CaO Found.	Error.	Remarks
1. Contained calcium sulphate only.	454	401	53	Filtrate turbid.
	454	403	51	" "
	454	426	28	Centrifuge, till clear.
2. Contained calcium bicarbonate only.	277	258	19	Filtrate clear.
	277	263	14	" "
	518	493	25	" "
3. Contained both calcium sulphate and bicarbonate.	310	293	17	" "
	230	174	56	" turbid.
	150	73	77	" "
	150	140	10	Centrifuge, till clear.
	390	358	32	Filtrate clear.
	150	67	83	" turbid.
	150	134	16	Centrifuge, till clear.
	615	552	63	Filtrate turbid.

NOTE.—The filtrates above described as turbid were, nevertheless, so nearly clear that the turbidity was apparent only to careful observation. They had repeatedly passed through ordinary filter paper, and in routine work would certainly have been considered satisfactory. The solutions worked on were prepared with great care.

It will be noted that this experimental investigation covers only the case in which lime is in solution. The influence of magnesia has not been specially studied in this connection; but the following table contains a series of naturally occurring waters in which magnesia was present.

The subjoined table contains a series of natural waters, in which the lime and magnesia were determined in the ordinary way, and the total hardness was also determined by the method of assay with "Soda Reagent" already described. The magnesia (found by gravimetric analysis) is multiplied by 1·4 to convert it into an equivalent of lime; and the sum of lime and magnesia gives the actual total hardness in terms of lime. It will be seen that in a few instances the number found by assay with soda reagent agrees very closely with the actual hardness; but, in most cases, it is considerably lower than this. I may say that no corrections have been introduced into any of these results,

* High chlorides. † Much soda.

and that the analytical numbers quoted are taken quite at random from the pages of my notebooks. It was the observation of this constant departure from the hardness as indicated by quantitative analysis that led me to investigate more closely the results given by the method of assay with "Soda Reagent." It will be seen that the amount of the difference referred to does not seem to bear any constant relation to the total amount of lime or magnesia in solution. For this reason I am inclined to think that a turbid filtrate (although the turbidity may seem so slight as to be negligible) is the most important source of error, and that which is least easily avoided or corrected by the use of an arbitrary constant.

The following conclusions are reached, in consequence of the studies just put on record:—

1. Great care must be taken to secure a clear liquid in determining the values r^1 and r^2.

2. Where a centrifuge is available, this is preferable to filtration through paper.

3. An error of defect is constantly found.

4. While this error may reach 50 parts of CaO per million, it does not usually reach more than 25 parts per million.

5. If a constant of 25 parts of lime per million is added to the results of experiment, a closer approximation to the truth will be obtained.

6. All indirect methods of determining magnesia, by taking the difference between the lime (directly estimated) and the total hardness as determined by assay with "Soda Reagent," and from this difference calculating magnesium by the factor 0·714 $\left(=\frac{1}{1\cdot 4}\right)$, will be inexact to the extent that determination of hardness is inexact.

7. When the magnesia is an important factor in the hardness, it is, for this reason, desirable that magnesia should be independently determined, by one or other of the methods of exact analysis.

8. The method of assay by "Soda Reagent" is rather to be recommended as a simple and expeditious than as an accurate and reliable mode of analysis.

Problem II.—Pfeifer (Zeits. angew. Chem., 1902, 201) says:—"The quantity of lime added may vary within certain limits without seriously affecting the resultant water." He gives examples of treatment, which may be summarised thus:—

—	IV.	VII.	IX.	X.
Total hardness of the sample....	377	345	885	403
Hardness due to magnesia......	102	293	504	137

Results of treatment, in which the theoretical quantities of soda ash were used, so that the only deviation from normal treatment is in the lime. (C = Causticity; H = Residual Hardness.)

—	IV.		VII.		IX.		X.	
	C.	H.	C.	H.	C.	H.	C.	H.
(1) Normal amount of lime...	12	48	22	26	17	42	12	56
(2) Deficiency of about 10 " ..	0	58	23	38	20	64	13	73
(3) Excess of about 10 "	9	34	22	17	26	12	9	5

The residual hardness is somewhat higher when a deficiency of lime is used, and somewhat lower when an excess of lime is used, the limit of 10 per cent. from the normal quantity being respected. These results justify Pfeifer's assertion that a variation of 10 per cent. from the normal lime quantum does not seriously affect the character of the resultant water.

In order to study the influence of an excess of lime, where only lime hardness is present, I treated an artificial water containing 500 parts of CaO as bicarbonate with lime as follows:—

Treatment.	Causticity.	Alkalinity.	Total Hardness.
(1) The natural water......	0	500	500
(2) Added 500 parts of lime, without expelling free carbon dioxide........	0	260	263
(3) Added 500 parts of lime, after expelling free carbon dioxide........	6	39	39
(4) Added 550 parts of lime, *i.e.*, 10 per cent. excess	20	39	28
(5) Added 600 parts of lime, *i.e.*, 20 per cent. excess	76	84	84

NOTE.—Determination (2) in the above table is introduced to show the influence of free carbon dioxide in interfering with lime treatment. It is true that the sample worked on is not a natural water. Nevertheless, it had stood in an open bottle for many hours and showed no bubbles of gas. I have found natural waters with more free carbon dioxide than was contained in this sample $\left\{(263 - 39) \times \frac{44}{56} = 176 \text{ carbon dioxide per million}\right\}$.

From this it appears that, up to 10 per cent. excess of lime, the hardness of the water is not increased, although the causticity is affected. Addition of more than 10 per cent. excess of lime is decidedly injurious.

Problem III.—I have put on record elsewhere (J. Amer. Chem. Soc., 1904, 184) the fact that bicarbonates of lime, magnesia, soda, and barium are more or less decomposed into monocarbonates and free carbonic acid, on prolonged agitation of their solutions. In the case of calcium and barium, the monocarbonates formed are immediately precipitated, excepting 15 to 20 parts per million, representing the solubility of these carbonates in pure water. Magnesium monocarbonate remains in solution up to at least 170 parts per million, and sodium monocarbonate is indefinitely soluble. All of these monocarbonates react alkaline to phenolphthalein; and despite their slight solubility, even calcium and barium monocarbonates give the pink coloration quite distinctly.

When using a current of air in order to drive off free (dissolved) carbon dioxide (*op. cit.*) there is danger of passing the point at which uncombined acid is disengaged, and bringing about decomposition of bicarbonates, as described above. By adding phenolphthalein to the sample and carefully noting the appearance of a pink tinge, it is easy to prevent any considerable error of this kind. When lime alone is present the pink tinge remains rather faint no matter how far the decomposition proceeds, because the maximum solubility of calcium carbonate is reached almost immediately after passing the neutral point. It is differen when magnesia or soda is present, because the decide solubility of their monocarbonates produces a cumulativ effect, and the red colour becomes increasingly intens In order to ascertain the rate and the extent of decomposi tion of bicarbonates on agitation the following experiment were made. Agitation was produced by a rapid current o air:—

Sodium Bicarbonate.—(1) A solution containing 53 Na_2O per million was used. After 10 minutes, 12 Na_2((= 2 per cent.) existed as monocarbonate. After 2 minutes, 28 Na_2O (= 5 per cent.) existed as mon carbonate. (2) A solution containing 778 Na_2O was use After 60 minutes it contained 117 Na_2O (= 15 per cent as monocarbonate.

Magnesium Bicarbonate.

MgO (per Million) in Solution.	Time of Agitation (Minutes).	MgO existing as Monocarbonate.	Per Cent.
276	60	37	13
276	150	39	14
276	360	51	19
343	15	28	8
343	20	30	[illegible]
343	25	34	10
343	30	40	12
343	60	62	18
600	15	107	18
600	30	147	24
600	60	193	32

The decomposition is more rapid in concentrated solutions. No precipitation of magnesium carbonate occurred in any of these solutions.

Calcium Bicarbonate.—Air was rapidly bubbled through a solution of calcium bicarbonate for periods of varying duration, and the resultant water assayed.

Time of Agitation.	Causticity.	Alkalinity.	Hardness by Soda Reagent.	Percentage of CaO removed.
Original sample.	0	518	493	..
10 minutes......	3	445	409	17
35 „	3	325	269	45
60 „	3	269	224	54
20 hours	3	90	50	89

It thus appears that a water which owes its hardness to calcium bicarbonate alone can be softened fully 50 per cent. by vigorous agitation for one hour, without addition of any chemicals.*

Problem IV.—A current of air was blown through a solution of 365 parts of magnesia as bicarbonate and 210 of lime as sulphate. In two hours the hardness (total) was reduced from 721° to 526°, and in three hours it was reduced to 448°. The softening of the water in this instance cannot, however, be wholly ascribed to precipitation of magnesia as monocarbonate, since reaction is possible between calcium sulphate and magnesium carbonate with the preciptation of calcium carbonate, leaving magnesium sulphate in solution. On allowing the above solution to remain at rest for 48 hours, a crystalline deposit was formed, which proved to be calcium carbonate. That the interaction between magnesium carbonate and calcium sulphate (which occurred in this case) is accelerated by agitation is shown by the following experiment. A sample containing 332 parts of lime as sulphate and 292 of magnesia as bicarbonate was agitated by an air current for periods of one and two hours, and the lime remaining in solution was determined:—

	Per Million.
Lime in solution at first	332
„ „ after 1 hour....................	224
„ „ „ 2 hours.................	157

Hence it may be inferred that magnesium carbonate and calcium sulphate cannot exist together in natural waters. Where, therefore, we find magnesia in a sulphated water, we are entitled to express it as $MgSO_4$ up to the extent of one or other of the radicles concerned.†

Problem V.—Böhlig (abst. in J. Chem. Soc., 36, 963) states that if, in waters containing lime and magnesia with carbon dioxide and sulphuric acid, the free carbon dioxide be removed below a boiling temperature, calcium carbonate is precipitated and magnesium sulphate remains in solution. This agrees with the work recorded in Problem IV. He further states that if the free carbon dioxide be removed by simple boiling, the precipitate consists entirely of calcium carbonate if sufficient magnesia is present; but when the boiling point becomes higher, as in the case of steam boilers, calcium sulphate is precipitated. On boiling magnesium sulphate with calcium bicarbonate Böhlig found carbon dioxide to escape, while calcium sulphate remained in solution, basic magnesium carbonate being precipitated, or even magnesium hydroxide when the boiling point was considerably raised. Böhlig considers that when the magnesia is not greater than the temporary hardness, it should be expressed as carbonate, and only the excess of magnesia as sulphate. This opinion is at variance with my own; and is dissented from by Allen (this J., 1888, 801). The following experiment in illustration of this point may be put on record.

Three volumes of a water sample (Pembina), having the composition given below, were concentrated by slow boiling, under atmospheric pressure, to two volumes. The precipitate contained the whole of the lime as carbonate, and only 5 per cent. of the magnesia present in the original sample.

Pembina.—Analysis gave:—

	Parts per Million.
Dissolved solids, dry at 160° C................	3,183
„ „ heated to redness..........	2,613
Loss on heating	570
Residue on sulphation........................	2,984
Lime, CaO.....................................	360
Magnesia, MgO................................	303
Soda, Na_2O..	524
Sulphuric acid, SO_3..............................	1,305
Chlorine (Cl)	24
Fully combined carbon dioxide.............	299 +

To determine whether any notable amount of calcium sulphate is formed on concentrating a solution containing lime as bicarbonate and soda as sulphate, a solution containing 370 parts of lime as bicarbonate and 500 of soda as sulphate was concentrated by slow boiling, at atmospheric pressure, to one-eighth volume. A very considerable precipitate of calcium carbonate was formed, containing only a trace of sulphates.

Problem VI.—Since barium carbonate is somewhat more soluble in water than barium sulphate, the continued agitation of barium carbonate with a solution of calcium sulphate might be expected to cause the gradual production of barium sulphate and calcium carbonate, both of which substances would be precipitated up to their limit of solubility. Barium carbonate, if in excess, would also remain dissolved up to its maximum of solubility; but the exceedingly small solubility of all these salts would leave the water practically a soft water.

Experiment.—300 c.c. of a sample containing 259 parts of lime as sulphate, and 269 of lime as bicarbonate, was agitated for 30 minutes with an excess of barium carbonate. The filtrate contained 317 parts of SO_3 as against 370 originally present, *i.e.*, about 15 per cent. of the sulphuric acid entered into reaction with barium carbonate, according to the following equation:—

$$CaO, SO_3 + BaO, CO_2 = BaO, SO_3 + CaO, CO_2.$$

An old sample of barium carbonate was used in this experiment. If freshly precipitated carbonate were used it is probable that the reaction would have proceeded further. The best results should occur when the barium carbonate reacts *in statu nascendi.*

Comment.—The sample contained no free carbon dioxide to begin with; but it may be that the carbon dioxide continually disengaged from the calcium bicarbonate may have aided solution of barium carbonate.

Problem VII.—The general case of the reaction between calcium sulphate and barium oxide may be expressed thus:—

$$\underset{a}{CaO}, \underset{a}{SO_3} + \underset{a}{BaO} = \underset{a}{BaO}, \underset{a}{SO_3} + \underset{a}{CaO},$$

where a = CaO originally present, or its chemical equivalent in other radicals. The constants for such a water, before and after treatment with barium, should be as follows:—

In Solution.	Before.	After.
CaO	a	a
SO_3..	a	0
Causticity	0	a
Alkalinity	0	a
Hardness (permanent).....................	a	0
„ (temporary)	0	a
„ (total)...........................	a	a

---

* It will be observed that the determination of hardness in such a water, with the use of "Soda Reagent" (see Problem I.), yields a result lower than the truth by about 25 parts of CaO per million. The "alkalinity" number is a truer index to the amount of lime in solution. The percentage of "lime removed" is calculated upon a basis of 493 per million originally present, as indicated by the assay number.

† According to Pfeifer (Zeits. f. angew. Chem., 1902, 194) the readily soluble magnesium salts react with the difficultly soluble calcium salts under boiler pressure, and give rise to the formation of difficultly soluble magnesium compounds, and more easily soluble calcium compounds. Magnesia is found as sulphate in many boiler scales, doubtless as the comparatively insoluble Kieserite modification ($MgSO_4$, H_2O).

Driffield states (this J., 1887, 178) that where waters containing magnesium carbonate are used, the magnesia found in the boiler scale occurs as oxide, and not as carbonate.

The above assumes that baryta is added in equivalent amount to the lime present; and that barium sulphate is absolutely insoluble.

The following samples contained calcium sulphate only, and were treated with an equivalent amount of barium hydroxide. Constants are stated in terms of CaO per million:—

Actual Value of "*a*."	Before Treatment. Assay with Soda Reagent.				After Treatment. Assay with Soda Reagent.			
	Caust.	Alk.	H.	Hp.	Caust.	Alk.	H.	Hp.
390	0	7	355	348				
	0	9	379	370				
	0	9	359	350	364	375	358	0
Mean	0	8	365	357				
441	0	21	442	421	363	368	387	19
573	0	11	543	532	493	506	523	17

It will be noted that the value of "*a*" as given by Soda Reagent varies farther from the actual value after treatment with barium hydroxide than before treatment.

When lime as bicarbonate is in solution along with calcium sulphate, and baryta is added in amount equivalent to the lime present as sulphate, there will be an immediate formation of barium sulphate and carbonate, the whole of the baryta being thrown out of solution in one or other of these combinations. We have seen (Problem VI.) that prolonged agitation will gradually bring about solution of barium carbonate and cause the final precipitation of most of the baryta as sulphate. If we assume the ultimate precipitation of all the baryta in this form, the general case may be thus expressed:—

a = CaO present as sulphate, or its chemical equivalent in other radicals.

b = CaO present as bicarbonate, or its chemical equivalent in other radicals.

Case I. (1)—$a = b$:—

$$\underset{a}{\mathrm{CaO}}, \underset{a}{\mathrm{SO_3}} + \underset{a}{\mathrm{BaO}} + \underset{b}{\mathrm{CaO}}, \underset{2b}{(\mathrm{CO_2})_2} = \underset{a}{\mathrm{BaO}}, \underset{a}{\mathrm{SO_3}} + \underset{2a}{2\mathrm{CaO}}, \underset{2b}{\mathrm{CO_2}}.$$

Case I. (2)—$a > b$:—

$$\underset{a}{\mathrm{CaO}}, \underset{a}{\mathrm{SO_3}} + \underset{a}{\mathrm{BaO}} + \underset{b}{\mathrm{CaO}}\underset{2b}{(\mathrm{CO_2})_2} =$$
$$\underset{a}{\mathrm{BaO}}, \underset{a}{\mathrm{SO_3}} + \underset{2b}{\mathrm{CaO}}, \underset{2b}{\mathrm{CO_2}} + \underset{a-b}{\mathrm{CaO}}.$$

Case I. (3)—$a < b$:—

$$\underset{a}{\mathrm{CaO}}, \underset{a}{\mathrm{SO_3}} + \underset{a}{\mathrm{BaO}} + \underset{b}{\mathrm{CaO}}\underset{2b}{(\mathrm{CO_2})_2} =$$
$$\underset{a}{\mathrm{BaO}}, \underset{a}{\mathrm{SO_3}} + \underset{2a}{\mathrm{CaO}}, \underset{2a}{\mathrm{CO_2}} + \underset{b-a}{\mathrm{CaO}}\underset{2(b-a)}{(\mathrm{CO_2})_2}.$$

The constants before and after treatment should be:—

In Solution.	Before.	After. I (1).	After. I. (2).	After. I. (3).
CaO	$a + b$	0	$a - b$	$b - a$
SO_3	a	0	0	0
CO_2	$2b$	0	0	$2(b - a)$
Causticity	0	0	$a - b$	0
Alkalinity	b	0	$a - b$	$b - a$
Hardness (permanent)	a	0	0	0
" (temporary)	b	0	$a - b$	$b - a$
" (total)	$a + b$	0	$a - b$	$b - a$

If a portion of the barium carbonate first formed remain undissolved, let x represent such portion. This case is expressed in the following equations:—

Case II. (1)—$a = b$:—

$$\underset{a}{\mathrm{CaO}}, \underset{a}{\mathrm{SO_3}} + \underset{a}{\mathrm{BaO}} + \underset{b}{\mathrm{CaO}}\underset{2b}{(\mathrm{CO_2})_2} =$$
$$\underset{(a-x)}{\mathrm{BaO}}, \underset{(a-x)}{\mathrm{SO_3}} + \underset{x}{\mathrm{BaO}}, \underset{x}{\mathrm{CO_2}} + \underset{(2a-x)}{\mathrm{CaO}}, \underset{(2a-x)}{\mathrm{CO_2}} + \underset{x}{\mathrm{CaO}}, \underset{x}{\mathrm{SO_3}}.$$

Case II. (2)—$a > b$:—

$$\underset{a}{\mathrm{CaO}}, \underset{a}{\mathrm{SO_3}} + \underset{a}{\mathrm{BaO}} + \underset{b}{\mathrm{CaO}}\underset{2b}{(\mathrm{CO_2})_2} =$$
$$\underset{(a-x)}{\mathrm{BaO}}, \underset{(a-x)}{\mathrm{SO_3}} + \underset{x}{\mathrm{BaO}}, \underset{x}{\mathrm{CO_2}} + \underset{(2b-x)}{\mathrm{CaO}}, \underset{(2b-x)}{\mathrm{CO_2}} + \underset{x}{\mathrm{CaO}}, \underset{x}{\mathrm{SO_3}} + \underset{(a-b)}{\mathrm{CaO}}.$$

Case II. (3)—$a < b$:—

$$\underset{a}{\mathrm{CaO}}, \underset{a}{\mathrm{SO_3}} + \underset{a}{\mathrm{BaO}} + \underset{b}{\mathrm{CaO}}\underset{2b}{(\mathrm{CO_2})_2} =$$
$$\underset{(a-x)}{\mathrm{BaO}}, \underset{(a-x)}{\mathrm{SO_3}} + \underset{x}{\mathrm{BaO}}, \underset{x}{\mathrm{CO_2}} + \underset{(2a-x)}{\mathrm{CaO}}, \underset{(2a-x)}{\mathrm{CO_2}} + \underset{x}{\mathrm{CaO}}, \underset{x}{\mathrm{SO_3}} +$$
$$\underset{(b-a)}{\mathrm{CaO}}\underset{2(b-a)}{(\mathrm{CO_2})_2}.$$

And the constants of the water before and after treatment should be as follows:—

In Solution.	Before.	After. II. (1).	After. II. (2).	After. II. (3).
CaO	$a + b$	x	$a - b + x$	$b - a + x$
SO_3	a	x	x	x
CO_2	$2b$	0	0	$2(b - a)$
Causticity	0	0	$a - b$	0
Alkalinity	b	0	$a - b$	$b - a$
Hardness (permanent)	a	x	x	x
" (temporary)	b	0	$a - b$	$b - a$
" (total)	$a + b$	x	$a - b + x$	$b - a + x$

NOTE.—In the above synopses, no account is taken of the solubility of barium sulphate and carbonate or calcium carbonate. Experimental numbers will naturally vary from the theoretical numbers given in the tables to the extent of the normal solubilities of these salts.

A comparison of the two cases shows that in proportion as baryta is thrown out of solution in the form of carbonate, the resultant water contains more lime, more sulphuric acid, and consequently a higher permanent (and total) hardness, the measure of the increase of each of these quantities being x.

The following work is in illustration of the case ($a > b$). If x had any value we should expect the hardness, after treatment by baryta, to exceed the quantity ($a - b$) by that value. In only one instance (No. 3) does the total hardness possess a higher value than ($a - b$). Even if we make a correction, to compensate for the inevitable error due to working with "soda reagent" (see Problem I.), the value of x indicated would be very small, and would still be zero, in cases 1, 2, and 5. It would therefore appear that barium hydroxide possesses its full value as a precipitant for sulphuric acid, even in the presence of carbonates, when vigorous agitation is used. In all the cases here recorded, the samples were shaken at frequent intervals, for an hour, and then allowed to stand at rest for 20 hours.

Serial Number.	Actual Values.			Values found after Treatment. "Assay with Soda Reagent."				Difference.	
	a	b	$a - b$	Caust.	Alk.	H.	Hp.	Excess.	Defect.
1	573	90	483	384	392	403	11	..	80
2	573	189	393	336	347	347	0	..	46

* Numbers high for causticity and alkalinity.

The experimental treatments recorded in the appended table are pretty fully explained by the accompanying notes. The following additional notes furnish what is lacking:—

Sample I. (1)—The natural water.

(2)—CaO equivalent to lime present. (Formula 9.)

(3)—Same, but free carbon dioxide not removed prior to treatment.

(4)—Like (2), but using 10 per cent. excess of lime.

(5)—Like (2), but using 20 per cent. excess of lime.

Sample II. (6)—The natural water.

(7)—Lime treatment, after carbon dioxide equilibrium. (Formula 9.)

(8)—Soda used for the magnesia component of hardness.

Sample III. (9)—The natural water, calculated.

(10)—The natural water, experimental.

(11)—Lime, to reduce temporary hardness only.

(12)—Normal lime + soda ash treatment. (Formulæ 9 and 12.)

(13)—Baryta, equal to sulphuric acid. (Formula 13.) The liberated lime reduces temporary hardness.

Sample IV. (14)—The natural water.

(15)—Normal lime + soda ash treatment. (Formulæ 9 and 12.)

(16)—Lime equivalent to the half bound carbon dioxide (Formula 6); soda equivalent to magnesia (Formulæ 7 and 10).

(17)—Soda equivalent to the magnesia existing as sulphate + twice the magnesia existing as bicarbonate.

(18)—Half the quantities used in (17).

Sample V. (19)—The natural water, calculated.

(20)—The natural water, experimental.

(21)—Normal lime + soda ash treatment. (Formulæ 9 and 12.)

(22)—Equivalent to (21), but used soda instead of sodium carbonate and lime. Less sludge will be formed.

(23)—Soda to precipitate magnesia only. (Formulæ 7 and 10.)

(24)—Baryta to precipitate half the sulphuric acid. (Formula 13 ÷ 2.)

Sample VI. (25)—The natural water, calculated.

(26)—The natural water, experimental.

(27)—Normal lime + soda ash treatment. (Formulæ 9 and 12.)

(28)—Baryta, to precipitate sulphuric acid. (Formula 13.)

Sample VII. (29)—The natural water, calculated.

(30)—The natural water, experimental.

(31)—Normal lime + soda ash treatment. (Formulæ 9 and 12.)

(32)—Baryta, equivalent to magnesia.

Sample VIII. (33)—The natural water, calculated.

(34)—The natural water, experimental.

(35)—The natural water, boiled 10 minutes.

(36)—The natural water, boiled 30 minutes.

NOTE.—In these treatments, the sodium bicarbonate is converted into monocarbonate, and this reacts with the magnesium sulphate, leaving sodium sulphate and magnesium carbonate in solution. Hardness, so far as magnesian hardness is concerned, is not removed, but is converted into temporary instead of permanent. The lime hardness is removed by boiling off the half bound carbon dioxide.

Sample VIII. (37)—Normal lime + soda ash treatment. (Formulæ 9 and 12.) Is not warranted, because *real* permanent hardness is non-existent in this sample.

(38)—Lime, to combine with the half bound carbon dioxide. (Formula 6.)

(39)—Lime, corresponding to the alkalinity and to the magnesia. (Formula 9.)

Regina. (40)—The natural water, calculated.

(41)—The natural water, experimental.

(42)—Normal lime + soda ash treatment. (Formulæ 9 and 12.)

(43)—Baryta treatment. $BaO = 1.912(SO_3 - 4/3Na_2O)$.

(44)—Same, using half quantity.

(45)—Baryta treatment, following lime to neutralise half-bound carbon dioxide.

Tables Illustrating Experimental Treatments.

The experimental treatments tabulated have been carried out on artificial water samples of 400 degrees of hardness (= 50 degrees English).

One litre of each sample contains as follows (the figures given are milligrammes):—

Sample I.—400 lime (CaO) dissolved in excess of carbonic acid. II. 124 lime and 194 magnesia (MgO) dissolved in excess of carbonic acid. III. 200 lime, dissolved as bicarbonate, and 200 lime as sulphate. IV. 116 magnesia as sulphate and 170 magnesia as bicarbonate. V. 200 lime and 143 magnesia, both as sulphates. VI. 72 lime and 86 magnesia, both as sulphates, together with 32 lime and 126 magnesia, both as bicarbonates. VII. 178 lime as bicarbonate, and 160 magnesia as sulphate, together with 240 soda (Na_2O) as sulphate. VIII. 178 lime as bicarbonate and 160 magnesia as sulphate, together with 240 soda as bicarbonate.

Regina.—Analysis gave:—Lime (CaO), 143; magnesia (MgO), 158; soda (Na_2O), 170; sulphuric acid (SO_3), 484; ully bound carbon dioxide (CO_2), 114.

For explanations as to the several treatments, see the text of the paper.

Reagents.—Quantity is given in lbs. per 1,000 gallons. Cost is given in cents per thousand gallons.

Sample.	Number of Treatment.	Reagents.			Hardness.					Soda (Na_2O).				Remarks.

Liverpool Section.

PRESENTATION TO DR. T. LEWIS BAILEY.

A dinner was held at the Hotel St. George on Tuesday, 26th April, at which Dr. Bailey was the guest of the members of the section.

During the evening Mr. Frank Tate (chairman of the section), after reading letters of regret at their inability to attend from Mr. Eustace Carey, Mr. Forbes Carpenter, and Dr. Chas. A. Kohn, presented to Dr. Bailey a silver salver. Letters were also received from Sir David Gamble, Mes W. H. Lever, Thos. Tyrer, H. T. Mannington, Wats Smith, Roscoe Brunner, and Wm. Earp.

The Chairman said when at the end of last year th heard with so much regret that Dr. Bailey had resign the local honorary secretaryship, it was felt he could be allowed to retire without the members of the secti showing their appreciation of his long and excellent servic In asking Dr. Bailey's acceptance of the salver on beh of the members of the section, he did so remembering many years of steady and unostentatious work Dr. Bai had performed for the section, his splendid powers organisation and command of detail, and his ever ready courtesy and kindness, and, on more than one occasion, his quiet diplomacy. He asked Dr. Bailey to receive the salver from the members of the Liverpool Section as a token of their gratitude for his past services and of their best wishes for his future happiness and prosperity.

The inscription on the salver read as follows: "Presented to Dr. T. Lewis Bailey by the members of the Liverpool Section of the Society of Chemical Industry as a token of their appreciation of his valuable services as Honorary Secretary to the Section, 1894–1904."

Dr. Bailey, replying, expressed his heartfelt thanks for the goodwill of the members in so hospitably entertaining him and presenting him with a lasting memento of his connection with them. The Liverpool Section held a very satisfactory position in regard to its papers, and subjects had been introduced of a type which was worthy of more consideration—such subjects as, for instance, Railway Rates on Heavy Chemicals, the Development of Canals, &c. A great deal might be gained by discussing subjects of general interest to chemical manufacturers and bringing such subjects to the notice of the proper authorities where changes were considered necessary for the well-being of the industry. He referred also to attempts made in the section to bring members together in such a way as to give more opportunity for an exchange of ideas than was possible at ordinary meetings. In a scattered section great difficulties were necessarily experienced in the attainment of such a desideratum, but perhaps his worthy successor would be able to see some way of bringing members together in such a way as to produce a firmer bond of union, and consequently a stronger and more weighty organisation. Thanking the members for their goodness to him that evening in recognising services which any member, he trusted, would willingly render to their Society, he could not refrain from expressing his thanks also to all with whom he had had dealings, chairmen and members generally, for the ever ready assistance they had at all times accorded him.

London Section.

Meeting held at Burlington House, on Monday, May 2nd, 1904.

MR. WALTER F. REID IN THE CHAIR.

The Chairman said the Committee of the Section had just decided to send a resolution to the Council, inviting the Society to meet in London in 1905. They had generally held the meeting in London every four years, but this year, being the fourth since they last met in London, the choice had fallen on New York. He understood that their American friends were providing a most lavish programme, and that they had made every preparation to receive the members with the utmost hospitality. He made this announcement now in the hope that the members would support the invitation when it came forward, and would also be prepared to help when the time came for making the arrangements for 1905. He was also pleased to announce that Prof. Liversidge, the chairman, and Mr. Walton, the secretary, of the New South Wales Section were present that evening.

DETERMINATION OF MINUTE QUANTITIES OF BISMUTH IN COPPER AND COPPER ORES.

BY T. C. CLOUD, A.R.S.M., F.I.C., F.C.S.

In the Journal of the Chemical Society for 1862 there appears a paper by Abel and Field entitled "On the Analysis of Commercial Coppers," in which they describe a qualitative test for bismuth based upon the fact that when lead iodide is precipitated in the presence of even minute traces of this metal, the iodide precipitate is coloured a dark orange or crimson tint, the depth of colour varying in intensity with the amount of bismuth present. They also show that this coloration is still more marked if the precipitate is re-dissolved by heating the liquid and allowing it to cool again, when the lead iodide crystallises out from the solution in the form of scales. If no bismuth is present these scales are of a brilliant golden yellow colour, while the smallest trace of bismuth gives to the scales a more or less orange or red tint.

Field, in the same journal, points out that the colour is seen to greater advantage if the lead iodide precipitate is dissolved in boiling dilute hydrochloric acid and then allowed to crystallise out on cooling. I confirmed this observation, and now make the qualitative test by adding to the mixed lead and bismuth solutions only just sufficient potassium iodide solution to precipitate the whole of the lead. I then add just sufficient hydrochloric acid to entirely dissolve the precipitate at the boiling temperature. On now allowing the solution to cool by placing it in cold water, the lead iodide crystallises out from the solution in the form of scales, which collect at the bottom of the test tube and indicate by their colour the presence or absence of bismuth. The delicacy of this test is proved by the fact that even so small a quantity of bismuth as 0·000001 grm. is distinguishable.

About 15 years ago I made a number of experiments on this reaction with the view of evolving a quantitative method from it, the result of which I now propose to place before you. I found, after a long investigation, that with quantities of bismuth of about 0·0001 grm., the colour of the crystalline precipitate varied considerably although the quantity of bismuth was the same and the experiments were performed under the same conditions so far as practicable. The rate of cooling had a marked effect, as might be expected, on the size of the crystals, and consequently on the colour of the crystalline precipitate. The lustre of the crystals also varied, and this increased the difficulty. Finally, this method was abandoned. It afterwards occurred to me that the colours of the precipitate produced in the first instance, and without re-solution and subsequent separation in a crystalline form, might be comparable. After a searching investigation, this was found to be the case, and a quantitative method was evolved which easily determines 0·00001 grm. of bismuth.

For the determination the following solutions are made up:—

Bismuth Nitrate, by dissolving pure bismuth oxide in nitric acid and diluting so that 1 c.c. contains 0·0001 grm. bismuth. Sufficient nitric acid must be present to prevent basic bismuth salt from precipitating when the solution is diluted.

Lead Nitrate Solution, made by dissolving 6 grms. of pure lead in nitric acid. The solution is evaporated until excess of nitric acid is removed and lead nitrate crystallises out. This is then dissolved in water and made up to one litre.

Potassium Iodide Solution, made by dissolving 35 grms. of the salt in water and making up to 4 litres. In order to make the determination I take the solution containing the unknown quantity of bismuth, and which must be free from lead, and add to it a definite quantity of the lead solution, and then precipitate the lead iodide with the potassium iodide solution in a Nessler's tube, and compare the colour of the precipitate produced with that formed under similar conditions, using known quantities of the bismuth solution run from a burette. A series of precipitates are produced in this way until one is made of the same shade as that produced in the solution under examination. The quantity of bismuth solution used in producing this particular shade of precipitate then gives the quantity of bismuth present.

The comparative experiments are made as follows:—5 c.c. of the lead solution are measured with a pipette into a Nessler's tube, to this is added 1 c.c. of dilute nitric acid (1—24), and then the known quantity of bismuth solution from a burette. The solution is now made up with water to the 25 c.c. mark on the tube and then potassium iodide solution added to bring the quantity up to the 50 c.c. mark.

The contents of the tube are well agitated and allowed to stand for 15 or 20 minutes before making the final comparison.

In dealing with metallic copper the following procedure is adopted. A suitable quantity of the metal is dissolved in nitric acid. To the cold solution carbonate of soda is added carefully until a permanent precipitate commences to form; the solution is now added very slowly drop by drop with constant stirring until a small quantity of permanent precipitate is produced. The beaker is allowed to stand in the cold with frequent stirring for about three or four hours and the solution is then filtered. The precipitate without washing is dissolved in dilute hydrochloric acid and precipitated with hydrogen sulphide. The precipitate is washed with a solution of hydrogen sulphide and is then dissolved in nitric acid, the solution being received in a $\frac{1}{4}$-litre flask. If the copper contains an appreciable quantity of lead the original solution must be evaporated with sulphuric acid, cooled, taken up with water and filtered, before precipitating with hydrogen sulphide. From the solution in the $\frac{1}{4}$-litre flask 125 c.c. are taken and to this 5 c.c. of the standard lead solution are added. After agitating, the solution is neutralised with ammonia and then ammonium carbonate is added drop by drop with constant stirring until in slight excess, and finally ammonia, also in excess, sufficient to keep all the copper in solution. It is heated on water bath and then allowed to cool. The precipitate is filtered off on to a small filter and washed with water containing ammonium carbonate until all copper is removed. The precipitate is dissolved on the filter with dilute nitric acid and the filter washed with dilute nitric acid and water, used alternately, the filtrate and washings being received in a small glass dish. The solution is evaporated on the water bath until the lead nitrate begins to crystallise out. The contents of the dish are dissolved in a little water and transferred to a Nessler's tube, using at first hot water, then diluted nitric acid (1—12), and finally water up to the 25-c.c. mark. The solution in the Nessler's tube is now made up to the 50-c.c. mark with the standard potassium iodide solution and the precipitate produced is compared with precipitates made as described above, using known quantities of standard bismuth solution until a precipitate of the same tint is produced, when the quantity of bismuth solution used for the production of this particular tint gives the quantity of bismuth present.

A large number of test experiments were made, using pure copper solutions to which known quantities of the standard bismuth solution were added and the process carried out as described. There was in no case any difficulty in determining quantities as small as 0·00001 grm., and differences of this amount are easily distinguishable in the colour of the precipitate produced.

In the case of copper ores, the method employed is to dissolve in a mixture of nitric acid and sulphuric acid, and evaporate until sulphuric acid fumes come off freely. When cool, the residue is treated with water, a drop or two of hydrochloric acid added and the solution filtered. The solution is now treated with hydrogen sulphide, and the process completed as described for metallic copper.

In the case of very pure copper or copper ores variations in the quantities of bismuth present, even when in so small a proportion as 0·001 per cent., is of the utmost importance.

After fifteen years' experience of this method in the very large number of determinations which I and my staff have had to make at the laboratory of the Wallaroo Smelting Works in South Australia, I can, with confidence, recommend it to your notice as a thoroughly reliable and delicate method for determining minute quantities of bismuth in copper or copper ores.

Discussion.

Mr. F. F. Renwick said that a method which depended on the variation in colour of a precipitate and which was to be used for the estimation of bismuth in small quantities must be used with the greatest caution, remembering the great variation in the colour of precipitates—especially the iodides—which was known to occur. He need only mention two; silver iodide varied considerably in colour according to the conditions under which it was precipitated and the treatment it received subsequently. A still more remarkable case was that of mercuric iodide. Under certain conditions the precipitate was yellow, whereas under others it had a brilliant red colour. An interesting example was recently described by Dr. Lüppo-Cramer in the Photographische Correspondenz for December 1903, who showed that if mercuric iodide was precipitated in the presence of gum arabic it had a brilliant red colour, whereas in the presence of gelatin it always came down yellow. There was a very marked difference in sensitiveness to light between the two varieties.

Mr. G. T. Holloway said he had used a qualitative method which he believed was first described to him by Mr. Arthur Wingham and which resembled that described as introduced by Abel. It was employed for testing the precipitate which had been weighed as bismuth oxide, to ascertain whether it contained lead. The method usually employed with metallic copper was to dissolve about 20 grms. in nitric acid, to add sodium phosphate and saturate with ammonia. Lead, bismuth, and iron were thus precipitated as phosphates, and after being filtered off were separated, the lead with sulphuric acid with the usual precautions, and the bismuth from the filtrate with sulphuretted hydrogen. The bismuth was finally weighed as oxide and then frequently contained a trace, and sometimes a good deal, of lead. One could obtain a good idea as to the amount of lead by a method similar to that described by Mr. Cloud. The weighed precipitate was dissolved in one drop of strong nitric acid, and about half a cubic centimetre of water, a couple of drops of cold saturated solution of lead nitrate, and a drop or two of 10 per cent. potassium iodide solution were added. If no bismuth was present the precipitate would of course be bright yellow, while bismuth rendered the precipitate more or less brown or reddish. If the original weighed precipitate, which perhaps only weighed half a milligramme, was practically pure bismuth oxide, the iodide precipitate would be distinctly red. With practice, the operator could tell whether the bismuth oxide was sufficiently pure to be counted as pure for ordinary purposes. He was speaking of ordinary commercial analyses, where, for instance, it was necessary to say whether the amount of bismuth present was above or below a certain stated limit.

Mr. Cloud, in reply, said the quantities of bismuth which affected Wallaroo copper was considerably smaller than generally occurred in ordinary commercial coppers. The average of a very large number of determinations over a period of some years showed they did not contain more than 0·001 per cent. If that amount was doubled it would materially affect the quality of the copper. The quantity he had named in the paper as being easily distinguishable was such that if that quantity was doubled, the difference in colour of the precipitate was most marked, and there was no difficulty in distinguishing between 0·001 mgrm. and 0·002 mgrm. Prepared as described, the precipitates were perfectly uniform in colour for the same quantity of bismuth, and the remarks of Mr. Renwick in reference to mercuric iodide did not in any way apply in the case of lead iodide, prepared as described in the paper.

DETERMINATION OF MINUTE QUANTITIES OF ARSENIC IN COPPER ORES AND METALLURGICAL PRODUCTS.

BY T. C. CLOUD, A.R.S.M., F.I.C., F.C.S.

The *Chemical News* of January 14th, 1881, quotes, apparently in full, a paper entitled, "On the Detection and Determination of Arsenic in Organic Matter," by Messrs. Chittenden and Donaldson, which appeared in the *American Chemical Journal*, vol. 2, No. 4. An arrangement of the Marsh apparatus is there described and figured; this arrangement I have employed for the last twenty years for the determination of minute quantities of arsenic in copper ore and metallurgical products with the most successfu results. When the process—as described in the paper mentioned—first came under my notice, I subjected it to a most severe investigation to ascertain if it was suitable for the purpose I had in view, *viz.*, the accurate determination of minute quantities of arsenic down to say 0·005 per cent. in cupriferous ores and metallurgical products. Numerous experiments were made with the apparatus, using known quantities of arsenic and conducting the experiments under the same conditions as would occur in practice with the materials under consideration. It was found that when all the precautions mentioned by the writers were observed in the use of the apparatus, thoroughly satisfactory results were obtained, with one curious exception which is not referred to by the authors of the paper. The experiments were performed in the following manner:—The solutions containing the known quantity of arsenic were evaporated with sulphuric acid until fumes of this acid came off freely; the cooled residue taken up with water and filtered, if necessary, into the funnel of the apparatus, from whence it was allowed to pass into the Marsh apparatus drop by drop. The portion of the tube containing the mirror was cut off and weighed with and without the mirror, the difference giving the amount of arsenic. I found that in the presence of iron salts the results were invariably low. I may say here that the authors recommend alloying the zinc with a small quantity of platinum. This precaution was not adopted as it was considered too troublesome, and pure zinc only was used. Some years previously Messrs. Gladstone and Tribe had introduced their copper zinc couple to the notice of chemists, and it occurred to me as being possible that if a small amount of copper were introduced into the Marsh apparatus so as to set up this combination, the defect to which I have referred might be removed. This was found to be the case. Duplicate experiments were performed, using the same quantities of iron and arsenic; in the one case there was no copper solution employed, and in the other the small necessary amount was added when starting the Marsh apparatus. In the former case—as previously stated—the amount of arsenic was invariably short of the proper quantity, while in the latter case the full amount of arsenic was evolved and collected in the form of a mirror.

Using 40 grms. of zinc it was found that the presence of 0·05 to 0·08 grm. of copper was required in order to ensure the complete evolution of all the arsenic. The Marsh apparatus which I have used is substantially as described in the paper to which I have referred, except that the funnel tube is very much shorter, the funnel being just clear of the stopper; the cork shown is not used, but a hollow glass stopper carrying the exit tube and the funnel is substituted for it. The generating bottle is placed in a beaker of cold water during the operation. For drying the gas I use a U tube, one leg of which is packed with filter paper and cotton wool and the second limb with granulated calcium chloride. The tube is of combustion glass 6 mm. internal diam. and of such length that at least two inches of the full-sized tube projects beyond the furnace, followed by about three inches drawn out to about 1 mm. internal diam., finishing with a finely drawn out jet.

The determination is made as follows:—2 grms. of the finely ground ore is treated in a covered beaker with 20—30 drops of concentrated sulphuric acid, then sufficient nitric acid is added and digested on a water bath until decomposed. I may here mention in passing that pyritic ores of copper are far more rapidly decomposed in this way than by heating at a higher temperature and without the annoying formation of sulphur globules. When the decomposition is completed, the cover and sides of the beaker are washed down and the solution evaporated n the beaker, first on the water bath and finally on the and bath, until nearly all excess of sulphuric acid is emoved. When cool, the residue is taken up with water, eated, and filtered. The filtrate is received in a beaker of uitable size for plating out the copper by the well-known lectrolytic method, either on a platinum cone or—as I refer—on a platinum cylinder. A previous determination f the copper on another portion of the ore having been made, it is easy to stop the electrolysis of the solution for he arsenic determination while it yet retains the proper mount of copper, *viz.*, 0·05—0·08 grm. The platinum cathode with its coating of copper is now washed in a dish, and the solution in the beaker with the anode is heated until all deposit on the anode has dissolved. The anode is then also washed in a dish and the contents of the dish added to the beaker and the whole evaporated down to a small bulk, about 5—10 c.c. The hydrogen bottle has, in the meantime, been charged with 40 grms. of zinc and dilute sulphuric acid (1—7 of water) run in, in sufficient quantity to cover the zinc. After the gas has been coming off freely for about 10 minutes, the gas burners are lighted and the tube heated to a red heat for a length of about 6 ins. At this stage the solution is transferred to the funnel, the stop cock of which has already been set so as to deliver the liquid in drops at the rate of about 2—3 a minute. Additional acid is added to the solution in the funnel, if necessary, in order to keep up an even production of gas, and the funnel is finally washed with this acid. The time required to pass the solution from the funnel to the flask will vary with the quantity of arsenic present. For quantities up to 2 mgrms. I allow about 2 hours and an extra hour for every additional mgrm. When the whole of the solution and washing have been transferred to the bottle, the heating of the tube is continued for about 15 minutes. The gas jets are now extinguished and the tube allowed to cool while the current of hydrogen still passes. When the tube is only just hand warm, the portion containing the mirror is cut off, wiped clean and placed in the desiccator, and weighed after 20 minutes. After weighing, the arsenic is dissolved from the tube with nitric acid, the tube washed with water and dried in the water oven and re-weighed, the difference between the two weighings giving, of course, the amount of arsenic.

It is needless to remark that blank experiments must be made with the zinc, sulphuric and nitric acids used.

It will be noticed that the process described involves the use of only three reagents, which are not difficult to obtain free from arsenic. The balance used is a fine instrument by Sartorius, which turns easily with 0·05 mgrm.

Discussion.

Mr. Fairley said as far as he could judge the process was an exceedingly good one. It seemed remarkable that the arsenic could be weighed in the manner described. It was evident that a very delicate balance was necessary, and he should like to know what the actual weight of arsenic obtained in a number of experiments might be. He gathered that the author operated on 2 to 4 grms. of ore which contained very minute quantities of arsenic, so he would have a very small quantity to weigh.

Mr. Grant Hooper asked if Mr. Cloud had had any experience in the estimation of arsenic in copper by Clark's process. A valuable paper was brought before the Society by Mr. Platten some years ago in which he pointed out the advantage and convenience with which arsenic in small quantities could be estimated in copper by dissolving the metal, preferably in the form of turnings, in ferric chloride solution and distilling it. He was aware that Mr. Cloud had specially referred to the estimation of arsenic in copper ores rather than in metallic copper, but it seemed to him that it must frequently happen that the quantity he had to deal with might turn out to be very much larger than would be suitably estimated by such a means as he had brought forward. If the nitric acid solution to which he referred were evaporated down, redissolved in hydrochloric acid, reduced by sulphurous acid or sulphite, and then added to Clark's solution in a small flask and distilled, a very ready means was presented of estimating even an exceedingly small quantity of arsenic. Two-tenths of a mgrm. of arsenious sulphide obtained by a distillation process of this kind could be accurately weighed and its identity established, but if the quantity of arsenic was still too small to be capable of any such gravimetric estimation then a portion of the same nitric acid solution reduced as described might be put into some such apparatus as Mr. Cloud had brought before them, but instead of weighing the tube with and without the arsenic mirror he would suggest that a more practical and certain way with such an exceedingly small quantity of arsenic would be to compare standard mirrors.

Mr. Cloud, in reply, said the quantities they had to deal with were too small for a distillation process, which they had used where they required to separate arsenic and antimony in any ores where these occurred in fairly large quantities. He quite agreed that in the case of very small quantities the standard mirror as applied to the process he had brought forward would very materially assist the work both in the matter of time and probably in accuracy. The quantities actually weighed were down to 0·1 mgrm. The balance turned to 0·05 mgrm., but anything lower was rarely actually weighed, for if 2 grms. of ore was taken and the arsenic in the tube appeared to be below the weighing capacity (the chemist soon got to know whether the quantity was worth weighing or not), he simply reported that it was below a certain amount which was sufficient for the practical operations of the smelting works.

TESTING COLLOIDS.

BY EDMUND J. MILLS, D.Sc., F.R.S., AND ARCHIBALD GRAY, F.I.C.

The testing of colloids is generally effected by methods which are in the main chemical, and have for their object to ascertain the amount of the particular colloid, ash, water, water absorbable, &c., in this way procuring some check on the quality and cost of the preparation. These methods are generally very easily carried out. On the other hand, and in supplement to the chemical processes, some physical examination is indispensable. Thus, we may determine the breaking strain of a glue-joint, or of the surface of a starch paste of known percentage value. For the most part, however, the manner in which the colloid behaves in practice is generally accepted. Such methods are distinctly imperfect, and beset with many difficulties.

In this paper we desire to place on preliminary record a physical method of testing which, though still far from being as successful as we could wish, is capable of giving results of some practical value, especially in the comparison of one colloid with another. Briefly described, it consists in coating a standard cotton thread with a given colloid, drying it, and determining the modulus of elasticity of the coat. The value of this modulus is directly related to the stiffening power of the colloid.

Preparation of the Thread.—The cotton thread we selected for our work was Brooks' No. 12 white, mainly on account of its freedom from finishing ingredients. In order to render the outside of this as smooth as possible, we constructed a little singeing apparatus, and with this burned away the projecting ends which surrounded the thread. The colloids we employed were potato starch, maize starch, and gum arabic. We made these into a paste or solution of known strength, immersed the thread in them, and then drew this through a perforated nozzle sectionally illustrated in Fig. 1. This having been repeated several times, the thread, generally a metre in length, was hung up to dry at the ordinary temperature with a weight of 18 grms. at its lower extremity. The nozzle was made of German silver, and its narrow tubulus was almost exactly 0·5 mm. in diameter. Various strengths of paste or solution were employed. The dried threads were cut into lengths of about 0·2 m. each, and the cuttings kept in tubes closed at both ends; these were opened the day before the readings were taken. Starch pastes could be dried in one night, but gum arabic required about four days.

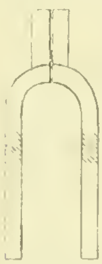

Fig. 1.—Nozzle for Coating Thread. × ½.

Determination of the Modulus.—The apparatus we used was extremely simple and constructed in the factory. As will be seen from Fig. 2, it consists of a couple of blocks capable of being moved towards or from each other by means of a right and left screw working in a bed below them. Each block carries a piece of quill glass tubing "scorched" at the inner end so as just to smooth the sharp edge. A thread was placed with either end in a tube, and its length measured by means of a verified millimetre scale. When the thread is lowered by a weight, or by its own weight, its length is $\frac{1}{3}[8a - A]$; where A is the chord of the whole arc = distance apart of the glass tubes, and a is the chord of half the arc. The deflections produced by adding a given weight, and the radii of the threads were measured with the laboratory kathetometer; doubtless a low-power microscope with micrometer eye-piece would do equally well. Our weights were S-shaped hooks of very thin copper wire, each weighing 0·03 grm., and up and down readings were always taken. A screen of thin transparent glass was placed between the observer and the thread.

If E is the modulus of elasticity, P the weight (kilos.) attached, l the exposed length (millimetres) of thread, s the deflection produced by the weight, and r the radius of the thread, $E = \frac{1}{12} \times \frac{P}{s} \times \frac{l^3}{\pi r^4}$; this is the ordinary formula for the modulus in the case of a circular section (kilos. per square millimetre of section). It is, of course, only approximately true for a mixed system of cotton and colloid. The value of the modulus for the thread alone was found to be—

$$E = \frac{1}{12} \times \frac{0{\cdot}00001}{0{\cdot}1885} \times \frac{(15)^3}{\pi(0{\cdot}2717)^4} = 86{\cdot}9,$$

a quantity to be deducted from all the observations.

Potato Starch.—The pastes were very roughly of 2, 3, 4, and 5 per cent. strength. They were prepared by grinding starch with cold water, heating on the water-bath until "made," and then straining through muslin. The exact amount of starch in the paste was determined, and corrected for ash. The results were as follows:—

Starch.	Deflection.	Radius.	E.	E calc.
Per Cent.				
1·83	0·2860*	0·225	135·2	..
2·68	0·2300*	0·220	183·9	181·9
3·34	0·3613	0·245	208·9	206·1
3·82	0·3125	0·250	222·7	226·7

* l = 50 mm. only; in all other cases 70 mm. nearly.

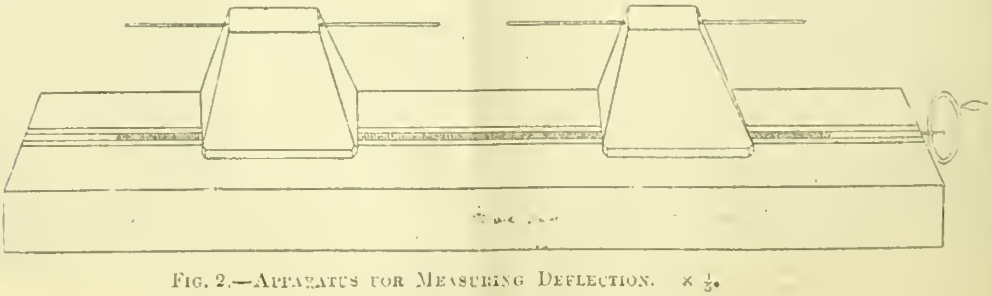

Fig. 2.—Apparatus for Measuring Deflection. × ⅓.

The equation is (c = colloid) E = 86·9 + 35·7 c. Probable error of a single comparison, 2·5 = 1·2 per cent. on the average E determined. Sum of the errors, 0·7.

[As regards the first experiment, see under Gum Arabic.]

Maize Starch.—Here the individual determinations were less satisfactory.

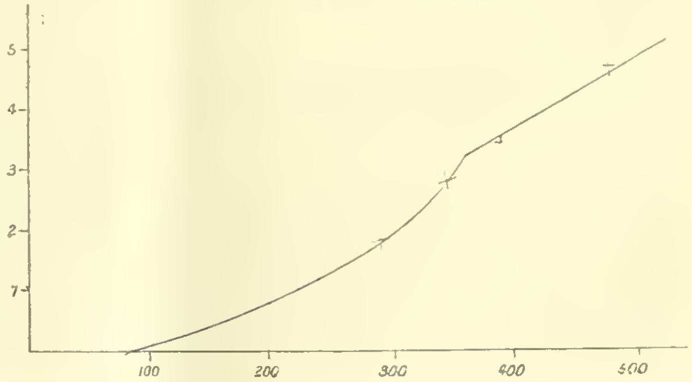
Starch.	Deflection.	Radius.	E.	E calc.
Per Cent.				
1·84	0·4517	0·1951	136·4	..
2·41	0·2855*	0·2074	187·5	203·5
3·70	0·4738	0·2160	263·6	270·3
4·62	0·4360	0·2079	333·7	310·5

The equation is E = 86·9 + 48·4*c*. Probable error of a single comparison, 13·8 = 5·3 per cent. on the average result. Sum of the errors, 0·7.

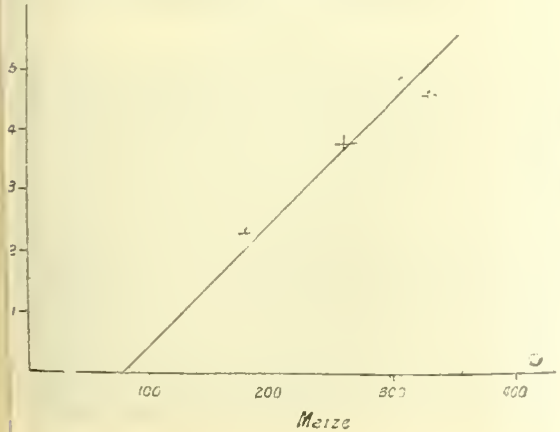
Gum Arabic.—The results were as follows:—

Gum.	Deflection.	Radius.	E.	E calc.
Per Cent.				
1·84	0·5940	0·1958	293·0	292·8
2·87	0·5022	0·1988	346·6	346·8
3·64	0·3898	0·2051	385·5	388·3
4·71	0·3633	0·1988	479·0	476·9

The equation, as before, to the last two results and the origin, is E = 86·9 + 82·8*c*; the equation to the first two results and the origin, is $E = \frac{194·7c}{1+0·4c}$. Probable error of a single comparison (first equation) 1·69 = 0·4 per cent. on the average value determined. Sum of the errors, 0·7.



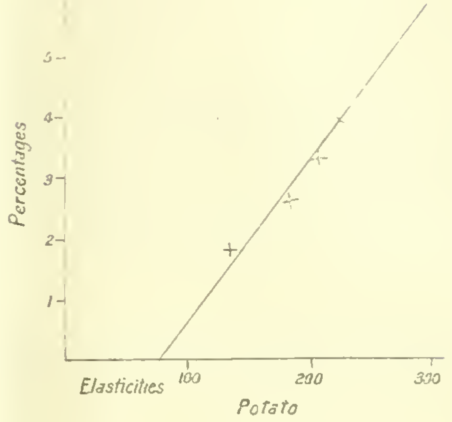
It was some time before we were able to interpret our experiments. At length it occurred to us that we were really dealing with two independent effects. Gum arabic may be regarded as an organic salt of lime, magnesia, and some other bases. When a solution of it is in contact with cotton, the cotton takes up lime or gum as a whole, and so becomes mordanted, or combined, making the elasticity too low. When this effect has ceased, further treatment with the gum produces the usual stiffening effect only. As other colloids generally contain a little mineral matter, the same result will be obtained with the earlier quantities of these, and for this reason we have not considered the first figures in our maize and potato experiments. In the case of gum arabic the phenomenon is naturally much more marked; the earlier effect is represented by the hyperbola usual in such cases; the later or normal effect by a straight line.



The two effects meet at the common point—

$$86·9 + 82·8c = \frac{194·7c}{1 + 0·4c}$$

whence *c* = 3·38 and E = 366·8.



Comparative Values. — The linear equations above obtained give us the modulus of elasticity per per cent. of coat. As the sum of their errors are in each case the same, we are in a position to compare the relative values of the three colloids. These are 35·7 : 48·4 : 82·8 for potato, maize, and gum respectively—numbers which are very nearly in the simple ratio 3 : 4 : 7 :—

$$\left.\begin{array}{l} 35·7 \div 3 = 11·9 \\ 48·4 \div 4 = 12·1 \\ 82·8 \div 7 = 11·8 \end{array}\right\}$$

In 1903 the average prices of potato starch and gum arabic were 12*s.* and 28*s.* per cwt.,—values strictly proportional to the elasticities. Maize starch is in general 3*s.*—4*s.* dearer than potato starch, and its price, therefore, should also follow the same relation. But quotations for maize starch were so anomalous and irregular (5*s.*—18*s.*) in that year as seldom to correspond to a true economical value.

In actual practice it would be easy to prepare and keep a number of smoothed threads coated to a given percentage (say 5 per cent.) with some given colloid; then coat some of the same thread with the same amount of a new sample, and place the two side by side in the machine. On opening the jaws, the weaker would be bowed the more. But for the comparative values of different colloids the work should be done as we have previously described.

We had intended determining some elasticities, using aluminium wire instead of thread; but circumstances have precluded our continuing these experiments.

We wish to record our thanks to Messrs. Findlay and Faill for assistance* in this investigation.

Discussion.

Mr. E. F. **Renwick** regretted the authors had given no information with regard to the behaviour of gelatine. Was it not possible in these 1 per cent. solutions that the material itself did not retain the form of the fibre? Possibly the section became elliptical instead of remaining circular, or the actual solution "ran" after the fibre was coated. Was the thread dried vertically or horizontally? In the case of gelatine he had frequently noticed marked changes in its properties according to the rate at which it was dried and he would like to know whether the drying conditions affected the elasticity in any way. Many people who had to do with colloids were concerned rather with different samples of the same colloid than with the differences between different colloids. Did different samples of the same material show marked differences of behaviour when tested by the author's method?

Mr. J. L. **Baker** thought the fluctuations which had been noticed in the price of maize starch were probably due to the glucose industry rather than to its colloidal nature, because the glucose manufacturer used the cheapest raw material on the market.

Mr. H. H. F. **Hyndman** asked if Prof. Mills had ever thought of using the method of oscillation instead of deflection. In such a method as this, where a fibre has been dealt with, it would be more accurate to employ an oscillation method, which could be used in a glass tube, and where the thread would be less affected by external conditions than by a deflection method, where there were more chances of inaccuracy. It might also possibly answer the question of the first speaker with regard to the testing of the same material under different conditions, because a fibre when hung vertically was less liable to alter its condition than when hung in the way described from two tubes, where a slight alteration of the arrangement of the tube, or the shape of the ends of the tube, would materially alter the coefficient of elasticity.

Mr. **Grant Hooper** asked if in these experiments Dr. Mills had had regard to the moisture of the atmosphere? In damp weather he thought it might be found that the moisture of the atmosphere was quite sufficient to considerably affect the result. As a practical application, he would like to hear whether any tests had been made with glues.

The **Chairman** said this was an exceedingly interesting paper, referring to a matter on which they all wanted more light. Even if this were not an ideal method, which would hardly be claimed for it, it was an important contribution to their knowledge. A method of estimating colloids, which would be absolutely accurate, was much sought after, and he was not aware that one had been devised. There were some points to be considered in connection with the method before them as to whether there might not be sources of error; for instance the fact that the thread used was a bundle of fibres, and the solution cemented the fibres together and in that way produced a greater or less stiffness of the thread on which to some extent the method was based. If a 5 per cent. solution of gum was compared with one of 2 per cent., the latter would sink into the fibres and cement them, but the former solution would not sink in so far and would cement them in a different way. There he thought there was likely to be a source of error not indicated in the figures obtained. Aluminium would, perhaps, be rather too strong, because the strength of the coating material would be small compared to the strength of the aluminium wire. Why not try a lead wire, or something still softer? Again, with regard to the coating of the thread. He feared that would differ according to the number of times it was passed through a solution, and also according to the strength of the solution. He had coated a great number of fibres of various kinds, including silk, cotton, ramie, and he found the weight per hundred yards varied very much according to the number of coats put on. They had either to take a considerable number of coatings, which would leave a very small margin for difference, or else to very carefully specify, not only the number of coatings but also the temperature at which it was done, and the ratio between the diameter of the thread in the loose state, and the nozzle through which it was pulled. Again, he thought the formula used for the thread, referred to a cylindrical body; but the thread was not only not cylindrical, it was spiral. It was also composed of fibres in a state of tension, and different samples might be in very different states of tension, although they might all be sold as Brook's best thread. They knew how thread was made, and how it differed not only according to the number of times the cotton was drawn out in the drawing rolls, but also according to the state of the drawing rolls; cotton might be passed in the process of spinning through the same rolls a definite number of times, but the same result was not obtained if the rolls had been in use for a fortnight or for two months. The difference might not be appreciable for sewing purposes, but for a test of this kind it was a serious consideration. Speaking in general terms he did not like the use of the thread at all. As to the prices, he thought there were many points besides the testing of the material which influenced them. He was inclined to believe that cordite had the most influence on the price of gum arabic.

Prof. **Mills** said he was much obliged for the various suggestions which had been made, and only regretted that Mr. Gray and himself could not continue their experiments and test some of them. They had unfortunately been unable to adopt the usually more accurate method of torsion, because it produced intrinsic twist. From the starch pastes, nothing soaked into the thread but water, leaving what had to be presumed to be a cylindrical coating of starch on the outside. On the other hand, gum arabic soaked in, and up to about a 3 per cent. strength produced the peculiar mordanting effect to which he had referred. A thread which had been pulled through the nozzle five or six times might be taken as having a fairly cylindrical coat. Their experiments, on repetition, gave very much the same results as before; they were always done in the same room heated by sufficiently distant water-pipes. Gelatines they had not tried, drying the threads in a horizontal position would have led to an undesirable bowing. He was, of course, aware that maize starch was largely in demand for glucose making, but its use as a stiffening material and as a finish by calico printers must be an important factor in the price, which, in any case, would depend on many other practical conditions. He was, however, informed on good authority that the main condition in very recent times had been the process now so well known under the name of "dumping."

INCANDESCENT ALCOHOL LAMPS.

BY THOS. TYRER.

Mr. **Thomas Tyrer** exhibited some incandescent lamps for burning alcohol which had been shown recently at the Society of Arts. The illuminating power, as could be seen, was certainly quite equal to or exceeded that of incandescent gas light. His object in showing these lamps now as well as at the Society of Arts was to illustrate an extended use of alcohol, which was daily becoming more common in Germany. Two of the lamps on the table were lent by Mr. W. H. Massey, Engineer to the Royal Palaces, who, hearing that a paper was going to be read at the Society of Arts, kindly offered to lend them. They were identical with those exhibited at Sandringham on a well known occasion. The lamps with glass bowls showed the arrangement of the wick and the wastage of spirit. These bowls as now seen had been alight about five hours. They had been again lit that evening and without replenishing all could see how little spirit had been used. There was no inconvenience or

---

* Our work was well advanced when we found (Polleyon's "Die Appreturmittel," p. 49) that Prof. Wiesner had been working in the same direction. His method consisted in pushing upwards a coated thread through a clamp, until the remote end fell over, and came to the same level as the clamped end: the bowed length was his measure of comparative elasticity. He must, however, have far exceeded the elastic limit: and the results obtained were consequently unsatisfactory. His process of coating consisted in passing the pasted threads through the fingers.

smell. If they had been petroleum lamps it would have been scarcely possible to have had so much service out of them without betraying some smell and sootiness. Ordinary methylated spirit was being employed in these lamps. One of the lamps belonging to Mr. Lorenz had been in use for more than two months constantly, and nothing had to be done to it, but the very simple operation of filling the reservoir through the ordinary screw inlet when required, and setting the lamp going by means of the ignition of a few drops of spirit. There was no corrosion, no interference with the mantle, which had not been renewed; and the lamp never need be disturbed, as was the case when ordinary petroleum was used. Mr. Massey told him that he had six of them in use, that they ran for 11 or 12 hours without replenishing, and there was no trouble with them whatever; very little heat was given off, and the cost was $\frac{1}{6}$th penny per hour with methylated spirit at 2*s.* 4*d.* a gallon. The lamp was very simply lit, being that known as the "Amor;" a little filling instrument was provided by which a very small quantity of spirit was poured on to a platform just below the mantle and then ignited. The heat from that small quantity was conveyed to the wick tubes, capillarity was excited, the spirit was vaporised, and incandescence reached its maximum in from $\frac{3}{4}$ to 1 minute. A suggestion had been made that a lamp of this kind would be very useful for microscopic purposes, and he had no doubt that Mr. Lorenz would make enquiry as to that. He, the speaker, brought the matter forward because the Society had been associated with the Chemical Committee of the London Chamber of Commerce in promoting the industrial use of alcohol; and as it was a rigid rule of the Council and the Publication Committee not to permit correspondence to the Journal, he had asked permission to put these lamps before them in connection with one application for alcohol. The other apparatus shown included cookers, large and small ironing heaters, water boilers, milk warmers, vaporisers, curling iron heaters, &c., all of which worked simply, cleanly, and sufficiently. He was indebted to Mr. Joseph Flack for their use. He would conclude his remarks by the statement that the use of alcohol for motive power had enormously increased on the continent, and the quantity used for power, lighting, and heating greatly exceeded that used for Chemical ndustries.

The CHAIRMAN said they were much indebted to Mr. Tyrer for this interesting exhibit, and also to Ir. Lorenz and Mr. Massey who had lent the lamps. They already owed a great debt to Mr. Tyrer in connection with this subject, to which reference was now being made n various quarters, and papers were read before various ocieties, but most of them were simply digests of those hich had appeared in the Journal of their Society.

New York Section.

Meeting held at Chemists' Club, on April 22nd, 1904.

DR. VIRGIL COBLENTZ IN THE CHAIR.

IDENTIFICATION OF GUTTA-PERCHA AND ALLIED GUMS BY MEANS OF THEIR RESINS.

BY WILTON G. BERRY.

Having had occasion to look up the subject of gutta-percha and chicle gums for methods of distinguishing them from each other and from certain other allied pseudo gums of similar appearance and composition, aside from their physical characteristics, which are sometimes misleading, it became evident that, with exception of gutta-percha, scarcely any available analytical data was at hand, so far as I am aware, to apply in such emergencies, the pseudo gums and even chicle having received scant attention aside from their physical appearance and characteristics.

While engaged in working out suitable methods for identifying the various gums, it seemed that the most promising field lay in ascertaining the characteristics and constants of the individual resins peculiar to each, together with their possible relations to the hydrocarbons present. This line of proceedure, in the case of the few already experimented upon, has been so satisfactory that it seems much may be hoped for, and it may be of interest to put forth what data has so far been gathered on the subject. Future work in this line will be presented later.

Owing to the difficulty of securing representative samples, and from these, sufficient quantities of the resins to work upon, results will necessarily be slow in attaining. The present article relates to the general appearance and characteristics of the various resins so far isolated, with their saponification and acid values. Other constants will doubtless likewise be of value towards distinguishing them, and it is hoped from these facts, from a quantitative analysis of the corresponding gum and the apperance of the extracted hydrocarbons, that it will be possible to identify any given sample. The resins present are more or less extracted by the various resin solvents, but in the following experiments boiling absolute alcohol is the solvent used on the previously dried material, the results given being in each case on the resins thus extracted. Possibly other solvents might yield resins differing somewhat in their constants.

The only resins thus far investigated by experimenters to any great extent seem to be those from gutta-percha (albane and fluavil), combined in the gum in the proportions of about one of the former to three of the latter. The resins of chicle gum, tuna, balata, and doubtless many of the other gums, may each likewise be separated into at least two resins, combined in proportions differing from those of gutta-percha and in some with very decided differences. Thus far only the corresponding resins of chicle have been experimented upon and treated of in this article, being designated as Resin A and Resin B in default of names.

The various resins are in general amorphous bodies, varying in color in the melted state from almost colourless to deep yellow. The hard resins when powdered are almost colourless or slightly yellow. Their consistency is hard or brittle, pasty or liquid. Some are capable of crystallizing. The constants were obtained by saponification, with boiling N/2 alcoholic potash and titration hot with normal hydrochloric acid, or in the case of acid values with N/10 acid. The acid values are very low, in some cases nil, hence the resins are combined and contain but small amounts of free resin acids. Saponification under pressure might afford higher values. Of course, to obtain satisfactory deductions many determinations should be taken on different specimens of the same gum, and the results given below can be taken only as indications of the probable constants in each case.

The accompanying quantitive determinations were obtained on the dry material by extracting successively with hot acetone, alcoholic potash, and petroleum ether. Quantitative determinations of the resins and gutta in gutta-percha are omitted, as they are too well known to remark upon.

Gutta-percha (P ilaquium Sp.).

Resins: Soft and pasty, yellow.

——	I.	II.	III.	IV.
Saponification value	79·8	77·4	79·5	77·3
Acid value...............	5·0	5·0	5·0	5·0
Ester value	74·8	72·4	74·5	72·3

Saponification value: Albane, 83·50; fluavil, 71·45.

A sample of very old, hard, oxidised gutta-percha ("dead gutta") consisted of 96·75 per cent. resins with 0·25 per cent. gutta. The resins are very dark brown yellow, about the consistency of beeswax, with saponification value, 166·75. This sample is interesting, as showing the deterioration and change which goes on as a result of oxidation, the gutta being changed almost completely into resins. The high saponification value of the resins would indicate that the oxidation of gutta proceeds much further than the change into albane and fluavil, the final product being resins of an entirely different nature.

Chicle (Achras Sapota).

Composition.

—	I.	II.	III.	IV.
Resins	55·78	38·08	43·78	35·60
Hydrocarbons	13·81	10·39	11·29	10·50

Resins: Hard, brittle, grayish-yellow.

—	I.	II.	III.	IV.
Saponification value	101·7	103·6	103·0	104·1
Acid value	trace	trace	trace	trace

Saponification value: Resin A, insoluble in cold absolute alcohol, 129·0; Resin B, soluble in cold absolute alcohol, 100·8.

Hydrocarbons: Tough, inelastic, almost colourless.

Tuno (sterile rubber tree, Cent. Am.).

Composition.

—	I.	II.
Resins	86·13	80·0
Hydrocarbons	3·50	7·06

Resins: Hard, brittle, dark yellow.

—	I.	II.
Saponification value	78·5	76·0
Acid value	5·76	5·46
Ester value	72·74	70·54

Hydrocarbons: Sticky, inelastic, brownish-grey.

Almeidina (potato gum, W. Africa).—Composition: Resins, 82·78; hydrocarbons, 9·40.

Resins: Hard, brittle, yellow. Saponification value, 50·4; acid value, 11·0; ester value, 39·4.

Hydrocarbons: Soft, sticky, greenish-brown.

Jelutong or Pontianak (Dyera Costula).

Composition.

—	I.	II.
Resins	76·55	75·00
Hydrocarbons	16·04	19·40

Resins: Soft, brittle, yellow.

—	I.	II.
Saponification value	76·6	78·4
Acid value	trace	trace

Hydrocarbons: Soft, sticky, dark brown.

Balata or Bully Tree (Mimusops Sp.).—Composition: Resins, 25·08; hydrocarbons, 47·60.

Resins: Turbid, liquid, yellow. Saponification value, 69·2; acid value, trace.

Hydrocarbons: Tough, inelastic, nearly colourless.

Payena ("Yellow Gutta").

Two samples of uncertain origin, probably payena sp., are interesting as illustrating a gum of dual composition containing the hard resins characteristic of chicle, and the elastic caoutchouc-like hydrocarbon characteristic of rubber. This gum is known as "yellow gutta," but seems to be more nearly allied to rubber than to gutta-percha.

Composition.

—	I.	II.
Resins	79·75	80·00
Hydrocarbons	11·59	12·38

Resins: Same as chicle resins, in appearance.

—	I.	II.
Saponification value	103·4	104·1
Acid value	trace	trace

Hydrocarbons: Similar to caoutchouc.

Balata is also sometimes classed as gutta. If the hydrocarbons respectively from gutta-percha, chicle, and balata, be extracted with ether and precipitated therefrom by alcohol, they will differ from each other in several particulars, as follows:—Gutta-percha separates in pinkish white flocculent masses; solution clear. Chicle separates in pure white flocculent masses; solution very milky. Balata separates quickly in tough pinkish white agglomerated masses; solution turbid.

Average Saponification Values of Resins.

Gutta-percha	78·5
Albane from gutta-percha	83·5
Fluavil „ „	71·45
Chicle	103·1
Resin A from chicle	129·0
Resin B „	100·8
Tuno	77·3
Jelutong	77·5
Almeidina	50·4
Balata	69·2
Payena Sp.	103·7

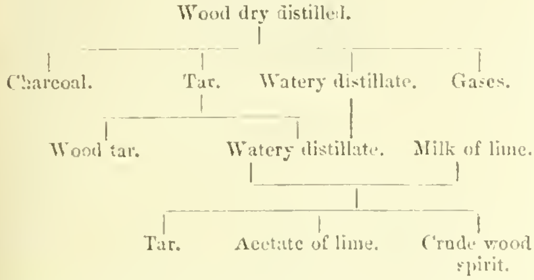
The saponification values of gutta-percha, tuno, and jelutong resins are nearly identical, but the accompanying hydrocarbons are quite different. A further separation of the resins of tuno and jelutong into their several component resins, as in the case of gutta-percha resins into albane and fluavil, will effectually differentiate the one species from the other.

ANALYSIS OF COMMERCIAL ACETATE OF LIME.

BY W. M. GROSVENOR, JUN.

As there has recently been considerable discussion of methods for the analysis of acetate of lime, it seems proper to present some points from the acid manufacturer's side. The financial aspect of the subject is as interesting to him as to the dealer. Added interest, however, is found when investigation of new methods of manufacture and minor economies begins. For some purposes, greater accuracy, but especially greater reliability is desired than for commercial work. No method is reliable until its sources of error are known and can be guarded against. The subject, therefore, has been investigated from time to time in several of the General Chemical Company's laboratories, but the work has been frequently interrupted and is not by any means complete. The rigorous testing of the distillation method has been done by Mr. Bishop at our Laurel Hill Works under the guidance of our chief chemist, Mr Ferguson.

Like many substances presented to the chemist for commercial assay, acetate of lime is a mixture of compounds s closely related as to practically defy attempts at accurat analysis. Those familiar with its manufacture can best realise its complexity. The grey lime on the market results, as a rule, from the following series of steps:—



The two watery distillates are combined and redistilled through boiling milk of lime. The products of this destructive distillation which are certain to combine with the calcium are the acids, formic (99° C.), acetic (119°), propionic (140°), butyric (163°), normal- and iso-valerianic (186° and 174°), caproic (205°), and normal- and iso-crotonic (182°). Further some 30 other products have been isolated, many of which may be present in traces along with calcium hydroxide, calcium carbonate and mineral acids, particularly hydrochloric, which is sometimes used to slightly acidify these liquids in recovering certain bye-products. The complete separation of acetic acid from such a mixture will be possible only by improvements that revolutionise organic analysis. Practically all the acids are volatile with steam, most of them distilling out faster than acetic. The solubilities of the salts are graded and electrolysis produces mixed condensation products. Several methods of separating the earlier members have been suggested, *e.g.*, that of Holzmann based on fractional liberation from salts and distillation, acetic and formic acids being liberated last and largely together. Also Leys determines formic acid in presence of acetic acid, alcohol, or aldehyde by a precipitation of mercurous acetate, while Haberland has proposed to remove propionic acid as a basic lead salt, formic acid by taking advantage of the insolubility of the zinc salt in absolute alcohol, and finally to separate the acetic and butyric acids by crystallising the silver salts.

So far as we can learn, the only analytical method relied upon in Germany is that originated by Fresenius and modified by Stillwell and Gladding, which will be considered in detail later. Some analysts show a strong proclivity for begging the question, assaying for acetic acid by determining calcium. Other workers precipitate the calcium with excess of sodium sulphate, filter, evaporate, ignite, dissolve in a known amount of hydrochloric acid and titrate back. Many experiments with this method have failed to remove all the acetic acid from the precipitate; organic impurities in the filtrate are likely to reduce the calcium and sodium sulphate on ignition and give high values, and the method has a further objection of frequent manipulations and loss of time. The precipitation method of Fresenius has not been carefully examined, but as described seems less rapid than the distillation test.

The two methods of analysis largely used in America are the so-called "English Commercial test" and the distillation test. The former has in the last few years been deservedly rejected. The method simply consists of a determination of the calcium by ammonium oxalate, and it seems strange indeed that chemists, of all men, should have been willing to buy acetic acid raw material on its contents of calcium. Obviously limes can be made to show 80 per cent. "Commercial Test" and yet contain anything from zero to 77 per cent. of actual acetic acid, equivalent to 102 per cent. of calcium acetate. Years of experience on commercial acetates show the error of this test to vary from + 3 to − 2 per cent. of the acid actually obtainable.

The distillation test at worst should give, within a few tenths of 1 per cent., the true value of the lime for manufacture of acid. From the seller's point of view, it has the advantage of never giving falsely low results, while the manufacturer knows that all the acid represented is saleable as acetic acid. Overlooking the inclusion of other organic acids (small percentages of which are not objectionable in commercial acetic acid), the method is sound, and only requires the use of proper precautions. Finally, it can be made available for many research purposes by avoiding in the experiment the presence of other fatty acids. Analytical difficulties occur solely in separation, as there is no difficulty in making correct determinations of pure acetic acid within 0·02 per cent. For commercial purposes, however, analysis must be preceded by correct sampling, the vital importance of which is too frequently overlooked. We are not, as a rule, dealing with material in bulk, but in bags. The material is not homogeneous. No lime plant in America makes a 50,000 lb. carload in a single pan; parts of a car are sure to come from different runs. Different parts of each bag will differ noticeably in composition, not through any sharp practice in filling, but because calcium acetate is hygroscopic and common changes of weather alter its moisture contents from 2 to 12 per cent. Thus the outer layers of the bag may be better or worse than the average, depending on the exposure. (Table I.) Even individual pieces of rge size will show variations, for the solid is not rystallized or even fished out, but dried down with its other liquor in it. (Table II.) When it is remembered at calcium acetate has the solubility curve shown in ig. 1, and that the dried material, consisting largely of $Ca(C_2H_3O_2)_2, H_2O$ formed at 85° to 100° C., is taken from the pan moist, cools as it goes to the drying benches, and is there heated from below, it is not surprising that large variations should exist. It is therefore desirable that at least every fifth bag should be sampled with a hollow brass

tube like an apple corer not less than 24 inches long, tapering backward from $1\frac{1}{2}$ to 2 inch bore, $\frac{1}{16}$th inch wall, with strong handles forming a cross about 2 inches from the large end. The small end should be screwed 18 inches into the end of the bag, preferably as it lies in pile, choosing top ends and bottoms about equally.

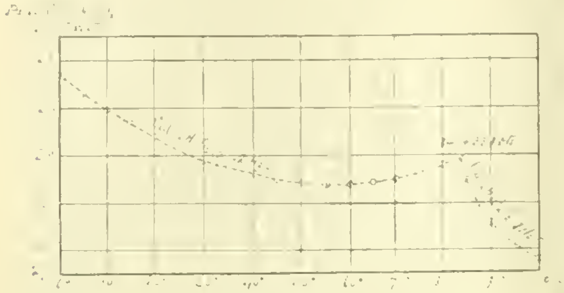

Fig. 1.

Table If.

Analysis of Lumps of Acetate of Lime selected at random from carload that had been about six weeks in dry storage loft. January and February.

——	2-in. Hard Scale.	1-in. Soft Lump.
Inside....................	65·16	65·14
Outside..................	66·27	63·72

In dealing with a hygroscopic and variable material we believe the present methods are open to criticism. Until after the whole sample is finely ground and thoroughly mixed, no small sample can be obtained that fairly represents the lot. Any attempt to thoroughly dry the large lumps is unsatisfactory, and loss by exposure during grinding should be carefully avoided. We therefore recommend the following procedure. The contents of the sampler are discharged into an air-tight vessel, as light in weight as possible, having a capacity of about 3 cb. ft. For this purpose thin-walled rubber bags having rubber necks ¼ in. thick, 3 ins. long, 2½ in. bore possess the advantages of lightness and ease of handling. Also when empty they contain no air to be displaced by the entering lime; the air currents being inward none of the dust is lost. These bags should be numbered, and their empty weights accurately taken. When the filled bag containing 25—50 lb. of lime reaches the laboratory it is carefully reweighed. Its neck is then connected with the inlet of any suitable form of mill having dust-tight casing and bearings, and it is ground through into a similar weighed bag attached to the outlet of the mill. The material retained by the mill should be checked by weighing both bags and contents, and should be less than 0·2 per cent. This could not under any circumstances affect the composition of the rest more than 0·01 per cent. Should the lime as received be too wet for grinding, the neck of the bag may be tightly plugged with cotton to catch dust, connected with a receiver containing pumice and sulphuric and the air exhausted by good suction. Leave in the warm room overnight and reweigh the bag before grinding. While in the second bag the samples may be thoroughly mixed by kneading and shaking. By connecting the neck of the rubber bag with a bottle, the record sample may be taken practically without air contact, and similarly the amount needed for acid and moisture determination placed in proper vessels and covered at once by glasses. Weighing by difference in weight of the bag and using the neck of the bag to distribute it the rest of the sample may be spread upon a large plate for the technical moisture determination to be carried out on 15—30 lb. The distillation sample may be taken after drying (grinding more finely if desired), quartering down systematically on the plate; correcting the distillation result by a special moisture determination on a part of the quarterings.

A most convenient sample jar is the "Lightning" preserve jar, made of glass, provided with rubber sealing rings and a wire fastener. The sampling should be done as near the time of weighing as possible, certainly the same day.

This care may seem unnecessary, but samples of lime have repeatedly lost 0·5 to 1 per cent. in ordinary grinding, and "average" samples from the same car have shown differences as high as 1 per cent. on distillation test. This method requires no more labour than is demanded by a car of 33 per cent. pyrites, which costs about 6 dols. a ton or 18 dols. per ton of sulphur. Acetate of lime is worth 35 dols. a ton, carries about 60 per cent. of acetic acid, equal to, roughly, 60 dols. per ton of acetic acid.

Four analytical samples are to be taken, two for acetic acid and two for moisture determinations. The moisture determination is not of vital importance to most manufacturers and will be passed over with the remarks that careful investigation has repeatedly shown that acetate of lime cannot be completely dried by heat alone without decomposition; that impure limes are much more readily affected than pure calcium acetate; that about 25° C. is the limit of perfect safety for commercial limes, and three hours at 100° C. generally gives nearly constant weight. (Fig. III.) The drying is best done on a ground watch glass in the steam bath, another glass, tared with the first, being used for a cover the instant it is removed from the bath, while cooling and weighing. There is no objection to drying agent in the desiccators used for cooling, as 16 hours over

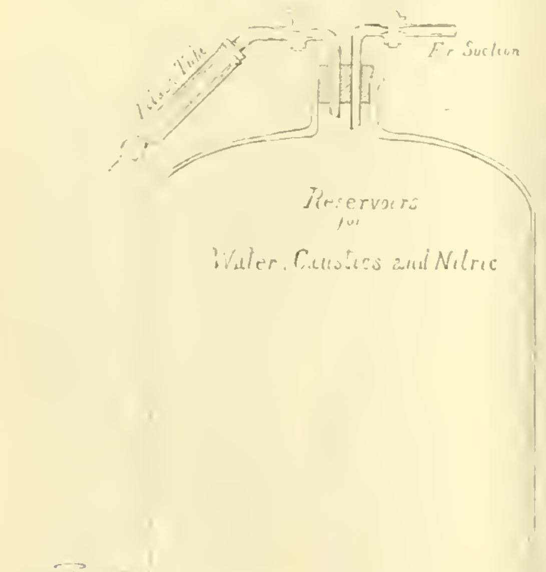
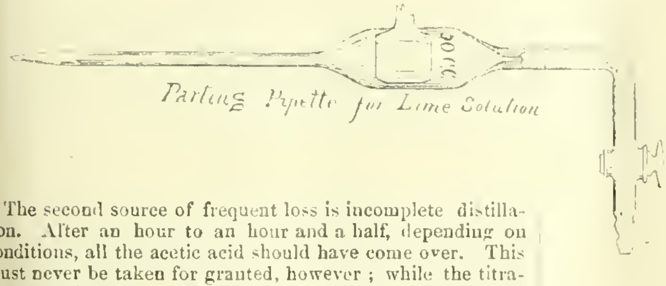
phosphoric anhydride made only 0·02 per cent. difference in weight. For the distillation test exact factor-weights should be used whenever possible, as much more accurate results are obtained. This cannot be done with acetate of lime unless the factor weight be large, and the surface exposed while weighing not only small but well below the rim of the weighing vessel to retard free circulation of air. Our experience indicates that the usual 2 grm. samples of acetate of lime, when either unusually dry or very moist cannot, except by accident, be factor-weighed on a watch glass within 0·1 per cent. Queen beakers of the deep pattern provided with covers of thin glass are very satisfactory, and 20 to 50 grms. is a better weight. After taking the three decimal tare of the beaker and cover, slightly more than the factor weight of acetate of lime is put in it, the beaker placed on the front edge of the balance pan, and the excess of acetate of lime quickly removed by a pair of broad nosed tweezers to within 2 mgrms. of swinging balance, *i.e.*, 0·01 per cent. on 20 grms. In referring to the record sample, portions for analysis may be removed from the sample jar by a thin walled glass tube of about 1 in.-bore, marked at a point which experience shows will contain more than the factor-weight; if this is pushed down at an angle into the ground lime in the sample jar, slightly more than the required depth, on inclining the jar about 60 it can be removed nearly horizontal, its end covered with the Queen beaker, its contents discharged and the beaker at once covered without appreciable error.



For the distillation test, the two samples first trimmed (40 grms. each) should be used. They are washed with cold water into porcelain mortars, gently stirred with successive portions of water decanted into a narrow necked litre flask until practically all of the calcium acetate is dissolved. The residue is thoroughly ground with final portions of water and washed into the flask, which is then made up to the mark, thoroughly mixed, and immediately parted with a 50 c.c. capillary pipette. The pipette should have a 1 mm. capillary upper tube and about $\frac{1}{4}$ in. lower tube drawn down to a 1 mm. opening. A free run from the pipette, taking only the first drop that falls after the stream stops, gives the most satisfactory draining. Working and standardising in the same way with solutions of about the same physical properties (sp. gr., capillary constant, and coefficient of viscosity) this parting can be done with less than 0·01 per cent. error. The pipette need not be quite 50 c.c., nor the flask marked at an exact litre, but 20 pipettes as used must fill the dry flask exactly to the mark. The standardising should have been done at about the working temperature. No correction need be made for temperature. Its effect is only indirect and very small, causing slight variations in draining. This 50 c.c. is placed in a 200 c.c. Kjeldahl distillation flask, and about 15 c.c. of 50 per cent. phosphoric acid is added, the neck of the flask being then washed down with a few c.c. of water from the wash bottle. The phosphoric must contain no volatile acids (particularly nitric). The flask is then connected by a glass tube of not less than $\frac{1}{4}$ in. bore with some form of straight glass condenser in such a manner that the flask shall be inclined at an angle of not less than 60 from the perpendicular. The $\frac{1}{4}$-in. gas exit should pass through the stopper as near the upper side as possible; the inner end be ground off at an angle. Through the same stopper a small glass tube is passed, extending only about quarter of an inch on the inside of the stopper and slightly bent, so that it may be brought near one of the walls. The distillation flask is supported upon a piece of heavy asbestos board through which a hole has been cut of such diameter (about 2 ins.) that only the portion of the flask covered by 50 c.c. of liquid will be exposed to the direct flame. The exit of the condenser is connected with a piece of $\frac{1}{4}$ in. glass tubing which passes through a rubber stopper in one tubular of a 500 c.c. Wolf bottle and reaches to the bottom. The other neck of this bottle should be provided, during the first hour of the distillation, with a tightly fitting stopper which carries a small tube of soda-lime. For titrating there are two other stoppers through one of which pass a small piece of capillary tubing and the delivery tip of a 20-c.c. burette divided to $\frac{1}{10}$ c.c. and approximately readable to hundredths. The other stopper carries only a similar burette. Above the entire distillation apparatus is located a reservoir which can be readily connected with the small tube in the stopper of the distillation flask by a piece of rubber tubing, the flow through which is regulated by a screw cock. Instead of pure water an extremely dilute solution of phosphoric acid free from carbon dioxide is used. Into the receiving bottle is exactly measured by a capillary pipette (standardised against the burettes) 100 c.c. of caustic soda solution containing approximately one-tenth as much barium hydroxide as sodium hydroxide, and of such alkalinity that 100 c.c. is equivalent to the acetic acid contained in 2 grms. of 80 per cent. calcium acetate. The first 20 c.c. burette contains nitric acid, of which 200 c.c. corresponds to the acetic in two grms. of absolute calcium acetate. The other burette contains caustic soda-baryta solution equivalent to the nitric acid.

After distillation has reduced the volume in the flask to 75 c.c., a slow stream of water should be admitted, the volume never being allowed to become less than 50 c.c. The rate of distillation does not seem to be as important as other considerations, and the fastest operation permitted by the ordinary Bunsen flame is quite safe. An hour and a half is ample time for complete removal of the acetic acid if the work has proceeded properly, and the complete test, from sample-weighing to final safeguards, may be carried out in about two and a half hours.

In the distillation itself we have found five common sources of error, and thoroughly tested the above method in these respects. First, phosphoric acid is extremely likely to be carried over with the distillate, so much so that we have been reliably informed that it is volatile with steam. This was definitely disproved by the use of a small centrifugal separator similar to that used for drying steam. The pressure necessary to operate this effectively was obtained by exhausting the receiver, a difference of 15 lb. being thus possible without risk of blowing up the distillation flask. Under identical conditions it was found practically impossible, using upright flasks, to avoid passing over the phosphoric acid without the separator, whereas, with it, no matter how violent the distillation, none was found in the distillate. It is therefore carried over solely in the form of mist, entrained vapour, and splashed particles. Phosphoric acid is very prone to form mist during the last stages of evaporation. To be conclusive, the test for phosphoric acid must be made on distillates after neutralizing, concentrating to about 25 c.c., adding 10 c.c. of ammonia and acidifying with nitric acid, and allowing to cool, and examining carefully for silica (which is apt to be precipitated at this point)or any other precipitate, which should be filtered off before testing for phosphoric acid. In the ordinary dilution of 500 c.c. the distillate may contain phosphoric acid equivalent to 0·1 or 0·2 per cent. of acetic acid without responding well to the molybdate test. At 50 c.c. 0·005 per cent. is easily detected. Further, commercial caustic soda contains phosphoric acid, which must be removed before using for these titrations. Mr. Stillwell kindly tested a number of these distillates and, finding no phosphoric acid, suggested an exchange of phosphoric samples. Before this was effected, however, a visit to his laboratory confirmed his tests, and called attention to the marked inclination of his distillation flasks. Several of these were placed upright, and immediately their distillate showed phosphoric acid. Surprising as it seems, the slow movement of gas in the neck of the flask is sufficient to overcome gravitation when directly opposed to it, and to carry over the mist; whereas, when the vertical component of this velocity is only half (ccs. 60°) as great, the effect on a given surface is only one-fourth as great, and the mass of the drop supported only about one-fourth. Similar considerations forbid the use of very narrow-necked flasks, for doubling the diameter gives four times the cross-section, one-fourth the velocity, and one-sixteenth of the lifting effect on a given drop. With the inclined flask, gravity quickly pulls the splashes downward against the lower side of the neck, the water introduced at the top washes them back, becoming itself less volatile thereby, finally mixing better with the residue in the flask, and carrying out the acetic Acid more quickly.



Parting Pipette for Lime Solution

The second source of frequent loss is incomplete distillation. After an hour to an hour and a half, depending on conditions, all the acetic acid should have come over. This must never be taken for granted, however; while the titration is being made, distillation should be continued, and this distillate tested. Using the apparatus above outlined, phenolphthalein (the same quantity as used in standardizing) is put into the barium hydroxide solution when the distillation is regarded as probably complete, and the stopper carrying the nitric acid burette inserted. The excess of alkali being almost neutralised, the distillation is allowed to proceed. If the colour then disappears, the second burette of equal strength alkali is used, and, drop by drop, the colour is restored, until 10 or 15 minutes' distillation no onger discharges it.

The third and most prolific source of disagreement is arbon dioxide present in the acetate of lime, in the water r steam added to the distillation, and in the standard alkali. n the latter it could be largely allowed for by frequent tandardising or by making the final titration boiling hot rom the acid side. If this is relied upon, the boiling of cetic acid solutions should be carried out with a very fficient reflux condenser not less than $\frac{1}{2}$ in. bore and 24 ins. ong. We finally found the cause of discordance in a long eries of results to be slight losses of acetic acid during the oiling and hot titration. For accurate boiling titration the olubility of the glass should be determined and, if need be, llowed for, as it sometimes affects results to the extent of ·05 per cent. On the whole, we have obtained much more tisfactory results with the sodium hydroxide containing aryta. This has the advantage of serving as a fairly nsitive indicator for both carbon dioxide and phosphoric id (the most common causes of high results) and, as a feguard, is sensitive to 0·02 per cent. Steam should ever be used for distillations, as it actually prolongs the ne required, increases the volume of the condensate, variably contains carbon dioxide, and is far more difficult regulate than a visible dropping of water. The use of ater freed from carbon dioxide is easily accomplished by having two reservoirs filled alternately with distilled water condensed hot directly into them, adding a few c.c. of phosphoric acid, and applying suction till violent boiling ensues. One is allowed to cool and settle while the other is being used. After exhaustion, these reservoirs should connect with the atmosphere only through potash bulbs and the connection with the distillation flask should be broken as seldom as possible

The fourth source of error, small but very general, we believe, lies in the use of sodium carbonate ignited at a red heat as a standard for acidimetric work. Sodium bicarbonate recrystallised, dried at 100°, washed with distilled water until it no longer gives the tests for chlorides or sulphates, again dried at 100° C., and heated to constant weight at 300° in an air bath, gives more correct results, differing from the other by approximately 0·01 per cent.

Lastly, hydrochloric acid is not infrequently present in acetate of lime, and although the amount present is small, we have, in some instances, found it equivalent to 0·05 per cent. of the acetic present.

Having proved the distillation to be complete, and having titrated the acetic acid, along with any carbon dioxide, phosphoric and hydrochloric acids, which may have been carried over, it now remains to test for the hydrochloric acid, and determine the amounts of phosphate and carbonate if the appearance of a precipitate has shown either to be present. To this end the now neutral solution is washed from the receiving bottle upon a filter, and the collected precipitate thoroughly washed with water, washings being added to the filtrate. In this filtrate the hydrochloric acid is directly titrated with silver nitrate, using potassium chromate as indicator. The precipitate with the filter is transferred to a flask, water is added, and the amount of carbon dioxide directly titrated with nitric acid, using Methyl Orange as indicator, shaking vigorously after each addition of acid. To this liquid, transferred to a porcelain vessel (alkalis, and even neutral salts, abstract detectable amounts of silica from glass), ammonia is added and excess of nitric acid to dissolve the barium phosphate. This liquid is boiled and brought to about 25 c.c.; it is then filtered and, after standing till cold, molybdic acid is added.

Tests of the above method show that, in the large majority of cases, the amount of hydrochloric acid obtained will be less than 0·01 per cent. of the acetic acid. No phosphoric acid should be found in the distillate, and less than 0·01 per cent. of carbon dioxide unless the lime contains carbonate. Checks have been obtained against a known quantity of absolute acetic acid to within 0·02 per cent.

It cannot be claimed that these methods are complete, as they have not yet been tested to our entire satisfaction, but they are certainly more reliable than the single distillation, and are offered for the benefit of those who care to test and further improve them.

The use of standard caustic baryta-soda to receive the distillate seems long and awkward in description, entailing, as it does, exclusion of air, but in practice it is found to be actually quicker, and certainly more reliable than boiling titration.

Obituary.

PROF. A. W. WILLIAMSON, D.C.L., LL D., F.R.S.,

EMERITUS PROFESSOR OF CHEMISTRY IN UNIVERSITY COLLEGE, LONDON; AN ORIGINAL MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY (1881–1887).

Alexander William Williamson was born at Wandsworth on May 1st, 1824, and studied chemistry under Gmelin in Heidelberg, and Liebig in Giessen, in the latter University also graduating PhD. He, further, spent some years in the study of the higher mathematics under Compte in Paris.

In 1849, Williamson was appointed professor of chemistry in University College, London, where he continued to teach till 1887, when he retired with the title of Emeritus Professor. He was elected Fellow of the Royal Society in 1855, and received a Royal medal in 1862. He was twice President of the Chemical Society (1863-65 and 1869-71), and was one of the six guests at the banquet given in London by the Chemical Society in 1898 in honour of those of its past presidents who had been Fellows for half a century. In 1873 Professor Williamson was elected President of the British Association, and in 1876 he succeeded Dr. Letheby as Chief Gas Examiner to the City of London, and continued to discharge the duties of the post till about three years ago, when advanced age and failing sight obliged him to resign. On Sunday, May 1st, he attained his 80th birthday, and died on May 6th. In the development of chemical doctrine half a century ago Williamson took a prominent part. Considering that the method of stating the rational constitution of bodies by comparison with water was susceptible of great extension, and would be of service in simplifying the ideas of chemists by the establishment of a uniform table of comparison by which bodies might be judged, Williamson was particularly active in supporting this conception, and one of his own contributions was the introduction of the doctrine of condensed types, according to which a double or triple water-type was employed to explain the construction of bodies that could not be well referred to the simple type. In the course of his study of this question he carried out the classical research with which his name will be ever associated, resulting as it did in the full elucidation of the process by which ether is formed by the interaction of alcohol and sulphuric acid. This research in establishing the theory of the etherification process has rendered eminent service to chemical industry. In another direction Williamson also showed himself a pioneer in chemical thought, being one of the first to introduce dynamical ideas into chemical science. Thus, so far back as 1850, in the same paper as that in which he explained etherification, he advanced a view which is fundamental in the hypothesis of ionic dissociation. In this the doctrine is evolved that the atoms composing the molecules of the compound are continually in motion and interchange, any particular atom now forming part of one molecule, then exchanging into another, next into a third, and so on through an unending course of ionic migration.

SIR CLEMENT LE NEVE FOSTER, F.R.S.,

Professor of Mining in the Royal School of Mines, one of His Majesty's Inspectors of Mines, &c.

Sir Clement Le Neve Foster was born at Camberwell in 1841, and was the second son of Peter Le Neve Foster, formerly a secretary of the Society of Arts. At the age of twelve he was sent to school in France, and returning to England in 1857 he entered the Royal School of Mines, where he had a brilliant career. He then went to study in the Freiberg School of Mines, and even before completing the course there was appointed to the Geological Survey of Great Britain by Sir Roderick Murchison in 1860. During the five years following this appointment he was engaged on the work of the Survey, first on the Wealden beds of Kent and Sussex and subsequently in Derbyshire and Yorkshire, his spare time being spent in preparing for the D. Sc. degree, which he took in 1865. In that year Le Neve Foster resigned his post to become Lecturer to the Miners' Association of Cornwall and Devon, and in that capacity he interested himself in the question of introducing improved appliances into the mines. Two years later he gave up this appointment for the sake of mining exploration in Sinai, and after visiting Venezuela in 1868 in connection with gold mining, he accepted an appointment with the Pestarena Gold Mining Co. in Italy, which he held until 1872. On the passing of the Metalliferous Mines Regulation Act of 1872, Le Neve Foster was appointed one of her Majesty's Inspectors of Mines to carry out its provisions. In 1894 he became Editor of the Mineral Statistics issued by the Home Office, and of the Annual Reports on the Mines and Quarries of the United Kingdom. He resigned his official position in 1901, and last year his services received the recognition of knighthood. In addition to numerous official and other publications, he was the author of a treatise on "Ore and Stone Mining," and of the articles on mining in both the ninth edition of the "Encyclopædia Britannica" and in the supplementary volumes. In 1890 he succeeded Sir Warington Smyth as Professor of Mining at the Royal School of Mines, and in 1892 the Royal Society elected him a Fellow.

Sir Clement Le Neve Foster was an ideal lecturer on subjects relating to mining.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, AND MACHINERY.

English Patents.

Drying and Evaporating Apparatus; Vacuum ——. J. and R. Glass, Leipzig. Eng. Pat. 9308, April 24, 1903.

See Fr. Pat. 323,961 of 1902; this J., 1903, 544.—T. F. B.

Drying Kilns. W. P. Thompson, London. From J. F. Hanrahan, Ottawa. Eng. Pat. 4602, Feb. 24, 1904.

A preliminary drying or "sweating" chamber is combined with a second or finishing drying chamber. Each is closed to the external air, and is provided with a heating coil at the bottom and a condenser with suitable cooling coils above. The heated air, laden with moisture, rises, deposits the condensed water, and, being now cooler, falls through suitable channels to the space beneath the heating coils to be used over again.—W. H. C.

Filters. A. J. A. Reeb, Paris. Eng. Pat. 10,498, May 8, 1903.

The filter is so arranged that the thickness and material of the filtering medium can be easily varied. It may be made of enamelled metal, and the rubber joints are protected from any action of the liquid being filtered.—W. H. C.

"*Heating Fluid; Utilising the Heat of Chemical Reaction for*" ——. A. Lang, Karlsruhe. Eng. Pat. 11,632, May 21, 1903.

This is a process for utilising the heat developed by the chemical reaction of "fluids of all kinds." The reacting material is contained in a thin-walled vessel of conducting material, which is wholly or partially immersed in the fluid to be heated—contained in another vessel.—W. H. C.

Mixing Liquids and Gases; Apparatus for ——. R. F. Wood-Smith, London. Eng. Pat. 13,224, June 12, 1903.

The liquid and gas are passed through a filter-pump into a trap, where the liquid and unabsorbed gas are separated. The liquid then overflows into a second pump, and, by the suction which it produces, draws the unabsorbed gas from the upper part of the trap along with it, a further mixing taking place. Any number of pumps and traps can be used in series.—W. H. C.

Centrifugal Machines. G. ter Meer, Hanover. Eng. Pat. 1505, Jan. 20, 1904.

The wedged-shaped chambers b, Fig. 3, are arranged radially about the driving spindle (Fig. 1) a; c and c^1 are the upper and lower limiting walls of the chambers, and are rigidly secured to the driving spindle a. The material to be treated is fed through the central supply pipe k, and delivered to the chambers b by the spouts k^1. The solid matter is driven by the centrifugal force to the outer end of b, whilst the liquid escapes through the rear perforated filtering wall d (Fig. 3), and passes by the spout h to the collecting channel i (Fig. 1). The discharge of the solid matter from b is effected by centrifugal force, the wall d^1 (Fig. 3), which occupies the position shown by the dotted lines whilst the chamber is filling, being caused to open and allow the solids to be discharged in the following manner:—A rotating worm shaft m (Fig. 1), the speed of which can be varied, rotates the circular track u, under the rollers t^1, ttached to a non-rotating carrier t. The sleeve s, about he central inlet pipe k, rests on balls on the carrier t, and s attached by the bell-crank r and the lever q to the pin n n the movable wall d^1 of the chamber b (Fig. 3). The rack u has two opposite projections u^3, and when these ass under the rollers t^1, the sleeve s is raised, the crank r ulls back the side d^1, and the solid is discharged. When he projections u^3 have passed the rollers t^1 the sleeve s rops again, allowing d^1 to close. Another concentric track , with projections v^1, rotates under the roller w (Figs. 2 nd 1), which is lifted by the projections, and closes the alve l by means of the crank x and lever y. When the

Fig. 1.

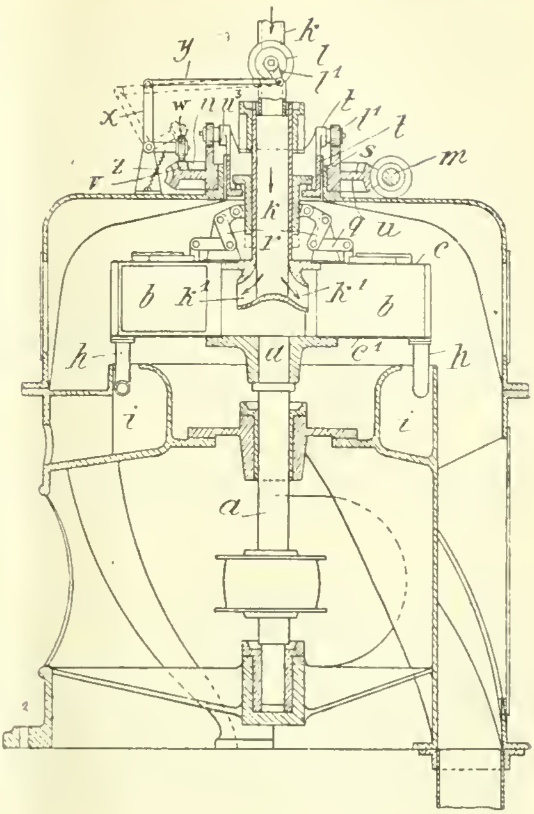

Fig. 2.

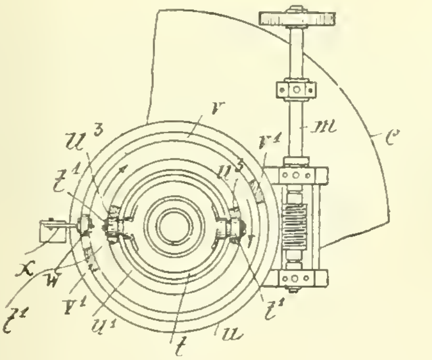

Fig. 3.

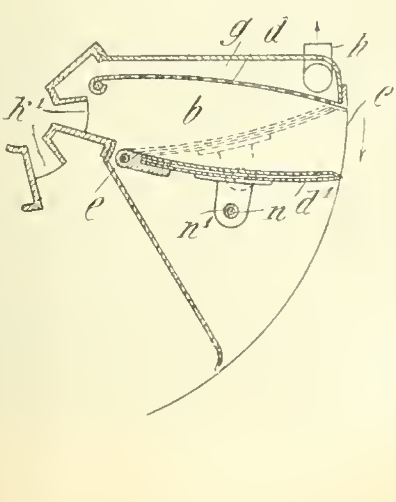

projection has passed, the valve is opened again by the action of the spring z. The projections n^5 and r^1 are so arranged that first the valve l is closed, then the side d^1 is opened, the solid discharged, and d^1 closed again, and last of all the valve l is opened again.—W. H. C.

Vacuum, Supplying an Absorbent, and Preventing Back Atmospheric Pressure; Apparatus for Producing a ——. O. Imray, London. From C. W. Stanton, Mobile. Eng. Pat. 5791, March 9, 1904.

Water or other suitable liquid from an overhead supply tank is passed down a vertical pipe, having a side tube which is connected to the apparatus in which a vacuum is to be created. The vertical pipe enters the bottom of an open-mouthed vessel, having an overflow pipe high up at the side. The flow of liquid from the overhead vessel to the bottom of the vessel down below, produces the vacuum by exhaustion through the side tube, and the liquid accumulated in the lower vessel, is of such a nature as to act as an absorbent.—W. H. C.

United States Patents.

Apparatus for Operating on [Purifying, &c.] Finely-divided Fluids or Solid Materials. J. Luhne, Aix-la-Chapelle. U.S. Pat. 757,757, April 19, 1904.

See Fr. Pat. 330,322 of 1903; this J., 1903, 1078.—T. F. B.

Heating or Cooling Liquids; Apparatus for ——. G. Braselmann, Darmstadt, and F. Lünnemann, Ruhrort. U.S. Pat. 758,045, April 26, 1904.

An agitator, with blades like those of a ship's propeller, is rotated by a hollow shaft in the liquid. The blades are hollow, and divided into two chambers by a partition. Through the hollow shaft a heating or cooling agent is admitted, through suitably placed openings, into the blades and caused to circulate in them. Means are provided for supplying and exhausting the circulating agent and for rotating the shaft.—L. F. G.

Steam-Condenser. O. H. Mueller, Berlin. U.S. Pat. 758,090, April 26, 1904.

The apparatus consists of a combination of jet-condensers, the first having a steam-inlet opening and a steam-outlet opening, whilst the steam-inlet of the second is connected to the steam-outlet of the first jet-condenser. A jet-device delivers cold water into the second condenser, and a second jet-device connected with the lower part of the second condenser discharges into the first. The condensers are otherwise unconnected, and an air-pump is connected to the second condenser.—L. F. G.

Filtration of Gases; Apparatus for the ——. G. C. Stone, Assignor to New Jersey Zinc Co., New York. U.S. Pat. 758,222, April 26, 1904.

The apparatus consists of a cylindrical drum with conical ends sloping outwards and each fitted with a gas inlet. The drum is divided into several compartments by conical diaphragms sloping upwards with a central hole, above these being placed screens on which is piled loose material. A deflecting plate in each screen protects the aperture in the diaphragm, and the spaces between the diaphragms and screens constitute liquid reservoirs and are provided with outlet pipes.—L. F. G.

Solutions; Process of Preparing Highly-diluted ——. E. Joseph, Berlin. U.S. Pat. 758,450, April 26, 1904.

The substances are dissolved in an appropriate solvent, and an indifferent salt added, which is soluble in the solvent, and of a higher specific gravity than water. The mixture is then poured into a great quantity of water containing a substance which is decomposed by the solvent mentioned above whilst chemically indifferent to the substance to be dissolved, an indifferent gas being obtained as the result of the action of the solvent on the substance dissolved in the water.—L. F. G.

French Patents.

Powder or Small Crystals from Saturated Solutions; Apparatus and Process for Obtaining Impalpable Crystalline ——. G. Ostini and A. Orlandi. Fr. Pat. 337,614, Oct. 14, 1903.

A continuous alternating or intermittent motion is imparted to the liquid, whilst it is being evaporated, by means of a paddle wheel and baffles placed in the evaporating tank. —W. H. C.

Fire-extinguishing Product; Manufacture of ——. M. Eberhardt. Fr. Pat. 338,076, Nov. 4, 1903.

Stated proportions of wheat starch, magnesium sulphate, sodium bicarbonate, sodium chloride, and water are mixed, a relatively large proportion of water is added, and, with active stirring, a solution of sodium silicate and another of calcium and magnesium chlorides. The mixture is completed for use by the addition of calcium phenate.—E. S.

Anti-Incrustant. A. Bonnotte. Fr. Pat. 337,796, Dec. 16, 1903.

A mixture of borax and potato starch with a small quantity of molasses and colouring matter in water. —W. H. C.

Evaporating Liquids, particularly those which Crystallise; Process and Apparatus for ——. E. N. Trump. Fr. Pats. 337,931 and 337,932, Dec. 22, 1903.

See U.S. Pats. 743,351 and 743,352 of 1903; this J., 1903, 1285.—T. F. B.

Drying, Decomposition, Absorption of Gases, &c.; Process for the Treatment of Substances, e.g., ——. E. N. Trump. Fr. Pats. 337,933 and 337,934, Dec. 22, 1903.

See U.S. Pats. 748,893 and 748,894 of 1904; this J., 1904, 111.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Peat Gas Works for Large Central Electric Power Stations. A. Frank. Z. angew. Chem., 1904, **17**, 289—296.

Since the author discussed this matter some years ago (this J., 1897, 663; 1898, 651), great progress has been made in the development of large gas-engines capable of being worked with low-grade gases; and in the distribution and transformation of electric currents of high potential. Generator-gas obtained from peat is stated as quite suitable for use in large gas-engines; and works are already

——		Fibrous Peat.	Pressed Peat.	Fibrous Peat.	Pressed Peat.
Percentage of water in the peat		25	22	24	36
Composition of the peat	Carbon	57·8	61·2	58·5	61·0
	Hydrogen	6·8	6·1	6·0	6·3
	Oxygen	34·0	30·6	33·3	30·6
	Nitrogen	1·4	2·1	2·2	2·1
Grate surface of the generators in sq. m.		0·0	2·64	0·84	1·6
Total capacity of the generators in cb. m.		22·8	22·4	1·9	21·9
Daily consumption of fuel in each generator		6262	7256	1495	8446
Number of times generator is filled in 24 hours		1·3	2·7	3·5	1·1
Temperature of the outflowing gases, C.		100	78	500	105
Yield of tar, calculated on the dry substance of the fuel, free from ash, per cent		3·4	..	..	8·5
Composition of the tar.	Carbon	79·6	..	..	79·8
	Hydrogen	9·3	..	..	9·2
	Oxygen	11·1	..	..	9·6
	Nitrogen		..	..	1·4
Composition of the generator gas.	Carbon dioxide	6·6	7·1	5·4	6·8
	Carbon monoxide	29·6	21·5	25·5	27·6
	Ethylene	0·7	0·4	0·3	0·4
	Methane	4·0	5·6	6·4	3·75
	Hydrogen	5·3	7·1	5·2	12·3
	Nitrogen	53·8	58·3	59·2	49·15

in operation in Germany and Sweden. Lürmann gives the foregoing figures with regard to the production of gas from peat in generators.

An important point is that for the production of peat-gas in generators, peat containing 45—50 per cent. of water can be used. 100 kilos. of peat yield about 250 cb. m. of gas having a calorific value of 1,200—1,400 cals. per cb. m. The author recommends the erection of a large central electric-power station at the place where the peat is found. On the assumption that 4 cb. m. of peat gas are consumed per h.p.-hour, it is calculated that for the production of 10,000 h.p. (*e.g.*, four large gas-engines, each of 2,500 h.p.), the yearly consumption of peat would be 96,000 tons, an amount which could be furnished for 60 years by a peat moor having an area of 7 sq. kilom. The use of peat-gas in this way would be specially advantageous in localities where lime also is found, the electric power produced being used in the manufacture of calcium carbide, and the latter being then employed as raw material for the production of calcium cyanamide by the aid of atmospheric nitrogen (see this J., 1903, 794, 809). With a central station capable of furnishing 10,000 h.p., 40 tons of calcium carbide could be produced in 24 hours, whilst by every 100 parts of carbide, 25 parts of atmospheric nitrogen could be fixed, with the production of 125 parts of calcium cyanamide containing 20 per cent. of nitrogen.—A. S.

Lamp; New Variety of Mercury Vapour Electric ——. H. Paweck. Z. Elektrochem., 1904, **10**, 297.

The progress of the mercury vapour lamp up to the present is briefly reviewed. The extreme greenness of the light can be mitigated by using amalgams, *e.g.*, of potassium, whereby red lines are introduced into the spectrum. The problem of starting the lamp by means of a momentary short circuit has been approached on three lines: (1) by bringing the electrodes together mechanically; (2) by causing a metallic film (when amalgams are used) to separate on the glass when cold; (3) by heating one electrode from outside and thus connecting the two through the condensed mercury. The author proposes a new lamp of the first variety, which is kept rotating whilst in action; the electrodes are in contact when at rest, and are kept asunder by centrifugal force during rotation.—W. A. C.

Sulphur in Oils, Bituminous Substances, Coal, and Similar Bodies; Determination of ——. E. Graefe. XXIII., page 563.

English Patents.

Fuel; Manufacture of Artificial ——. S. L. Gregor, F. C. Yeo, H. C. B. Forester, all of Swansea. Eng. Pat. 7871, April 6, 1903.

HE fuel consists of 5—6 per cent. by weight of gas-tar itch, about 2—3 per cent. of gas-tar, and 91—93 per cent. f bituminous or semi-bituminous coal. If more than 8 per ent. of pitch be used, the proportion of tar must be kept etween 1 and 2 per cent., and if more than 10 per cent. of itch be used, the tar added should not exceed 1 per cent. weight. Another suitable composition consists of 1—2 er cent. by weight of creosote oil, 5—7 per cent. of pitch, id 93—92 per cent. of crushed coal. The aforesaid ma- rials are thoroughly mixed together, and heated in a pug- ill by superheated steam to 700°—800° F., and the liquid ixture then cooled before passing to the presses. The oling may be effected by passing the mass by means of an rchimedean screw through a horizontal trough, the hot air ing exhausted by a fan at one end, whilst cold air is own in at the other end. After cooling, the mass is essed into briquettes.—L. F. G.

rnaces; Pulverised Fuel ——. W. W. Weaver, Chicago. Eng. Pats. 18,787 and 18,788, Sept. 1, 1903.

WDERED coal is supplied from a hopper to a feed-valve, ich consists of a drum with spiral pockets revolving in a sing, and which feeds the coal-dust gradually and con- uously into a pipe leading to the furnace. Air pre- ted to about 400° or 500° F. by passing through a pipe ng in the furnace, is blown into the coal-feed tube, and injects the coal-dust into the combustion chamber. The discharge ends of the feed tube are conical and flattened, and surrounded by a conical casing through which sufficient cold air is admitted to keep them from burning. The mixture of hot air and coal-dust thus blown into the furnace, impinges on an arch of firebrick kept incandescent by the burning fuel, and ignites; the fine coal-dust is immediately burnt, whilst the heavier particles of coal become coked and fall on to the grate, where they then undergo complete combustion. The furnace is provided with a regulating damper, and means are provided for cleaning out the tubes of the boilers with compressed air. —L. F. G.

Coal, Ores, and other Minerals; Method of and apparatus for Treating ——, *for draining them of Water.* F. Baum, Herne. Eng. Pat. 2485, Feb. 1, 1904.

A transporting belt carrying perforated draining buckets is made to pass slowly beneath the surface of a large body of quiescent water, through which the washed coal, &c., falls into the buckets. The buckets are gradually raised above the surface and the water drains away. The water level is kept constant by means of an overflow, and the fine sludge falls into pockets at the bottom, is lifted, and again discharged along with fresh-washed coal. A shield is provided to deflect this fine sludge to the sides away from the returning belt.—W. H. C.

Gas-Producers. R. M. L. Rowe and R. Bickerton, Manchester. Eng. Pat. 9818, April 30, 1903.

To eliminate tarry matters from producer-gas, the latter is passed through a pipe or retort, heated externally, containing incandescent coke or the like. The retort may be arranged vertically in the centre of the producer itself, having its inlet within the latter; or it may be arranged horizontally or vertically in a separate heating furnace.—H. B.

Lime and Fuel Gas; Method of, and Apparatus for the Manufacture of ——. R. Pearson, London. Eng. Pat. 10,624, May 9, 1903.

Chalk or limestone, fuel, and steam are continuously supplied to a kiln, the gaseous products from which are passed into converters regeneratively heated, in which converters the greater part of the carbon dioxide is transformed into carbon monoxide and the steam into water-gas. The waste heat of the incombustible gases resulting from the reheating of the converters is utilised in heating the steam supply to the kiln, as well as for drying the raw material and the fuel. The heat of the converted gases is utilised by passage of the gases through the boiler in which the steam is generated. Part of the air heated in the regenerators is used to ensure the complete combustion of the gases escaping from the converters. Reference is made to Eng. Pat. 3347 of 1903; this J., 1904, 316.—E. S.

Combustible Gases from Volatile Liquid Hydrocarbons; Apparatus for Producing ——. F. Jas, Paris. Eng. Pat. 13,206, June 12, 1903.

A horizontal carburetting cylinder is divided transversely into three chambers, in the first of which there rotates a horizontal shaft on which four helicoidal coils of pipes are wound. One end of each pipe is open, whilst the other communicates with a hollow portion of the shaft. The cylinder is filled to a certain level with volatile hydrocarbon drawn from a reservoir overhead, the level in the cylinder being maintained by means of a float-valve arranged in the third chamber. As the shaft rotates, the free ends of the pipes dip successively into the hydrocarbon; air and liquid are thus forced through the coils and emerge from the hollow portion of the shaft into the second chamber, where the unvolatilised hydrocarbon is separated from the carburetted air, which is led off for use.—H. B.

Gas; Apparatus for the Purification of ——. F. Jas, Paris. Eng. Pat. 13,222, June 12, 1903.

The apparatus is similar to that referred to in the preceding abstract, excepting that the third chamber and overhead reservoir are omitted. The apparatus is filled with water to a certain level, the gas to be purified is admitted to the first chamber, and, as the shaft rotates, water and gas alternately are forced along the coils, entering the second chamber, where the washed gas separates from the water, under pressure.—H. B.

Coal-Gas; Process for the Recovery of the Residual Products Obtained in the Purification of ——. H. Gutknecht, Zürich. Eng. Pat. 9396, April 25, 1903.

See Fr. Pat. 324,767 of 1902; this J., 1903, 620.—T. F. B.

United States Patents.

Retort Coke-Oven. A. C. Kloman, Assignor to W. M. Scott, both of Saxton. U.S. Pat. 757,469, April 19, 1904.

The horizontal bottom of each retort is composed of two sections, hinged together and supported on the pivot principle, and means are provided for raising the hinged portion, so that each section is swung into an inclined position, whereby a fulcrum is formed for breaking up the cake of coke. One section has a fixed pivot, whilst the other is pivoted on wheels which run on tracks when the hinged portion is pushed up. A portion of the oven flues is arranged in the movable bottom.—H. B.

Retort Coke-Oven. W. M. Scott, Saxton. U.S. Pat. 757,509, April 19, 1904.

The bottoms of the coke-ovens are mounted on the pivot principle, and are adapted to be swung upon their mountings by means of a beam carried on a truck which travels in a passage-way below the ovens. Compare preceding abstract.—H. B.

Gas; Apparatus for Making ——. P. Naef, New York. U.S. Pat. 753,296, March 1, 1904.

Several generators are connected together in series, either with or without the interposition of superheating stoves, and the end generator communicates with a tubular cooler and a scrubbing plant. The plant may be operated in various ways, according to the object aimed at. Water-gas may be produced by means of the usual intermittent process. If the by-products are of considerable value, the raw fuel may be charged only into the last producer, so that unnecessary heating of the volatile products is avoided; the coke formed can then be charged into the earlier producers. If, on the other hand, it is desired to convert the tarry matters of bituminous fuel into permanent gases, the raw fuel is charged into the earlier generators, and the coke produced is transferred to the later ones. The air supplies may be heated by circulation through the tubular cooler. —H. B.

Calcium Carbide; Process of Producing ——: also Electric Heating; Process of ——. W. S. Horry, Assignor to Union Carbide Co. U.S. Pats. 757,617—757,620, April 19, 1904. XI. A., page 548.

Electric Furnace. W. S. Horry and E. F. Price, Assignors to Union Carbide Co. U.S. Pat. 757,621, April 19, 1904. XI. A., page 548.

French Patents.

Fuel Blocks. Soc. Chavoise, Jäger et Cie. (des procédés Cadoret). Fr. Pat. 337,771, Dec. 16, 1903.

The fuel is made by mixing 1 part of resin with 1 part of tar, and adding to the molten mass 1 to 5 parts of coal dust, dried leaves, or other vegetable refuse, one-half to 5 parts of a nitrate (such as potassium or sodium nitrate), 1 to 3 parts of nitrocellulose, and one-half to 2½ parts of crude camphor, which last two ingredients may be replaced by 1½ to 5½ parts of celluloid waste.—L. F. G.

Combustible [Briquettes]; Manufacture of a —— burning without Smoke, or with little Smoke. Hildesheimer Sparherd Fabrik A. Senking. Fr. Pat. 337,801, Dec. 16, 1903.

'Fatty' or 'meagre' [anthracitic] coal, coke, or lignite, are powdered, and mixed together, if necessary with the addition of an agglutinant, and pressed into briquettes. —L. F. G.

Gas Producer [Suction]. G. Viarmé. Fr. Pat. 337,974, Dec. 23, 1903.

A mixture of air and steam is aspirated from an annular superheater into the fuel near the lowest part of the producer, and the gas produced is withdrawn through a series of lateral orifices provided in the periphery of the producer, midway up the column of fuel. Each orifice communicates, by a separate pipe, with the off-take main at the top of the apparatus, and by means of a fixed perforated plate, covered by a rotating perforated slide, arranged between the main and the smaller pipes, each of the latter is successively placed in open communication with the main. The effect is that the gas produced is withdrawn through each of the lateral orifices in succession, and unequal consumption of the fuel is prevented. On raising the slide the gas may be drawn off from all the orifices simultaneously. The uniform consumption of the fuel permits of the use of the plant for gas engines of high powers.—H. B.

Carbon Dioxide in Furnace Gases; Method and Apparatus for the Determination of ——. A. Schlatter and L. Deutsch. Fr. Pat. 337,992, Dec. 24, 1903. XXIII., page 561.

Magnesium Carbides; Direct Manufacture of —— from Carbon and Oxides or Carbonates of Magnesium. H. Auziès and A. Ségoffin. Fr. Pat. 337,878, Nov. 11, 1903.

Magnesium oxide or carbonate is heated with carbon to about 3,000° C., in an electric furnace, to obtain magnesium carbide, to which the formula MgC_2 is attributed; when decomposed by water it is stated to yield more acetylene than calcium carbide. Dolomite may be similarly heated with carbon to obtain a calcium-magnesium carbide.—E. S.

Incandescence Lighting with Gas Generated by Aluminium Alloys. N. A. Helouis, L. Manclaire, and E. Meyer. Fr. Pat. 337,722, Dec. 14, 1903.

Hydrogen is generated by the action of aluminium-zinc, or aluminium-zinc-sodium, on a dilute solution of caustic soda the gas is carburetted in any suitable manner, and is burne in conjunction with an incandescence mantle. Compar Fr. Pat. 335,954; this J., 1904, 325.—H. B.

Carbons; Mineralised —— for Arc Lamps, for Regulating their Light. A. Blondel. Fr. Pat. 338,049, Oct. 2 1903. Under Internat. Conv., Oct. 24, 1902.

See Eng. Pat. 23,262 of 1902; this J., 1904, 112.—T. F.

Arc Lamp with Osmium Electrodes. Comp. Général d'Électricité. Fr. Pat. 337,927, Dec. 22, 1903.

Arc lamps are provided with electrodes of osmium, opera ing in an atmosphere of inert gas. The electrodes ma be obtained, for example, by producing an arc betwee carbon electrodes in an atmosphere of osmic acid, by mea of an alternating current. The osmium is deposited on t hottest parts of the electrodes in the form of extremely ha metallic pellets.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM AND MINERAL WAXES.

Petroleum Acts. Home Office Memorandum, May, 190

It has recently come to our knowledge that attempts being made by officers of Local Authorities to apply legal test for petroleum to samples of liquid metal-poli and we have satisfied ourselves by experiment that the results thus obtained are sometimes entirely misleading, as they do not represent the temperature of the portion of the liquid from which inflammable vapour is being evolved.

In carrying out the test prescribed in the Petroleum Act, 1879, the sample under examination is slowly heated in a closed cup, and the temperature is indicated by a thermometer the bulb of which is immersed in the liquid in the centre of the vessel. In these circumstances the heat communicated to the sample through the walls of the cup creates in such a liquid as petroleum convection currents, and through the circulation thus set up the temperature of the contents of the cup is equalised and the thermometer correctly indicates the temperature at which inflammable vapour is evolved by the liquid.

On the other hand, if the sample contains solid matter in suspension, as is the case with the liquid metal-polish in question, the formation of convection currents is interfered with, and the surface of the liquid from which inflammable vapour is evolved acquires a higher temperature than that of the portion in contact with the bulb of the thermometer. Thus, as we have ascertained experimentally, the thermometer may indicate a temperature of 59° F. when the temperature of the surface is 83° F., and a sample may be erroneously reported as having a flash point below the legal limit of 73° F. when the true flash point is far above the limit.

No doubt this would have been provided for when the Act was passed if at that time the need for applying the test to such substances had been foreseen, but it was not until judgment in the case of the London County Council *v.* Holtzapfel's Compositions Co., Ltd., was given in 1899 that mixtures containing petroleum were held to be petroleum within the meaning of the Acts.

In our handbook on petroleum published in 1901, we referred on page 90 to the necessity for a stirrer in the oil cup when the test specified in the Petroleum Act is employed for the testing of paints and other substances containing petroleum, and when opportunity occurs for a revision of the law this addition will doubtless be legalised.

We are, however, of opinion that in the meantime authorities charged with the administration of the Petroleum Acts should be made aware of the circumstances we have referred to, and that testing officers should take steps to ascertain the true flash point of samples of liquid metal polish or other substances which are not thoroughly liquid, and therefore cannot be satisfactorily tested in precise accordance with the directions given in the schedule to the Act. In many instances it may be possible to obtain a sample of the petroleum used in the substance, or the solid matter present in the sample can be removed by straining or filtration, care being taken to avoid loss of the more volatile constituents by evaporation, when the separated liquid can be tested in the prescribed manner. The liquid should not, however, be separated by distillation, as this operation may yield a distillate of lower flash point than that of the petroleum with which the mixture was made. For guidance in determining whether there has been any infraction of the law, the sample may also be tested in an apparatus provided with an efficient stirrer. In any case of doubt as to the true flash point of the material, we would suggest that reference should be made to H.M. Inspectors of Explosives, at the Home Office, who will be prepared to give advice as to the course which should be adopted.

(Signed) J. H. Thomson,
Captain, H.M. Chief Inspector of Explosives.
(Signed) Boverton Redwood,
Adviser on Petroleum to the Home Office.

"Asphalts"; Examination of ——. E. Donath and B. M. Margosches. Chem. Ind., 1904, **27**, 220—226.

In consequence of the appearance of Lunge and Krepelka's article (this J., 1904, 436), the authors publish some preliminary results of an investigation. They find that successive extractions of the product with light petroleum spirit (petroleum ether), benzene, and carbon bisulphide give useful indications as to its nature. For distinguishing between individual products, the following method is recommended: 10—15 grms. are subjected to dry distillation.

—		Petroleum Spirit Extract.	Benzene Extract.	Carbon Bisulphide Extract.	Residue.
		Per Cent.	Per Cent.	Per Cent.	Per Cent.
Coal-tar pitch	Soft	25·05	44·98	6·57	22·82
	Medium	15·14	49·03	7·10	38·06
	Hard ..	15·51	39·86	15·21	29·39
Lignite-tar pitch	Soft	81·30	15·50	0·70	2·60
	Hard ..	11·90	86·50	0·30	1·80
Petroleum pitch	Soft	68·50	28·50	1·50	1·50
	Hard ..	59·00	27·00	4·50	9·00
Sicilian asphaltum...		7·80	3·70	0·30	88·20

In the case of wood-tar pitch, a small quantity of a strongly acid aqueous liquor is obtained on which an oily layer floats. A confirmatory test for wood-tar pitch is that, when treated with carbon tetrachloride, the latter is scarcely coloured. In the case of coal-tar pitch the oily distillate dissolves completely in absolute alcohol and glacial acetic acid. Coal-tar pitch also always contains anthracene, which can be recognised by oxidising it to anthraquinone by means of chromic acid, and testing for the latter by Liebermann's reaction (production of intense red coloration by boiling with caustic soda solution and zinc dust). If the distillate does not give a clear solution with alcohol and glacial acetic acid, the product may be lignite-tar pitch, petroleum pitch, asphaltum, or a stearine pitch. A portion of the original product is boiled for some time with alcoholic potash, and the hot liquid filtered. In the case of wool-fat pitch, a fairly abundant precipitate forms on cooling, which gives the cholesterol reactions. In the case of stearine pitch no separation, as a rule, takes place, but on evaporating the alcohol and treating with dilute hydrochloric acid, the fatty acids separate. Natural asphaltum, when treated with alcoholic potash, colours the liquid only slightly at first, but more intensely after some time; lignite-tar pitch colours the liquid immediately; and petroleum pitch gives either no coloration at all or an extremely weak one. The behaviour on successive extractions with petroleum spirit, benzene, and carbon bisulphide also affords a means of distinguishing between lignite-tar pitch, petroleum pitch, and asphaltum. In the case of the last-named, the insoluble residue consists entirely of inorganic mineral matter. In practice the most common form of adulteration is the addition of coal-tar pitch to natural asphaltum. The authors recommend extraction of the product successively with petroleum spirit, benzene, and carbon bisulphide. If the sample be pure natural asphaltum, the insoluble residue will consist entirely of inorganic mineral matter. If coal-tar pitch be present, the residue will be black and will give a brownish-red solution with concentrated nitric acid. The presence of anthracene and the production of a coloured fluorescent solution with methyl or ethyl alcohol or chloroform yield additional evidence of the presence of coal-tar pitch.—A. S.

Pyridine Bases in Ammonia and Aliphatic Amines; Determination of ——. J. Milbauer and V. Staněk. XXIII., page 563.

Sulphur in Oils, Bituminous Substances, Coal, and Similar Bodies; Determination of ——. E. Graefe. XXIII., page 563.

English Patent.

Destructive Distillation; Recovery of By-Products in Processes of ——, *and Apparatus therefor.* The Otto-Hilgenstock Coke-Oven Co., Ltd., London. From C. Otto and Co., Dalhausen a/Ruhr. Eng. Pat. 16,005, July 20, 1903.

The condensing pipe of an apparatus such as a coke-oven or gas-retort is inclined upwards, and is of such a length that the products which condense above 70° C., or thereabouts, flow back along the tube, towards the retort, meeting the hot ascending gases; in this way a more effective separation of the products is obtained.—T. F. B.

UNITED STATES PATENT.

Wood; Apparatus for the Distillation of —— and Production of Charcoal. H. A. Mackie, Assignor to E. E. Wood, New Orleans. U.S. Pat. 757,939, April 19, 1904.

A LONG inclined retort, set in a charcoal kiln, is provided with doors at each end, and with a liquid-discharge pipe at its lower end, and a vapour-discharge pipe leading from the top of its lower end to a condensing tank. The charcoal kiln is provided with air inlets, and with a discharge pipe, with which a fan communicates.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

p-Phenylenediamine; New Base from ——. L. Paul. Z. angew. Chem., 1904, **17**, 589—591.

CERTAIN samples of impure *p*-phenylenediamine are converted on keeping into a blue or bluish-brown basic dyestuff, or into an insoluble black base, ammonia being formed. A sample which had undergone partial transformation consisted of *p*-phenylenediamine, an intermediate product easily soluble in water, and a black powdery base, insoluble in water, but soluble in hydrochloric acid. The solution can be diazotised and then couples with amines and phenols. The hydrochloric acid solution of the new base dyes unmordanted cotton in bluish-brown, tannined cotton in bluish-black, and wool in brownish-black shades. Unmordanted cotton, after being dyed with the new base, shows considerable affinity for ordinary basic dyestuffs. The new base can also be diazotised on the fibre. With fuming sulphuric acid it yields a sulphonic acid which dyes wool in brown shades. The brown soluble intermediate product forms the new base when its aqueous solution is evaporated or allowed to stand a long time. The new base is also formed if an aqueous solution of *p*-phenylenediamine containing hydrochloric acid is evaporated, also if an aqueous solution of *p*-phenylenediamine and common salt is boiled. In all cases where the new base is formed on evaporation, an insoluble violet dyestuff, soluble in hydrochloric acid, is formed on boiling in an open vessel.
—E. F.

Rosaniline; Root Carbinol of —— and its Isomers. A. Bistrzycki and J. Gyr. Ber., 1904, **37**, 1245—1253.

THE authors have prepared diphenyl-*o*-tolylcarbinol from *o*-toluic acid methyl ester by Grignard's method (Ber., 1904, 663). It is readily reduced to the corresponding methane, which is not identical with the isomer obtained from Rosaniline. From *m*-toluic acid methyl ester they have obtained a carbinol, presumably diphenyl-*m*-tolyl carbinol, which is entirely different from that obtained by E. and O. Fischer (Ber., 1876, 899) by elimination of the amino groups from leucaniline and oxidation of the diphenyltolylmethane so formed. On reduction it yields a methane which is seemingly identical with that obtained from leucaniline, but on careful oxidation the original isomeric carbinol is re-formed. The authors point out that the diphenyltolylmethane obtained by Hemilian, by oxidising the condensation product of diphenylcarbinol and *p*-xylene, reducing in alkaline solution, and splitting off carbon dioxide, is probably identical with the compound obtained from leucaniline (Ber., 1883, 2368).—E. F.

Quinone-di-imide. R. Willstätter and E. Mayer. Ber., 1904, **37**, 1494—1507.

THE authors obtain quinone-di-imide, $NH : C_6H_4 : NH$, by treatment of quinonedichloro-di-imide with dry hydrochloric acid gas in ethereal solution according to the equation $NCl : C_6H_4 : NCl + 4HCl = NH : C_6H_4 : NH . 2HCl + 2Cl_2$. The dihydrochloride first obtained yields the base on treatment with dry ammonia in ethereal solution. The base is mono-molecular and very unstable, unless very pure, when it is much more stable. It readily polymerises with explosive violence, also on standing for some days in the air. With aromatic amines and phenols it at once forms indamines and indophenols. On warming with dilute mineral acids it is hydrolysed to quinone and ammonia. Aqueous and alcoholic solutions rapidly darken in colour, with formation of a substance closely resembling tetraminodiphenyl-*p*-azo-phenylene.—E. F.

Indophthalone. C. Renz. Ber., 1904, **37**, 1221—1225.

WHEN 2 mols. of α-methylindole are heated to 150°—160° C. with 1 mol. of phthalyl chloride, indophthalone hydrochloride, $C_{26}H_{20}N_2O_2 . HCl$, is formed, with evolution of hydrochloric acid, according to the equation $2C_9H_9N + C_8H_4O_2Cl_2 = C_{26}H_{20}N_2O_2 + 2HCl$. The product is a red powder, from which sodium carbonate liberates the base $C_{26}H_{20}N_2O_2$, a brick-red precipitate, readily soluble in alcohol and in chloroform. Indophthalone has also the properties of a weak acid, and forms a well-defined potassium salt. A product, which is either identical with, or an isomer of indophthalone, is obtained by heating 2 mols. of α-methylindole with 1 mol. of phthalic anhydride to 185—190° C., but the yield is in this case small.—E. F.

Dyestuffs from Quinoline-α-carbonic Acids; New Class of ——. [Quinoline Dyestuffs.] E. Besthorn and J. Ibele. Ber., 1904, **37**, 1236—1243.

IF quinaldinic acid be heated to 140° C. with acetic anhydride a red dyestuff is formed, with evolution of carbon dioxide. The substance is extremely sensitive to light, being rapidly decolorised. Its absorption spectrum shows two absorption bands, one in the yellow, the other in the green portion of the spectrum. It has only very weak basic properties and only very slight affinity for the fibre, dyeing silk from alcoholic solution in pale salmon-red shades, with slight greenish-yellow fluorescence, very fugitive to light. The dyestuff is completely destroyed by weak oxidising agents, even by cold dilute nitric acid. It is relatively stable tawards reducing agents, and seems to form no leuco compound. The acetic anhydride in the above reaction may be replaced by benzoic anhydride or the anhydrides of other organic monocarboxylic acids. Anhydrides of dicarboxylic acids, such as phthalic and succinic acids, do not effect the reaction, which seems to apply to quinoline-α-carboxylic acids in general, but not to picolinic acid and other pyridine derivatives.—E. F.

Dyestuffs for Wool; New Classes of —— and New Reactions of Aldehydes. M. Prud'homme. Rev. Gen. Mat. Col., 1904, **8**, 129—130.

IT has been shown (this J., 1900, 729) that when acid solutions of dyestuffs, leuco-bases, or chromogens containing amino groups are treated with formaldehyde and sodium bisulphite, acid dyestuffs are obtained. If sodium hydrosulphite be used instead of sodium bisulphite, another class of dyestuffs is produced. Magenta and Acid Magenta, when decolorised with sodium hydrosulphite, treated with a mineral acid and formaldehyde, and then heated, give new violet-red dyestuffs. When no formaldehyde is used, orange dyestuffs are formed. On heating the diazo derivatives of certain basic dyestuffs, substituted primary amines, or diamines with sodium hydrosulphite, other acid dyestuffs are obtained. When a solution containing 0·5 grm. of Magenta, 2 grms. of hydrochloric acid, and 500 c.c. of water is diazotised in the ordinary way, 12 grms. of sodium bisulphite solution of 35° B. added, and the mixture left to stand for 24 hours, the solution turns orange. If it be heated on a water-bath to 60° C. and 12 grms. of hydrochloric acid of 21° B. added and again heated, the liquid turns deep violet and dyes wool a prune shade. The leuco-base formed on the condensation of diphenylcarbinol and *m*-sulphanilic acid, oxidised with lead dioxide, diazotised, and treated with sodium bisulphite and hydrochloric acid, gives a green fast to alkalis. Under the same conditions nitranilines give a pale yellow and benzidine an orange dyestuff. Better colours are obtained if, immediately after the addition of the sodium bisulphite and acid, aldehyde or a sugar be added, the hydrazines, formed by the action of the bisulphite and acid on the diazo bodies, probably giving hydrazones and osazones. Treated thus Magenta gives a much bluer shade, and *p*-Nitraniline Yellow, which is only a pale colour, dyes a full orange. If in the above cases the sodium bisulphite be replaced by sodium hydrosulphite, new colours with different and brighter shades are produced. When diazotised Magenta or Acid Magenta is acted on by benzaldehyde and sodium hydrosulphite, a pure blue is formed, that from the Magenta being only slightly soluble, and the one from the Acid Magenta quite soluble.

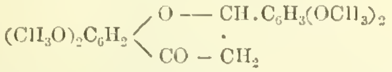
New Reactions for Aldehydes.—Schiff's reaction for aldehydes is much more delicate when the Magenta is decolorised with sodium hydrosulphite or bisulphite instead of with sulphur dioxide.—R. S.

Quercetin; Synthesis of ——. St. v. Kostanecki, V. Lampe, and J. Tambor. Ber., 1904, **37**, 1402—1405.

2′-Hydroxy-4′.6′.3.4-tetramethoxychalkone—

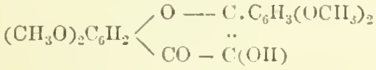
$$(CH_3O)_2(OH)C_6H_2.CO.CH:CH.C_6H_3(OCH_3)_2$$

is converted by boiling with dilute hydrochloric acid into 1.3.3′.4′-tetramethoxyflavanone—



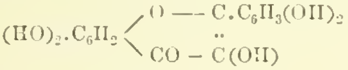
$$(CH_3O)_2C_6H_2\begin{cases}O - CH.C_6H_3(OCH_3)_2\\ \qquad\quad \cdot\\ CO - CH_2\end{cases}$$

This is converted into an isonitroso-derivative, which yields with dilute mineral acids 1.3.3′.4′-tetramethoxyflavonol—



$$(CH_3O)_2C_6H_2\begin{cases}O - C.C_6H_3(OCH_3)_2\\ \qquad\quad \cdot\cdot\\ CO - C(OH)\end{cases}$$

This is completely demethylated by hydriodic acid, forming quercetin—



$$(HO)_2.C_6H_2\begin{cases}O - C.C_6H_3(OH)_2\\ \qquad\quad \cdot\cdot\\ CO - C(OH)\end{cases}$$

Halogen Derivatives of Oxyanthraquinones; Manufacture of ——. [*Anthracene Dyestuffs.*] M. Iljinski, Krefeld, and R. Wedekind and Co., Uerdingen. Eng. Pat. 8503, April 14, 1903.

New halogen derivatives of *m*-hydroxyanthraquinone, anthraflavic acid, iso-anthraflavic acid, alizarin, flavopurpurin, and iso-purpurin are prepared by treating those substances in aqueous suspension with a halogen, or with a halogen compound adapted to allow the action of halogen in the nascent state in presence of an acid. The new products are very stable and can be sulphonated by means of fuming sulphuric acid without loss of halogen.—E. F.

Basic [*Acridine*] *Dyestuffs.* T. R. Shillito, London. From Aniline Colour and Extract Works, formerly J. R. Geigy, Basle. Eng. Pat. 11,882, May 25, 1903.

See Fr. Pat. 330,487 of 1903 and addition thereto; this J., 1903, 1082 and 1241.—T. F. B.

Anthracene Derivatives [*Nitro-amino-anthraquinones*]; *Manufacture of* ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld. Eng. Pat. 12,099, May 27, 1903.

See Fr. Pat. 332,321 of 1903; this J., 1903, 1241.—T. F. B.

Sulphurised [*Sulphide*] *Dyestuffs; Manufacture of* ——. O. Imray, London. From Soc. Anon. Mat. Col. et Prod. Chim. de St. Denis, Paris. Eng. Pat. 12,298, May 29, 1903.

See Addition, of May 19, 1903, to Fr. Pat. 292,400 of 1899; this J., 1903, 1241.—T. F. B.

Aniline Dyeing Compound. G. Rowland, Knoxville. Eng. Pat. 1502, Jan. 20, 1904.

An aqueous solution of a basic or neutral dyestuff is incorporated with a soap so as to form a hard cake readily soluble in water. Goods can be cleaned and dyed in one operation with this substance.—R. S.

French Patents.

Monazo Dyestuffs; Production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 338,103, March 9, 1903.

See Eng. Pat. 5269 of 1903; this J., 1904, 183.—T. F. B.

Sulphide Dyestuffs; Process for Preparing Black ——. Kalle et Cie. Fr. Pat. 337,278, Dec. 3, 1903.

By melting amino compounds of the benzene series and nitrophenols with alkali polysulphides, avoiding too rapid reduction of the nitro compound, dyestuffs are obtained which give black shades on cotton from a sodium sulphide solution. The dyestuff prepared from *p*-phenylenediamine and *o*-nitrophenol is described. The same class of dyestuff is also produced by melting benzene azo-*o*-nitrophenol or dinitrophenol with small quantities of sodium tetrasulphide.—T. F. B.

Tetrazo Dyestuffs, Dyeing Violet to Blue, derived from Aminonaphtholdisulphonic Acid 2.5.1.7; Production of New ——. [*Azo Dyestuffs.*] Soc. pour l'Ind. Chim. à Bâle. Fr. Pat. 337,891, Dec. 19, 1903.

See Eng. Pat. 28,033 of 1903; this J., 1904, 319.—T. F. B.

Azo Dyestuffs and Lakes produced therefrom; Preparation of New ——. Soc. Anon. F. Bayer et Cie. Fr. Pat. 337,942, Dec. 22, 1903.

Diazo derivatives of aminoanthraquinones or of aminoanthraquinone sulphonic acids are combined with naphthol sulphonic acids. Red to reddish-blue dyestuffs are so obtained of value for the production of lakes, fast to light, which are produced by dissolving, or suspending in water, an alkali salt of the dyestuff, and then adding a solution of a compound of calcium, barium, strontium, magnesium, aluminium, &c.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Azo Dyestuffs on Cotton; Action of Copper Sulphate on Direct ——. J. Mueller. Chem.-Zeit., 1904, **28**, 423.

According to the author, the theory of A. Scheurer on the protection of dyestuffs against sunlight by copper oxide, still remains intact. Observations made show that the copper sulphate acts chemically on the direct azo dyestuffs on treating for some time with this salt after dyeing. A copper salt is formed with the dyestuff, the copper going, in the first place, into the sulpho group, and, in the second, into the hydroxyl groups. When sulpho and hydroxyl groups are found in the same molecule, the copper can, under certain conditions, go into both groups. —R. S.

"*Crude Fibre*"; *Preparation* [*Determination*] *of* —— *from Vegetable Fibres containing Lignin, by means of Sodium Peroxide.* A. Duschetschkin. XXIII., page 563.

Engraving Rollers for Calico and Carpet Printing; Employment of Photography in ——. P. J. Lamp'l. XXI., page 560.

English Patents.

Dyeing Sliver and other Textile Fibres: Apparatus for ——. H. H. Lake, London. From D. Mattei, Genoa. Eng. Pat. 6731, March 23, 1903.

See Fr. Pat. 334,681 of 1903; this J., 1904, 115.—R. S.

Cops, Cheeses, or the like; Machine for Dyeing, Scouring, Bleaching, or Treating with Liquids, Textile Fibres in the form of ——, *without Perforated Broaches or Tubes.* R. Rawson and E. Lodge, Huddersfield. Eng. Pat. 10,035, May 4, 1903.

This machine consists of a frame made up of bars and cross-bars forming a number of recesses into which the cops or cheeses fit so as to close up all openings. A number of these frames are placed one above the other in a vessel, and the liquid is forced through them by means of a pump. —R. S.

Printing Fabrics with Indigo. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst-on-the-Maine. Eng. Pat. 13,116, June 11, 1903.

In printing indigo by the hydrosulphite method, strong caustic alkalis are substituted for the alkali salts previously used, and the hydrosulphite is displaced by one of the new aldehyde-hydrosulphite compounds described in Eng. Pat. 5867, March 13, 1903 (this J., 1904, 369). Good results are obtained as follows:—120 grms. of formaldehyde-sodium hydrosulphite compound are dissolved in 50 grms. of water at 40°—50° C., cooled, and slowly stirred into 500 grms. of alkaline thickening agent; to this is added 150 grms. of 10 per cent. indigo paste, mixed with 180 grms. of the thickening agent. The thickening agent can be made from 120 grms. of "gomme industrielle" dissolved in 430 grms. of hot water, and when cold 450 grms. of solid caustic soda added with continuous stirring. The cotton, bleached, or dyed with Turkey red, is printed with this mixture, dried, steamed in a Mather-Platt for 2—3 minutes at 100° C., then washed, whereupon the Indigo White oxidises to Indigo Blue, which, if necessary, is finally acidified and soaped.—R. S.

United States Patents.

Matting or Felting Fibres together; Method of ——. G. Goldman, Baltimore. U.S. Pat. 758,243, April 26, 1904.

A dry finely-divided binding material, such as gelatin, is introduced between the fibres, together with a hygroscopic substance capable of imparting moisture to it, *e.g.*, magnesium chloride; or, after the introduction of the gelatin, the material may be treated with a solvent of the latter. The fibrous material is then submitted to heat and pressure.—A. B. S.

Felting or Matting Fibres together; Process for ——. G. Goldman, Baltimore. U.S. Pat. 758,244, April 26, 1904.

A dry, finely-powdered mixture of a soluble soap and a metallic salt, such as alum, is introduced between the fibres; the material is then submitted to the action of steam and pressure, which cause the formation of an insoluble metallic soap, which binds the fibres together.—A. B. S.

Uniting or Matting Fibres together; Process for ——. G. Goldman, Baltimore. U.S. Pat. 758,245, April 26, 1904.

A dry, finely-divided mixture of a resin and of a metallic oxide, such as zinc oxide, is introduced between the fibres. On submitting the fibrous material to the action of heat and pressure, a metallic resinate is formed, which binds the fibres together.—A. B. S.

Uniting or Matting Fibres together; Process for ——. G. Goldman, Baltimore. U.S. Pats. 758,246 and 758,247, April 26, 1904.

Finely-divided resin alone, or mixtures of finely-divided resin and a metallic resinate, or of resin and a metallic soap, are introduced between the fibres; the material is then submitted to heat and pressure.—A. B. S.

Felting or Matting Fibres together; Method of ——. G. Goldman, Baltimore. U.S. Pat. 758,311, April 26, 1904.

Dry flour is introduced between the fibres together with a substance containing water of crystallisation, such as crystallised sodium carbonate. The material is then submitted to heat and pressure in the presence of steam. —A. B. S.

Dyeing Apparatus; Automatic ——. J. Marshall, Fall River. U.S. Pat. 757,478, April 19, 1904.

A horizontal cylindrical dye-vat is divided into compartments by perforated vertical plates. A shaft, supported approximately in the axis of the vat, carries forks or prongs at short intervals; the mechanism provided gives the shaft a wide-angle oscillating movement, so that the forks raise the goods to be dyed out of the liquor, keeping them out for a short time, and then return them to the liquor, and out of it again at the other extremity of their oscillations. Steam- and water-inlets and a vapour outlet are also provided. —T. F. B.

Sizing [for Textiles]. A. Müller-Jacobs, Richmond Hill, Assignor to Cosmos Chemical Co., New York. U.S. Pat. 757,948, April 19, 1904

A sizing, suitable for fibrous substances, consists of an amide of a higher fatty acid suspended in "a soluble magma having the property of keeping it in a finely-divided, discrete, and insoluble state."—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

Record Ink; Commonwealth of Massachusetts Specifications for a Standard ——. Commissioner R. F. Swan. Govt. Specif. Commonwealth of Massachusetts, U.S.A.

The following specifications were prepared by B. F. Davenport, and have been adopted by the Commonwealth of Massachusetts. The ink must be a gallotannate of iron ink, not inferior in any essential quality to a typical ink properly prepared according to the following formula, the ingredients being of the quality prescribed by the U.S.P., and the percentage of true acid in the tannic acid having been determined by the Loewenthal and Schroeder method. Typical ink:—Dry pure tannic acid, 23·4 parts by weight; crystallised gallic acid, 7·7; ferrous sulphate, 30·0; gum arabic, 10·0; dilute hydrochloric acid, 25·0; phenol, 1·0; and water sufficient to make up the mixture at the temperature of 60° F. to the volume of 1,000 parts by weight of water. The ink must not contain less iron than the typical ink, and must have a specific gravity of 1·035—1·040 at 60° F. A fluid ounce of the ink allowed to stand at rest in a white glass vessel, protected from dust, but freely exposed to the air, in diffused daylight for two weeks, at a temperature of 50°—60° F., must remain as free from deposit as the typical ink under similar conditions. It must be as fluid, flow as well, and develop its colour as quickly as the typical ink, and must not penetrate the paper more readily, nor remain more sticky immediately after drying than the latter. The colour produced when the ink is used upon the standard record paper must, after a week's exposure to diffused daylight, be as intense a black as that produced by the typical ink, and must be equally resistant to the action of light, air, water, or alcohol.—A. S.

English Patent.

Spraying Colour on to Paper Fabrics and other Surfaces; Apparatus for ——. C. L. Burdick, Wood Green. Eng. Pat. 8703, April 16, 1903.

See Fr. Pat. 328,714 of 1903; this J., 1903, 994.—R. S.

VII.—ACIDS, ALKALIS, AND SALTS.

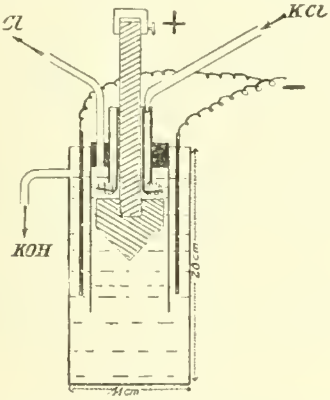
Weak Acid in presence of one of its Normal Salts; Apparent Diminution of Energy of a ——. G. Chesneau. Comptes rend., 1904, **138**, 968—970.

The addition of acetates to dilute acetic acid causes a considerable diminution in the rate of evolution of hydrogen by the action of the acid on zinc. The diminution does not, apparently, depend on the ionisation of the salt, since zinc acetate, which is little ionised, causes a much greater decrease in the evolution of hydrogen than does sodium acetate; whilst acetone, which is not ionised, reduces the rate of evolution to one-tenth.

Aqueous N/10 nickel acetate solution is not precipitated by sulphuretted hydrogen; the addition of small quantities of acetic acid gives a slight precipitate, which is redissolved on further addition. In presence of sodium acetate and acetic acid, however, a complete precipitation of nickel sulphide results. It is found that no alkali sulphide is formed on passing sulphuretted hydrogen into alkali acetate solution, even in presence of free acetic acid; this fact, then, the author concludes, accounts for the apparent diminution of the energy of the sulphuretted hydrogen and the incomplete precipitation of the sulphide.—T. F. B.

Electrolysis of Alkali Chlorides; "Bell Process" for ——. O. Steiner. Z. Elektrochem., 1904, **10**, 317—331.

The "bell process," now employed in one Austrian and three German works, relies (see Eng. Pat. 16,129 of 1898; this J., 1898, 1147) on the influence of density and a steady supply of fresh chloride solution to the anode for the effective separation of the anode and cathode products, no diaphragm being employed. To prevent the mixing caused by evolution of gas at the electrodes, the cathode and anode are separated by a bell, which covers the latter and reaches well below the electrodes (see figure). Extended laboratory experiments have been previously carried out to study this process (see Adolf; Z. Elektrochem., 1901, **7**, 581; this J., 1901, 715), but since their publication the German patent has been issued, which deals more fully with some of the principles of satisfactory working; and this information the present author has made use of, particularly in studying the conditions required for continuous production. Of primary importance is the way in which the chloride solution is allowed to flow into the anode chamber; it should form a homogeneous mixture with the solution around the anode, and not flow down, as it tends to do, on account of its density, and disturb the layers of solution at a lower level. If this condition be observed a neutral zone separates the alkaline cathode solution from the anode liquid, which is saturated with chlorine. This boundary layer can be clearly seen, on account of the difference in refractive index. If the addition of chloride solution correspond to the strength of current and cross-section of the bell, the downward motion of chloride prevents the hydroxyl-ions from reaching the anode, and the separating zone maintains its position unchanged. The clear definition of the boundary seems to depend to some extent on the formation of acid in the anode chamber, due, for instance, to the small amount of oxygen volved there in addition to chlorine; the hydrogen-ions hen migrate and neutralise the hydroxyl at the separating one. The lower the concentration of the chloride solution nd the lower the current density as measured in relation the cross-section of the bell, and further, the higher the lkali content of the cathode solution, the greater will be he distance of the boundary layer above the bottom edge of he bell, and consequently the less its distance from the node. For satisfactory working the neutral zone should be at least 1 cm. below the bottom of the anode. The uthor has shown by his experiments that an alkali lye of 0 to 130 grms. of caustic potash per litre can be connuously produced with a current yield of 85 to 94 per cent., nd that the anode gases contain 97 to 100 per cent. of lorine. The current density was 2 to 4 ampères per . dcm. of cross-section of the bell, and the difference of tential (P.D.), 3·7 to 4·2 volts. Up to a maximum of 0 grms. of caustic potash per litre, the yield is almost dependent of the strength of the alkali solution obtained. ith an anode of ordinary electrode carbon a colourless hode lye cannot be obtained without special treatment, Acheson graphite was found to be quite satisfactory. —R. S. H.



Barium Nitrate; Decomposition of —— by Heat. B. N. Gottlieb. Chem.-Zeit., 1904, **28**, 356.

By gentle and long-continued heating of barium nitrate in a current of dry air, only 30·7 per cent. of the nitrate was decomposed and 24·6 per cent. of nitric acid recovered, whereas by raising the temperature rapidly to a high point, 95·6 per cent. of the nitrate was decomposed and 38·6 per cent. of nitric acid recovered. Technically the best result is obtained by subjecting the nitrate, in small quantities at a time, to a white heat, so that decomposition takes place before the mass melts.—G. W. McD.

Silica; Reduction of —— by Hydrogen. A. Dufour. Comptes rend., 1904, **138**, 1101—1103.

Silica is reduced by hydrogen at a temperature above the fusing point of silicon, silicon hydride and water being formed. At rather lower temperatures silicon is formed, whilst lower still the inverse reaction takes place, *viz.*, silica and hydrogen are re-formed.—T. F. B.

Hydrofluoric Acid and Hydrofluosilicic Acid; Titration of ——. J. Katz. XXIII., page 562.

Sulphites; Electrolytic Oxidation of —— and Electrochemical Formation of Dithionate. A. Friessner. XI. A., page 548.

English Patents.

Acid Towers and Condensers; Packing for ——. J. S. Smithson, London. Eng. Pat. 10,053, May 15, 1903.

Calcined flints are used as packing for Glover or Gay-Lussac towers for sulphuric acid, or in condensers for other chemical gases.—W. H. C.

Hydrocyanic Acid and Cyanides; Manufacture of —— Grossmann's Cyanide Patents Syndicate, Ltd., and J. Grossmann, Manchester. Eng. Pat. 13,412, June 16, 1903.

See Fr. Pat. 331,331 of 1903; this J., 1903, 1130.—T. F. B.

[Acid] Sulphates of the Alkali Metals; Process for the Manufacture of Dry ——, and the Products thereof. S. Trivick, South Norwood. Eng. Pat. 8819, April 18, 1903.

See U.S. Pat. 728,335, of 1903; this J., 1903, 742.—T. F. B.

Lime and Fuel Gas; Method of and Apparatus for the Manufacture of ——. R. Pearson. Eng. Pat. 10,624, May 9, 1903. II., page 539.

United States Patents.

Nitric Dioxide and Nitric Acid; Process of Making ——. G. Pauling, Olbernhau. U.S. Pat. 758,774, May 3, 1904.

See Fr. Pat. 325,244 of 1902; this J., 1903, 696.—T. F. B.

Iron Pyrites; Preparing —— for Desulphurisation. U. Wedge, Ardmore. U.S. Pat. 757,531, April 19, 1904.

Iron pyrites, in small particles, is mixed with iron oxide (in the form of leached pyrites cinders or of purple ore, for instance) and with sulphuric acid, with or without ferrous sulphate, and the mass is made up into blocks or briquettes. Or iron pyrites is made into briquettes with ferrous sulphate, with or without iron oxide or lead sulphate. Another mixture consists of iron pyrites, ferrous sulphate, lead sulphate, sulphuric acid, and pyrites cinder, or the like, for briquetting.—E. S.

Titanous Compound [Titanous Sodium Sulphate], and Process of Making same. H. Spence, Assignor to Peter Spence and Sons, Ltd., Manchester. U.S. Pat. 758,710, May 3, 1904.

See Fr. Pat. 324,205 of 1902; this J., 1903, 628.—T. F. B.

French Patents.

Alkaline-Earth Bases; Manufacture of ——. E. Marlier. Fr. Pat. 338,059, Oct. 26, 1903.

A mixture of scrap zinc, crystallised hydrate of barium hydroxide, and of water, is gradually heated to 100° C. in a closed iron vessel. Barium sulphide solution is then added, whilst the solution of the zinc still proceeds, with continuous evolution of hydrogen. The "zincate" of barium formed in the process reacts with the barium sulphide in presence of water to form barium hydrate and zinc sulphide, which are separated by filtration. The process is applicable to the production of the hydrates of the alkaline earths generally.—E. S.

Magnesium and Zinc Peroxides; Electrolytic Process for the Manufacture of ——. F. Hinz. Fr. Pat. 337,285, Dec. 4, 1903. XI. A., page 549.

Nickel Monoxide; Preparation of a —— *suitable for Reduction in an Electric Furnace.* Soc. Siemens und Halske A.-G. Fr. Pat. 337,712, Dec. 12, 1903.

The nickel hydroxide thrown down from solutions of nickel chloride or sulphate by oxides or carbonates of alkali or alkaline-earth metals, is calcined, and plunged into water whilst yet hot, whereby it is freed from soluble chlorides and sulphates, and rendered suitable for reduction in an electric furnace. The same process is claimed as applicable to the purification of similar hydroxides, and especially of zinc hydroxide.—E. S.

Brine; Process and Apparatus for Evaporating Weak ——. E. Moll. Fr. Pat. 337,989, Dec. 24, 1903.

See Eng. Pat. 28,518 of 1903; this J., 1904, 441.—T. F. B.

Cyanides; Process for Preparing ——. J. Grossmann. Addition, dated Dec. 24, 1903, to Fr. Pat. 331,331, April 18, 1903.

See Eng. Pat. 4513 of 1903; this J., 1904, 370.—T. F. B.

VIII.—GLASS, POTTERY, ENAMELS.

Silicates; Reduced ——. C. Simmonds. Proc. Chem. Soc., 1904, **20**, 21.

The substance left when lead silicates are reduced by heating in hydrogen (this J., 1903, 1261) is in general shown to be a compound which can be regarded as a combination of the metal and silica, in the same sense as the original silicate is a combination of the metallic oxide and silica. In some cases, however, a certain proportion of metallic lead is mixed with the substance; this occurs when the original silicates (for example, orthosilicates and basic silicates) contain a greater number of basic than of acidic oxides in the silicate molecule. The reduced residues are generally more refractory than the original silicates. Treatment with the commoner acids and oxidising agents has little effect on them, but they are decomposed by hydrofluoric acid and by fusion with alkali carbonates. The term "silicites" is suggested for these reduced silicates. Similar results were obtained with the silicates of copper, iron, nickel, and cobalt.

English Patent.

Glass; [Use of Electric Current in] Working of ——. H. J. Hays, Pittsburg. Eng. Pat. 4501, Feb. 23, 1904.

The glass to be worked is maintained hot during the working by passing an electric current through the glass. A variable resistance is interposed in the circuit, so that the strength of the current can be altered.—A. G. L.

United States Patent.

Enamelled Ware; Manufacture of ——. T. M. Lunan, Newark, Assignor to the Central Stamping Co., New York. U.S. Pat. 758,325, April 26, 1904.

The cleaned article is subjected to the action of an oxidising agent, such as potassium chlorate solution, which will attack the metal of which the article is made. An enamel "carrying metallic bodies" and acid in character is then applied, followed, whilst still moist, by an agent suitable to precipitate the metallic constituents of the enamel, such as a non-metallic hydroxide. The whole is then heated, to flux and set the enamel.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Ultramarine; Constitution of ——. P. Rohland. XIII. A., page 551.

English Patents.

Tiles or other Glazed Articles; Method of Manufacturing —— *from Slate or Slate Refuse.* K. N. Frydenlund, Christianshavn. Eng. Pat. 5985, March 11, 1904.

The finely-powdered slate, to which 5—8 per cent. of powdered chalk may be added, is moistened with a liquid prepared by heating 3 parts (by volume) of powdered sodium hydroxide with 16 parts of colophony and 30 parts of water, until a uniformly thin mixture is obtained, and then adding to this mixture a solution of 30 parts of sodium silicate and 10 parts of water to which 1 part of kaolin is preferably added. The plastic mass obtained is pressed into plates or tiles, using a pressure of 15 to 40 kilos. per sq. cm., which are then kept for some days at the ordinary temperature, after which they are dried for three days at 60° to 100° C., glazed, and burnt at 800° to 1000° C. —A. G. L.

Stone, Blocks, or Bricks; Manufacture of Artificial ——. V. Steger, Bonham. Eng. Pat. 6007, March 11, 1904.

See U.S. Pat. 756,295 of 1904; this J., 1904, 490.—T. F. B.

United States Patents.

Plaster of Paris; Manufacture of ——. W. Brothers, Prestwich. U.S. Pat. 757,649, April 19, 1904.

See Fr. Pat. 333,858 of 1903; this J., 1904, 20.—T. F. B.

Refractory Material [Cement]; Basic ——. A. T. Macfarlane, Rochester. U.S. Pat. 757,821, April 19, 1904.

See Eng. Pat. 4298 of 1902; this J., 1903, 366.—T. F. B.

Cementing Material, and Process of Making same. T. W. Cappon, Ossining. U.S. Pat. 757,883, April 19, 1904.

Calcined magnesian limestone, or a mixture of magnesia and lime, is partially hydrated, and a certain proportion of hydrochloric acid or of a suitable chloride is added, to form a cementing material. Dry mortars are prepared by mixing partly hydrated magnesia and lime with a large proportion of sand or the like, and adding a suitable chloride. Or the solution of such a chloride is sprinkled upon an agitated mixture of partially hydrated calcium-magnesium oxides.—E. S.

French Patents.

Stones, Artificial, suitable for Pavements, Buildings Above and Below Ground, and for Hydraulic Purposes; Process of Making ——. J. J. Niessen. Fr. Pat. 338,077, Nov. 4, 1903.

See Eng. Pat. 25,393 of 1903; this J., 1904, 254.—T. F. B

Stone; Process of Making Artificial ——. C. Reinke. Fr. Pat. 337,843, Dec. 19, 1903.

See Eng. Pat. 26,478 of 1903; this J., 1904, 188.—T. F. B

Paving or Asphalt Compositions, Waterproof Compounds and Paints, &c. W. P. Thompson. Fr. Pat. 338,106 Dec. 8, 1903.

See Eng. Pat. 24,807 of 1902; this J., 1904, 61.—T. F. B

Waterproofing Bricks, Stone, and Similar Porous Substances. N. Farnham. Fr. Pat. 337,846, Dec. 19, 1903.

See U.S. Pat. 748,595 of 1994; this J., 1904, 116.—T. F.

X.—METALLURGY.

Gold and Silver; Extracting —— *at Wallstreet Mill Colorado.* F. C. Perkins. Electrochem. Ind., 1904, 24—26.

The method used is that of electro-chlorination as devis by Greenawalt. The crushed ore is roasted, and dro from the roasting furnace into a furnace pit, where the silver and the base metals are converted into chlorides by means of common salt. The ore is then conveyed to leaching vats, where the gold is dissolved by a solution containing free chlorine and bromine, and oxygen compounds of these elements, obtained by electrolysing in "regenerating cells" a 15 per cent. solution of common salt containing $\frac{1}{2}$ per cent. of bromine in the form of a bromide. A current-density of 20 ampères per sq. ft. and an E.M.F. of $4\frac{1}{4}$ volts per cell are employed, with graphitised carbon anodes, lead cathodes, and diaphragms of asbestos. Any free chlorine or bromine escaping at the anodes is led into the furnace-pit to aid the chlorination. From the leaching vats the solution passes, in zigzag fashion, through precipitating cells fitted with lead anodes and cathodes, arranged $1\frac{1}{2}$ in. apart. By a current-density of $\frac{1}{36}$ ampère per sq. ft., the gold and silver are deposited together as a black slime upon the cathodes.—A. S.

Gold; Melting Point of ——. A. Jacquerod and F. L. Perrot. Comptes rend., 1904, **138**, 1032—1034.

A gold wire completing a telephone circuit was heated in a platinum resistance furnace in immediate proximity to the vitreous silica bulb of a constant volume thermometer, and the pressure of the enclosed gas read at the instant of interruption of the circuit. The result obtained, with nitrogen, at a pressure of 200 mm. at the ordinary temperature, as the thermometric gas, was 1067° C.
—J. T. D.

Copper and Arsenic; Alloys of ——. A. H. Hiorns. Electrochem. and Metall., 1904, **3**, 648—655.

Alloys containing from 0·1 to 43·0 per cent. of arsenic were prepared by adding the requisite amount of arsenic to melted copper and keeping at a temperature near 800° C. for an hour before finally cooling. No volatilisation of arsenic occurred with the poorer alloys; but alloys containing more than 43 per cent. of arsenic cannot be kept melted without continuously altering in composition from the rapid burning off of the arsenic. The freezing points and the microscopic appearance (both of the surface and of sections parallel and perpendicular to it) of the alloys were examined and recorded. The freezing-point curve shows a steady fall from 1060° C. (pure copper) to 685° C. (arsenic 19·2 per cent.), a rise through a point of inflexion it 750° C. (arsenic 28·3 per cent.; Cu_3As) to 807° C. (arsenic 32·19 per cent.; Cu_5As_2), a rapid drop to 695° C. arsenic 35 per cent.), a rise to a maximum at 740° C. arsenic 37·2 per cent.; Cu_2As), and a fall to 702° C. arsenic 41·0 per cent.). Alloys, the freezing-points of hich are at or near a maximum on the curve, show on icroscopic examination of the etched surface a uniform ıbstance—crystal grains with fine boundaries; leaving the ıaximum in either direction, the boundaries widen and are lled with a striated matter different from the crystal-grains -no doubt a eutectic; and at a minimum the eutectic :cupies the whole surface.—J. T. D.

Lead-Aluminium Alloys. H. Pécheux. Comptes rend., 1904, **138**, 1042—1044.

hen aluminium is melted and lead is added in proportion eater than 10 per cent., the metals separate on cooling to three layers: lead, aluminium, and between them an oy containing from 90 to 97 per cent. of aluminium. ıe alloys with 93, 95, and 98 per cent. have densities of 745, 2·674, 2·600 respectively, and melting-points near ıt of aluminium. Their colour is like that of aluminium, t they are less lustrous. All are malleable, easily cut, ter than aluminium, and have a granular fracture. remelting, they become somewhat richer in lead, ough a tendency to liquation. They do not oxidise moist air nor at their melting-points. They are attacked the cold by hydrochloric and by strong sulphuric acid, h evolution of hydrogen, and by strong nitric acid when ; strong solution of potassium hydroxide also attacks m. They are without action on distilled water, whether d or hot.—J. T. D.

Zinc-Aluminium Alloys. H. Pécheux. Comptes rend., 1904, **138**, 1103—1104.

Well-defined alloys were obtained from zinc and aluminium corresponding to the formulæ Zn_3Al, Zn_2Al, $ZnAl$, $ZnAl_2$, $ZnAl_3$, $ZnAl_4$, $ZnAl_6$, $ZnAl_{10}$, and $ZnAl_{12}$. Their fusing points and densities all lie between those of zinc and aluminium, and those containing most zinc are the hardest. They are all dissolved by cold hydrochloric acid and by hot dilute nitric acid. Cold concentrated nitric acid attacks the first three, and cold dilute nitric acid the first five. The alloys Zn_3Al, $ZnAl_6$, $ZnAl_{10}$, and $ZnAl_{12}$ are only slightly affected by cold potassium hydroxide solution; the others are strongly attacked, potassium zincate and aluminate probably being formed.—T. F. B.

Manganese in Presence of Iron [in Iron Ores, &c.]; Volumetric Determination of —— by Potassium Permanganate, Guyart-Volhard-Wolff Method. L. L. de Koninck. XXIII., page 562.

English Patent.

Coal, Ores, and other Minerals: Method of and Apparatus for Treating ——, for Draining them of Water. F. Baum. Eng. Pat. 2485, Feb. 1, 1904. II., page 539.

United States Patents.

Iron-Sand; Method of Converting —— into Briquettes or Lumps. T. Rouse, Assignor to H. Cohn, London. U.S. Pat. 758,853, May 3, 1904.

See Eng. Pat. 21,880 of 1902; this J., 1903, 1090.—T. F. B.

Copper and Zinc from Ores; Process of Electrolytically Extracting ——. S. Laszczynski, Kielce. U.S. Pat. 757,817, April 19, 1904.

See Fr. Pat. 326,542 of 1902; this J., 1903, 805.—T. F. B.

Metals; Apparatus for Extracting —— by Chemical Process. T. B. Joseph, San Francisco. U.S. Pat. 758,367, April 26, 1904.

The apparatus consists of a tank having a filter bottom, above and near which is placed a perforated pipe, connected to an air compressor, the pipe having lateral parallel branches extending across, such perforations being arranged to discharge small streams of air upwardly, with only a slight inclination, to drive the superincumbent slimes upwards. Compare U.S. Pats. 718,633, 728,397, and 732,639 of 1903; this J., 1903, 214, 747, and 914.—E. S.

Ores; Treating ——. W. F. Hannes, Assignor to W. J. Browning, both of Deming. U.S. Pat. 758,532, April 26, 1904.

Solid fuel and ore are supplied through separate vertical compartments merging together in the body of the furnace. Oxygen is admitted to the fuel compartment, and the resulting gases are led into the ore space in the body portion, to which excess of oxygen is supplied to burn any sulphur or other like impurities. The roasted ore is then fed into the zone of the fuel combustion, where reduction is effected, and the fused metal is withdrawn. Apparatus for the manipulation of the ore and fuel within the furnace is provided. Compare Eng. Pat. 10,929 and U.S. Pat. 712,374 of 1902; this J., 1902, 1141; and Fr. Pat. 321,087 of 1902; this J., 1903, 148.—E. S.

French Patents.

Steel Ingots; Process for Making Faultless —— a short time after Melting, and for Improving their Quality. R. W. Hunt. Fr. Pat. 337,876, Nov. 3, 1903.

See Eng. Pat. 23,821 of 1903; this J., 1904, 374.—T. F. B.

Cast-Steel Ingots; Process of Improving ——. R. W. Hunt. Fr. Pat. 338,071, Nov. 3, 1903.

See Eng. Pat. 23,821 of 1903; this J., 1904, 374.—E. S.

Cast-Steel Ingots; Process of Producing —— immediately before lifting the Moulds, without Defects, and Improved in Quality. R. W. Hunt. Fr. Pat. 338,073, Nov. 3, 1903.

See Eng. Pat. 23,821 of 1903; this J., 1904, 374.—E. S.

Iron-Nickel-Chromium Alloy. F. and M. Laur. Fr. Pat. 337,967, Dec. 23, 1903.

A SELECTION is made of chrome iron ore and of nickeliferous ores, such as "garnierite" (a magnesium-nickel silicate), a mixture of which is heated with the minimum of carbon necessary for reduction, in an electric or other furnace. The product may contain ordinarily from 10 to 30 parts each of iron, chromium, and nickel, 3 to 12 parts of silicon, and 3 to 5 parts of carbon. Such alloys are stated to be especially applicable in the preparation and refining of steel.—E. S.

Crucible Furnace. The Morgan Crucible Co., Ltd., England. Fr. Pat. 337,802, Dec. 16, 1903.

THE crucible is fixed in a double-cased iron furnace, lined with refractory material. The furnace stands on a hollow base, through which the air is led to the tuyères. A removable cover is arranged above the furnace, with a jacketted flue for the waste gases. The air supply is led between the flue and the jacket to the base, in this way taking up some of the waste heat. The furnace with the crucible can be elevated, turned and tilted by suitable means, enabling the contents to be poured without removing the crucible.—W. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Sulphites; Electrolytic Oxidation of ——, and Electrochemical Formation of Dithionate. A. Friessner. Z. Elektrochem., 1904, **10**, 265—289.

BY the electrolysis of neutral or alkaline solutions of alkali sulphite, under suitable conditions, dithionate as well as sulphate is formed at the anode. The formation of dithionate takes place according to the equation—

$$2SO_3'' + 2OH' + 2H' + 2\,(+) = S_2O_6'' + 2H_2O.$$

Dithionate is not produced by the electrolysis of acid, *i.e.*, bisulphite solutions, under any conditions, but on electrolysing without a diaphragm, besides sulphate at the anode and hydrosulphite at the cathode, thiosulphate is also produced, probably at the cathode. The formation of dithionate occurs both at polished and at platinised platinum anodes, but not at the latter at the ordinary temperature if these have been previously subjected to cathodic or chemical depolarisation. A high anode potential favours formation of dithionate, and this is best attained by using a platinised platinum anode which has been previously subjected to anodic polarisation in caustic soda solution. The formation of dithionate is retarded by a high current density, but favoured by rise of temperature.—A. S.

Platinum; Electrolytic Solution of ——. New Process for Preparing Platinocyanides. A. Brochet and J. Petit. Comptes rend., 1904, **138**, 1095—1097.

PLATINUM is very rapidly dissolved in cyanide solutions when subjected to the action of an alternating current, platinocyanides being produced; starting with barium cyanide, barium platinocyanide is easily obtained from the resulting solution by evaporation. Platinum is dissolved to a smaller extent in hydrochloric acid under the same conditions. In these respects it closely resembles iron and cobalt.—T. F. B.

UNITED STATES PATENTS.

Calcium Carbide; Process of Producing ——. W. S. Horry, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 757,617, April 19, 1904.

A RESISTANCE furnace is employed; the electric current being led to several electrodes in contact with different parts of a charge of carbide-forming materials. The current density is concentrated along the path of the current in the charge, as, for instance, by causing it to converge from the several electrodes towards one common electrode at the base of the furnace. In this way a sufficiently high temperature is obtained to produce carbide or to bring it into a molten condition suitable for tapping.—R. S. H.

Electric Heating; Process of ——. W. S. Horry, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 757,618, April 19, 1904.

ANY conducting material is heated by causing different phases of a polyphase current to simultaneously flow along paths which cross each other through the material. The path of the phase of maximum E.M.F. is progressively shifted, each phase being caused to traverse a resistance corresponding to its E.M.F. There are 29 claims; the process of heating, in its several modifications, being applied to the reduction of compounds and to the formation of carbide.—R. S. H.

Electric Heating; Process of ——. W. S. Horry, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 757,619, April 19, 1904.

THE heating is effected by the passage of polyphase currents through conducting material, but the different phases are caused to converge to a common point within the material. Applications to the reduction of compounds and to the production and tapping of carbide are mentioned.—R. S. H.

Electric Heating; Method of ——. W. S. Horry, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 757,620, April 19, 1904.

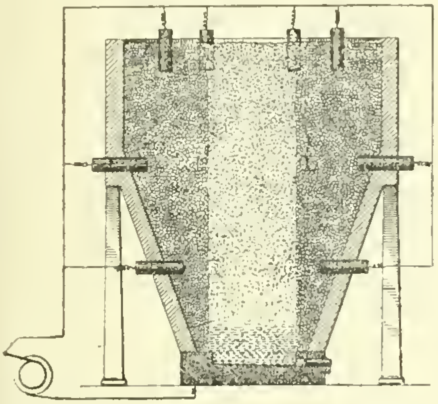
BY passing superposed electric currents through a pool of conducting material of varying cross-section, and thus maintaining a region of maximum current density, a heated zone is obtained suitable for effecting chemical or other changes in material fed into the pool. For the production of calcium carbide, the carbide-forming mixture is fed into the hottest zone of a pool of carbide, heated as above described, the product being withdrawn directly from this zone.—R. S. H.

Electric Furnace. W. S. Horry and E. F. Price, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 757,621 April 19, 1904.

A RESISTANCE furnace is constructed with a hearth t support a charge of molten conducting material. Th several electrodes which conduct the current to the materi are so arranged as to produce a zone of maximum currer density. This object can also be attained by construc ing the hearth so that it converges towards the regio where the highest temperature is desired. The product withdrawn by gravity from this zone.—R. S. H.

Electric Heating [Calcium Carbide]. E. F. Price, Assi nor to Union Carbide Co., Niagara Falls. U.S. P 757,633, April 19, 1904.

A RESISTANCE furnace is constructed with a conduc ing core of broken or granular material. The su stances which are to be heated are placed in proximity this conductor. Superposed electric currents are led to t core in such a manner as to increase the current dens along the path of the current, so that finally a point is reached at which the substances react, are fused or become heated to the required temperature. Special mention is made of the production of calcium carbide and the tapping of it, in a molten condition, from the furnace.—R. S. H.



Electric Resistance Furnace. E. F. Price, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 757,634, April 19, 1904.

Electric currents are led to a fixed "resistance conductor" n such a manner that the current density increases along it. n this way the conductor is heated ununiformly and the aterial in contact with the conductor is brought to the mperature required for its treatment.—R. S. H.

irculating Liquids [Electrolytes]; Apparatus for —— in Tanks. G. E. Dunton, New York. U.S. Pat. 758,430, April 26, 1904.

iquid is pumped by a centrifugal pump into a casing aced over a tank, from which the liquid is distributed to rions pipes running lengthwise over the tank. The pipes e fitted with nozzles, which are so arranged as to disarge the liquid lengthwise and towards the centre of the nk, each nozzle aiding the preceding one, so that a ntinuous circulation of the liquid in the tank is produced.
—L. F. G.

rculating Liquids [Electrolytes]; Apparatus for —— in Tanks. G. E. Dunton, New York. U.S. Pat. 758,513, April 26, 1904.

es are provided along opposite sides of a tank, and end along its upper portion, the pipes being fitted h nozzles disposed alternately, which discharge liquid ards the centre of the tank. Pumps connected to tion pipes supply liquid to the pipes. The tank may an electrolytic bath. (See also preceding abstract.)

(*B.*)—ELECTRO-METALLURGY.

Metals; Electrolytic Stripping of ——. C. F. Burgess. Electrochem. Ind., 1904, 2, 8—11.

The process of removing the superfluous spelter from brazed bicycle frames (see this J., 1903, 1356) is described in detail. The goods are hung from anode bars in long wooden tanks between alternate sheet-iron cathodes, the electrolyte being a 5 per cent. solution of sodium nitrate. In a freshly made solution the steel anodes fail to become passive for some minutes, unless a little nitrite has been previously added. In time, again, the liquid becomes ammoniacal, the passive condition is lost, and active corrosion of the steel sets in; this is obviated by adding nitric acid day by day so as to preserve a slight acid reaction. The stripped brass settles to the bottom of the tank as a sludge of hydrated copper and zinc oxides. A current-density of 5—15 ampères per square foot may be used, for which 3—5 volts are required. After stripping, the goods are brushed wet, dipped in hot water, and allowed to dry. Many other metals can thus be stripped, and the recovery of tin from tinned iron is merely a question of securing good contact. Nickel cannot be dissolved away, but after continued electrolysis the plating is loosened and may be removed mechanically.—W. A. C.

Aluminium; Protection of —— against Corrosion. W. R. Mott. Electrochem. Ind., 1904, 2, 129—130.

In a solution of acid sodium phosphate a film is deposited on aluminium anodes which is thicker than, and chemically different from, the film due to tarnishing. Plates thus coated are acted on by hydrochloric acid a hundred times more slowly than bright surfaces, though the rate of action becomes identical after a few hours. Potash solutions attack both equally. Experiments made with both direct and alternating currents show that the resistance of the film is proportional to the voltage applied in forming it.
—W. A. C.

Aluminium; Electro-Plating upon ——. C. F. Burgess and C. Hambuechen. Electrochem. Ind., 1904, 2, 85.

The goods are first roughened by immersion in dilute hydrofluoric acid, then cleaned with a mixture of concentrated sulphuric and nitric acids, and covered with a firmly adherent coating of zinc by electrolysis in a bath of zinc and aluminium sulphates containing 1 per cent. of free hydrofluoric acid A current-density of 10—20 ampères per sq. ft. for 15 mins., is prescribed. The goods can then be silver- or copper-plated in the cyanide bath. Gold cannot satisfactorily be deposited directly on the zinc, but must be applied as a third coating upon copper.—W. A. C.

English Patents.

Electro-deposition of Metals; Apparatus for ——. [Agitators.] J. H. and A. Collis, London, and W. Head, St. Albans. Eng. Pat. 15,317, July 10, 1903.

A device for the agitation and circulation of the electrolyte in depositing tanks. The apparatus consists of a series of perforated tubes at the bottom of the tank connected with a supply of electrolyte under pressure. The solution is driven through the perforations and causes agitation of the liquid contents of the vat. It is drawn off at the top by means of a pump.—R. S. H.

Electric Furnaces. C. P. E. Schneider, Le Creusot. Eng. Pat. 28,805, Dec. 31, 1903.

A system of tubes projects from the melting chamber or crucible of an electric or other furnace, "serving as secondary winding for an alternating current transformer." The tubes open into the melting chamber at two points situated at different levels and at an inclination, in order to establish a continuous circulation between the crucible and the tubes, which latter are of relatively small section, so as to impart greater resistance to the circuit. The tubes may be ⊃-shaped, both ends entering the side of the crucible; or separate crucibles, or different chambers in the same furnace, may be connected by pairs of tubes carrying the field magnets. This system of electric heating may be used singly; or as supplementary to the employment of electrodes; or as accessory to the use of fuel in a Siemens' or other regenerative furnace. Reference is made to Eng. Pat. 7338 of 1901.—E. S.

Electric Melting Furnaces. Soc. Anon. l'Industrie Verrière et ses dérivés, Brussels. Eng. Pat. 5921, March 10, 1904. Under Internat. Conv., March 21, 1903.

In a resistance furnace containing a conducting charge, the current conductors or sets of electrodes are arranged at different heights in the wall of the furnace. In this way layers of charge of different thickness can be included in the circuit as desired. The heating action of the current is regulated, movable electrodes are dispensed with, and entrance of air to the furnace is avoided by the above arrangement.—R. S. H.

United States Patent.

Tin; Process of Obtaining —— by Electrolysis. E. Quintaine, Argenteuil. U.S. Pat. 699,012, April 29, 1902. Reissue, No. 12,214, April 26, 1904.

The acid solution of tin nitrate used as electrolyte in the original patent (this J., 1902, 779) is neutralised with ammonium sulphate instead of with ammonium chloride.
—T. F. B.

French Patents.

Monoxide of Nickel; Preparation of a ——, suitable for Reduction in an Electric Furnace. Soc. Siemens und Halske A.-G. Fr. Pat. 337,712, Dec. 12, 1903. VII., page 546.

Ores and Metallic Matters in General; [Electrical] Treatment of ——. M. Perreur-Lloyd. Fr. Pat. 337,763, Dec. 16, 1903.

Ores and metallic matters are digested with suitable solvents of their metals, and the solutions are subjected to electrical action to obtain the crude or spongy metal, which is refined by electrical solution and re-deposition.
—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Fats; Enzymic Decomposition of ——. E. Hoyer. Ber., 1904, **37**, 1436—1447. (See also this J., 1902, 1541, and 1903, 428.)

Attempts to Isolate the Enzyme.—No solution of the enzyme could be obtained either by extraction with solvents or by Buchner's method of isolating zymase, the filtrates being inactive or, at most, only slightly active. It was found that in seeds in process of germination the enzymic activity in that portion of the seed adjoining the germ was weaker than in that further removed from the germ. In strongly germinated seeds there was but little enzymic activity either in the seed or in the germ, the amount of hydrolysis effected in 72 hours being only 3 and 1 per cent. respectively. The turbid oil from expressed castor-seeds contained the active agent, and, on dilution with ether or carbon bisulphide, yielded a fine deposit with high enzymic activity. In experiments to determine whether larger quantities of the enzyme could be separated by repeated treatment of the crushed seed with oil, 200 grms. of cotton-seed oil and 100 grms. of crushed decorticated castor-seeds (= 50 per cent. of oil) were rubbed for 30 minutes with 100 grms. of sand, and pressed through linen. The turbid oil expressed effected 81 per cent. of hydrolysis in three hours. On filtration this turbid oil yielded a clear filtrate with no enzymic activity, whilst 0·1 grm. of the white residue on the filter effected the decomposition of 10 grms. of castor-seed oil to the amount of 70 per cent. in 16 hours and 80 per cent. in two days. The trituration and straining through linen was repeated until eventually hardly any solid particles passed through the cloth, and the final residue had then only slight enzymic activity. Instead of oil, acidified water could be used for this treatment with very similar results, a milky emulsion being obtained, which effected the decomposition of 86 to 87 per cent. of oil in two to five days. Quantitative separation of the enzyme by such methods was not effected, but only a certain degree of enriching. Since active particles are simultaneously removed, the value of such enriching from a technical point of view is problematical.

Influence of Time of Trituration.—50 grms. of castor seeds were triturated with 50 grms. of cotton-seed oil or 50 grms. of 0·6 per cent. acetic acid, samples tested under parallel conditions, and the amount of decomposition effected in 24 hours determined, with the following results:—

——	Seeds triturated with Oil.	Seeds triturated with Acidified Water.
	Per Cent.	Per Cent.
5 minutes' triturating	78	78
15 " "	81	83
30 " "	82	84

For technical purposes the author recommends a short vigorous trituration of the decorticated seeds by means of, *e.g.*, a paint-grinding mill. The addition of sand to the mass offers no advantage.

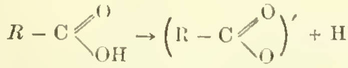
Addition of Acid.—There was found to be a definite relationship between the amount of seeds and the absolute amount of acid required, whilst there was a marked difference between the behaviour of different acids. Thus, in the case of formic acid the optimum concentration was 0·04 per cent., whereas acetic acid required a concentration of 0·06 per cent. under the same conditions as to amount of liquid, &c. But whilst with acetic acid at a concentration of 0·1 per cent., the emulsion obtained, possessed a relatively high degree of activity, formic acid in a concentration of 0·08 per cent. caused marked diminution in the activity of the enzyme. Sulphuric acid and oxalic acid were very similar in their action. With each the maximum decomposition was soon reached (0·08 to 0·1 per cent.), and the further addition of only small quantities of the acids was similarly injurious. Of the two, sulphuric acid gave better results than oxalic acid. To obtain the maximum results with butyric acid a much higher amount of acid was required, but the addition of still more acid had not any pronounced injurious effect. Thus a decomposition of 87 per cent. was effected in the presence of 0·3 to 0·5 per cent. of butyric acid, whilst on increasing the amount of acid to 1 per cent. the decomposition of the oil was 85 per cent. The absolute amount of acid present, and not its concentration, was proved to be the essential factor. Thus in the case of oxalic acid in 30 c.c. of water, a concentration of 0·1 per cent. effected, in presence of the enzyme, the same amount of hydrolysis as a concentration of 0·05 per cent. in 60 c.c. of water. Decomposition can also be effected in the presence of fatty acids, *e.g.*, old linseed oil but a relatively larger amount of acid must be used. Carbonic acid is practically useless for the purpose.
—C. A. M.

Saponification; Theory of ——. F. Goldschmidt. Z. Elektrochem., 1904, **10**, 221—222.

In commonly accepted theories of saponification in the presence of alcohol, the ionisation of the glyceride may be represented by $CH_2.CH.CH_2'''$ / 3(OR)', where represents the fatty acid radicle, whilst it is also assumed that the alcohol is dissociated into (C_2H_5) and (OH). Henriques (this J., 1898, 673) has confirmed the older observations of Duffy (J. Chem. Soc., 1852, 203) and Bouis (Comptes rend., **45**, 35), showing that ethyl esters of fatty acids are formed; and it is thus surprising, assuming the correctness of the ordinary ionisation theory, that a weak base like alcohol should combine with the fatty acid radicle when a strong base like potassium is present. The author explains the formation of soap from the ethyl esters by the assumption that the active groups in the reaction are the acyl group ($(RCO)^{\cdot}$) and the group ($(OC_2H'_5)$), soap ions $K^{\cdot}$ and $(RCOO)'$ and alcohol, being produced. The first step must be an ordinary reaction of the ions, in which the base ($RCO^{\cdot}.OH'$) is liberated by the alkali. Since the ester is undoubtedly only dissociated to a slight extent, undissociated acyl base can only be formed in small proportion, owing to there being no great concentration of acyl cations. The author assumes that there is an intramolecular transformation within this acyl base, which renders possible the formation of fatty acid anions from the acyl cations. For if the acyl group be assumed to have a normal constitution its cationic function appears inexplicable. But if we ascribe to the acyl group a totally different constitution to that of the anion, its basic function can be explained on the assumption that the oxygen atom has become tetravalent. The acyl base could then be assumed to have the following constitution:—

$$R - C \equiv O - OH \rightarrow (R - C \equiv O)^{\cdot} + OH'$$

whilst the constitution of the fatty acid might be represented by—



$$R - C\begin{matrix} \diagup\!\!\diagup O \\ \diagdown OH \end{matrix} \rightarrow \left(R - C\begin{matrix} \diagup\!\!\diagup O \\ \diagdown O \end{matrix}\right)' + H^{\cdot}$$

The transformation of the basic into the acid modification n alkaline medium could be explained by the principle of nstable equilibrium. In the author's opinion the assumpion of a cationic group, $(R - C \equiv O)^{\cdot}$, can also be made he basis of a systematic explanation of the formation of erivatives of carboxylic acids from components of different olarity. (See also Lewkowitsch, this J., 1898, 1107; 899, 1031; 1900, 254; 1903, 596.)—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

Ultramarine; Constitution of ——. P. Rohland. Z. angew. Chem., 1904, **17**, 609—616.

E sodium in ultramarine can be replaced in equivalent portions by silver, potassium, and lithium, and as the ult of these experiments the sulpho-silicate formula $2Na_2Al_2Si_2O_8Na_2S_2$ has been proposed for ultramarine. From its isomorphism with the minerals, *Hauyn*, *Sodalite*, and *Nosean*, however, the formula $Na_4[Al(NaS_3)]Al_2SiO_4)_3$ has been deduced. Ultramarine in certain ways also resembles the natural trasses and puzzuolanas; it possesses hydraulic properties, which are increased by the addition of lime. It increases the binding power of Portland cement, even when as much as 40 per cent. of ultramarine is added. It seems possible that the high percentage of soda in ultramarine may be due to a part of the soda existing in a condition which resembles that of the free lime in Portland cement. The author concludes that probably the constituent to which ultramarine owes its colour exists only in comparatively small quantity in the substance, and is evenly disseminated throughout the mass in the state of a solid solution.—A. G. L.

Venetian Red; New Process of Preparing ——. J. G. McIntosh. Chem. News, 1904, **89**, 197.

The process consists in furnacing an intimate mixture of molecular proportions of waste peroxide of lead and dehydrated ferrous sulphate. The reaction takes place according to the equation: $2FeSO_4 + 2PbO_2 = 2PbSO_4 + Fe_2O_3 + O$, and it is claimed that when the proportions of the components of the mixture are correctly adjusted, no fume is produced. If an excess of lead peroxide be used, an equivalent amount of red lead is produced, with escape of oxygen. Manganese peroxide may be substituted for the lead peroxide, and the resulting manganese sulphate removed from the product by washing.—A. S.

English Patent.

White Lead; Manufacture of ——. H. H. Lake, London. From Syndicat pour l'Exploitation des Inventions du Prof. Oettli, Berne. Eng. Pat. 12,713, June 5, 1903.

Iron Putty; Preparation of —— to Replace Putties of White or Red Lead. O. E. Picquet and A. Dubosc. Fr. Pat. 337,833, March 2, 1903.

A solution of a soap (an alkali oleate for instance) is precipitated by a ferric salt, such as ferric sulphate, and the washed precipitate is thickened with an oxide or other suitable substance.—E. S.

Azo Dyestuffs, and Lakes produced therefrom; Preparation of New ——. Soc. anon. F. Bayer & Co. Fr. Pat. 337,942, Dec. 22, 1903. IV., page 543.

(*B.*)—RESINS, VARNISHES.

Resin of Hopea Odorata ("Rock Dammar") from Burma. Bull. Imp. Inst. (Suppl. to Board of Trade J.), 1904, **2**, 23—24.

The specimen consisted of large, irregular tears of a yellow colour. It melted at 115° C. and yielded 0·56 per cent. of ash. Saponification value, 37·1; acid value, 31·5. It was completely soluble in turpentine and partially soluble in alcohol. The resin was valued at 2*l*. 5*s*. per cwt. It may be regarded as a second-quality dammar, and could be used for the preparation of "paper" or "crystal" varnishes.
—A. S.

Gommier Resin from Dominica. Bull. Imp. Inst. (Suppl. to Board of Trade J.), 1904, **2**, 24—26.

The resin exudes from natural fissures or from cuts in the bark of the gommier tree, in the form of an opaque, viscous liquid, which solidifies eventually into hard, brittle white masses. It is commonly known as "dry" or West Indian elemi, and has been sold in Europe as a substitute for the elemi resin from the tree, *Canarium commune*. The specimen examined consisted principally of large flattened lumps of hard white resin, together with a small amount of lumps of soft, slightly yellow resin. The hard lumps consisted almost entirely of minute needles, but the soft resin was crystalline only on the surface. The following are the results of the chemical examination:—

——	Hard Resin.	Soft Resin.
Saponification value	24·7	41·6
Acid value	14·1	37·3
Ash.	0·08 per cent.	0·36 per cent.
Melting-point	158°—161° C.	Below 100° C.

The hard resin is completely soluble in alcohol and partially so in turpentine, whilst the soft resin is entirely soluble in turpentine oil and only partially so in alcohol. The resin was valued at 17*s.* to 18*s.* per cwt., but it is probable that if it were exported in a fresh and clean condition, it would realise prices more nearly equal to those obtained for true elemi (50*s.* to 55*s.* per cwt.).—A. S.

English Patent.

Gums and Resins; Treatment of ——, and the Preparation of Varnishes. H. Terrisse, Vernier. Eng. Pat. 14,554, June 30, 1903.

Gums and resins, such as copals, are dissolved in phenols or naphthalene, without melting the resin, by heating under pressure to 250—290° C., linseed oil or other drying oil is added to the solution, and the phenol or naphthalene distilled off. For example, 1 kilo. of Zanzibar resin is heated with 3 kilos. of naphthalene, under a pressure of $4\frac{1}{2}$ atmos., at 290° C., for two hours, 250 grms. of linseed oil are added, and the mixture again heated under pressure at 290° C. for 45 minutes, when it is filtered if necessary. 750 grms. of linseed oil, heated to 220° C., are next added, and the mixture is distilled, exhaustion to a partial vacuum being resorted to as the temperature approaches 280° C., at which point distillation will be finished. The varnish is completed by diluting the product with $2\frac{1}{2}$ kilos. of thickened linseed oil and adding the requisite amounts of spirit of turpentine and siccative.—T. F. B.

(*C.*)—INDIA-RUBBER.

Gutta-Perchas from the Straits Settlements. Bull. Imp. Inst. (Suppl. to Board of Trade J.), 1904, **2**, 16—21.

Six specimens were examined, with the results shown in the accompanying table. The sample of Gutta Taban Merah, No. 6, represents the highest class of gutta-percha. It was far superior to any of the other specimens. Nos. 4 and 5 are not true gutta-perchas, and could not be used for insulating purposes; No. 5 resembles Pontianac. The samples were valued commercially as follows:—No. 1, 2*s.* per lb.; No. 2, 1*s.* 6*d.*; No. 3, 2*s.* 4*d.*; and No. 6, 6*s.* per lb. No. 5 would be of about the same value as Pontianac. (See also this J., 1898, 470.)

English Patent.

Rubber; Substance Similar to ——, and Process of Manufacturing same. C. E. Pensa, Paris. Eng. Pat. 14,001, June 23, 1903.

See Fr. Pat. 334,833 of 1903; this J., 1904, 122.—T. F. B.

French Patent.

Caoutchouc Substitute [" Ixophene "]; Process of Manufacturing a ——. E. H. Fayolle. Third Addition, dated Dec. 1, 1903, to Fr. Pat. 335,584 of Sept. 26, 1903. (See this J., 1904, 195 and 448.)

The name Ixophene is adopted for the material obtained by the interaction of glycerin (1 part), strong sulphuric acid (2·2—3·3 parts), 40 per cent. formaldehyde (1 part), water (0·7—1 part), phenol (2—3 parts), or these constituents in various proportions. When the amount of phenol is limited to 1 part, the product is readily obtained (after 15 days' contact) by vigorous stirring with 10—20 per cent. by weight of concentrated sulphuric acid; if more phenol is used it may be necessary to heat on the water-bath, and incorporate 10—20 per cent. of flowers of sulphur, or further to add casein, starch, or other carbohydrate. When only 0·7 part of phenol is employed, the product is a wax-like solid, soluble in alcohol (4 parts), and suitable for varnish-making.—R. L. J.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Water-softening [in Tanneries]; Use of Barium Hydroxide for ——. J. Hülsen. Collegium, 1904, 120.

The usual lime and soda mixture, when employed for softening purposes, leaves sulphates of sodium and calcium in solution, which are objectionable in the case of tannery waters. (See Nihoul and van de Putte, this J., 1904, 122.) Barium hydroxide removes soluble sulphates as well as other compounds, and gives a very soft water.

—R. L. J.

Liquors of Equal Tanning Strength from Various Tanning Materials and Extracts; Composition of ——. J. Paessler. Collegium, 1904, 116—120 and 121—123.

This is an investigation of the meaning of the frequentl employed barkometer—(*i.e.*, density)—readings of tan-liquors, which require some comparative standard such as i given in the following table, which shows the ratios an corresponding densities for most of the usual liquors (arranged in order of tannin strength of liquors of simila density). For similar densities those liquors containing th least non-tannins have the largest amount of total solubl matter and of tannin; and high density is not necessaril associated with high tannin strength (*cf.* myrobalan extrac and quebracho wood). The barkometer gives a false appea ance of strength with liquors rich in non-tannins. This bears on the composition of extracts where, by overheating, &c., the non-tannins are developed at the expense of the tannins. Thus three liquors were found to give the following readings: 20·9°, 50·1°, and 97·1° Bk., and contained 0·1, 1·3, and 4·1 per cent. of tannin respectively.

Table showing Relation between Density and Composition of certain Tanning Liquors.

asein Composition [Adhesive], and Process of Producing same. W. A. Hall, Bellows Falls, Assignor to Casein Co. of America, N.J. U.S. Pat. 758,064, April 26, 1904.

x adhesive composition is made by mixing a solation of modified" starch with granular casein whilst agitating gorously, until the starch is absorbed by or thoroughly corporated with the particles of casein. The casein is alkalised" during the agitating process by the addition an alkaline solution with the other ingredients.—J. F. B.

French Patents.

lue and Gelatin [Varieties of]; Manufacture of ——. L. Faucheux and A. J. Boissière. Fr. Pat. 337,598, Feb. 25, 1903.

NES, waste pelts, &c., are agitated, with or without addition water, in closed rotating cylinders, whilst sulphur dioxide, re or impure, under pressure or otherwise, is admitted. e flesh, grease, and other impurities, together with the eater part of the mineral matter of the bones, &c., form a dge, which is discharged. The gelatin remaining may be rified by solution in water, settling out impurities, and sequent concentration. To obtain the best quality of atin, the bones, &c., are previously cleansed by petroleum rit, boiling water, &c., and are then subjected to the joint ion of dilute hydrochloric and sulphurous acids in the ating cylinder. The acid liquor separated from the gelatin, taining calcium phosphate and chloride, may be preitated by sulphuric acid, and the cleared solution be in used, in conjunction with sulphurous acid, in the atment of bones as before. The process may be modified treating bones with phosphoric acid, the mineral matter g then removed as a sludge with the impurities. Such udge, on treatment with hot water, gives off sulphurous acid, the grease, which floats, is removed, and, after separation of tricalcium phosphate, the liquor may be used again. —E. S.

Horn, Pearl, Ivory, and other Similar Materials; Preparation of Imitation ——. Soc. anon. La Cornalithe. Fr. Pat. 337,695, Dec. 12, 1903.

Casein, 10 kilos., is macerated for 24 hours in a solution containing 62 grms. of anhydrous sodium sulphite, 625 c.c. of water, 10 litres of 95 per cent. alcohol and 250 c.c. of glycerin. The mass is then milled, alone or with the admixture of colouring or other matters, between hot rolls. The articles so manufactured are finally steeped for 30—60 days in a dilute solution of the bisulphite compound of formaldehyde and dried.—J. F. B.

UNITED STATES PATENT.

Starch ; Separation of —— *by Centrifugal Action.* R. Schrader, Sierakowo. U.S. Pat. 757,778, April 19, 1904.

CRUDE starch-milk is continuously subjected to a succession of centrifugal actions as it flows in one direction, whilst fresh water is mingled with the starch during the last centrifugal action and the saturated water is passed from one centrifugal treatment to the other in a direction opposite to that of the starch.—J. F. B.

FRENCH PATENT.

Sugar Juices ; Process of Defecating and Decolorising ——. J. A. Besson. Second Addition, dated Feb. 19, 1903, to Fr. Pat. 308,384, Feb. 25, 1901. (See also this J., 1902, 1406 and 1545.)

THE concentration of saccharine juices is conducted in presence of alumina, which may either be added as such or produced in the juice by electrolysis with aluminium electrodes or by the addition of readily decomposable aluminates or aluminium salts.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Enzymes ; Influence of Acidity on ——. P. Petit. Comptes rend., 1904, **138**, 1003—1004.

BARLEY meal was extracted with distilled water, as also with solutions containing 0·2, 0·49, and 0·98 grm. of lactic acid per litre, and filtered. The aqueous extract saccharified, but did not liquefy starch paste. The extracts made with the two more dilute lactic acid solutions saccharified and liquefied starch paste, while the last extract did not liquefy starch paste, and saccharified it to a much smaller extent than did the aqueous extract. On extracting barley meal with ten times its weight of sodium hydroxide solution (0·48 grm. per litre) the extract obtained had no action on starch paste; the addition of lactic acid to this extract gave it the power of liquefying and saccharifying. A solution of lactic acid alone has no liquefying or saccharifying action on starch paste. An extract of barley made by means of a solution containing 0·24 grm. of sodium hydroxide per litre is acid to phenolphthalein, and has a strong saccharifying action. It is concluded that barley contains an enzyme in the form of a compound decomposed by acids, without the aid of germination.—T. F. B.

Barley Corn ; Absorption of Water by the —— *during Steeping.* G. Bode. Woch. f. Brau., 1904, **21**, 267—268.

THE author draws a comparison between the barley corn emerging from its period of rest, whilst it is being steeped, and the vital processes which go on in a green plant or organ such as a leaf. The proportion of water in the latter, in relation to the osmotic pressures under which transference of material takes place, is regulated by the living protoplasm of the cells. Whilst salts may play a very small part in creating these osmotic pressures behind the semi-permeable membranes of the cells, the chief part is played by the carbohydrates which are converted into soluble sugars or insoluble starch by the protoplasm, according to requirement. In the same way, the embryo and endosperm of the corn in the steep are to be regarded as composed of living cells, the protoplasm of which acts as a governor in regulating the osmotic processes. If the corn contained a large quantity of preformed diastase and if the protoplasm were dead, so much sugar would be produced and so much water would be attracted by it that the membranes would burst. Hence it is important, whilst providing sufficient water during steeping, to maintain the vitality of the protoplasm unimpaired, so that it may regulate the production of sugar and the consequent absorption of water by osmotic pressure, in order to avoid the "over-steeped" condition which would result without this check. This vitality of the protoplasm can only be maintained by providing sufficient air to permit of normal respiration.—J. F. B.

Protein in Malt; Digestion of —— *through Moist Storage.* F. Schönfeld. Woch. f. Brau., 1904, **21**, 257—258.

THE use of malt which has become "slack" by storage in a moist atmosphere introduces a bad flavour to the beer, owing to the development of micro-organisms. It also causes bad fermentation, poor yeast, and deficient secondary fermentation; the "head"-retaining properties of the beer are considerably impaired. The extent of such defects depends largely on the quantity and activity of the enzymes present in the malt, and consequently on the treatment during germination and the temperature of kilning. The author divided two samples of high-kilned malt each into two portions, storing one portion in a bag and the other in a bottle closed by a stopper bearing a tube with calcium chloride, so as to permit the access of dry air. At the end of 13 months the nitrogenous constituents were analysed, both by cold extraction and by hot extraction. The following results were obtained :—

	Malt I.		Malt II.	
	Stored dry.	Stored in Bag.	Stored dry.	Stored in Bag.
Moisture in malt (per cent.)	2·6	11·7	2·8	10·7
Total protein on dry substance (per cent.)....................	10·71	10·71	9·7	9·7
Nitrogen per cent. of malt, dry substance :—				
Cold extraction :				
Total soluble..............	2·475	2·648	2·54	2·68
Coagulable..................	0·787	0·654	0·672	0·631
Albumose....................	1·068	0·808	1·117	1·063
Extraction at 50° C. :				
Total soluble..............	3·12	3·12	3·23	3·33
Coagulable..................	0·482	0·396	0·438	0·348
Albumose....................	0·965	0·913	0·957	0·854

The increase in the total soluble nitrogenous matter and the decrease in the coagulable and albumose constituents indicate the activity of the proteolytic enzyme during moist storage, in a manner detrimental to the "head"-retaining properties of the beer; this activity would, moreover, be far more considerable in the case of low-dried malts. —J. F. B.

Malting ; Use of Formaldehyde in ——. H. Tomann. Oesterr. Brauer- u. Hopfen-Zeit., 1904 [7] ; Z. ges. Brauw., 1904, **27**, 297.

BY adding commercial formaldehyde to the steeping water in sufficient quantity to make a solution of about 0·6 per cent. strength, the author obtained a malt of more uniform growth, a fresher and purer aroma, improved modification, and a higher percentage of extract than when the barley was steeped in water only.—C. S.

Barley and Malt; Conversion of Insoluble Protein in —— into the Soluble Form during Growth and Mashing. R. Nilson. Hopfen-Zeit., 1904, [53]; Z. ges. Brauw., 1904, **27**, 297.

This conversion is ascribed to enzyme action, stimulated by the presence of acid bacteria (short rods and cocci), the acid products of which, being liberated in the immediate vicinity of the insoluble protein, act thereon while in the nascent state.—C. S.

"Spring" Mashing Process. A. L. Woch. f. Brau., 1904, **21**, 273.

The writer points out an error into which he fell in his first trials of the "spring" mashing process. He sprung his cool mash into such a large quantity of boiling water that the desired saccharification temperature of 72° C. was only reached when the whole of the cool mash had been "sprung." The result was that the whole of the diastase was so crippled, whilst the temperature of the water was being reduced to the desired point, that saccharification was imperfect. In order to avoid such a crippling of the diastase, he now works with a smaller quantity of hot water at 87·5° C., so that the saccharification temperature of 71·2° C. is reached after one half of the cool mash has been "sprung"; the other half is then run in slowly whilst the requisite temperature is maintained by the application of sufficient heat. The results are in every way satisfactory, the attenuation being less than by the old method of high temperature mashing, and approximating closely, after eight weeks' cellarage, to the maximum attenuation possible in the wort produced.—J. F. B.

Wort; Subsequent Appearance of a Starch Reaction in a Fully Saccharified ——. F. Schönfeld. Woch. f. Brau., 1904, **21**, 225—226.

The author records a case in which the first runnings of wort gave a perfectly normal iodine reaction, indicating complete saccharification, but in which the later runnings showed an ever-increasing blue iodine reaction, indicating the presence of untransformed starch. The whole mashing process only lasted $1\frac{1}{4}$—$1\frac{1}{2}$ hour, and the mash was "struck" at a temperature of 75° C. The malt was a pale variety of poor quality, very steely and very short-grown, the average length of acrospire being one-half to two-thirds the length of the corn. It had been grown with couch and floor temperatures as low as possible, and kilned after 7—8 days' growth. The consequence was a very poor modification; in many cases one-half of the corn was unmodified. In addition to this, the grist-mill was very much worn, so that many large particles of grist would be perfectly raw grain. Owing to the short duration of mashing, these raw particles would be merely gelatinised on the surface, and the result was the presence of apparently fully saccharified wort and raw starch side by side. These lumps of starch would be gradually dissolved under the prolonged action of the hot sparging water, and so entered the wort. Unfortunately the diastase remaining in the wort was so enfeebled, although it had not been heated higher than 75° C., that an hour's rest in the wort copper was not sufficient to saccharify the starch which was washed through. Longer mashing periods rectified the fault.—J. F. B

Beer; Metallic Turbidities in ——. C. F. Gabel. Woch. f. Brau., 1904, **21**, 273—274.

The author disputes the contention that tin, when pure, is nsuitable for the internal coating of beer filters. The very few complaints of metallic turbidities which he has received have been traceable to the use of cheap impure tin for coating the filter parts. The fact that these filters should have been rejected indicates that the majority of filters which are coated with pure tin are perfectly satisfactory. The author states that in dealing with low temperatures, such as hose in the lager cellars, turbidities when employing filters oated with pure tin are not to be feared; but it is otherwise f the beer be filtered at higher temperatures. That warmth ncreases the liability to metal-albuminoid turbidities is shown by the experience of export brewers in their attempts to pasteurise beer in bulk, employing steel casks coated with tin or even with gold or silver. In such vessels, at a pasteurising temperature of 68°—70° C., metallic turbidities invariably appear in the beer.—J. F. B.

Beer; Metallic Turbidities in ——. C. Sellenscheidt. Woch. f. Brau., 1904, **21**, 274.

The author explains that when he stated (this J., 1904, 333) that zinc and lead are the worst metals for the construction of beer filters he referred to their poisonous properties, and not to their liability to cause turbidities, which is small. He repeats that no metallic filter is absolutely indifferent towards beer. Filters constructed of tinned metals are far more liable to cause turbidities than those of solid tin. When several metals are used simultaneously in the construction of a filter, electric currents are set up, the effect of these currents in causing turbidities being greater the greater the differences of potential involved. Turbidities from this cause are least frequent in the case of tin filters and most disastrous in aluminium filters.—J. F. B.

Beer; Carbon Dioxide in ——. T. Langer. Z. ges. Brauw., 1904, **27**, 307—311.

In 1879 Schultze and Langer determined that, within the limits of 0° C. to 5° C., a rise or fall of 1° C. in the temperature of the beer in the lager cellar caused a fall or rise of 0·01 per cent. by weight of the carbon dioxide absorbed by the beer, corresponding to a difference of 50 c.c. per litre per 1° C. The proportion of carbon dioxide in the beer can be increased by increasing the pressure in the cask, but an increase so obtained is not so advantageous as one obtained by lowering the temperature, since the combination is more stable in the latter case. An increase of 50 c.c. of carbon dioxide per litre is obtained by an increase of 31 mm. of mercury in the pressure in the cask. Thorough and long-continued agitation only liberates about three-fourths of the total carbon dioxide absorbed by the beer. Beer with a higher proportion of residual extract retains more carbon dioxide than a weaker beer under the same conditions. The author's experiments have further shown that, owing to the production of a hydrate of alcohol, dilute alcohol absorbs far less carbon dioxide than corresponding quantities of water and absolute alcohol would absorb separately. In spite of this fact, beer absorbs more carbon dioxide than water under the same conditions. From the above facts it must be concluded that the beer-extract plays an important part in the absorption of carbon dioxide. The greatest and most important influence from the brewing point of view is undoubtedly the physical absorption induced by the beer-extract, owing to its viscosity and the surface tension of the emulsified constituents. The sparkle and the fine spongy compact head is to be attributed to the carbon dioxide loosely bound by the physical influence of the extract constituents. But it cannot be denied that unstable chemical compounds, to a less extent, also play a part, which has been demonstrated in the case of the base choline, and in the production of bicarbonates from the secondary phosphates. To the influence of such loose chemical compounds is to be attributed the full round flavour of the beer.--J. F. B.

Matabele Beer. Loir. Brewers' J. Suppl., April 21, 1904, 13.

In a report presented to the Rhodesia Scientific Association, the author describes the method used by the Matabele for the preparation of a kind of beer from raw and malted maize, sorghum or millet, in the proportion of about 3:1. The grain is malted by steeping in water for 24 hours, allowing to germinate in bags for about 48 hours and finally drying in the sun. The ground raw grain is mixed with twice its bulk of water, and boiled; it is then left to cool in open vessels and inoculated with yeast and amylomycetes by means of flies and other insects. At the end of 24 hours, the ground malted grain is added. Vigorous fermentation takes place, and on the third day the beer is passed through a wicker-work rush filter and is ready for drinking. The beer contains 2·9 per cent. of alcohol, 0·35 per cent. of acid (as acetic acid), 4·2 per cent. of dry extract, 0·2 per cent. of maltose and a high proportion of starch. It is stated that with an improved method of manufacture the beer would be highly suitable for the local climatic conditions.—A. S.

Disinfectants in the Brewery; Errors in the Use of ——. P. Lindner. Woch. f. Brau., 1904, **21**, 256—257.

Solutions of calcium bisulphite, if used too strong, are unpleasant in application, but they disinfect efficiently. Very often, however, the solutions are used too dilute, in which state they kill the culture yeast cells without destroying the wild yeasts, especially if the latter be in a sporulating, semi-dry condition. If spores be present, the concentration must be increased beyond that prescribed for vegetative cells. It should never be attempted to reinforce the action of one disinfectant by the subsequent or simultaneous application of another, since the two are liable to neutralise each other. For instance, caustic lime or hypochlorites ["antiformin"] must never be applied in conjunction with bisulphites. A case is quoted also in which a wash of salicylic acid was followed by one of "antiformin," with the result that an odour and flavour of creosote were imparted to the beer. Only one disinfectant should be used in each treatment, and the concentration should be calculated with due regard to the quantity of water already absorbed in the wood of the tun. All residues of disinfectants should be thoroughly removed before the tuns are taken into use again, so as to avoid any influence on the flavour of the beer and on the vigour of the culture yeast.—J. F. B.

Cider Vinegar; Examination of ——. A. E. Leach and H. C. Lythgoe. XXIII., page 563.

English Patent.

Iron Vessels, such as those in which Beer is Prepared or Stored; Providing —— with a Protective Coating. V. Lapp, Leipzig. Eng. Pat. 3682, Feb. 13, 1904.

Iron vessels intended for holding beer, particularly pasteurising vessels, are first treated with tannic acid and then subjected to the action of boiling oil. Linseed, castor and rosin oils are suitable for this purpose, particularly the rosin oil, which distils at temperatures between 450°—500° C. After the vessels have been treated with hot oil for two hours, they may be further subjected to the action of hot air at 350°—400° C. under pressure, whereby the protective layer is hardened.—J. F. B.

United States Patents.

Grain Germinating Apparatus. V. Lapp, Leipzig. U.S. Pat. 758,083, April 26, 1904.

See Fr. Pat. 326,114 of 1902; this J., 1903, 756.—T. F. B.

Air Purifier [for Breweries]. J. St. P. Macardle, Dundalk. U.S. Pat. 757,475, April 19, 1904.

See Eng. Pat. 23,456 of 1902; this J., 1901, 264.—T. F. B.

French Patent.

Malt; Apparatus for Germinating ——. R. Plischke and A. Beschorner. Fr. Pat 337,983, Dec. 23, 1903.

The apparatus consists of a number of endless horizontal bands of wire-netting arranged in a vertical series, and provided with mechanism which enables them to move in alternate opposite directions. Steeped grain is distributed on the uppermost band whilst in motion. After the top band is filled, the apparatus is stopped, and left at rest for 24 hours. It is then started again, and the couch of grain on the top band is broken up by rakes at the end of the apparatus and caused to fall on the second band, travelling in the opposite direction, fresh grain being meanwhile fed upon the top band. The process thus proceeds continuously, and the green malt issues from the lowermost band, one band being provided for each day of germination.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A.*)—FOODS.

Leaf Lard; High Iodine Absorption of ——. W. D. Richardson. J. Amer. Chem. Soc., 1904, **26**, 372—373.

Samples of leaf lard from individual hogs or droves frequently have an iodine value of 80 to 85. The animals yielding this lard are allowed to run wild in the woods, and are supplied with but little food. Four specimens of leaf lard from different animals gave the following results:—Melting-point, 32° to 37·5° C.; solidification point ("titre"), 27·9° to 30·8° C.; and iodine value, 78·8 to 82·0. The corresponding back fat from the same hogs had the following values:—Melting-point (1) 32° C.; solidification point ("titre"), 24·7 to 27·3; and iodine value, 81·5 to 84·7. Amthor and Zink found a specimen of the fat of a wild boar to have an iodine value of 76·6.—C. A. M.

Milk-Chocolate; Analysis of ——. O. Laxa. XXIII., page 564.

Indicator; New ——. Its application to the Detection of Boric Acid, especially in Foods. L. Robin. XXIII., page 561.

English Patents.

Butter Substitute. H. T. Mapleton, Manchester. Eng. Pat. 12,159, May 28, 1903.

Barcelona, Brazil, walnut or other nuts are thoroughly dried, the skins are removed by rubbing on a sieve, the nuts are then broken and finely ground and suitable proportions of "cokernut fat" and nut oil are added, the whole being incorporated by grinding. When almonds are used they may be "blanched" before treatment as above. —J. F. B.

(*B.*)—SANITATION; WATER PURIFICATION.

Manganese; Precipitation of —— from Well Waters. C. A. Neufeld. Z. Untersuch. Nahr. Genussm., 1904, **7**, 478—479.

In a paper which appeared in this Journal (1902, 681) the rapid growth of *Crenothrix* in manganiferous waters was described. The author points out that this growth, attended with deposition of manganese sesquioxide, has been noticed recently by other observers, who ascribed the precipitation to *Crenothrix manganifera*, not to *Crenothrix polyspora*. In one instance cited, where the water first passed through iron mains and then through lead branch pipes, the mains were blocked by a deposit consisting principally of iron oxide, whilst the scale in the lead pipes was composed of manganese sesquioxide. The precipitation of manganese occurs chiefly in waters from deep wells, and not in surface waters.—W. P. S.

French Patent.

Sewage and Water containing Albuminoid Matter; Process and Product called "Phospho-zinco-alumino-magnesien" suitable for the Treatment of ——. J. M. Lallemand and A. Goutierre. Addition, dated March 3, 1903, to Fr. Pat. 323,900, Aug. 14, 1902. (See this J., 1903, 568.)

By treating with sulphuric acid, aluminium or iron phosphate which has previously been strongly heated, and adding a zinc salt to the product, a suitable precipitant for organic matter is obtained.—T. F. B.

(*C.*)—DISINFECTANTS.

Root Blight of the Sugar Beet (Rhizoctonia violacea Tul); Experiments on the Destruction of —— in the Soil. F. Bubák. Z. Zuckerind. Böhm., 1904, **28**, 344—345.

The author proved by field experiments that ferrous sulphate has a very favourable effect on the growth of the sugar-beet, the proportion of infected roots falling from 47·5 per cent. on an untreated plot to 28·75 per cent. on a plot treated with ferrous sulphate. Copper sulphate, on the other hand, caused an increase in the percentage of infected roots, from 68·18 to 97·78. Quicklime also had no injurious effect on the *Rhizoctonia.*—A. S.

United States Patent.

Insecticide [*from Dioxynaphthylmethane*] ; *Process of Making an* ——. P. Bachmann, Cologne. U.S. Pat. 759,208, May 3, 1904.

See Fr. Pat. 323,230 of 1902 ; this J., 1903, 510.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Hydrocellulose. C. F. Cross and E. J. Bevan. Proc. Chem. Soc., 1904, **20**, 90.

The residues described by Stern (Chem. Soc. Trans., 1904, **85**, 336 ; this J., 1904, 264—266) having the empirical composition of cellulose, are no doubt products of hydrolysis and reversion, and are constitutionally different from the original cellulose ; but they are in no case identical with those described by Girard, and therefore this investigator's exhaustive account of the actions of acids on cellulose remains unaffected by the criticisms contained in the above-mentioned paper. The statements (*loc. cit.*) as to the causes of the attendant structural changes are considered improbable. Cellulose is a chemically labile and structurally plastic aggregate, occupying an intermediate position between the two extreme products, formed from ordinary cellulose by the action of (*a*) alkali hydroxides, (*b*) the halogen hydracids, both in presence of water. It is suggested that the terms hydracellulose and hydrocellulose respectively may for the present be retained to designate the two groups of derivatives obtained by the processes (*a*) and (*b*).

"*Crude Fibre*" ; *Preparation* [*Determination*] *of* —— *from Vegetable Fibres containing Lignin, by means of Sodium Peroxide.* A. Duschetschkin. XXIII., page 563.

English Patents.

Acetylised Cellulose Derivatives ; Manufacture of Soluble ——. R. M. Balston and J. F. Briggs, Maidstone. Eng. Pat. 10,243, May 5, 1903.

Dry, fibrous cellulose, 10 parts, is treated with an acetylating mixture composed of acetic anhydride 30 parts, glacial acetic acid 30 parts, and phosphorus oxychloride 1·7 parts. The mixture is maintained at a temperature of 55° C. with occasional stirring until the product is sufficiently soluble in chloroform or phenol. Instead of phosphorus oxychloride, phosphorus pentachloride or anhydrochlorides of other mineral acids may be employed.—J. F. B.

Filters [*for Waste from Paper or Cellulose Factories*]. O. Mehnert and P. Pape, Coethen. Eng. Pat. 8061, April 7, 1903.

A perforated cylinder *c* with open ends is arranged between two annular projections *r r*, of the end pieces *m* and *m'*, in the tank *a* (Fig. 2). The cylinder *c* is surrounded by an endless band of filtering material *g* (Fig. 2). At the upper part of the cylinder, not covered by the band, a tightening arrangement *d*, adjustable by the screws *e* and *f*, is placed. The liquid to be filtered (such as waste from paper or cellulose manufacture) is led through the pipe *a'*, into the tank *a*, filling it to the level W (Fig. 2). Some clean water is led into the interior of the cylinder *c*, and the valve *v*, in the telescopic pipe *n*, which dips into water in a tank below, is opened, and a partial vacuum is thus produced in *c*, causing the liquid in *a* to pass through the filtering band *g* into the cylinder, and leaving the residue behind on the band. The level of liquid in the cylinder is adjusted by the float *z*. The endless band *g* passes between the rollers *p p*, which

Fig. 1.

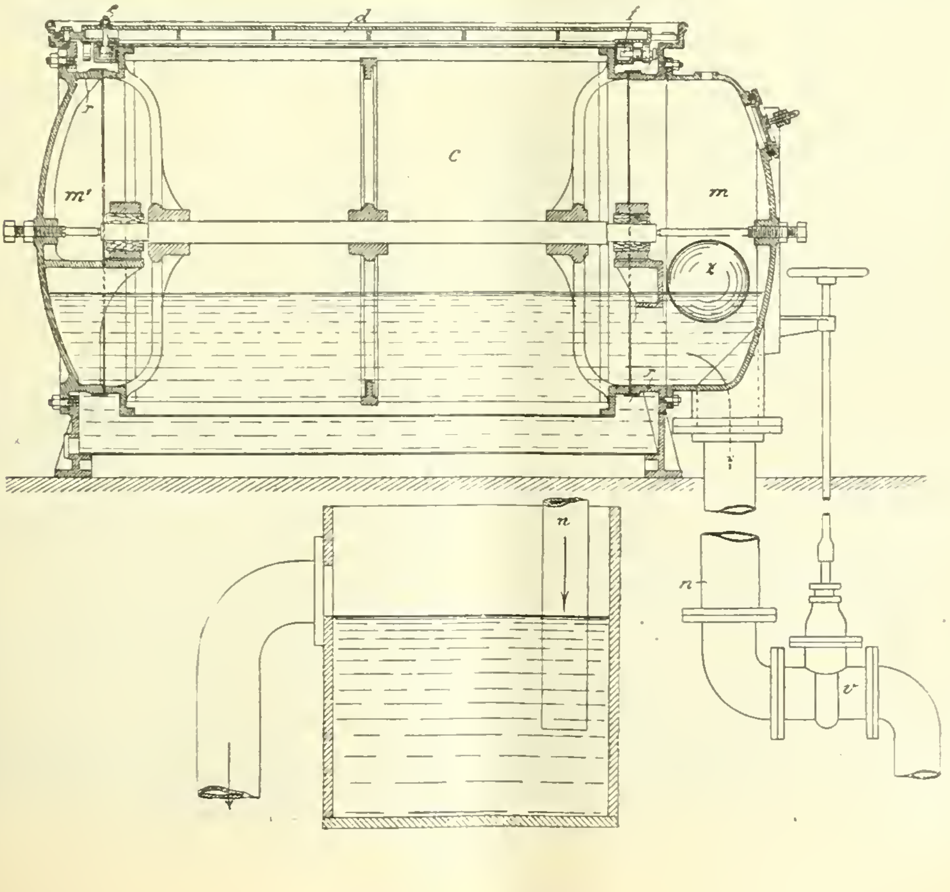

Fig. 2

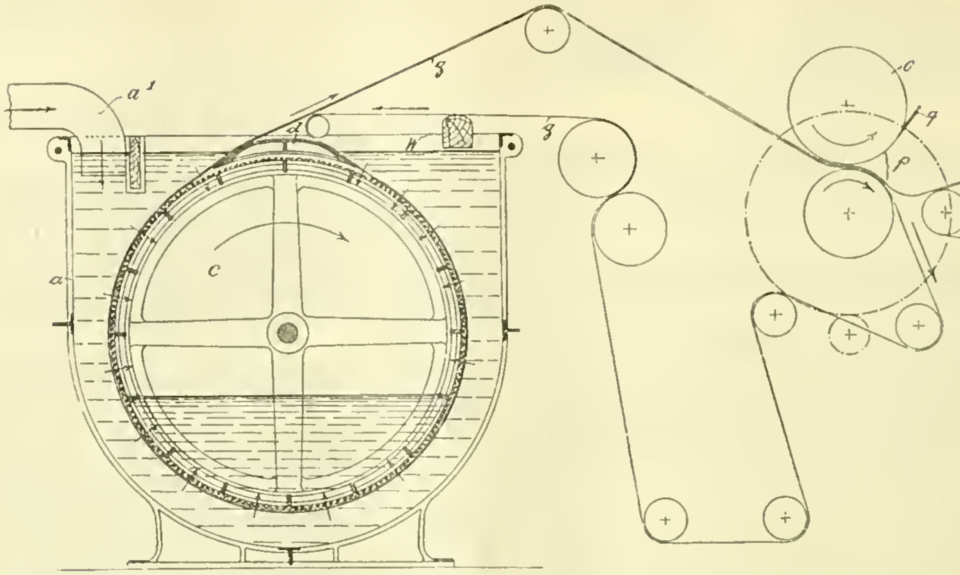

cause the band to move and so rotate the cylinder c, at the same time pressing the remainder of the water out of the residue on g. The pressed residue is removed by the apron u and the scraper q.—W. H. C.

United States Patent.

Celluloid Compound. A. Schmidt, Assignor to Farbwerke vorm. Meister, Lucius und Brüning, Höchst-on-the-Maine. U.S. Pat. 758,335, April 26, 1904.

See Eng. Pat. 25,434 of 1899; this J., 1901, 62.—T. F. B.

French Patents.

Paper-making Machines. L. Tailfer. Fr. Pat. 337,911, Dec. 21, 1903.

The web of paper is passed through a couch press consisting of three rolls. The making wire returns round the bottom roll, whilst a short endless couch-felt encircles the centre roll; the uppermost roll carries a long endless wire cloth which traverses the whole series of drying cylinders and acts as an undeformable drying felt. The paper is transferred from the making wire to the couch-felt, and from the couch-felt to the drying wire by means of the triple press. The drying wire accompanies the paper over the hot cylinders, which are arranged in such a way that direct contact between the paper and hot cylinders does not take place until the paper is partially dry.—J. F. B.

Paper; Process of Making —— from old Printed Matter. W. B. Meixell and T. Holt. Fr. Pat. 337,980, Dec. 23, 1903.

See U.S. Pat. 748,968 of 1904; this J., 1904, 128.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Aucubin. E. Bourquelot and H. Hérissey. Comptes rend., 1904, **138**, 1114—1116.

Aucubin is the name assigned to the glucoside extracted from the seeds of *Aucuba japonica*; it is soluble in water and alcohol, but insoluble in ether or chloroform. It is easily decomposed by dilute acids or emulsin, forming dextrose and a compound $C_7H_9O_3$, which the authors call *aucubiginene*. Aucubin contains water of crystallisation, and its composition is represented by the formula $C_{13}H_{19}O_8,H_2O$.—T. F. B.

Essential Oils of Amorpha Fruticosa. V. Pavesi. Estr. aus Ann. della Soc. Chim. di Milano, 1904, **11**, [1 and 2]; Chem. Centr., 1904, **1**, 1146—1147.

The leguminous plant *Amorpha fruticosa*, of the genus *Galega*, appears to contain different essential oils in its various organs. On distillation with steam, the fruit yielded 1·5—3·5 parts and the leaves 0·5—0·8 part per 1,000 of a clear yellowish oil having a bitter after-taste. The oil from the leaves resinifies more quickly than that from the flowers. The latter distils over mainly between 250° and 270 C., and undergoes slight alteration during distillation. The constants which have been determined up to the present are shown in the following table:—

——		Specific Gravity at 15° C.	Refractive Index in Pulfrich's Refractometer at 17·5° C.
Oil extracted from—			
Leaves	Fresh	..	1·50083
	Sour	..	1·50928
Fruit	Green	0·9019	1·49951
	Ripe	0·9057	1·50036
Oil distilling at—			
230°—250° C.		..	1·50233
250°—270° C.		0·9254	1·50484
Above 270° C.		..	1·51637

The oils are soluble in the usual organic solvents, but almost insoluble in 50 per cent. alcohol. The portion distilling at 250°—270° C. becomes fairly solid at—17 C. The oil from the fruits probably belongs to the class of oils containing hydrocarbons, but it appears to contain also a small quantity of an oxygenated compound.—A. S.

Essential Oils; Two New Algerian [Gouft and Scheih]. P. Jeancard and C. Satie. Bull. Soc. Chim., 1904, **31**, 478–480.

Gouft.—The oil obtained by the distillation of the entire herb is bright yellow in colour and resembles absinthe in odour. It has the following characters: Sp. gr. at 9·5 C., 0·8720; a_D at 10° C.,—15°20′; specific viscosity at 9·5° C., 49; acid value, 1·12; saponification value, 14; saponification value after acetylating, 42; solubility in alcohol (96 per cent.), 2:1, with slight turbidity on further addition of the solvent; 75 per cent. of the oil distils below 170° C. The major fraction distilling between 160°—165° C. contains *l*-pinene; that distilling above 170 C. yields a trace of an alcohol having the odour of geraniol.

Sheih.—The oil obtained by distilling the entire herb is reddish-brown and has a terebinthous odour, recalling that of mastic. Its characters are: sp. gr. at 9·5° C., 0·9540; specific viscosity, 170; acid value, 8·4; saponification value 66·5; saponification value after acetylating, 129·5. The oil contains 15 per cent. of phenols soluble in sodium hydroxide solution, from which the dimethyl ether of pyrogallol was isolated. The nonphenolic portion appears to contain thujone and thujol.—J. O. B.

Californian Laurel; Constituents of the Essential Oil of ——. F. B. Power and F. H. Lees. Proc. Chem. Soc., 1904, **20**, 88.

The Californian laurel, *Umbellularia californica* (Nuttall), a handsome, evergreen tree, occurring in California and Oregon, is also known as "mountain laurel," "cajeput," "spice tree," "California olive," "California bay tree" and "pepper-wood." The essential oil of the leaves has a pale yellow colour and an odour which is at first agreeably aromatic, but when more strongly inhaled becomes exceedingly irritating to the mucous membranes of the nose and eyes. The oil had a sp. gr. 0·9483 at 16°/16° C., and a_D −22° in a 100 mm. tube; it was completely soluble in 1·5 parts of 70 per cent. alcohol. The principal constituents of the oil in their relative proportions are approximately as follows:—umbellulone (a new, unsaturated, cyclic ketone, $C_{10}H_{14}O$), 60; cineol, 20; eugenol methyl ether, 10; *l*-pinene, 6, and eugenol, 1·7 per cent. respectively, together with a very small amount of safrol. Umbellulone is a colourless liquid with a somewhat mint-like odour; it boils at 219°—220° C., has a sp. gr. of 0·9581 at 15°/15° and $[\alpha]_D$ − 37°.

(Compare Ber., 1897, **30**, 230, 251; 1900, **33**, 562, and 1903, **36**, 4377.)

Platinum; Electrolytic Solution of ——. *New Process for preparing Platinocyanides.* A. Brochet and J. Petit. XI. A., page 548.

English Patents.

Ionone; Manufacture of ——. A. Verley, Paris-Neuilly, and L. Givaudan, Vernier. Eng. Pat. 26,089, Nov. 30, 1903.

Cyclo-citrylidene acetic esters (Fr. Pat. 326,774 of 1902; this J., 1903, 819) are converted, by the action of acetone (1 mol.) and sodium ethylate (1 mol.), into the sodium salt of acetyl-ionone, $C_9H_{15}.CH:CH.CO.CHNa.CO.CH_3$, which is converted into acetyl-ionone by addition of acids. Ionone is obtained by boiling this acetyl-ionone with alkalis.
—T. F. B.

Hæmatoxylin and Formaldehyde; Manufacture of a Condensation Product from ——. R. Lepetit, Garessio. Eng. Pat. 6428, March 16, 1904.

See U.S. Pat. 736,529 of 1903; this J., 1903, 1063—T. F. B.

United States Patents.

Dicarbo Acids and Bromated Phthalic Acids with Naphthols; Process of making Condensation Products from ——. A. Denguine and S. Levinsohn. U.S. Pat. 753,372, March 1, 1904.

Hydroxynaphthoylbenzoic acid is obtained by condensing phthalic anhydride with *a*-naphthol in presence of boric acid. Substituted hydroxynaphthoylbenzoic acids are obtained imilarly from hydroxy- or bromo-phthalic acids and naphthols. The hydroxynaphthoylbenzoic acids are onverted into the corresponding hydroxynaphthacenequinones by heating to about 160° C. with concentrated ulphuric acid.—T. F. B.

Sulpho-iodine Compound of Hydrocarbon. F. T. F. Stephenson, Detroit. U.S. Pat. 755,808, March 29, 1904.

Compounds of the general formula R.SI, where R represents an aromatic radical, are prepared from phenols, in alkaline solution, by the action of alkali sulphydrates and iodine in presence of oxidising agents, *e.g.* an alkali hypochlorite. The compounds are insoluble in water, slightly soluble in concentrated alkalis and in absolute alcohol, and soluble in ether and chloroform, and are suitable for medicinal use.—T. F. B.

Ortho-oxy-carbon Acids [Hydroxy-Carboxylic Acids]; Process of Making ——. G. Wichmann, Berlin, Assignor to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin, and Soc. Chim. des Usines du Rhône, ancien. Gilliard, P. Monnet et Cartier, St. Fons. U.S. Pat. 757,702, April 19, 1904.

See Fr. Pat. 307,186 of 1901; this J., 1902, 68.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photography; Review of ——. A. Granger. Monit. Scient., 1904, **18**, 331—340.

Developers.—Süss has proposed lithium carbamide as substitute for alkalis in developers; it is said to give excellent results with "edinol." Sodium amino-acetate has also been proposed for a similar purpose, and is sold under the name of "pinakol salt." "Adurol" and metol together are said to give a more energetic developer than quinol-metol. Lebreton proposes to use a developer containing only pyrogallol and sodium sulphite for over-exposed negatives: for normal exposures, a few drops of ammonia are added, and for under exposures, acetone.

Negative Processes.—Reiss (Bull. Soc. Franc. Phot., 1903, 273) has used plates which can be developed by 3 per cent. solution of sodium carbonate. These plates are prepared by immersing an ordinary dry plate in a solution of quinol (hydroquinone), 1 grm.; acetone sulphite, 10 grms.; water, 100 c.c.

Positive Processes.—Homolka (Phot. Korr., 1903, 452) finds that bromide papers, exposed to daylight for 15—20 secs., can be developed by immersing for two or three hours in a 0·1 per cent. solution of gold chloride acidified with phosphoric acid. A paper of the same type as platinotype has been prepared by Szigeti (Phot. Ind., 1903, 248) by the use of selenious acid and ferric oxalate; the ferrous salt formed reduces the selenious acid to selenium; the image is intensified by a solution of potassium oxalate. Von Hübl (Bull. Soc. Franc. Phot., 1904, 47) uses a mercury citrate solution for toning platinotype prints sepia. Valenta (Chem. Ind., 1904, 117) gives a process for preparing celloïdin (printing out) papers with a silver chlorocitrate emulsion.

Toning Solutions.—Mercier has obtained good brown and black tones on "printing out" papers by the use of a solution of potassium palladium chloride, citric acid, and sodium chloride, or ammonium molybdate. Aluminium acetate is recommended (Phot. News, 1903, 446) for use in combined toning and fixing solutions containing gold. "Pinakol" (see above) in conjunction with potassium ferricyanide is said to form a powerful reducer.—T. F. B.

Silver Bromide; Centrifugalised —— *for Bromide Emulsions.* L. Backeland. Monit. Scient., 1904, **18**, 362—365.

The centrifugal separator used for filtering silver bromide in gelatin emulsion should have a drum composed entirely of silver, rather than of bronze lined with silver, since the silver is inclined to wear off the latter. The cover of the drum should be clamped on, not screwed, to avoid the introduction of particles of metal into the bromide by the wearing of the thread. In order to obtain uniform preparations, it is necessary to keep the apparatus at approximately the same temperature, about 30°—35° C., and to keep the machine running at a uniform rate, and not too fast, as otherwise the photo-chemical properties of the product will be modified. The liquid to be filtered should be added in small quantities at short intervals, and the total quantity filtered in one operation should not exceed that obtained from 5 kilos. of silver nitrate. The bromide should be washed, on the drum, with a small quantity of warm water, as it is important to remove from it all ammonia and soluble salts. To remove the gelatinous matter which usually accompanies precipitated silver bromide, the product is macerated with hot water and again centrifugalised. Silver bromide prepared in this manner, and stored in a cool place, has been found, after two years, to have increased only very slightly in sensitiveness, the emulsions giving prints of rather less density than originally.—T. F. B.

Photographic Paper ; Influence of Moisture in the Atmosphere in Making [Drying] ——. L. Backeland. Monit. Scient., 1904, **18**, 355—358.

When the emulsion of "developing papers" (*i.e.*, those containing insoluble silver halides) is slowly dried, the papers are more rapid and give flatter prints than those more rapidly dried. Emulsions containing soluble silver salts, when slowly dried in damp air at relatively high temperatures, give reddish coloured prints, difficult to tone, and which deriorate rapidly. These emulsions should, therefore, be rapidly dried, in dry air, at relatively low temperatures. A satisfactory method of preparing the air consists in first lowering the temperature to below 0° C., thus removing the moisture, and then warming it, in another apparatus, to a suitable temperature. If the air be too dry, especially when preparing certain kinds of paper, the friction and pressure of the paper on the drying frame sets up a static electric charge, which attracts dust particles; this inconvenience may be remedied by the use of strips or wires of silver attached to the frame of the machine.—T. F. B.

Photographic Plates ; Some Substances which give Impressions on ——. E. von Aubel. Comptes rend., 1904, **138**, 961—963.

Colophony, copal, Canada balsam, abietic acid, and similar compounds, give impressions on photographic plates, even through black paper, but not through copper, after two days. If, however, the resin has been heated much above its melting point, it has no effect on the plate. An almost saturated solution of phenol in absolute alcohol gives, in a similar manner, a negative after 24 hours.—T. F. B.

Development in Daylight. A. and L. Lumière and A. Seyewetz. Monit. Scient., 1904, **18**, 351—354.

The method recommended is essentially that of Fr. Pat. 334,915 of 1903 (see this J., 1904, 130). The authors give the mixture of sodium sulphite and magnesium picrate the name "chrysosulphite." When working with "metoquinone," metol-quinol, pyrogallol, edinol, eikonogen, quinol, metol, adurol, or ortol developers, it is advisable to use 2 parts of crystallised sodium sulphite and 1 part of magnesium picrate, while, when using "hydramine," "glycine" *p*-aminophenol or diaminophenol, 2 parts of anhydrous sodium sulphite should be mixed with every part of magnesium picrate. Formulæ are given for the use of the method with the various developers, and directions as to use in daylight and different artificial lights.—T. F. B.

Engraving Rollers for Calico and Carpet Printing ; Employment of Photography in ——. P. J. Lamp'l. Z. Farb. Textil-Chem., 1904, **3**, 62—66.

Difficulties are met with in producing, by means of photography, designs of flowers, &c., upon rollers, according to the methods proposed respectively by Rolffs (this J., 1902, 47) and Mertens. The chief of these lies in bringing the negative film, composed as it is of gelatin or indiarubber, without distortion upon the curved surface of the roller (engraving die or printing roller) to be engraved. It is especially great when fine lines are to be reproduced, and when the size of the negative film is relatively large. Another difficulty is caused by the presence of air-bubbles between the negative film and the sensitised film on the roller. This is partly due to the impracticability of applying strong pressure to the negative film, as in the process of photographing upon flat metal surfaces. The exposure to light for the purpose of producing the positive print would, further, appear at present to be carried out without regard to the necessity of causing the rays of light to fall vertically upon the negative film. (See also this J., 1904, 181.)—E. B.

United States Patent.

Photographic Developing Paper. F. Günther, Assignor to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. U.S. Pat. 758,312, April 26, 1904.

See Fr. Pat. 335,807 of 1903; this J., 1904, 268.—T. F. B.

French Patent.

[Flash Lights] Illuminating Compositions suitable for Photography ; Process for Making ——. G. Krebs. Fr. Pat. 337,901, Oct. 21, 1903.

Compositions suitable for producing "flashlights" consist of a mixture of magnesium or aluminium powder, 100 parts; alkali or alkaline earth nitrate, 200 parts; a metallic silicate, 10 parts; and amorphous phosphorus, 3 to 5 parts. Slow-burning "illuminating cartridges" are prepared by enclosing the above composition in a celluloid casing, and inserting a fuse which has been impregnated with potassium chlorate and perchlorate; the whole is then coated with a mixture of celluloid, collodion, and amyl acetate.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosion ; Circumstances attending an —— *which occurred in the Drying House for Nitrocotton at the Factory of Messrs. Curtis and Harvey, Ltd., at Cliffe, Kent, on Feb. 4, 1904.* By Captain A. P. H. Desborough, H.M. Inspector of Explosives.

Just before the explosion occurred, about 400 lb. of dry collodion cotton were in the stove. The cause of this explosion is attributed to friction set up between the trays and the racks, which approached too near together. Experiments showed that it was not possible to ignite dry guncotton dust by blowing it across the 1-cm. spark-gap of an induction coil, nor by means of a Leyden jar discharge. Recommendation is made that stoves should not be unloaded by artificial light, that the explosive should be cooled down before unloading, and that the clearance between trays and racks should be at least 2 ins. instead of the $\frac{1}{4}$ in. existing hitherto.—G. W. McD.

English Patents.

Nitrocellulose ; Manufacture of ——, *and Apparatus therefor.* J. M. and W. T. Thomson, Waltham Abbey. Eng. Pat. 8278, April 9, 1903.

The acids are removed from the nitrocellulose, without the use of machinery, by means of displacement with water. The charge of mixed acids is introduced into a rectangular vessel of lead or earthenware, provided with a perforated false bottom and a cock at the lowest point. The cellulose is then immersed in the acid in the usual way. A layer of dilute sulphuric acid (for the purpose of preventing nitric acid fumes) is gently run over the surface of the mixed acids, from perforated troughs on the sides of the vessel. When nitration has been completed, water is supplied to the perforated troughs and allowed to float very gently over the surface of the sulphuric acid. The cock at the bottom of the apparatus is then opened, and the acid slowly drawn off, water being supplied to maintain a constant level. A suitable rate of displacement is about 2 ins. per hour.
—G. W. McD.

Nitrated Cellulose ; New Process of Manufacturing —— A. Voigt, Schoaebeck. Eng. Pat. 5126, March 1, 1904.

Cellulose (1 part) is treated with concentrated sulphuri acid (5 parts) at 2° C. until the structure is destroyed an a pulpy mass obtained. Concentrated nitric acid (2 parts is then added, the temperature being kept at 2° C., and the end of 2—3 hours the nitrocellulose is completely pre cipitated, and forms a solid cake. After purification th nitrocellulose is obtained in the form of a very fine powde
—G. W. McD.

Explosives or Blasting Compositions. J. Wetter, Londo From Westfälisch Anhaltische Sprengstoff Act.-Ge Berlin. Eng. Pat. 13,531, June 17, 1903.

UNITED STATES PATENT.

Explosive Compound. J. P. Arnold, Colfax. U.S. Pat. 757,713, April 19, 1904.

The composition consists of potassium chlorate, yellow prussiate (ferrocyanide) of potash, sulphur, saltpetre, and tannin, this last existing in the compound as a coating of the insoluble ingredients, "brought to this condition by being dissolved in alcohol, which is afterwards evaporated."
—G. W. McD.

FRENCH PATENTS.

Explosive. J. B. P. Bouthoux. Fr. Pat. 337,638, Sept. 1, 1903.

The explosive consists of sodium nitrate (74 parts), anthracite (12 parts), and sulphur (14 parts).
—G. W. McD.

Explosive. M. Chakoor. Fr. Pat. 337,781, Dec. 16, 1903.

The composition consists of potassium chlorate (100 parts), powdered sugar (45 parts), and grated wax (1·5 parts).
—G. W. McD.

Matches; Manufacture of ——. W. Cernás. Fr. Pat. 337,811, Dec. 17, 1903.

Before dipping, the tips of the match sticks are so opened out that the fibres form a small brush-like end. The advantages claimed are that the match composition penetrates the head more readily, and does not rise between the individual match sticks when the latter are dipped in bundles.—G. W. McD.

Matches without Heads; Process for Making ——. J. H. Christensen. Fr. Pat. 338,128, Dec. 26, 1903. Under Internat. Conv., Jan. 9, 1903.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Saccharimeters; Determination of the Hundred Point on the Ventzke Scale of ——. O. Schönrock. Z. Ver. deutsch. Zuckerind., 1904, 521—558.

HE author's results are briefly as follows:—The differences n the rotations of sugar solutions obtained by different bservers and by the use of different sources of white light, anish when the light is purified by passing through a ·5 cm. layer of 6 per cent. potassium bichromate solution. quartz plate of 100° Ventzke rotation gives, with ectrally purified sodium light, a rotation of 34·657° at ° C. The fact that a substance gives different rotations ith different lights is due to a difference in rotary dis-ersion between the substance and quartz. The rotation, corresponding with the hundred point, increases with the mperature according to the equation: $wt = w_{20} + w_{20} \times$ 000148 $(t - 20)$. The rotation values of the quartz-ates in the saccharimeter are independent of the temperare, if the quartz-plates and wedge-compensator have the me temperature. If S_{20} be the rotation of an approximately rmal sugar solution at 20° in a saccharimeter at 20° C., d St its rotation at $t°$ in the same saccharimeter at $t°$ C., en $S_{20} = St + St \times 0{\cdot}000609\ (t - 20)$. The rotation the normal sugar solution in degrees for spectrally rified sodium light at 20° C. is 0·010° greater than that the normal quartz plate giving a reading of 100° ntzke at 20° C. In all accurate sugar analyses, observa-n tubes should be used which allow of the introduction the solution after the two end-plates are in position. e rotation of the normal sugar solution in a saccharimeter h wedge-compensation is 0·156° Ventzke greater for the low-green mercury light than for sodium light.
—T. H. P.

FRENCH PATENT.

Acidimetry; Process of ——, *and Apparatus for its Application.* A. M. Pereira. Fr. Pat. 337,283, Dec. 1, 1903.

The apparatus consists of a stoppered tube, of which the lower part is of less diameter than the middle or intermediate part, which latter is contracted near the top to a relatively narrow neck, and then widens upwards, to receive a perforated stopper. The lower, more contracted part of the tube has a mark upon it to show the level of the liquid to be tested; and the wider portion of the tube has another mark showing the height to which the liquid used as an indicator reaches. Hermetically closed capsules of thin glass, containing a measured portion of the neutralising liquid are provided, and are placed, one at a time, resting in the contracted neck, the stopper being furnished with a movable piercing rod whereby the capsule may be crushed so as to discharge its contents.—E. S.

INORGANIC—QUALITATIVE.

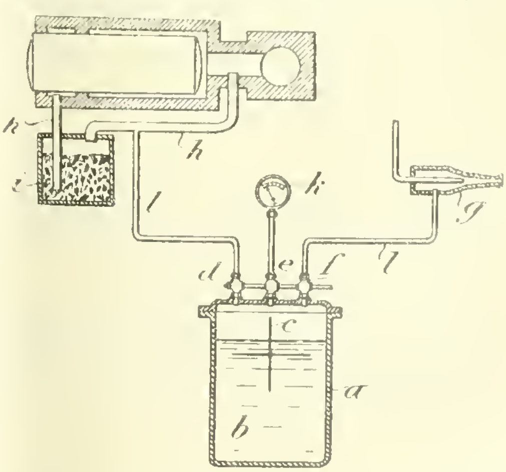
Indicator; New ——. *Its Application to the Detection of Boric Acid, especially in Foods.* L. Robin. Comptes rend., 1904, **138**, 1046—1048.

The indicator is prepared from mimosa flowers, 10 grms. of which are digested with 200 c.c. of water, to which on cooling, 50 c.c. of alcohol are added, and the liquid is filtered after an hour. It is straw-yellow, and has practically no tinctorial power in neutral or acid solution, but is turned bright golden yellow by alkalis. Boric acid turns it yellow, and when alkali is added, the yellow becomes red, and the substance (or paper soaked with it) applied to the ash of wines, milk, &c., forms a delicate test for the presence of boric acid.—J. T. D.

INORGANIC—QUANTITATIVE.

Carbon Dioxide in Furnace Gases; Method and Apparatus for the Determination of ——. A. Schlatter and L. Deutsch. Fr. Pat. 337,992, Dec. 21, 1903.

The method consists in treating a certain volume of the gas with a suitable absorbent (preferably lime water), and noting the diminution in pressure caused by the absorption of the carbon dioxide. The lime-water, *b*, having excess of lime in suspension is contained in the vessel *a*, which is fitted with a paddle-wheel, *c*, and three stop-cocks, the plugs of which are on a single shaft. The plugs are so bored that *d* and *f* are open when *e* is shut off. When a test is to be made, a quantity of the furnace gases is drawn through the pipe *l* into *a* by means of the injector *g*; cocks *d* and *f* are then closed, whilst *e* is opened, and the carbon dioxide is absorbed by the lime. The gauge *k* indicates the reduction in pressure. The filter *i* removes dust and soot from the gases before they reach the pipe *l*.—H. B.



Hydrofluoric Acid and Hydrofluosilicic Acid; Titration of ——. J. Katz. Chem.-Zeit., 1904, **28**, 356—357, 387—389.

Pure hydrofluoric acid can be accurately titrated with sodium, potassium, or barium hydroxide solutions, using phenolphthalein as indicator. Should hydrofluosilicic acid, however, be present, the method is unsatisfactory, since an alkaline reaction is obtained towards the end of the titration, but somewhat rapidly disappears, the final colour change only being reached after a succession of such changes, on the addition of fresh alkali. This is due to the fact that hydrofluosilicic acid does not act as a dibasic acid towards sodium hydroxide, &c., but is gradually decomposed into six equivalents of hydrofluoric acid, the final reaction only being reached when the whole of the hydrofluosilicic acid has been thus changed. It was found that a hydrofluosilicic acid solution containing 50 per cent. of alcohol could be titrated as a dibasic acid with 2N potash. When hydrofluoric acid is also present under these conditions, the precipitated potassium silicofluoride carries down with it a definite amount of hydrofluoric acid, which the author has determined and for which he gives constants of correction. The following method is recommended for the titration of a mixture of hydrofluoric and hydrofluosilicic acids. The sample should be diluted until it contains from 3 to 6 per cent. of acid. 10 grms. are titrated in a platinum basin, at the boiling point with 2N potash, using phenolphthalein as indicator. This gives the total acid in terms of hydrofluoric acid, the whole of the hydrofluosilicic acid being converted into six equivalents of hydrofluoric acid. 10 grms. are then weighed into a paraffined glass beaker, 100 c.c. of 60 per cent. alcohol added, and titrated as before with potash. This gives the hydrofluoric acid present as such and the hydrofluosilicic acid as a dibasic acid. From the difference of these two titrations, the hydrofluosilicic acid can be calculated, after allowing for the constants of correction mentioned above.—G. W. McD.

Calcium, Barium, Strontium, and Potassium; Gasometric Method of Determining ——; also Copper; Gasometric and Gravimetric Method of Determining ——. E. Riegler. Z. anal. Chem., 1904, **43**, 205—214.

The general principle of the method is described and illustrated in this J., 1903, 46, with reference to the determination of phosphoric acid and magnesia. In the present paper further application of the method, with some modifications, is made to the determination of the alkaline-earth metals and copper.

To give the case of calcium as a general example:—(1) Soluble calcium salts form, with iodic acid, calcium iodate, $Ca(IO_3)_2$, but slightly soluble in water and insoluble in dilute alcohol. (2) Calcium iodate with solution of hydrazine sulphate liberates nitrogen. $Ca(IO_3)_2 + 3N_2H_4H_2SO_4 = CaSO_4 + 2H_2SO_4 + 2HI + 6H_2O + 3N_2$.

The nitrogen is collected in a measuring tube, and from its volume the corresponding weight of calcium oxide is calculated.—A. S.

Manganese in presence of Iron [in Iron Ores, &c.]; Volumetric Determination of —— by Potassium Permanganate. Guyart-Volhard-Wolff Method. L. L. de Koninck. Bull. Soc. Chim. Belg., 1904, **18**, 56—62.

The author has proved, by the method described in this J., 1904, 456, that under suitable conditions, and especially by avoiding an excess of zinc oxide for precipitating the iron, quite accurate results can be obtained in the determination of manganese in presence of iron by titration with permanganate, without the use of any arbitrary coefficient for correcting the results.—A. S.

Chromic Oxide in Chrome Leather; Determination of—— and Separation of the same from Aluminium Oxide in the presence of Aluminium Salts. W. Appelius. Collegium, 1904, 124—128.

The following methods are used at the German Leather Industries Research Station.

I. *Determination of Chromic Oxide.*—1 to 2 grms. o leather are incinerated in a platinum dish, 2—3 grms. of mixture of sodium carbonate (60 parts), potassium carbonat (20 parts), and potassium chlorate (4 parts) are added and the dish is heated, at first gently, and finally over th blow-pipe for 10—15 minutes, a further pinch of th mixture being added if required. The contents of the dis are dissolved in hot water, cooled, and the chromic aci titrated by the usual thiosulphate method, and calculated t the sesquioxide. The results are usually slightly unde the weight of real ash.

II. *Separation of Chromium and Aluminium.*—2 to 5 grms of leather are incinerated and fused as in I. The melt is transferred by hot water to a porcelain dish, any barium present being filtered off as carbonate, whilst iron can b determined in the usual manner. The clear solution is now reduced with alcohol and hydrochloric acid, any acetic aci that may be formed by oxidation being expelled by heatin on the water-bath. The oxides of chromium and aluminiu are precipitated together by ammonia, washed, collected ignited in the platinum dish, and weighed. The mixe oxides are now fused with the alkali-chlorate mixture an the chromium determined by titration with thiosulphate as in I.—R. L. J.

ORGANIC—QUALITATIVE.

Aldehydes; General Reaction of ——. L. J. Simon an A. Conduché. Comptes rend., 1904, **138**, 977—980.

Equimolecular weights of oxalacetic ester and an aldehyd are mixed together in alcoholic solution, and a weight o ammonia solution, equal to that of oxalacetic ester used, i added. After standing, an almost colourless crystallin product separates, which is washed with alcohol. I consists of the ammonium salt of an acid, which can b liberated on the addition of mineral acid. The free aci reacts acid to phenolphthalein. The ammonia can b replaced by primary, but not by secondary amines Methyloxalacetic ester will not give the reaction.—T. F. B

Indophenine Reaction. F. W. Bauer. Ber., 1904, **37**, 1244—1245.

This reaction for the presence of thiophene in benzen (shaking with concentrated sulphuric acid and isatin) doe not take place if "chemically pure" sulphuric acid is use unless oxidising agents, such as ferric chloride or nitri acid, are added. It does take place, without addition of a oxidising agent, if ordinary commercial strong sulphuri acid is used.—E. F.

Dyestuffs for Wool; New Classes of —— and New Reactions for Aldehydes. M. Prud'homme. IV., page 54

ORGANIC—QUANTITATIVE.

Sulphur; Accurate Determination of —— in Organ Substances. W. E. Barlow. J. Amer. Chem. Soc., 19 **26**, 311—367.

There is invariably a considerable loss of sulphur calcining organic matter, such as plant substance or co without the addition of alkali. Part of the volatile sulph compounds (dioxide, trioxide, &c.) formed from t organic sulphur is retained by the alkali bases in t ash; but when phosphoric and silicic acids are prese the amount of sulphur compounds retained by the ash may insignificant, since these acids expel sulphuric acid at a heat. The loss is not prevented even when sufficient alk base to combine with all the acid is present. Absolut accurate results for total sulphur can, however, be obtai by combustion in a current of oxygen, with absorption the products of charring and combustion containing sulphur, either in the combustion tube or in a spe apparatus. Details of manipulation are given, and it stated that it is essential to introduce a lateral current oxygen at a certain point in the combustion tube completely burn the escaping gases before absorbing sulphuric acid produced by them.—C. A. M.

Sulphur; Determination of —— in Oils, Bituminous Substances, Coal, and Similar Bodies. E. Graefe. Z. angew. Chem., 1904, **17**, 616—619.

The author recommends the use of Hempel's method for the determination of sulphur (this J., 1893, 181), in which the substance is burnt in a glass bottle in an atmosphere of oxygen under normal pressure. The volatile products of combustion are absorbed by means of sodium peroxide solution. Non-volatile liquids are absorbed directly in cotton wool; coal is used in small pieces or pressed into little blocks. Very volatile liquids are absorbed in cotton-wool contained in a little glass tube closed by pressing paraffin wax against its open end. The tube is placed with the stoppered end downwards in the cone, so that as soon as the paraffin is melted by the heat of the burning cotton in the cone, the substance is vaporised and burnt.

—A. G. L.

"Crude Fibre"; Preparation [Determination] of —— from Vegetable Fibres containing Lignin, by means of Sodium Peroxide. A. Duschetschkin. J. russ. phys.-chem Ges., 1904, **36**, 71—77. Chem. Centr., 1904, **1**, 1227.

For the determination of "crude fibre" in vegetable fibres containing lignin, the author makes use of a reagent consisting of 2 parts of sodium peroxide and 6 parts of magnesium sulphate for 1 part of substance. The duration of the action varies from 1½ to 6 hours, according to the mount of lignin contained in the fibre. If the proportion f lignin be high, a preliminary treatment with a 1 per ent. solution of caustic soda is required, but this is not ecessary in the case of fibres containing a low proportion f lignin, *e.g.*, sulphite-cellulose. With fibres containing a arge percentage of lignin also, the treatment with the odium peroxide reagent must be repeated two or three imes, first over the naked flame, and then on the water-ath. The purity of the "crude fibre" is recognised by neans of a solution of phloroglucinol in concentrated ydrochloric acid. If the lignin is not completely removed y the above treatment, the material may be finally ibjected to the action of a 0·1 per cent. solution of otassium permanganate for a short time (5—10 minutes) nd of sodium bisulphite. The method is stated to be uch more rapid than those of Schulze and other authors.

—A. S.

mmonia and Aliphatic Amines; Determination of Pyridine Bases in ——. J. Milbauer and V. Staněk. Z. anal. Chem., 1904, **43**, 215—222.

a mixture of ammonia and pyridine be treated with lcium chloride, and carbon dioxide be passed through liquid, calcium carbonate and ammonium chloride are rmed, whilst the pyridine, which forms no carbonate, nains free. The reaction proceeds similarly when salts both bases are treated with calcium hydroxide, and bon dioxide is passed through the mixture. The aliphatic ines behave like ammonia. The pyridine is then racted by means of ether. In more precise detail a thod is recommended on the following lines:—

yridine Bases in Ammonia.—100 to 200 c.c. of mercial ammonia are diluted with an equal volume of er and poured into dilute sulphuric acid, to which a drops of a 1 per cent. aqueous solution of "Patent-e V N Superfein" have been added. The strongly solution is evaporated nearly to dryness, brought into parating funnel, a sufficient quantity of a freshly pre-d sodium bicarbonate solution and an equal volume of r, added, and the whole agitated for from 10—15 minutes. ridine forms no carbonate.) After drawing off the layer her, fresh ether is added, and the whole again shaken as re. The united ethereal solutions of the pyridine bases iltered through a filter moistened with ether, the filtrate ed with a few drops of Patent Blue solution, and ughly shaken up with N/10 sulphuric acid. The d thus acquires a yellowish-green tint. Subsequently ss of sodium chloride is added, and the liquid titrated with N/10 sodium hydroxide solution till a blue is produced, the change being distinct and rapid. authors recommend shaking a third time with ether, ove that no more pyridine remains behind.

Pyridine Bases in Ammonium Salts.—50 to 100 grms. of the finely powdered sample are placed in a separating funnel, treated with 25 to 30 c.c. of water, neutralised, a sufficient quantity of solution of sodium bicarbonate added, and the process above described followed.—A. S.

Starch; Determination of —— by Hydrolysis with Hydrochloric Acid. A. Rössing. Z. oeffentl. Chem., **10**, 61—64. Chem. Centr., 1904, **1**, 1177.

The author has previously pointed out (this J., 1904, 386) that Sachsse's inversion method gives low results in the determination of dextrin. The same remark also applies to the determination of starch by this method. The author's method (*loc. cit.*) gives good results if instead of the old factor 0·90, the factor 0·93 be used.—A. S.

Cider Vinegar; Examination of ——. A. E. Leach and H. C. Lythgoe. J. Amer. Chem. Soc., 1904, **26**, 375—382.

Detection of Malic Acid.—The following test for malic acid, devised by the authors, has been used for the last two years in the Massachusetts State Laboratory:—Five c.c. of the vinegar are mixed with about 1 c.c. of a 10 per cent. solution of calcium chloride and rendered alkaline with ammonium hydroxide. The precipitated ferric hydroxide, &c., is filtered off, and the filtrate mixed with three times its volume of 95 per cent. alcohol and heated to the boiling point, a flocculent precipitate of calcium malate being formed in the presence of malic acid. Dextrin or sulphates would also be precipitated, so the absence of these must be assured. As a confirmatory test the precipitate is collected, dried (to remove alcohol), and dissolved in dilute nitric acid, and the solution evaporated to dryness on the water-bath, to convert calcium malate into calcium oxalate. On boiling with sodium carbonate solution, the calcium oxalate is decomposed into calcium carbonate, which is to be separated by filtration. The filtrate is acidified with acetic acid and tested with calcium sulphate solution, a precipitate at this stage confirming the presence of malic acid in the vinegar. Both of these tests should be made.

Determination of Malic Acid: (*a*) *Calcium Chloride Method.*—100 grms. of vinegar are treated with 10 c.c. of 10 per cent. calcium chloride solution and rendered alkaline with ammonium hydroxide. After one hour's standing the liquid is filtered and the precipitate washed with water. The filtrate and washings are evaporated to about 25 c.c., mixed with 3 volumes of 95 per cent. alcohol, heated to the boiling point, and filtered through an ash-free filter. The calcium malate on the filter is washed with hot 75 per cent. alcohol and ignited in a platinum crucible. The ash is dissolved in 35 c.c. of boiling N/10 hydrochloric acid, and the excess of acid determined by titration with N/10 sodium hydroxide solution, phenolphthalein being used as indicator. The number of c.c. of acid consumed by the ash, multiplied by 0·0067, gives the percentage of malic acid in the vinegar.

(*b*) *Lead Acetate Method.*—100 grms. of the vinegar are neutralised with sodium hydroxide and treated with an excess of lead acetate. The lead malate is collected, washed, and suspended in water, which is heated to the boiling point and saturated with hydrogen sulphide. The resulting lead sulphide is filtered off and washed with hot water, and the filtrate evaporated to about 75 c.c., cooled, and mixed with 10 c.c. of 10 per cent. calcium chloride solution and sufficient ammonium hydroxide to render it alkaline. A precipitate occurring at this point indicates the presence of an acid other than malic acid. Such precipitate is removed, and the filtrate treated as in the calcium chloride method. These methods yield results in close agreement.

Total Acids and Solids.—Few of the samples examined by the authors gave results lower than the 4·5 per cent. of acid and 2·0 per cent. of solids required by the Massachusetts standard.

Ash should be about 10 per cent. of the total solids. Less than 8 per cent. rarely occurs in genuine cider vinegar.

Alkalinity of the Ash.—Cider vinegar yields a very alkaline ash. One grm. of the ash should require about 90 c.c. of N/10 acid for neutralisation, and the number of c.c. required for the neutralisation of 100 grms. of the ash will be approximately equal to the percentage of ash, multiplied by 100. If the alkalinity be less than 65 per cent. of this figure (per cent. ash × 100) the sample is suspicious.

Ratio of Soluble to Total Phosphates.—At least half of the total phosphates in cider vinegar are soluble in water.

Reducing Sugars.—The amounts of these should be the same before and after inversion. An increase after inversion points to the presence of cane sugar, or dextrin from glucose, added to increase the solids.

Reducing Sugars in the Solids.—Any samples containing more than 20 to 25 per cent. of reducing sugars in the total solids are suspicious. The highest amount found by the authors was 16·6 per cent.

Polarisation.—Pure cider vinegar is always lævo-rotatory, and vinegars behaving differently may at once be condemned. Excessive lævo-rotation points to the addition of invert sugar or incomplete acetification of the vinegar. Dextro-rotation before and lævo-rotation after inversion indicate added cane sugar, whilst dextro-rotation before and after inversion points to the presence of glucose. It is suggested as a standard that the polarisation (in a 200 mm. tube) of undiluted vinegar should lie between − 0·1° and − 4·0° (Ventzke).—C. A. M.

Milk-Chocolate; Analysis of ——. O. Laxa. Z. Untersuch. Nahr. Genuss-m., 1904, **7**, 471—477.

The results of the analyses of various makes of milk chocolate are given in the following table :—

Kind.	Moisture.	Total Proteids.	Casein.	Other Proteids.	Fat.	Lactose.	Saccharose.	Other Non-Nitrogenous Substances.	Ash.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent

The casein was determined by heating the milk-chocolate on a water-bath with a quantity of 1 per cent. ammonium oxalate solution for 30 minutes, with frequent agitation. After cooling, the volume was made up to 250 c.c., filtered, and 150 c.c. of the filtrate precipitated with acetic acid. The precipitate was collected on a filter, washed, and the nitrogen determined in it by Kjeldahl's method, the factor 6·37 being used to convert the nitrogen found into proteids. The difference between the total amount of nitrogen and the casein-nitrogen was multiplied by 6·25 to give the quantity of other proteids present. The lactose was determined by Kjeldahl's copper reduction process and the saccharose either by polarisation or by Rüber's method (Z. anal. Chem., 1901, **40**, 97), the latter being preferred. Taking the ratio of proteids to lactose and ash in milk as 10:13:2 (Vieth), it will be seen from the above table that samples 3, 4, 5, 8, and 10 contain an undue amount of lactose, this being due to the fact that milk-sugar has been added to the milk before condensation. The Reichert-Meissl value of the fat extract from the sample affords evidence as to whether whole or skimmed milk has been employed. Milk-chocolate prepared by the simple addition of dry casein and lactose cannot be distinguished by analysis from that made with skimmed milk, unless the quantity of casein be disproportionately high, but the author considers that these products should not be called "milk-chocolate."
—W. P. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Silicon; Action of —— *on Water at Temperatures near* 100° *C.* H. Moissan and F. Siemens. Comptes rend., 1904, **138**, 939—941.

When silicon is heated with water in a test-tube to 95°—98° C., hydrogen is evolved and hydrated silica is formed. The reaction is considerably increased by the addition of small quantities of alkali. The experiment was repeated in a vessel made of silica, using water which had been distilled in a platinum still; no reaction was observed in this case, showing that the reaction first noted was caused by traces of alkali from the glass of the test-tube.—T. F. B.

Argon; Presence of —— *in the Gases from Smoke-Fissures in Guadeloupe.* H. Moissan. Comptes rend., 1904, **138**, 936—938.

Two samples of gas from smoke-fissures in Guadeloupe contained respectively 0·68 and 0·73 per cent. of argon.
—T. F. B.

Gold; Colloidal ——. Hanriot. Comptes rend., 1904, **138**, 1044—1046.

The author has prepared colloidal gold by Henrich's method: 1 litre of water containing 1 grm. of auric chloride, and rendered just alkaline with sodium carbonate, is boiled and then poured into 300 c.c. of a cold solution of catechol (pyrocatechin) containing 11 grms. per litre. A red coloration is produced, turning to violet. On mixing ten such preparations and just acidifying with sulphuric acid, the liquid becomes blue, and soon deposits a blue powder, which is washed with water and then with 70 per cent. alcohol, dissolved in ammonia, and reprecipitated by sulphuric acid. This solution and reprecipitation can be many times repeated, so that the solution is not simply the suspension of very fine particles. The substance manifest acid properties, forming salts with some of the heavy metal some soluble and others insoluble.—J. T. D.

Gases; Expansibility of —— *between* 0° *and* 1000° *C* A. Jacquerod and F. L. Perrot. Comptes rend., 1904 **138**, 1032—1034.

The gases were heated in a platinum resistance furnace i a bulb of fused silica, and the increase of pressure betwee 0° C. and the melting point of gold was determined. It i established that (1) the coefficients between 0° and 1000° (of nitrogen, air, oxygen, and carbon monoxide are closel alike; (2) that of carbon dioxide is distinctly higher tha those of the gases just enumerated, though lower than th of carbon dioxide between 0° and 100° C.—J. T. D.

Diazobenzene Chloride on Diphenylamine; Action of — L. Vignon and A. Simonet. Comptes rend., 1904, **13** 1104—1105.

An alcoholic solution of 1 mol. of aniline hydrochlori containing rather less that 1 mol. of diphenylamine w diazotised by the addition of an aqueous solution of 1 mol. sodium nitrite, the temperature was kept at 18°—20° C. (15 minutes, and the product precipitated by ice-cold wat On drying, a yellow crystalline compound was obtained m. pt. 47° C., rather unstable in air; it had feeble basic p perties, giving a violet, unstable hydrochloride. On heat with acids the compound was decomposed into phen diphenylamine, and nitrogen, whence the authors regar as phenyldiazo-aminobenzene.—T. F. B.

Uranium Pitchblende Ore. U.S. Cons. Reps., No. 19 April 25, 1904.

The *Neue Wiener Tagblatt*, of Vienna, reports that a meeting of the Mineralogical Society, Dr. F. J. Becke, P fessor of mineralogy, mentioned experiments which were made with uranium pitchblende ores at the Imperial Museum of Natural History. These ores have been in the possession of the museum since 1806. The experiments demonstrated that they have lost none of their intensity of radio-activity and of the energy of their electric properties. They do not differ in any way from the ores now taken at Joachimsthal.

New Books.

Gold Assaying : A Practical Handbook giving the *Modus Operandi* for the Accurate Assay of Auriferous Ores and Bullion and the Chemical Tests required in the Processes of Extraction by Amalgamation, Cyanidation, and Chlorination, with an Appendix of Tables and Statistics. By H. Joshua Phillips, A. Inst. C.E., &c. Crosby Lockwood and Son, 7, Stationers' Hall Court, Ludgate Hill, London, 1904. Price 7*s.* 6*d.* net.

Small 8vo volume containing 85 pages of subject-matter, with 62 illustrations, followed by an appendix of 46 pages, chiefly tabular matter, and the alphabetical index. The subjects are subdivided as follows :—I. Natural Occurrence and Forms of Gold. II. Physical Characters of Gold. III. Chemical Properties of Gold. IV. Sampling of Gold Ore. V. Fusion. VI. Cupellation. VII. Parting. VIII. Scorification. IX. Assay of Bullion. X. Assays in Cyanidation, Chlorination, and Amalgamation Processes.

Chapters on Papermaking, comprising a series of lectures delivered on behalf of the Battersea Polytechnic Institute in 1902, by Clayton Beadle. H. H. Grafton, 17, The Borough, London Bridge, S.E. Price 5*s.* nett.

Small 8vo volume containing 145 pages of subject-matter nd the alphabetical index. The text is subdivided according to the lectures delivered, which are as follows :—

Lecture I.—Examination of Fibrous Raw Materials for aper Making. II.—Art Papers as applied to Process rinting. III.—Bleaching. IV.—Chemistry of Bleaching. .—Influences of Moisture on Paper. VI. and VII.—hemical Residues in Paper. VIII.—Function of Water the Formation of a Web of Paper. IX.—Permanence Paper. X. and XI.—Sundry Physical Qualities of aper.

nnual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions, 1903. Volume I. [Cd. 2043.] Price 7*s.* 1*d.*

us is the first volume of the statement of the foreign de of the United Kingdom for the year 1903, and contains stract tables showing the total imports and exports of ry article enumerated, as well as detailed figures of the ports and exports of each article from and to each ntry. A new feature of the present issue is the inclusion tables showing the imports and exports of the United gdom classified in the same manner as in the tables fixed to the "Monthly Accounts of Trade," but distinshing the trade with foreign countries from that with tish Colonies ; statements are added showing the articles uded under each of the categories exhibited in these es.

everal alterations have been made in the classification of orts and exports in the present volume, and new headings ear for glycerine, electrical machinery, white lead, ain classes of skin and furs, soap, &c. The imports of rent kinds of petroleum are now distinguished, whilst e export returns coal is subdivided into various classes. headings for "iron and steel" in the statistics both of rts and exports have been re-classified.

R ort to the Board of Trade by the Advisory mmittee on Commercial Intelligence, with ference to their Proceedings. [Cd. 2044.] ice 4½*d.*

publication contains a history of the work accomed by the Commercial Intelligence Committee since its pointment in May, 1900.

e steps which have been taken to bring the existence of e Commercial Intelligence Branch and the scope of its rk under the notice of the commercial community, both in this country and in India and the Colonies, are recorded.

A short account is given of the work of the Commercial Intelligence Branch, regarding the business of which the statistics show that the number of annual inquiries has risen from 1,244 in 1900 to 3,599 in 1903.

The objects of the Commercial Missions despatched by the Committee to Siberia and Persia are detailed, and an account is also given of the other purposes to which, up to the present, the "grant in aid" of 1,000*l.* per annum has been allocated.

The appendices to the report include copies of the Notice sent to Mayors of Boroughs, Chambers of Commerce, &c., respecting the establishment of a Commercial Intelligence Branch, and of the circular sent by the Colonial Office to Colonial Governments on the same subject ; a list of British Commercial Attachés and Commercial Agents in Foreign Countries, and of the Correspondents of the Commercial Intelligence Branch in the Colonies ; and the Reports by the Committee to the Board of Trade respecting the German Tariff, the new Russian Tariff, and the proposed new Austro-Hungarian Tariff.

Trade Report.

I.—GENERAL.

Germany ; Trade of ——.

Foreign Office Annual Series, No. 3153.

The following tables show the values of imports and exports of chemical interest during the last three years :—

Imports.

Articles.	Value in 1,000,000 Marks.		
	1901.	1902.	1903.
Drugs, dyestuffs, &c.	267·61	263·39	267·41
Iron and ironware	66·56	51·83	57·22
Earths, ores, precious metals, &c.	498·52	355·66	522·90
Hides and skins	213·82	259·00	292·28
Copper and copper goods	113·55	109·01	120·63
Caoutchouc and gutta percha	60·02	73·26	76·25
Leather and leather goods	56·20	64·38	66·54
Oils and fats	249·83	261·10	285·29
Petroleum	91·98	93·11	101·23
Stone and stoneware	45·01	45·15	44·72
Coal, coke, and other fuel	179·97	163·23	1[illegible]0·39
Tar, pitch, resin, and asphalt	32·41	31·83	36·30
Zinc and zincware	30·60	34·05	34·[illegible]

Exports.

Articles.	Value in 1,000,000 Marks.		
	1901.	1902.	1903.
Drugs, dyestuffs, &c.	361·78	380·63	400·15
Iron and ironware	517·26	603·38	658·25

Stone and stoneware	36·80	38·05	39·71
Potteryware	75·63	77·87	85·25
Zinc and zincware	31·01	39·65	38·29

Chemical Industries in Italy.

Bd. of Trade J., May 5, 1904.

Among the chemical industries a great number are foreign concerns ; their aggregate capital in 1892 was about 800,000*l.*, while it is now over 4,000,000*l.*, showing an extraordinary development in less than 10 years. This industry is the one that has made the greatest progress in Italy, and yet there is still much to be accomplished. Aside from the manufacture of soda ash, for instance, made impossible by the high taxation of salt and the cost of coal, there are a number of other chemical products that might profitably be manufactured locally. Among the principal ones might be mentioned citric and tartaric acid, the raw material thereof being grown in Italy in greater quantities than elsewhere. Over 3,000 tons of lemon juice are annually exported and manufactured abroad into calcium citrate and citric acid, while in Italy the production of the manufactured article does not exceed 400 tons, which is far from supplying the local demand, thus necessitating the importation of large quantities. In the last few years the local manufacture of calcium citrate has somewhat increased, but the crude material is still largely exported.

In 1902 Italy exported 16,200 tons of tartar and wine dregs, importing at the same time 100 tons of tartaric acid. The production of cream of tartar is, however, increasing, 600 tons being exported in 1901 and 12,000 tons in 1902. The manufacture of tartaric acid has also increased in recent years, and 600 tons thereof were exported in 1902; but the manufacture of this product is still out of proportion to the production of the crude material. Such an industry, intelligently established and conducted, would undoubtedly prove very profitable, the local conditions being so favourable.

Another lucrative industry would be found in the extraction, by improved methods, of the resin from the larch-fir tree, of which enormous quantities exist in Calabria. Although very rich in this product, Italy imported 13,400 tons of colophony and green resin and 1,000 tons of copal and oil varnish in 1902.

Bilbao, Spain; Chemical Industry of ——.

Foreign Office Annual Series, No. 3152.

Two ironworks, manufacturing coke by the Simon-Carvès and Semet-Solvay processes, produced in 1903 5,017 tons of tar, which were sold to the distilleries at Elorrieta. These distilled 6,194 tons of tar, producing 2,141 tons of creosote and 3,832 tons of pitch. 836 tons of creosote were used in the country, 1,094 tons were shipped to France, and 209 tons to Algiers. The whole of the pitch produced was taken up by native requirements.

The above-mentioned ironworks also produce 1,753 tons of ammonium sulphate, which is principally sent to Southern Spain, although a portion is used in this district.

For the production of the ammonium sulphate, sulphuric acid was obtained from the two important works existing here, which likewise supply the soap factories, petroleum refineries, and superphosphate and nitro-glycerin works.

Large quantities of superphosphates are taken inland, as farmers are awakening to its usefulness.

Twenty tons of carbolic acid were produced and exported last year to Germany.

A private monopoly exists in Spain in regard to explosives and loaded cartridges, the Government, however, reserving its right to import ammunition for military purposes.

In 1902 the exploitation of turpentine, resins, &c., was warmly taken up by Bilbao enterprise, a company being formed which bought up all the small pine tree holdings.

The pine plantations are situated in Old Castile, and there are some 6,000,000 trees in cultivation. In that year 2,540 tons of turpentine and 1,706 tons of colophony, besides important quantities of resins and resinous oils, were produced.

Last year the output of 17 factories was 3,146 tons of turpentine and 10,825 tons of colophony. The sales during the same period were: turpentine, 2,868 tons; colophony, 9,524 tons. The best quality of this last product is exported, whilst turpentine is used in the country, where the demand exceeds the supply. Prices generally follow the foreign markets.

The cultivation of beetroot and the manufacture of beet-sugar was begun in the provinces of Santander, Burgos, and Logroño after the loss of the Spanish colonies. So many factories were opened and provided with expensive machinery, that the supply soon outran the demand, and disaster followed in many cases. Trusts were then formed in order to maintain the price of sugar, which is high. The sugar cane growers in Southern Spain did not join these trusts, but they eventually came to terms, by which the beet sugar producers engaged to supply 80,500 tons annually, whilst the others were to put out 9,500 tons, thus making between them a production of 90,000 tons, an amount estimated to cover the consumption of sugar in Spain.

Jamaica Exports in 1902–3.

Bd. of Trade J., May 5, 1904.

The following are statistics of some of the chief articles of export from Jamaica:—

Article.	Quantity.		Value.		Price.	
	1901–2.	1902–3.	1901–2.	1902–3.	1901–2.	1902–3.
			£	£	s. d.	s. d.
Logwood	41,107 tons	37,895 tons	103,796	97,106	50 6 per ton	51 3 per ton
Rum	1,422,010 galls.	1,927,150 galls.	124,426	156,581	1 9 „ gall.	1 7½ „ gall.
Sugar	321,659 cwt.	408,455 cwt.	136,705	167,663	8 6 „ cwt.	8 3 „ cwt.

III.—TAR PRODUCTS, PETROLEUM, Etc.

Mineral Wax: German Tariff Classification.

Bd. of Trade J., May 12, 1901.

Mineral wax, bitumen, and black wax (which is obtained in the course of the process of purifying mineral wax), are to pay duty under No. 26*m* of the Customs Tariff at the "conventional" rate of 10 marks per 100 kilos. (5*s*. 1*d*. per cwt.).

Petroleum Refining in France.

Bd. of Trade J., May 12, 1904.

H.M. Consul at Calais reports that the petroleum refining industry of that district is increasing largely, as shown in the practical cessation of importation of refined petroleum. The refineries are situated at Douai, production 200,000 casks; Lomme, 80,000 casks; Le Cateau, 20,000 casks; Croix, 50,000 casks; and Dunkirk, 40,000 casks. The price of the cask, which contains about 40 galls., c
$1\frac{1}{2}$ cwts., is quoted at 2*l*. 8*s*.

Petroleum Exports from Russia.

Eng. and Mining J., April 21, 1904.

Exports of crude and refined petroleum from Russia
1903 are estimated at 80,000,000 poods, or 1,310,400 metr
tons, an increase of 8 per cent. over 1902. Part of t
gain was in exports to Europe, which were 27,000,000 pood
and part in exports to the East, chiefly China.

Petroleum Production of Roumania.

Bd. of Trade J., May 12, 1904.

Thirty-four companies have been formed in Rouma
since 1868 for the extraction of petroleum, and t
number of wells exploited in the districts of Praho,
Dambovitza, Buzen, and Bacau amounted to 105 at
end of 1903; 83 of these were in the district of Prahova

The petroleum is still extracted in the most rudimentary fashion, with wells worked by hand, or borings. The production for the last three years was: 1901, 270,000 tons; 1902, 310,000 tons; 1903, 384,303 tons.

CARBOLINEUM: U.S. CUSTOMS DECISION.

April 7, 1904.

Carbolineum used as a wood preservative is dutiable at 20 per cent. *ad valorem* under paragraph 15 of the present Tariff Act, as a "coal tar preparation, not a colour or dye," and not free of duty as "dead or creosote oil" under paragraph 524 as claimed.—R. W. M.

RESORCINOL; PURE ——. U.S. CUSTOMS DECISION.

April 18, 1904.

It was held that pure resorcinol, differing only from the forms used in the manufacture of dyes in purity and cost, is dutiable as a "medicinal coal tar preparation," at 25 per cent. *ad valorem*, under paragraph 59 of the Tariff Act.

—R. W. M.

X.—*METALLURGY.*

IRON AND STEEL PRODUCTION OF GREAT BRITAIN.

Eng. and Mining J., April 21, 1904.

The report of the British Iron Trade Association for the ear 1903, just issued, gives the production of pig iron in he United Kingdom as follows, in long tons:—

——	1902.		1903.	
	Tons.	Per Cent.	Tons.	Per Cent.
orge and foundry	3,860,494	45·0	3,875,826	44·0
essemer pig	3,648,948	42·5	3,760,422	42·7
asic pig	892,218	10·4	991,610	11·3
piegeleisen	185,033	2·1	183,346	2·0
Totals	8,586,693	100·0	8,811,204	100·0

The total production for 1903 is slightly greater than any the estimates heretofore published.

The increase was chiefly in pig iron intended for conver- on into steel; forge and foundry iron production being most stationary.

The production of steel in the United Kingdom was as follows, in long tons:—

——	1902.		1903.	
	Tons.	Per Cent.	Tons.	Per Cent.
Bessemer	1,825,779	37·2	1,910,018	38·0
Open-hearth	3,083,288	62·8	3,124,083	62·0
Totals	4,909,067	100·0	5,034,101	100·0

The proportions of steel made by the acid and basic processes during 1903 were as follows:—

——	Acid.		Basic.	
	Tons.	Per Cent.	Tons.	Per Cent.
Converter	1,316,915	26·2	593,103	11·8
Open-hearth	2,613,274	51·9	510,809	10·1
Totals	3,930,189	78·1	1,103,912	21·9

The acid process continues to predominate in British practice, and will continue to do so as long as the present sources of ore supply continue to furnish the raw material.

The proportions of finished steel made by the two processes are as follows, in long tons:—

——	Bessemer.	Open-hearth.	Total.
Blooms and billets	239,119	400,664	639,783
Rails	1,061,441	84,942	1,146,383
Bars	221,283	537,745	759,028
Merchant steel	125,444	169,394	294,838
Plates and angles	21,840	1,248,079	1,269,919
Totals	1,669,127	2,440,824	4,109,951

QUEENSLAND; MINERAL PRODUCTION OF —— IN 1903.

Bd. of Trade J., May 12, 1904.

The following table shows the quantity and value of minerals produced in Queensland during the year 1903, comparative figures for 1902 being added:—

Mineral.	1902.			1903.		
	Ozs.	Tons.	Value.	Ozs.	Tons.	Value.
			£			£

LATINUM INDUSTRY IN THE NINETEENTH CENTURY [IN RUSSIA].

W. Schneider. Chem.-Zeit., 1904, **28**, 359—360.

he history of the development of the platinum industry o he last century may be divided into four periods:— (1 From the beginning of the century to 1828, when the co ng of platinum money was begun in Russia; (2) from 18 to 1845, when coining was stopped; (3) from 1845 to 18 , when the platinum refining industry was made free, *i.e.*, the obligatory refining of all platinum in the mint was stopped; (4) from 1867 to the present time. Platinum was first discovered in the Urals, accompanying gold in 1819, in the districts of Nishneturinsk and Nishnetagilsk in 1824, and in Bissertsk in 1830. The first attempts to bring Ural platinum on the market were attended with difficulty and consequently the production remained small. The total amount produced in Russia up to 1828 was about 40 poods, and the demand was mainly supplied by South American platinum. In 1829 the cost of refining platinum was from three to four times as great as that of the raw material. In consequence of the difficulties attending the sale of Ural platinum, Count Krankin, the Russian Minister of Finance, conceived the idea of coining platinum money. This was begun in 1828, and in the period 1828 to 1845, 1,201,838 roubles (metal) worth of platinum money was coined. The amount of platinum mineral produced in this period was about 2,000 poods, of which 1,900 poods came from Nishnetagilsk. The experiment of coining platinum money was not attended with success, and, in fact, only the Nishnetagilsk works reaped any advantage from it. It was discontinued in 1845, and about the same time a tax was levied on platinum mineral according to its content of metal, and the refining of platinum in the Royal Mint was made obligatory. By the discontinuance of the platinum coinage, the Nishnetagilsk works lost their chief customer, the Crown; the works were shut down temporarily, and only gradually resumed work again later. In the period 1845 to 1867 the works of Schuwalow, in Krestowosdwishensk were developed; the total production of platinum mineral in Russia was 1,391 poods, of which 1,284 poods came from Nishnetagilsk. In this period the Crown, which had a large stock of refined platinum to dispose of, sought foreign customers, the chief ones being Quenessen and Co., in Paris, and Johnson, Matthey, and Co., in London; the price fell continuously, being 3,071 to 3,199 roubles per pood in 1846 to 1850, 2,941 to 3,077 in 1859, and 1,877 to 2,253 roubles per pood in 1866. In 1867 the compulsory refining of platinum in the Royal Mint was no longer enforced, the importation and exportation of platinum in any form was permitted, and a tax of 4½ to 3 per cent. *in natura* (on the crude platinum) was levied. Neither the producers nor outside firms in Russia availed themselves of the permission to refine the crude platinum, consequently large stocks were sent abroad, and the predominance thus secured by the foreign refiners has been retained up to the present time. From 1867 to 1901, 7,142 poods of platinum were produced, and in the whole period 1826 to 1901, 9,860 poods, or according to other statements, 10,429 poods. The increase of price of crude platinum in the seventies led to the establishment of refineries in Russia. The first was the firm of Kolbe and Lindfors, which subsequently passed into foreign hands, whilst in 1879 the Tentelewsche Chem. Fabr. entered the business. These two firms competed with the foreign refiners in the purchase of crude platinum in the Urals. In the eighties some small refineries were established in foreign countries which also competed. The development of the Goroblagodat works by small producers also tended to keep up the price of the crude platinum, as also does the increased demand for the metal. The average price of crude platinum per pood since 1870 is shown in the following table :—

Year.	Price.	Year.	Price.
	Roubles (metal).		Roubles (metal).
1870	1.248	1896	5,628
1880	1,932	1897	6,700
1888	2,915	1898	7,370
1889	4.326		
1890	6,171		Price in St. Petersburg.
1891	4.141	1899	8,609
1892	3.717	1900	10,050
1893	4,571	1901	10,050
1894	4,690		
1895	4.690		

The fluctuations of price in the period 1889 to 1892 were due to the struggle between the foreign refiners and the Russian producers.—A. S.

IRON ORE IN BILBAO, SPAIN.

Foreign Office Annual Series, No. 3152.

4,085,438 tons of iron ore were exported from the Bilbao River in 1903, as compared with 4,196,851 tons in 1902 and 4,056,710 tons in 1901. Of these amounts, the exports to the United Kingdom were 2,649,004 tons, 2,996,908 tons, and 2,281,198 tons respectively. The total quantity of all ores exported from the districts of Biscay, Guipuzcoa, and Santander in 1903 was 5,662,071 tons. Average prices per ton during the year were, for limonite, 1st quality, 10*s.* to 11*s.*; 2nd quality, 8*s.* to 8*s.* 6*d.*; hæmatite, 10*s.* 6*d.* to 11*s.* 3*d.*; siderite, 1st quality, 11*s.* 6*d.* to 12*s.*; 2nd quality, 10*s.* 6*d.* to 11*s.*

ONTARIO; MINERAL PRODUCTION OF ——.

Eng. and Mining J., April 21, 1904.

The following table shows the mineral production of the province of Ontario for the year 1903. The tons used are short tons of 2,000 lb. :—

Product.		Quantity.	Value.
			Dols.
Metallic :—			
Gold	Oz.	10,383	188,036
Silver	"	16,688	8,949

LEAD DROSS: U.S. CUSTOMS DECISION.

April 12, 1904.

Dross containing 37·63 per cent. of lead and 51·65 p cent. of tin was held not to be free of duty as "tin dross" or "tin grain" under paragraph 683 of the Tariff Act, b dutiable at 2½ cents per pound as "lead dross," und paragraph 182.—R. W. M.

XII.—FATS, FATTY OILS, Etc.

WHALE OIL.

C. H. Stevenson. U.S. Fish Commission Report for 19 *Scient. Amer. Suppl.*, 1904, **57**, 23,549—23,552; 23,566—23,568.

The total annual production of whale oil at the prese time is about 3,000,000 galls., of which 750,000 galls. co from the United States, 900,000 from Norway, and remainder principally from Scotland, Russia, Japan, Newfoundland. The yield of oil from the various kinds whales is shown in the following table.

	Yield of Oil in Barrels of 31½ Galls.		
	Minimum.	Maximum.	Average.
Right whale, Pacific	25	250	90
„ Atlantic	25	150	75
Bowhead	30	250	100
Sperm whale, cows	5	145	25—30
„ bulls			75—90
Humpback, Pacific	10	110	42
„ Atlantic	10	100	10
Finback, Pacific*	10	70	35
„ Atlantic*	20	60	38
California grey whale	15	60	30
Bottle-nose whale†	4	25	12
Orca or killer whale	1	6	2½
Beluga or white whale‡	¾	3	1½
Black-fish	⅓	4	1⅓

* Oil inferior to that from right whales.

† Next in quality to sperm oil; gives no residuum, and is thus useful for lubricating small machines, &c.

‡ Excellent lubricating oil.

The principal seats of the whale-oil refining trade in the United States are at New Bedford, Mass., and San Francisco, Cal. At the latter port, 20 per cent. of the sperm oil and 60 per cent. of the whale oil are refined. The oil is of two chief kinds, *viz.*, sperm oil, from sperm whales, and whale oil, from all other varieties of whales, and also from walrus, black-fish, sea elephant, &c. The crude product ranges in colour from clear amber to very dark brown. A considerable amount of whale oil is used, in the crude state, by steel-workers, miners, and cordage manufacturers. The crude sperm oil is separated, by processes of refrigeration and pressing, into (1) "winter sperm oil," congealing below 38° F., about 75 per cent.; (2) "spring sperm oil," congealing at 50°—60° F., 9 per cent.; (3) "taut-pressed oil," melting at 90°—95° F., 5 per cent.; and (4) "crude spermaceti," melting at 110°—115° F., 11 per cent. The crude whale oil is separated, by similar methods, into (1) "winter whale oil," congealing at 36°—40° F., and (2) "whale-foots," or stearine. Occasionally, "spring" and "summer" whale oils are also prepared. By the usual method of pressing, the oil of the right whale, taken in high northern latitudes, gives about 8 per cent. of "foots" or stearine; if taken in the vicinity of the equator, or south of it, about 15 per cent; humpback or finback whale oils, 12 per cent.; menhaden oil, 5—10 per cent,: sea-elephant oil, 5—6 per cent.; and seal oil, 3—4 per cent of stearine.—A. S.

WAX; CHINESE ——. U.S. CUSTOMS DECISION.

April 14, 1904.

Merchandise invoiced as Chinese wax, composed of 70 per cent. of cerotic acid, 15 per cent. of ceryl alcohol, and 15 per cent. of wax, was assessed for duty at 20 per cent. *ad valorem* as a "manufactured article unenumerated," under section 6 of the present tariff. The Board of General Appraisers held that it was free of duty as "vegetable wax," under paragraph 695. The evidence is not conclusive whether it is the secretion of the wax insect or is produced from the sap of the tree under the influence of animal life. Similar natural products, such as lac and beeswax, are provided for by name in the tariff, and the element of doubt in this case is resolved in favour of the importer. The unusual composition of the sample does not govern, for the reason that the nature of the article has not been altered sufficiently to make it anything other than wax in its physical properties and technical uses.—R. W. M.

XIII. C.—INDIA-RUBBER, Etc.

GUTTA-PERCHA: U.S. CUSTOMS DECISION.

April 9, 1904.

Gutta-percha moulded into cylindrical rods and partly freed from impurities, was held to be free of duty as "crude gutta-percha," under paragraph 570 of the present Tariff Act.
—R. W. M.

XVI.—SUGAR, STARCH, Etc.

BEET-SUGAR STATISTICS.

U.S. Cons. Reps., No. 1936, *April* 25, 1904.

The following tables are largely based upon the reports of Mr. Otto Licht, the sugar statistician, of Magdeburg.

Production of Beet Sugar.—The following is a comparative statement showing production of beet sugar in European countries during the last three years:—

Country.	1901-2.	1902-3.	1903-4.
	Met. Tons.	Met. Tons.	Met. Tons.
Germany	2,304,923	1,762,461	1,960,000
Austria	1,301,549	1,057,692	1,175,000
France	1,123,533	833,210	810,000
Russia	1,098,983	1,251,311	1,200,000
Belgium	331,960	225,696	220,000
Holland	203,172	102,411	125,000
Sweden	125,948	72,444	108,500
Denmark	55,132	37,067	49,000
Italy	74,299	95,191	120,000
Roumania	20,844	16,381	18,000
Spain	73,576	96,160	116,000
Other countries	15,329	13,919	10,500
Total	6,752,218	5,573,943	5,910,000

Average Consumption.—The following is a comparative statement showing how much sugar was consumed by each inhabitant of European countries and of the United States during the last two years:—

Country.	1901-2.	1902-3.	Number of Inhabitants in 1903.
	Pounds.	Pounds.	
Germany	30·07	28·31	58,512,000
Austria	18·34	17·86	47,600,000
France	25·13	23·56	39,000,000
Russia	17·44	17·88	109,000,000
Belgium	24·88	22·37	6,800,000
Holland	46·66	30·55	5,270,000
Sweden and Norway	45·51	39·57	7,450,000
Denmark	53·94	51·97	2,500,000
Italy	7·19	7·37	33,000,000
Spain	9·32	10·91	18,650,000
Roumania	6·27	6·73	6,100,000
Bulgaria	6·16	6·11	3,780,000
Greece	8·07	8·53	2,500,000
Servia	6·88	7·83	2,550,000
Turkey, including Asia	8·05	7·96	24,000,000
Portugal and Madeira	14·1	14·41	5,600,000
Switzerland	61·05	62·83	3,450,000
England	97·83	89·8	41,900,000
United States	70·44	66·39	78,700,000

Acreage and Crop Yield.—The following is a comparative statement showing the acreage sown to beets, the total beet crop, the crop yields per acre, and the amount of sugar per acre, during the past two years, and also the percentage of sugar in the beets:—

Country.	Area sown to Beets.		Total Beet Crop.		Yield per Acre.		Amount of Sugar per Acre.		Percentage of Sugar in Beets.	
	1902-3.	1903-4.	1902-3.	1903-4.	1902-3.	1903-4.	1902-3.	1903-4.	1902-3.	1903-4.
	Acres.	Acres.	Met. Tons.	Met. Tons.	Met. Tons.	Met. Tons.	Met. Tons.	Met. Tons.	Per Cent.	Per Cent.
Germany	1,056,708	1,027,580	11,270,978	12,700,000	10·66	12·36	1·668	1·9	15·64	15·48

Production and Consumption.—The following table for year 1903–4 shows that most beet-growing countries have sugar to sell, after supplying their own wants :—

Country.	Stock on Hand Sept. 1, 1903.	Production.	Consumption.
	Met. Tons.	Met. Tons.	Met. Tons.
Germany	320,880	1,960,000	970,000
Austria	63,959	1,175,000	450,000
France	635,322	810,000	690,000
Russia	239,881	1,200,000	925,000
Belgium	104,370	220,000	90,000
Holland	23,175	125,000	100,000
Sweden and Norway	5,000	106,500	150,000
Denmark	2,250	49,000	60,000
Italy	19,200	120,000	115,000
Spain	18,552	116,000	95,000
Roumania	..	18,000	19,000
Switzerland	6,000	10,500	256,000
England	138,724	..	1,870,000
United States (beet and cane)	260,411	530,000	2,570,000
Total	1,837,724	6,110,000	8,270,000
Previous year	1,573,637	5,995,217	7,339,122

Production of Sugar-cane.—The following is a comparative statement showing production in cane-sugar countries during the past three years. Of course the figures for 1903–4 can only be approximate estimates, as the harvesting in some of the cane-producing countries, according to the latest advices, has just begun, and the results had to be anticipated :—

Country.	1901–2.	1902–3.	1903–4.
	Met. Tons.	Met. Tons.	Met. Tons.
Cuba	683,312	943,500	1,150,000
Porto Rico	82,179	77,737	125,000
Trinidad	44,918	38,804	40,000
Barbados	46,314	29,786	35,000
Martinique	31,733	33,107	35,000
Guadeloupe	40,576	38,828	35,000
Demerara	118,193	122,357	110,000
Brazil	268,000	139,000	150,000
Java	749,814	784,169	850,000
Philippines	67,331	114,343	110,000
Mauritius	145,268	147,630	180,000
Réunion	30,120	40,962	35,000
Jamaica	16,242	14,916	20,000
Lesser Antilles	95,000	80,000	80,000
Peru	100,000	110,000	100,000
Egypt	96,000	90,000	85,000
Hawaiian Islands	322,590	397,319	395,000
Total	2,907,586	3,202,158	3,535,000

World's Production and Consumption of Sugar.—It is expected that the decrease in sowings in Europe will be moderate, and that the acreage will be about 308,000 acres less. On the other hand, the production of cane-sugar will be increased by at least 150,000 tons. The world's consumption will increase about 500,000 tons.

XVII.—BREWING, WINES, SPIRITS, Etc.

ALCOHOL; DUTY-FREE —— IN POLAND.

Pharm. J., May 7, 1904.

The year 1903 was a bad one for Polish spirit distilleries on account of the failure of the potato crop. Large quantities of maize, according to the consular report, were imported from Bessarabia and the Caucasus to replace potatoes, but were of course much dearer. According to the law of 1903, permission was granted for the use of denatured spirits, free of excise, for industrial and technical purposes, but little advantage was taken of it on account of the shortness of spirits and the low price paid by the monopoly (4*d.* per gallon) for spirits to be denatured, which did not encourage distilleries to sell spirits to the monopoly for that purpose. Denatured spirits were sold by the monopoly only at Warsaw at 6*d.* per gallon. The consumption of denatured spirit was small, as special permission to use it has to be obtained from the Ministry in each case, even for a single lamp.

SPIRIT; PRODUCTION OF —— IN POLAND.

Pharm. J., May 7, 1904.

According to the law of June 12, 1900, which was in force till the end of 1903, Poland was allowed to produce 22,500,000 gallons of spirit a year. The production of spirits in 1903 was 17,517,558 gallons, of which 13,160,835 gallons were sold to the monopoly for export to other parts of Russia, and the remainder, together with the balance from 1902, covered the consumption of spirits in Poland, which annually is about 10,000,000 gallons. The consumption of spirits in Poland is yearly decreasing, whereas in Russia it is increasing. A new law, which came into force in January 1904, does not restrict in any way the production of spirits in Poland, and the annual requirements of the monopoly have been fixed by the Ministry at 18,191,355 gallons for the period 1903–07, the monopoly taking this quantity at a fixed rate.

SPIRIT; MANUFACTURE OF —— FROM PEAT.

Bd. of Trade J., May 12, 1904.

According to the *Neue Hamburgische Börsen-Halle* of 29th April, a company has been formed in Rendsburg with a capital of 1,500,000 marks to undertake the manufacture of spirit from peat. The factory will be built in the neighbourhood of Aalborg, and will at first have a capacity for producing 50 hectols. (hectolitre = 22 imperial gallons) daily. It is stated that it is intended in the first place to find a market in the free port district of Hamburg, where there are several large establishments using spirit, and at the same time export the product abroad from Hamburg. It is anticipated that the spirit produced will be especially suited for heating purposes. The company is to commence operations in July.

XIX.—PAPER, PASTEBOARD, Etc.

PAPER MANUFACTURE IN ALGERIA.

Dépêche Coloniale, May 2, 1904; *Bd. of Trade J., May* 12, 1904.

At the present time, the greater portion of the alfa cultivated in Algeria is sent to the United Kingdom; the amount imported into this country during 1903 being 63,974 tons. All this alfa is utilised in the manufacture of paper: the better quality for high-class paper and cigarette papers; the inferior quality for the manufacture of ordinary paper.

If account is taken of the cost of carriage to the factories and of the fact that nearly $2\frac{1}{4}$ tons of alfa are used in the manufacture of one ton of pulp, an idea is obtained of the advantage to be gained by dealing with the alfa on the spot.

A company has been formed with a view to working a patent for the manufacture of paper from fresh alfa. A factory has been established at Bou-Jaffar, and several others are about to be erected in the heart of the alfa-growing districts.

XX.—FINE CHEMICALS, Etc.

ETHER FOR MANUFACTURING PURPOSES.

Times, May 14, 1904.

Mr. Gray having asked whether his attention had been drawn to the fact that ether from pure spirit should be used in the manufacture of certain articles required by the War Office; that this spirit was subject to a heavy duty, and hence, if the article was to be manufactured at a reasonable price, methylated ether must be substituted for the pure, or the contract sent abroad where manufacturers obtain spirit duty free for manufacturing purposes; and whether, under these circumstances, he would consider the desirability of permitting the manufacture of such goods in bond under practicable conditions, or of allowing in the price paid by the War Office for the duty received by the Excise, the Chancellor of the Exchequer says: "Section 8 of the Finance Act of 1902 appears to cover such cases as the hon. member has in view. Manufacturers desiring to be allowed the benefit of that section should address an application to the Board of Inland Revenue, by whom it will be carefully considered."

Cocaine Manufacture in Peru.

Bulletin Commercial (Brussels), April 30, 1904 ; *Bd. of Trade J., May* 12, 1904.

Peru is the only South American country in which cocaine manufactories have been established. At the present time there are two in Lima, one at Callao, two in the Province of Cuzco, one at Catamarca, two in the Department of La Libertad, and about a dozen more or less important ones in the district of Huanuco. The quantity exported in 1901 amounted to about 210 cwts., nearly the whole of which was sent to Hamburg, the principal market for this product. The demand for cocaine is continually increasing. The subjoined figures show how largely the xportation of this article has developed :—

Year.	Coca Leaves.	Cocaine.
	Kilos.	Kilos.
1897	494,000	4,200
1898	408,000	4,350
1899	312,000	4,500
1900	566,000	7,750
1901	610,000	10,688

As the average price of cocaine in 1901 was 30*l.* per ilo., the value of the amount exported was more than 20,000*l.*

Antipyrine : U.S. Customs Decision.

April 12, 1904.

Following previous decisions on similar goods, the Board f General Appraisers held that antipyrine is dutiable at cents per lb. under paragraph 67 of the present tariff, a "medicinal preparation in the preparation of which cohol is used."—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and .S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an erisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of mplete Specifications Accepted, those of the Official Journals which acceptances of the Complete Specifications are advertised. omplete Specifications thus advertised as accepted are open to pection at the Patent Office immediately, and to opposition thin two months of the said dates.

,, 10,538. Alsop. Method of generating a gaseous medium from air. [U.S. Appl., May 29, 1903.]* May 7.
,, 10,607. Kennedy. Gas producers. May 9.
,, 10,620. Wilshere. Manufacture of artificial fuel. May 9.
,, 10,733. Hills and Lane. Gas-producing apparatus for use with fuels of a bituminous nature. May 10.
,, 10,734. Hills and Lane. Production of producer gas. May 10.
,, 10,873. Voelker. Manufacture of electric incandescent bodies. May 11.
,, 10,926. Dempster and Sons, Ltd., and Scott. Gas retorts. May 12.
,, 11,101. Roux and Gonin. Ovens for the carbonisation of peat and other carbonaceous materials. May 13.
,, 11,105. Guénot. Manufacture of water-gas. [Fr. Appl., May 14, 1903.]* May 13.
[C.S.] 11,827 (1903). Lake (Selas Ges.). Apparatus for producing mixtures of gas and air. May 18.
,, 13,047 (1903). Beaven. Treatment of coke. May 18.
,, 14,893 (1903). Paul. Gas producers. May 11.

[C.S.] 15,147 (1903). Johnson (Deuts. Continental Gas-ges., and Bueb). Manufacture of gas. May 11.

„ 27,579 (1903). Delassue. Gas producers and purifying apparatus for use with gas engines. May 11.

„ 5015 (1904). Myers. Furnaces specially applicable for burning tan and like fuel. May 18.

„ 6527 (1904). Thompson (Moore). Process and apparatus for quenching and bleaching coke. May 11.

„ 6718 (1904). West. Construction of regenerator furnaces. May 11.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[C.S.] 6891 (1904). Zimpell. Saturator for the recovery of sulphate of ammonia from ammonia gases. May 11.

„ 7204 (1904). Bokelberg and Sachse. *See under* XII.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 10,235. Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Manufacture of 1-diazo-2-oxy- and 2-diazo-1-oxy-naphthalene mono-, di-, and tri-sulphonic acids. May 4.

„ 10,678. Lake (Oehler). Halogenised nitro compounds.* May 9.

„ 10,895. Johnson (Badische Anilin und Soda Fabrik). *See under* XIII. A.

„ 10,925. Lilienfeld. Manufacture of indigo or homologues or derivatives thereof. May 12.

[C.S.] 13,192 (1903). Newton (F. Bayer and Co.). Manufacture of new dyestuffs of the triphenylmethane series. May 11.

„ 15,493 (1903). Johnson (Badische Anilin und Soda Fabrik). *See under* XIII. A.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 10,005. McNaught. Machinery for scouring and washing wool and other fibrous materials. May 2.

„ 10,156. Hall. Method and means of removing oil and grease from sponge cloths, cotton waste, and all kinds of grease-laden textile material. May 3.

„ 10,272. Kellner. Process and means for washing textile fabric.* May 4.

„ 10,499. Brandt. Process for producing figured patterns upon velveteens, plushes, and other pile goods. May 7.

„ 10,617. Waddelow. Process for making fabrics highly combustible. May 9.

„ 10,918. Roberts, Taylor, and Taylor. Carbonising or completely destroying all vegetable matter and silk in wool or rags automatically. May 12.

[C.S.] 10,255 (1903). Crompton and Horrocks. Machines for mercerising, scouring, bleaching, dyeing, washing, and like treatment of yarn in hank form. May 18.

„ 5201 (1904). Lesenne. Wool-washing machinery. May 18.

„ 8433 (1904). Serkowski. Waterproofing of materials, such as tissues, fabrics, paper, leather, and cords. May 18.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 10,232. MacIvor and Barnett. Apparatus for the manufacture of oxide lead. May 4.

„ 10,360. Johnson (Badische Anilin und Soda Fabrik.). Manufacture and application of reducing agents, and of intermediate products relating thereto. May 5.

„ 10,897. Bloxam (Neue Photographische Ges. Act.-Ges.). Manufacture of stable mangane salt solutions. May 11.

„ 11,172. Cie. Française de l'Acétylène Dissous. Manufacture of oxygen. [Fr. Appl., May 15, 1903.]* May 14.

[C.S.] 12,719 (1903). Lake (Synd. pour l'Exploitation des Inventions du Prof. Oettli). Manufacture of oxide of zinc. May 11.

„ 14,749 (1903). Davis. Utilisation of nitre cake and the manufacture of useful products therefrom. May 11.

„ 17,588 (1903). Johnson (Chem. Fabr. Griesheim Elektron). Treatment of alkali chromates for the production of bichromates and alkali therefrom. May 18.

„ 17,589 (1903). Johnson (Chem. Fabr. Griesheim Elektron). Treatment of chrome ironstone for the production of potassium chromate. May 18.

„ 6891 (1904). Zimpell. *See under* III.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 10,670. Bottomley, Hutton, and Paget. Manufacture of silica glass. May 9.

[C.S.] 13,046 (1903). Dausette. Manufacture of ceramic articles. May 18.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 10,170. Grau. Manufacture of cement. May 3.

„ 10,275. Schmidt and Unger. Coloured cement, and the process of manufacturing the same. May 4.

„ 10,496. Hadlington. Brick kilns, &c. May 6.

„ 10,650. Blakeslee. Building blocks.* May 9.

„ 11,151. Hamblet. Brick kilns, &c. May 14.

[C.S.] 11,324 (1903). Thum. Manufacture of Portland cement. May 18.

„ 16,125 (1903). Sandwith and Rayner. Lubricating substance for use in the manufacture of bricks, tiles, pottery, and the like. May 18.

„ 24,911 (1903). Earle (Traschler). Manufactur of white cement. May 18.

„ 3760 (1904). Perkiewicz. Coating bricks, an apparatus therefor. May 18.

„ 4478 (1904). Bach. Manufacture of refractory articles. May 11.

„ 4939 (1904). Weiss. Process of making a bindin agent or cement. May 11.

X.—METALLURGY.

[A.] 10,007. Kugel. Heating furnace for the continuo heating of metals without oxidation.* May 2.

„ 10,241. Bailey. Extraction of gold from refracto ores. May 4.

„ 10,682. Heberlein and Hommel. *See under* I.

„ 10,902. Imray (Soc. Anon. pour l'Industrie l'Aluminium). Process for the deoxidation ingot iron, ingot steel, and the like. May 11.

„ 10,976. Dake. Aluminium alloys. May 12.

[A.] 11,019. Brand. Apparatus for and methods of precipitating zinc from solutions of the same. May 13.

,, 11,123. MacArthur. Treatment of ores containing antimony. May 14.

,, 11,164. Wheatley. Metallic alloy. May 14.

[C.S.] 14,731 (1903). Willis (Shields). *See under* XI.

,, 15,032 (1903). Spencer. Manufacture of steel. May 18.

,, 15,188 (1903). Rouse and Cohn. Method of hardening lumps artificially agglomerated, of iron sand, or of concentrated powdered iron ore for transport and for reduction in furnaces. May 18.

,, 25,032 (1903). Galbraith and Steuart. Method of and apparatus for the reduction of iron sand, iron oxides, and other suitable substances. May 11.

,, 25,033 (1903). Galbraith and Steuart. Method and apparatus for the reduction of iron sand, iron oxides, and other suitable substances. May 11.

,, 26,292 (1903). Ellis and Flanigan. Flux for soldering aluminium. May 18.

,, 27,516 (1903). Jacobsen. Metallic alloys or compounds. May 11.

,, 2273 (1904). Hadfield. Manufacture of magnetic material. May 18.

,, 5671 (1904). Lake (Bassett, Parker, and Strout). Brazing of metals, and fluxes for use therein. May 18.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 10,559. Siemens Bros. and Co., Ltd., and Eichenauer. Galvanic batteries. May 7.

,, 10,709. Stöckigt. Dry cells.* May 10.

,, 10,794. Blackmore and Byrnes. Electrolytic apparatus. May 10.

[C.S.] 14,731 (1903). Willis (Shields). Electrolytic separation of copper and nickel from mattes and ores. May 18.

,, 14,963 (1903). Willis (Sjösted). Electric furnace. May 18.

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who propose to attend the meeting are requested to inform the General Secretary, as soon as possible, by what steamer they will travel. Each boat will be met on arrival at New York by a representative of the Reception Committee, with a list of apartments, at various prices, which have been reserved for the Society. The same system will be observed at all the other cities visited by the special train. A revised programme appeared in the March 31st issue.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Wm. H. Nichols has been nominated to the office of President under Rule 8; Dr. Edw. Divers, Prof. W. R. Eaton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. Parker have been nominated Vice-Presidents under Rule 8; and Sir Wm. Ramsay has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the Annual General Meeting at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Andrews, G. D., l/o Old Ford; c/o J. and J. Colman, Ltd., Carrow Works, Norwich.

MR. FRANK TATE IN THE CHAIR.

STUDIES ON THE CLAUS REACTION.
PART II.

BY R. FORBES CARPENTER AND S. E. LINDER, B.Sc.

In the paper read before this section in March, 1903 (this J., 1903, pages 457—464), we said, page 460: "We are not able to present any figures of sulphur loss corresponding to those in Table II. for ordinary gasworks Claus plants (composition of gases, 20—25 per cent. sulphuretted hydrogen to 80—75 per cent. carbon dioxide); but such figures as are contained in the Alkali Reports from 1884 onwards indicate that the losses are lower, especially in sulphur as sulphur dioxide. Probably the counter reaction between water vapour and sulphur is much less active at the lower temperatures induced by presence of so much carbon dioxide." During the past twelvemonth opportunities for more exact research have presented themselves, enabling us to conduct some fairly exact experiments on the question of sulphur loss, based on examination of the inlet and outlet gases, to compare with the results of similar losses as ascertained by the practice in the Chance-Claus process, where routine testing of both inlet and outlet gases is regularly practised. Early in the year, as indicated in the above quotation, it had been somewhat anticipated that in the former process, where the amount of carbonic acid bears such large proportion to the total volume of gases passing through the kiln, the lower resulting temperature would tend to diminish loss of sulphur resulting from the operation of a counter reaction, hitherto supposed to take place, to a certain extent, in the kiln at high temperatures—

*(2) $3S + 2H_2O = 2H_2S + SO_2$ For net calories evolved see (1) (i.), (4) (ii.) below; (2) being (4) reversed,

by which the concurrence of these two gases in the exit gases from the kiln has been explained. Some later experiments, however, directed to this point, have not confirmed the probability that this equation exclusively represents what occurs in the kiln after the supposed primary reaction—

*(1) $H_2S + O = H_2O + S$ At 316° C. (600° F.) if sulphur is vaporised net calories evolved 38,890,

has operated in the upper active layer of contact substance.

There are, however, considerations based on thermochemical data, which suggest that the kiln reactions may proceed on less simple lines than those represented by the wo equations (1), (2), above, both of which have a ositive value when expressed thermochemically, and lead o the adoption of the alternative equations—

*(3) $3H_2S + 3O = 2H_2S + SO_2 + H_2O$ At 316° C. net calories evolved, 124,450.

*(4) $2H_2S + SO_2 = 3S + 2H_2O$ At 316° C. (600° F.)
i. If sulphur is not vaporised, net calories *evolved*, 26,860.
ii. If sulphur is vaporised, net calories *absorbed*, 7,890,

affording a better explanation of the observed facts, ggesting that what actually takes place is not so simple (1), but that the same end result is reached in *two* ages.

In the first of these, (3), only 45,180 calories are generated per 32 of sulphur; but very little of this is rendered latent in the form of water vapour, in fact, only about one-sixth part of that in the direct reaction (1), where under kiln conditions more than one-third (about 22,500 calories) passes into the potential form as vapour of water and sulphur; hence this reaction (3) is the one giving the highest *temperature* to the resultant gases (see p. 587). It is possible, therefore, that the *whole* of the oxygen present goes to complete the oxidation of one-third of the sulphur present to sulphur dioxide (excluding from consideration the possible presence of sulphuric acid), the energy developed by the action of the chemical forces proceeding on the lines of highest temperature, *i.e.*, of greatest kinetic heat energy, before expending itself, in part, by assuming the latent or potential form. On this latter hypothesis at temperatures not less than 316° C. (600° F.), at which we may reasonably assume that all the sulphur will be in a state of vapour under kiln conditions (and with gases of 20 per cent. sulphuretted hydrogen and upwards, the boiling point of sulphur, 440 C. (824° F.) will be far exceeded), reactions will proceed on the lines of highest temperature — (3) having a positive value—(4, ii.), a negative, when expressed thermochemically—the temperature intensity of (3) being more or less modified by the heat *absorbed* in (4, ii.).

The residual sulphuretted hydrogen and sulphurous acid in the exit gases must, on this hypothesis, be regarded as due, partly to the incomplete operation of (4, ii.) and partly to the action of steam on sulphur vapour (2), a reaction which has been proved to take place within the range of temperature conditions existing in the Claus kiln (Watts' Dictionary of Chemistry, Vol. II., p. 725).

In view, however, of the difficulty of effecting an exact analysis of gaseous mixtures of SO_2, H_2S, H_2O, vapour of S, and possibly also SO_3, existing at a high temperature in a kiln, from which it is impossible to withdraw a sample without effecting some change in the proportion of the various constituents present, it is desirable to accept any hypothesis based on such analyses with considerable reserve. While it is not difficult to find equations which quantitatively express the kiln reaction when *solely* viewed in the light of the final products condensed in the sulphur chamber, and carried away in the exit gases, it would appear to be a matter of the greatest possible difficulty to determine the stages followed by the reactions within the kiln itself, operating, as they do, usually within a range of temperature exceeding that (400° C.) at which sulphuretted hydrogen wholly dissociates into its elements, and at which, therefore, such reactions as—

(*a*) $H_2S = H_2 + S$
(*b*) $SO_2 + 2H_2 = 2H_2O + S$

cannot be wholly disregarded.

The conditions for reaction (4, i.) seem to be more favourable in the case of kiln gases weak in sulphuretted hydrogen, such as those in Table I. of our paper of last year (this J., 1903, p. 458), where, in the lower part of the kiln, sufficient heat would not be present to maintain sulphur entirely in the form of vapour.

Nor is there evidence lacking that at the top of the kiln in the gas space above the contact-material, temperature is extremely high, as the result of chemical reaction in this space, as it is not of infrequent occurrence, even in Claus plants connected with gas liquor works, where carbonic acid is present to absorb heat, to find the wrought iron top of the kiln subjected to such heavy wear and tear as to necessitate renewal after a few years' working, no other part of the kiln bearing evidence of like stress. Such evidence points to intensity of reaction in this gas space.

If (3) is the first and primary reaction there may be means of inferring that sulphurous acid is in marked predominance at this particular point, and whether in lower zones of the kiln it suffers a progressive reduction. At this stage of the inquiry it is only possible to set out the theoretical considerations which have led to this hypothesis, which it is now sought to put to the test of experimental research.

---

* For the sake of simplicity, nitrogen is excluded from the ations under discussion here.

In the Appendix, pp. 586 *seq.*, later, are given the calculations in detail, based on thermochemical data showing that the governing factor for conditions suitable for reversing reaction (2) is the large amount of heat required to vaporise the sulphur.

Conditions of investigation, as will be seen later, are somewhat more complex in the sulphur recovery plants attached to processes where gas liquor is distilled than in those attached to the Chance process of treatment of alkali waste.

It was during the research at Work B. (p. 582) that the disturbing influence of ammonia, already thought possible, in examining results in Work C. (p. 582), made itself distinctly felt, and this proved a subject of interest in itself, as evidence was obtained that there was a greater proportion of ammonia in the outlet than in the inlet gases. This led to the following up of a suggestion that this increase might be due to the conversion of volatile cyanogen compounds into ammonia in the kiln. As indicated later, p. 584, direct laboratory experiments confirm the actual possibility of this reaction.

Determination of the "Efficiency" of the Claus Kiln and Chamber.

(*Gas Liquor Processes.*)

The "efficiency" of any given Claus kiln—as measured by the amount of free sulphur produced per 100 parts of sulphur as sulphuretted hydrogen entering—is governed by the nature and volume of the contact-material, and by the composition and rate of flow of the reacting mixture. Theoretically speaking, the effect of any of these factors upon the efficiency can be ascertained by varying one of the conditions while maintaining the others constant. Similarly, the efficiencies of different types of plant may be compared by measuring the yield of free sulphur obtained under corresponding conditions of working.

These ideal conditions are very difficult to approach in actual practice, but the results already obtained will serve to illustrate some of the general principles that govern a high yield of sulphur under the conditions of working imposed by the obligation to remove both sulphurous acid and sulphuretted hydrogen from the exit gases, before their discharge into the atmosphere, by means of limestone tower and oxide purifier. A *direct* determination of the free sulphur produced has not been found practicable owing to the difficulty of collecting that body without promoting decomposition of the residual sulphurous acid and sulphuretted hydrogen accompanying it. Moreover, it would provide us with no data for ascertaining the total efficiency of the *plant*, *i.e.*, the efficiency of kiln *plus* chambers—as the sulphur is almost entirely deposited before the exit is reached. We are compelled to rely, therefore, upon an *indirect* method of estimation by which the "free sulphur" is got by subtracting the sum of the sulphurs leaving as SO_2 and H_2S in a given volume of gas from the sulphur entering as sulphuretted hydrogen in an equivalent volume of saturator gas, or of reacting mixture.

As will appear later, this method is open to possibly serious error in cases where ammonia is present or is formed as a product of reaction in the kiln gases. Correctly speaking, the difference figure is sulphur "free and in other forms." We give examples later, based on actual works tests, showing how the efficiency measured as a difference figure departs very widely from that as measured by examination of the sulphur yield on emptying the "flowers" chamber in respect of sulphur combined with ammonia in the form of ammonium sulphate. On the other hand, when ammonia is absent, analysis of the sulphur for sulphuric acid and other free sulphur acids shows these to be present in such small quantities as not materially to affect the accuracy of measuring the efficiency by the difference method above.

The following description will, it is hoped, make clear the application of the methods of analysis adopted and means of calculation employed to reach the desired end.

Measurement of Gaseous Volumes.—It is of importance, if time is to be saved and accuracy ensured, that the water used in the aspirators and gas burettes should all be o approximately the same (air) temperature. If this conditio is observed, and if the analyses are further conducted a temperatures not much exceeding 10° C., corrections for temperature are rendered unnecessary in any of the gaseous volumes other than that of the H_2S in the inlet gas determined by iodine titration. Corrections for pressure also are unnecessary, save in exceptional cases.

This procedure is of special importance in the case of the exit gases, where residual H_2S and SO_2 are liable to react upon one another in the burette unless soda be promptly added to fix these compounds as alkaline salts. Rapid addition of soda must be preceded by prompt adjustment of water level for reading off the gaseous volume in the burette, and this again is only possible when apparatus and contained water are at air temperature to enable the reading to be made at the sampling hole.

Inlet Gas.

Apparatus consists of Bunte burette, graduated throughout, with levelling vessel.

Volume of gas is read off at once at air temperature, followed by removal of water from the burette by suction.

Volume taken = $CO_2 + H_2S$ + residual air * = 100 c.c.

Add 10 c.c. of 20 per cent. caustic soda (free from nitrites), then distilled water;

$CO_2 + H_2S$ = contraction observed.

Run the solution slowly from the burette into N/10 iodine, diluted to about 300 c.c. with distilled water and sufficiently acidified with hydrochloric acid, the flask being constantly shaken to ensure complete oxidation of the liberated H_2S, addition of further iodine being made from time to time, if necessary, to ensure a slight excess throughout. Wash out the burette with some of the solution and finish with N/10 thiosulphate, starch indicator.

H_2S at 0° C., 760 mm. = 1·12 × c.c. N/10 iodine.

Multiply H_2S found by suitable factor to reduce to air temperature and pressure—

CO_2 = contraction observed less corrected H_2S.

Exit Gases.

(i.) By burette method.

The analysis is carried out exactly in the same way as with the inlet gases.

Volume taken = 100 c.c.

Reduction of the volume of residual nitrogen, left after addition of soda, to air temperature is conveniently made by immersion of the burette in a cylinder of water.

Then, as before, we have—

$CO_2 + H_2S + SO_2$ + residual nitrogen† = 100 c.c.

And after soda absorption,

$CO_2 + H_2S + SO_2$ = contraction observed.

After titration with N/10 iodine,

$H_2S + SO_2$ = 1·12 × c.c. N/10 iodine, 0° C. 760 mm.

No correction is necessary to air temperature and pressur unless the volume exceeds 5 per cent.

(ii.) *Aspiration Method.*

Apparatus consists of Winchester quart aspirator wit 10 mm. layer of cylinder oil above the water to preve solution of CO_2. An 800-c.c. flask with small bore inl tube with its end sealed half an inch in 10 c.c. N/10 iodi + 10 c.c. N/10 $NaHCO_3$ and *not more than* 40—50 c.c. water. The water run from the aspirator is measured in

---

* It is assumed throughout that the small volume of residual left in the burette after treatment of the inlet gas with soda is a it may well be nitrogen. Except in the case of the Granton sampl the volume is too small to materially affect the calculations, and attempt has been made, therefore, to determine its exact co position.

† Oxygen is absent from the exit gases or present only exceptional cases, *e.g.*, as at Granton, where gases were weak a kiln temperature low; negligible traces only have been detected gasworks kilns, even when excess of air in the reacting mixture been large.

1,000-c.c. graduated cylinder; 11 c.c. is added to the water run to make up for volume of $H_2S + SO_2$ absorbed = 10 × 1·12 c.c.

It was proved by independent research on special mixtures of air, CO_2 and H_2S, that the errors introduced by solution of CO_2 in the absorbing liquid far exceed those resulting from volatilisation of traces of iodine from the solution, and that if the above procedure is followed the errors due to solution of CO_2 and loss of iodine and acid are all reduced to negligible amount, exact agreement being established between the results yielded by the burette and aspiration methods (i) and (ii).

The rate of aspiration should not exceed 100 c.c. of gas per minute (much slower at finish) and, if the highest degree of accuracy is desired, aspiration should be stopped before the last traces of iodine have been destroyed, and the excess allowed for by titration with N/10 thiosulphate and starch indicator.

Volume of water run + 11 c.c. = volume of gas aspirated, measured at air temperature and pressure.

Volume of $H_2S + SO_2$ in above = 1·12 × c.c. N/10 iodine. (0° C. 760 mm.)

Volume of N/10 bicarbonate needed to neutralise the reduced solution × 1·12 = volume of SO_2. (0° C. 760 mm.)

The results obtained by methods (i) and (ii) are combined, as shown in the worked example given below, to arrive at the correct average.

It should be pointed out that this method of differentiating between sulphur as H_2S and SO_2 is only *strictly* accurate when both these bodies enter the absorbing solution (N/10 odine *plus* equivalent of N/10 sodium bicarbonate) in the *ree* state, *i.e.*, uncombined with ammonia as sulphide or ulphite, as the equations upon which the method is based, amely:—

(*a*) $H_2S + I_2 = S + 2HI$ (*b*) $SO_2 + I_2 + H_2O = SO_3 + 2HI.$ } (In absorbing flask.) (*c*) $4HI + 4NaHCO_3 = 4NaI + 4CO_2 + 4H_2O.$

(*d*) $SO_3 + 2NaHCO_3 = Na_2SO_4 + 2CO_2 + H_2O.$ (In final acidimetric titration)

ssume that the *full* equivalent of hydriodic acid is formed both reactions (*a*) and (*b*), to be neutralised (*c*) by the quivalent of sodium bicarbonate present in the absorbing olution. The corresponding equations for the ammonium alts—

(*e*) $(NH_4)_2S + I_2 = S + 2NH_4I.$

(*f*) $(NH_4)_2SO_3 + I_2 + H_2O = (NH_4)_2SO_4 + 2HI,$ or, $= H_2SO_4 + 2NH_4I,$

early indicate that while the total amount of iodine reduced the same whether H_2S and SO_2 enter in the free state or ammonium salts, the acidimetric titration for SO_2 will be w in proportion as reactions (*e*), (*f*) replace reactions), (*b*).

Viewed thus, the figures for sulphur as SO_2 given in the bles must in every case be regarded as *minimum* figures, ose for sulphur as H_2S as *maximum* ones, the total sulphur gure for $SO_2 + H_2S$ (deduced from the total iodine reduced) ing alone *strictly* accurate. On the other hand, the esence of free sulphuric acid in the sample aspirated ould affect the SO_2 figure in the opposite direction, that of monium sulphate, of course, would not affect the test.

While ammonium sulphide can hardly be present under y circumstances, ammonium sulphite is undoubtedly ind in the exit gases under certain conditions of working, p. 584, while the existence of sulphuric acid in certain ns may be inferred from the fact that ammonium sulphate undoubtedly a product of the kiln reaction in some works e pp. 582–3). The presence of thiosulphuric and polyonic acids, also, must not be entirely overlooked in any ict discussion of the results, though the amounts found insignificant. As regards the origin of the sulphuric d found, finally, in combination with ammonia in the exit gases (almost the sole acid in some cases), we make ne remarks later. It has an important bearing on the ctions that take place in the Claus kiln.

Calculation of Efficiency of Claus Plant (= Kiln + Sulphur Chamber) in Gas Liquor Works.

Example.

Temperature of atmosphere, burette and aspirators approximately 10° C.

Inlet test—

Gas taken = 100·0 c.c.
$CO_2 + H_2S$ = 99·2 c.c.
Residual air* = 0·8

H_2S 0° C. 760 mm. = 1·12 × 27·1 c.c. (N/10 iodine).
dry = 30·3 c.c.
Corrected to 10° C. moist } = $\frac{30{\cdot}3}{0{\cdot}953}$ = 31·8 c.c.

Whence, saturator gas, per 100 vols.—

CO_2 = 67·4
H_2S = 31·8 × 6·25 × 0·953 = sulphur per cb. ft. of saturator
Air = 0·8 gas (10° C.) entering kiln = 189·7 grains.

Exit chamber test—

(i) Burette method—

Gas taken .... = 100·0
$CO_2 + H_2S + SO_2$ .... = 36·7
Residual nitrogen................. = 63·3
$H_2S + SO_2$ (0° C. 760 mm.) = 1·12 × 2·95 c.c. (N/10 iodine) = 3·28 c.c.

(ii) Aspiration method—

N/10 iodine reduced .. = 10·0 c.c.
Total N/10 bicarbonate = 18·9

SO_2 = 8·9 }
H_2S = 1·1 }

Water run = 330 c.c.
Add H_2S, SO_2 absorbed = 11 c.c.
Total gas aspirated = 341 c.c.

Whence—

$$SO_2 \text{ per 100 c.c.} = \frac{8{\cdot}9 \times 1{\cdot}12 \times 100}{341} = 2{\cdot}92 \text{ c.c.}$$

$$H_2S \text{ per 100 c.c.} = \frac{1{\cdot}1 \times 1{\cdot}12 \times 100}{341} = 0{\cdot}36 \text{ c.c.}$$

$H_2S + SO_2$ = 3·28 c.c. (0° C. 760 mm.)

Combining methods (i.) and (ii.) we have—

Mean $H_2S + SO_2$ = 3·28 = 3·3 approx.
SO_2 = 2·92
Correct H_2S = 0·36

Whence, exit chamber gases, per 100 vols.—

CO_2 = 33·4 and sulphur leaving per cb. ft. of gases (10° C.)
H_2S } = 3·3 as H_2S = 0·36 × 6·26 = 2·25 grains.
SO_2 } SO_2 = 2·92 × 6·26 = 18·28 „
N = 63·3 Total = 20·53 „

Also, 1 cb. ft. of saturator gas entering (10° C.) becomes 1 × $\frac{67{\cdot}4}{33{\cdot}4}$ cb. ft., leaving, since the percentage of CO_2 in the inlet gas (67·4) is reduced to 33·4 in the exit gases as the net result of dilution by residual nitrogen from air supply and reduction of volume due to chemical reactions in the kiln and chamber.

We have, therefore, per 1 cb. ft. of saturator gas entering at 100° C.

Sulphur entering, see above = 189·7 grs.

Leaving as $H_2S = \frac{67{\cdot}4}{33{\cdot}4} \times 2{\cdot}25 = 4{\cdot}5$

$SO = \frac{67{\cdot}4}{33{\cdot}4} \times 18{\cdot}28 = 36{\cdot}9$ = 41·4 „

"Free sulphur" (including sulphur in other forms) by difference........................ } = 118·3 „

Whence, per 100 parts of sulphur as H_2S entering

"Free sulphur" = 78·1 = "Efficiency of plant."†
As H_2S = 2·4 } = "Loss."
As SO_2 = 19·5 }
100·0

---

* See footnote, p. 578, col. 2. † See p. 578, col. 1.

Calculation of Air Supply.

Volume of air entering per 100 volumes of saturator gas—

$$V = 100\frac{(x - x')}{x'} + 1{\cdot}5\frac{(x'y - xy')}{x'}$$: for proof, see p. 589, col. 2.

Where, x = per cent. CO_2 in saturator gas = 67·4
x' = per cent. CO_2 in exit gases = 33·4

$x - x'$ = 34·0

y = per cent. H_2S in saturator gas = 31·8
y' = per cent. H_2S in exit gases = 0·36

$$\text{Whence, } V = \frac{100\,(34)}{33{\cdot}4} + 1{\cdot}5\,\frac{(33{\cdot}4 \times 31{\cdot}8 - 67{\cdot}4 \times 0{\cdot}36)}{33{\cdot}4} = 148{\cdot}4$$

Now, theoretical air required for reaction $H_2S + O = H_2O + S$ per 100 vols. saturator gas entering kiln = 31·8 × 2·5 = 79·5.

Air admitted = 148·4
*Add air in gas = 0·8

Total air in reacting mixture .... } = 149·2 − 79·5 = 69·7 air in excess of theoretical required.

$$\text{Whence, excess air, per cent. of theoretical required} = \frac{69{\cdot}7 \times 100}{79{\cdot}5} = 87{\cdot}7 \text{ per cent.}$$

* See footnote, p. 578.

* The "efficiencies" of various types of *kiln* are only strictly comparable when based on *ex-kiln* tests, as reactions continue to so extent in the hot end of the sulphur chamber (see Table III.). Opportunity did not occur to sample the ex-kiln gases at Works A. an on the occasions when plant was tested.

† See remarks, p. 578, col. 1.

Calculation of the Efficiency of Claus Kilns, taking Chance Process Gases.

As before, the efficiency of the kiln is defined to be the amount of "free sulphur" produced per 100 parts of sulphur as sulphuretted hydrogen entering.

The absence of all but traces of carbon dioxide in the holder gas, and the practice of intimately mixing gas and air before admission to the kiln necessitates some modification in the calculation given for gasworks plant.

The data required are as follows:—

(*a*) Volume per cent. of H_2S in the reacting mixture.
(*b*) „ „ H_2S in exit gases.
(*c*) „ „ SO_2 in exit gases.
(*d*) Relation of volume of exit gases to the equivalent volume of reacting mixture entering.

(*a*), (*b*), and (*c*) are obtained by the methods of analysis usual in such works: temperature and pressure considerations govern the results in the same way as indicated in the calculation on p. 579.

(*d*) is shown in the Appendix, p. 586 *seq.*, to take the form of the equation—

$$v'' = \frac{(100 - 1{\cdot}5y)}{(100 - 1{\cdot}5y')}$$

where—

v'' is the volume of exit gases leaving per 1 cb. ft. of reacting mixture entering.

y and y' are the volumes per cent. of H_2S in the reacting mixture and exit gases respectively.

The "free sulphur" is then obtained, as before, by subtracting from the weight of sulphur entering per 1 cb. ft. of reacting mixture the sum of the sulphurs leaving as H_2S and SO_2 in an equivalent volume of exit gases; and the "free sulphur," calculated as a percentage figure on the total sulphur entering as H_2S, will be the "*Efficiency.*" In this case, ammonia being absent, the qualification mentioned, p. 578, col. 2, does not apply.

Works Tests.

In Tables I. to III. are set out the results of actual tests at the works mentioned, p. 582. They largely explain themselves.

Table I. is comparable with Tables I. and II. of last year's paper, J. 1903, pp. 458, 459, but is more elaborated, as the rate of flow of gases through a cubic foot of contact-material, and the excess of air per cent. over that required by theory, are both given as the second and third columns of the table.

On p. 583 are set out the analyses of the liquors employed at Works A. and B. The presence of cyanide in the latter should be noted; it forms the subject of remarks later, in which the possibility of conversion of a large proportion of the cyanogen into ammonia is discussed.

From the particulars of plant at Works A. to D. that follow the tables, it will be seen that at Work A. the sulphur flowers chamber is divided into two parts, of a hot and cold section respectively. It will be noted, Work A.,

NOTE.—Work A—Gases enter cold chamber from hot section. Work B—Gases enter cold chamber from kiln direct.

Table III., that when the temperature drops, as it does, to 52° C. at the point where the residual gases enter the cold chamber, extremely little further interaction takes place, only 0·4 per cent. of the whole sulphur entering the kiln being formed in this chamber. At Work B. there is no subdivision, but it may be safely inferred that the bulk of the reaction whose extent is indicated in the last column has taken place in the first few bays of the chamber where the gases are still very hot, entering from the kiln at over 300° C.

At Work A. nothing could be more satisfactory than the regularity of the air supply attained by the simple means to be immediately described. At Work B., on the other hand, considerable trouble was caused by the difficulty in getting desired regulation of air supply with the means at command. (These latter are now to be modified and improved.) This is a reason for regarding with some reserve the results in the sulphur chamber in this case. At Work C. the same difficulty existed as one of those experienced. At Work D. it will be noticed how enormous was the excess of air at time of experiments. Here, too, proper control of supply has been followed by improvement in results obtained.

Description of Claus Plants tested in various Works.

Works A.

Gas Liquor.—1,514 gallons per hour of average strength and composition as shown below.

Air Supply.—The necessary pressure for supplying the kiln is obtained by allowing water from the tubular cooler to fall down one limb of a ∩-shaped pipe, air being sucked in through a hole at the bend and delivered by the falling water into a box provided with blow-off cock and feed valve.

Great regularity of feed is secured by this simple means.

Reacting Mixture.—Air and gas mix in an iron box before admission to the kiln.

Claus Kiln.—Dimensions: 7 ft. 7 ins. internal diameter with 4 ft. of contact material graded in 6-in. layers from the bottom upwards as follows:—

6-in. iron oxide (4-in. cube).
6 „ fire brick (3 „). Total depth iron oxide = 3 ft.
6 „ iron oxide (2½ „). Total depth fire brick = 1 ft.
6 „ „ (2 „).
6 „ fire brick (1½ „).
6 „ oxide (1½ „).
6 „ „ (1 „).
6 „ „ (¾ „), with two bucketfuls of fine oxide to finish.

Area of contact material = 45 sq. ft superficies.
Volume „ „ = 180 cb. ft.

Sulphur Chambers.—Hot end (built separately), 12 ft. wide × 14 ft. long × 11 ft. high (outside).
Volume = 1,310 cb. ft. (approx.).

Cold End.—12 ft. wide × 65½ ft. long × 11 ft. high (outside).
Volume = 6,720 cb. ft. (approx.).
Total volume = 8,030 cb. ft.
Chamber space, cubic feet per 1 cubic foot exit gases per minute,

$$(15\cdot6^\circ\text{ C., }760\text{ mm.}) = \frac{8{,}030}{46\cdot41} = 173\text{ cb. ft.}$$

Exit Gases.—To two limestone towers in sequence, each 5 ft. square (inside) × 15 ft. high, thence to one of two oxide purifiers, in alternate use, with hydraulic valve.

Gas pressure was positive throughout the plant, varying from $\frac{3}{10}$ in. water at the inlet to kiln, to $\frac{1}{10}$ in. water at limestone towers.

Works B (one unit of plant tested).

Gas Liquor.—750 galls. per hour (approx.) of average strength and composition as shown below.

Air Supply.—From a Donkin's exhauster, which maintains a pressure of about 30 ins. of water in the air vessel (8 ft. diameter × 6 ft. 4 ins. high), from which the kiln is fed by 6-in. pipe. The delivery end of the air pipe is surrounded by that supplying saturator gas on the blowpipe principle; air and gas thus discharge together, in intimate contact, into a brick chamber (6 ft. 10 ins. × 22 ins. high at the centre) placed *below* the contact material, the reacting mixture passing *upwards* through the brick packing and leaving the kiln near the top of one side.

Kiln.—Dimensions: 8 feet internal diameter, with 2 ft. 9 ins. depth of fire brick packing measured from the surface to the centre of the chamber arch.
Area of contact material = 50·3 sq. ft. superficies.
Volume (corrected for curvature of arch) = 156·9 cb. ft.

Sulphur Chamber.—10 ft. 3 ins. wide × 10 ft. high × 39 ft. 3 ins. long (outside), divided into 10 compartments by 9-in. baffle walls.
Volume = 2,920 cb. ft. (approx.).
Chamber space, cubic feet per cubic foot exit gases per minute,

$$(15\cdot6^\circ\text{ C., }760\text{ mm.}) = \frac{2{,}920}{35\cdot58} = 82\text{ cb. ft. (approx.).}$$

Exit Gases.—To limestone tower 4 ft. diameter × 26 ft. high (outside), thence to oxide purifier, 20 ft. × 22 ft. × 3 ft. oxide (inside).

Gas pressure had a slight positive value throughout the plant.

Gas Liquor.—1,667 galls. per hour.

Kiln.—Internal diameter, 6 ft. 9 ins.; depth of packing, 3 ft.

Contact Material.—Oxide of iron.
Volume = 107·3 cb. ft.
Area = 35·76 sq. ft.

Works D.

Gas Liquor.—1,867 galls. per hour.

Kiln.—Cross section an annulus; large diameter 17 ft., smaller 5 ft. (inside measurements); depth of packing. 2 ft. 6 ins.

Contact Material.—2 ft. of oxide of iron, 6 ins. of Weldon mud.
Volume = 517·5 cb. ft.
Area = 207 sq. ft.

Ammonia in Recovered Sulphur from Claus Kilns attached to Gas Liquor Processes.

It is a well-established fact that ammonium salts are found in some sulphur chambers attached to Claus kilns taking saturator gases:—samples of recovered sulphur are occasionally picked out containing a high percentage of ammonia, while at one works the amount has been such as to pay for its recovery by washing, having regard to the destructive action of ammonia on the nitrous compounds used in sulphuric acid manufacture. Moreover, tubes employed for sampling the exit gases from the kiln frequently become blocked with a white deposit which proves upon analysis to contain sulphite and sulphate of ammonia in notable amount. The effect of this ammonium sulphite upon the iodine aspiration test for estimating H_2S and SO_2 in exit gases has already been considered. Analyses of a few samples of sulphur from Claus kilns and Chance process kilns are given in the following table:—

The presence of some of this ammonia, perhaps a large roportion, may frequently be attributed to imperfect bsorption in the saturator. In some cases saturators have een found designed with so steep an angle in the bottom rom back to front that when there is ample depth of acid u the front or fishing part of the saturator, where the alphate formed is withdrawn from time to time, either echanically or by hand, the ammonia-distributing pipe in he closed portion at the back is either unsealed or has too mall a layer of acid liquor above it to ensure neutralisation f the ammonia passing in bubbles of greater or less imensions. This defect, in one instance, has led to the iscarding of a new and expensively constructed saturator. imilar losses may occur from neglect of the attendant to aintain sufficiency of acid at any period, especially when e level of liquor in the saturator is being lowered by withrawal of the salt, also from gradual enlargement of the oles in the ammonia-distributing pipe above referred to, ter the lapse of time, causing the vapours to issue rough the acid in too great volume at particular points, that acid and ammonia are not in actual contact. In me works the liability to losses of this character is cognised, and provision is made for scrubbing the gases ter leaving the saturator with fresh sulphuric acid flowing the saturator in a suitably-devised arrangement for inging the gases into close contact with thin films of acid. The point concerns the manufacturer from the economic point of view. The presence of escaping ammonia, however, does not add any difficulty to the problem of dealing with the residual noxious gases escaping from the process.

Study of the preceding table, however, shows that the hydrocyanic acid present in certain gas liquors may bear such a considerable proportion to the sulphur present as sulphide that, were the whole of the former converted into ammonia in the kiln, the yield of sulphur would be most materially diminished. In example 2 in the above table as much as 13 per cent. of the sulphur in the gases might appear as ammonium sulphate in the sulphur "flowers" chamber, the available sulphur only amounting to 87 per cent. of that possible had cyanide been absent.

It became of interest, therefore, to ascertain by concurrent inlet and outlet tests, extending over several hours (to cover all periods of working) the exact relation existing between the amounts of ammonia in equivalent volumes of gases entering and leaving the kiln at a works where the presence of ammonium salts in the recovered sulphur was an undoubted fact.

This it was possible to do at Works B. The following method was adopted:—

(1) *Inlet Gases.*—3·1 cb. ft. of saturator gases were slowly aspirated (4½-hour test) through a bottle containing

dilute acid to decompose the volatile ammonia compounds —sulphide, carbonate, cyanide, &c.—and fix the ammonia.

(2) *Exit Gases.*—1·508 cb. ft. of exit kiln gases (= approximately 1 cb. ft. of saturator gases entering) were similarly aspirated through 200 c.c. of water over the same period.

Analysis of Resulting Solutions.—The ammonia in both samples was determined by distillation with excess of caustic soda. The results are fully set out in Table V. immediately following.

The behaviour of the two solutions under distillation at once indicated a striking difference in the character of the ammonia-yielding contents: the inlet gas sample evolved only 25 per cent. of the total ammonia obtained from it in the first 150 c.c. distillate, while evolution continued regular and with no appearance of coming to an end throughout the whole period of distillation—4½ hours—with a total distillate of 1,150 c.c. The exit gas sample, on the other hand, yielded the whole of its ammonia in the first 150 c.c.

TABLE V.

Ammonia-yielding Compounds in Equivalent Volumes of Inlet and Exit Gases to Claus Kiln.

Total ammonia (grains)....	1·467

For the suggestion that the source of the additional ammonia in the exit gases might be found in volatile cyanogen compounds in the foul gases, and originating in the gas liquor used, we are indebted to Mr. F. N. Suttoo, then assisting in the conduct of the experiments at Works B.

It is quite obvious from these results that the amount of ammonia entering the kiln as cyanide and carbonate (not exceeding 0·856 grains NH_3 per cubic foot of saturator gases) is insufficient to account for the ammonia as sulphite and sulphate in an equivalent volume of the gases leaving (5·201 grains NH_3), and that the inlet sample must have contained, in addition to the comparatively small proportion of volatile ammonia compounds (carbonate, &c.), nitrogenous compounds that slowly yield ammonia on distillation with soda, *e.g.*, hydrocyanic acid which yields sodium formate and ammonia under these conditions.

$$HCN + NaHO + H_2O = NH_3 + HCOONa.$$

Analysis of inlet sample (1) showed that it contained hydrocyanic acid equivalent to—

8·81 grains HCN per cubic foot of saturator gases
= 5·57 „ NH_3 „ „ „

an amount more than sufficient to account for the whole of the ammonia leaving the kiln, even if we disregard the fact that the tension of hydrocyanic acid is such as to render it probable that only a portion of this body actually present in the saturator gases was retained in the acid absorbent used.

This interesting result led to the working hypothesis that the ammonia found in these exit gases is in large measure due to the decomposition of cyanogen compounds in the kiln by steam resulting from oxidation of the sulphuretted hydrogen by air—

$$HCN + H_2O = NH_3 + CO,$$

a reaction analogous to the formation of ammonia from metallic cyanides when heated with steam. (*Vide* Watts' Dictionary, Vol. I., p. 197; also, Lunge's "Coal Tar and Ammonia" (3rd Edition), pp. 674–682).

This hypothesis has been put to experimental proof, and sufficient evidence has been already obtained to justify its adoption, as the results of experiments given below indicate that very substantial conversion of hydrocyanic acid into ammonia takes place when a mixture of that gas and carbon dioxide is passed through a highly heated contact material, *e.g.*, broken brick, with excess of steam, and that this percentage was increased when sulphuretted hydrogen was added to the carbon dioxide and water vapour.

The apparatus employed in the preliminary work was on the lines of that adopted for the laboratory Claus kiln experiments described in 36th Alkali Report, 1899, pp. 181–184:—

The contact material was broken brick, graded in two layers, the upper being in a state of fine powder, to ensure intimate contact with the reacting mixture. Temperatures were approximately determined by means of the Siemens calorimeter in exactly the same manner as in the works' tests, the lid of the small iron kiln being modified to allow of the insertion of a thin steel tube with closed end surrounded by the contact material, to protect the copper bolt from corrosion by the reacting gases.

A suitable reacting mixture was obtained by passing a rapid stream of washed carbon dioxide from a Kipp's apparatus through a decomposing flask containing dilute sulphuric acid (1 acid to 10 of water) into which a solution of potassium cyanide of determined strength was allowed to slowly drop from the end of a capillary tube coupled to a burette. The acid in this "decomposer" was maintained throughout the "run" at a temperature somewhat below 100° C., so as to ensure a sufficient volume of steam in the reacting mixture. An approximate estimate of the weight of steam used is deduced from the weights of reacting solutions before and after passage of the gas, and its volume is included in the total volume of the exit gases leaving the kiln.

The exit gases passed, first, through a glass retort to condense the ammoniacal liquor, the last traces of ammonia being retained by an acid catch placed on the exit of the retort, thence through a small Drechsel's bottle containing water, to a large aspirator with a layer of cylinder oil above the water to prevent solution of carbon dioxide. A small T-tube inserted between the acid catch and water seal enabled samples of the residual gases to be withdrawn from time to time for analysis by Bunte burette. A blank run was first undertaken to test the apparatus, in which a slight insuck of air was noted. This leakage increased markedly during progress of experiment D, which concluded the series.

The results obtained are set out below in parallel column to facilitate comparison. The yield of ammonia in experiment A is very satisfactory, considering the fact that this body commences to dissociate into its elements at a temperature of 500° C. (see Watts' Dictionary, Vol. I., p. 198, and especially Ramsay and Young, Journ. Chem. Soc., 1884), and also that no special precautions were taken to exclude the oxygen of residual air (5 to 8 per cent.), which can hardly fail to have some destructive action on ammonia at the high temperature employed, and in addition reacts with hydrocyanic acid itself to form carbonic acid, water, and nitrogen. It is not desired at this stage to attempt to draw any conclusions from these experiments as to the conditions most favourable for a high yield of ammonia; but it is hoped that opportunity will be found during 1904 to determine the data required to decide the exact limits of the reaction under a range of conditions inclusive of those operating in the Claus kiln, where vapour of sulphur, sulphuretted hydrogen, and sulphurous acid are present to modify the reaction, and also to ascertain whether other nitrogenous bodies, *e.g.*, pyridine and other bases, are contributing factors to the yield. The possible influence of this reaction on the yield of ammoniacal liquor from gas retorts, coke ovens, and especially from producer gas processes where large quantities of steam are admitted, is one that is not lost sight of; the conversion of cyanogen into ammonia has indeed from time to time engaged the interest and attention of many technological chemists. (*Cf.* Lunge, "Coal Tar and Ammonia," 3rd Edition, pp. 675–682.)

Another modern instance in which both hydrocyanic acid and ammonia are products in a high temperature reaction is the treatment of "Schlempe" (the waste product of refining the molasses of beetroot sugar) by the Bueb process at Dessau. (*Cf.* G. T. Beilby, "Advances in Chemical Industry during the Nineteenth Century," pp. 27–29, Roy. Phil. Soc., Glasgow, 1904.)

" O per cent.	..	..	..	..	0·2

* Note.—The conditions of the experiment rendered it impossible to determine the amount of steam resulting from partial oxidation of the sulphuretted hydrogen admitted to the decomposer by adventitious air. Analysis proves that sulphurous acid, free sulphur, and sulphuretted hydrogen, were all present in the gases leaving the kiln, thus closely imitating actual Claus kiln conditions of working on the manufacturing scale.

Estimation of Cyanide in Ammoniacal Liquors.

The method devised in this research for the estimation of hydrocyanic acid in the ammoniacal liquors examined consisted in distilling the liquor with excess of tartaric acid into caustic soda in an apparatus provided with receiver and Liebig's condenser similar to that employed for the estimation of fixed ammonia, lead nitrate being added in excess to retain the sulphide, and ferric chloride to convert any ferrocyanide present into Prussian blue, a substance which evolves no hydrocyanic acid under the observed conditions. The cyanide obtained in the distillate was determined by titration with N/10 silver nitrate or N/10 iodine in the usual way.

The methods of W. Feld—"Jour. für Gasbeleuchtung," 1903, **46**, (29) to (33), pp. 561 to 666—were unknown to us when the above procedure was elaborated. The omission of tartaric acid by Feld is a distinct simplification, as he shows that not only is completeness of evolution of hydrocyanic acid attained, but that risk of concurrent decomposition of sulphide, evolving sulphuretted hydrogen, is also entirely obviated by employing lead nitrate as the sole reagent.

The results in Table VI. above clearly prove that a large conversion of hydrocyanic acid into ammonia is effected by the agency of steam in presence of a catalytic substance maintained at a temperature of 300°—600° C.

and that Claus-kiln conditions *quâ* sulphuretted hydrogen are specially favourable to a high yield. We have now to enquire how far such a reaction as $HCN + H_2O = NH_3 + CO$ is likely to affect the kiln reaction itself in gas-liquor works, where cyanides are not infrequently present in the reacting mixture.

No complete data are yet available for tracing the kiln reactions by quantitative estimation of the gaseous constituents at various stages in their descent through the kiln. We are compelled to rely, therefore, in this preliminary inquiry upon analyses of the final gaseous mixture leaving the kiln and chamber, and of the solid and liquid products that separate. The limitations of the methods for analysing exit-kiln and chamber gases have been already discussed, and need not be rehearsed; methods for the direct estimation of SO_3 and other constituents in addition to H_2S and SO_2 are now under consideration. Analysis of the recovered sulphur from the chamber, though presenting less difficulty in itself than that of the gaseous products, is unfortunately complicated by the impossibility of exactly determining how far the chamber product obtained is the result of the high temperature reactions in the kiln itself, and how far of the low temperature reactions that subsequently proceed to a limited extent in the chamber; *e.g.*, interaction of residual H_2S and SO_2, in presence of moisture, to form free sulphur and thionic and thiosulphuric acids, see Table III., while a further factor is introduced by reason of the oxidising action of air on the recovered product when withdrawn from the chamber. Analysis indicates, however, that we may regard the recovered product of the Chance-Claus process as consisting essentially of pure sulphur, and that of the Claus process in gas-liquor works as a mixture of free sulphur and ammonium sulphate with more or less associated moisture, in proportions determined almost entirely by the reactions in the kiln itself, the low temperature products of the chamber reaction being present only in insignificant amount.

The kiln reactions yielding free sulphur have been already fully discussed; it remains only to consider those responsible for the presence of ammonium sulphate in gas-liquor works kilns the amount of which on occasions approaches, and even exceeds, that of the free sulphur itself. See Table IV.

As regards the base, ammonia, the tests at Works B. indicate that a large proportion of that found in the exit gases from the kiln—certainly not less than 85 per cent. of the total amount found on the occasion of our tests—was derived from the decomposition of cyanides by steam. It is impossible to state the exact proportion in any given instance, because there exist no means of ascertaining how far the ammonia entering the kiln as such, during periods of irregular working of the saturator, survives the high temperature in what we may call the oxidising zone of the kiln, where oxygen is present in large excess over that required for the simple reaction $H_2S + O = H_2O + S$ (the excess amounting in one case to over 200 per cent.), and where steam is at a minimum. Whatever its previous history, however, ammonia is undoubtedly present in the exit kiln gases, mainly in combination with sulphuric acid as ammonium sulphate, but in lesser degree also with sulphurous acid as ammonium sulphite (see analysis, p. 584); the latter body would, of course, rapidly suffer oxidation to sulphate when the recovered product is exposed to the air on opening the chambers.

The origin of the sulphuric acid found in combination with ammonia in the exit kiln gases has an important bearing on the Claus-kiln reactions; *free* sulphuric acid does not appear as a final product of the kiln reaction in normal working, either in the Chance-Claus process or in the Claus process as applied in gas-liquor works, the small traces of that acid found in the recovered sulphur in certain parts of the chamber being attributed entirely to the oxidation of occluded sulphurous acid on exposure to air. The presence of combined sulphuric acid in the latter class of works appears to be governed entirely by the presence of ammonia in the reacting mixture in actual or potential form (as hydrocyanic acid), and under such conditions sulphuric acid must be regarded as much a product of the kiln reaction as sulphurous acid itself. Whether it is formed in the upper and oxidising zone of the kiln in normal working, to be subsequently reduced by vapour of sulphur and sulphuretted hydrogen in the lower zones, when ammonia is not present to combine with it, is a question that can only be decided by a complete analysis of the gases, extending to an estimation of all its constituents. Indirect evidence, however, in the case of Works B. does exist—suggesting this formation and survival—in the fact that the oxygen deduced from the products of the kiln reaction (water and free sulphur) shows a marked divergence, 2·6 grms. (on 11 grms. per 100 litres of reacting mixture) in place of 13·6 grms. entering the kiln as deduced from gas analysis, while in the case of Works A., where no cyanogen is present, the amounts were 9·1 and 9·7 grms. respectively (see example, Works A., p. 582). Analysis does prove, however, that sulphuric acid and ammonia are ultimately present in the recovered sulphur in *equivalent* proportions, and that we may take the amount of ammonia as governing the amount of sulphuric acid that survives. We have shown that the amount of ammonia itself in normal working is controlled by the hydrocyanic acid present in the reacting mixture, and the conclusion is reached, therefore, that this latter body is a factor that governs the character of the recovered sulphur to a very material extent. Given the amount of cyanide and sulphide in the gas liquor, we can calculate the percentage amounts of free sulphur and ammonium sulphate in the recovered sulphur. The result is both interesting and instructive.

Thus, taking works B, C, we have per 100 parts of gas liquor used :—

——	Works B.	Works C.
Total H_2S entering kiln in terms of sulphur	0·362	0·220
Less sulphur combined with NH_3 as $(NH_4)_2SO_4$	0·033	0·029
Net free sulphur by difference	0·329	0·191
Ammonium sulphate equivalent of HCN entering kiln	0·135	0·119
Total product recovered	0·464	0·310

Whence, per 100 parts of dry recovered product :—

——	Works B.	Works C.	
	Calculated.	Calculated.	Found.
Free sulphur	71	62	63
Ammonium sulphate	29	38	23

Note.—The above calculations are entirely theoretical. They indicate the percentage composition of the recovered sulphur on the assumption that the ammonium sulphide and cyanide in the gas liquor yield the full equivalents of sulphuretted hydrogen and hydrocyanic acid respectively in the reacting mixture and that reactions proceed to completion to free sulphur and ammonium sulphate. No exact data yet exist for attempting a solution based on practical working.

Appendix.

Calculation of Theoretical Temperature attained in Claus Kiln by Products of Reactions.

Data for Calculation.—See Jour., 1903, pp. 462, 463.

Discussion of the Thermal Effect of the Reversible Reactions (2), (4), p. 577, *on their simplest basis, excluding Nitrogen.*

(4) $2H_2S + SO_2 = 3S + 2H_2O$; *i.e.* (2) reversed.

Temperature of reaction assumed to be 316° C. (= 601° F.).

(4) i. Sulphur entirely in the form of liquid.
(4) ii. „ „ „ vapour.

(4) ii—Available heat—

Brought in by reacting gases — Total.

SO_2 = 0·1544 × 316 × 64 = 3,123

$2H_2S$ = 0·2423 × 316 × 68 = 5,206

$2H_2 + O_2$ (water vapour) = 114,800 = + 123,129

Heat absorbed—

To decompose $2H_2S$ = 9,480

" SO_2 = 71,970

To raise products to 316° C. and vaporise the sulphur—

$2H_2O$ = 0·54 × 36 × 316 = 6,143

3S (as below, vapour) = 43,430 = − 131,023

Net heat (absorbed) = − 7,894

To raise 3S (96 grms.) from 0° C. to 316° C., and vaporise, we have—

(*a*) Solid to 115° C. = 96 × 20·7

(*b*) To melt at 115° C. = 96 × 9·4

(*c*) Liquid to 316° C. = 96 × 60·3

(*d*) To vaporise at 316° C. = 96 × 362·0

96 × 452·4 = 43,430

(4) i. Available heat—

Total as above.................. = + 123,129

Heat absorbed—

To decompose H_2S, SO_2 as above = 81,450

To raise products to 316° C., sulphur assumed to remain liquid—

$2H_2O$, as above = 6,143

3S (as below, liquid) = 8,678 = − 96,271

Net heat (evolved) = + 26,858

To raise 3S (96 grms.) from 0° C. to 316° C., we have—

Total heat = 96 [20·7 + 9·4 + 60·3]

= 96 (90·4) = 8,678

Theoretical Maximum Temperature attainable in the Claus Kiln with Sulphuretted Hydrogen, 100 per cent., proceeding on the assumption that Reaction occurs in two Stages (3) and (4). See p. 577, col. I. Nitrogen included.

(3) $3H_2S + 3O + 12N = 2H_2S + SO_2 + H_2O + 12N$.

(4) $2H_2S + SO_2 + H_2O + 12N = 3S + 3H_2O + 12N$.

Reaction (3) is assumed to take place at 16° C. 760 mm. (moist gases).

Reaction (4) is assumed to take place at the temperature theoretically attained in (3) 1,330° C.

(*c*) Air for the purpose of all these calculations is assumed to have the composition, *by volume*, 1 of oxygen to 4 of nitrogen.

Reacting mixture per 100 volumes (moist 16·0° C. 60 mm.).

Sulphuretted hydrogen	= 28·1	= 40·4 grms.	per	100	litres.
Oxygen	= 14·0	= 19·0	"	"	"
Nitrogen	= 56·2	= 66·6	"	"	"
Aqueous vapour	= 1·7	= 1·3	"	"	"
	100·0				

Assuming that of every three atoms of oxygen reacting, wo form sulphur dioxide and one forms water, we have r 100 litres—

Sulphur dioxide produced = 2/3 × $\frac{64}{32}$ × 19 grms.

= 25·33 grms.

	Grms.
Total sulphuretted hydrogen entering	= 40·40
1/3rd reacting to sulphur dioxide	= 13·46
Sulphuretted hydrogen available for reaction (4)	= 26·94

Whence, per combustion of 100 litres of moist reacting mixture (15·6° C.).

Heat evolved by (3)—

Sulphur dioxide produced yields—

71,970 × $\frac{25·33}{64}$ = 28,400

less sulphuretted hydrogen decomposed = 4,740 × $\frac{13·46}{34}$ = − 1,876 26,614

Water vapour produced yields —

57,400 × $\frac{13·46}{34}$ = 22,724

Total heat evolved = 49,338

Products :—

	Grms.
Sulphur dioxide	= 25·33
Sulphuretted hydrogen	= 26·94
Aqueous vapour	= 8·42 (= 18 × $\frac{13·46}{34}$ + 1·3 carried)
Nitrogen	= 66·6

Then—

Rise of temperature = (t − 16°) C.

Sulphur dioxide absorbs—

25·33 × 0·1544 × (t − 16) = (t − 16) × 3·91

Sulphuretted hydrogen—

26·94 × 0·2423 × (t − 16) = (t − 16) × 6·53

Aqueous vapour—

8·42 × 0·92 × (t − 16) = (t − 16) × 7·75

Nitrogen—

66·6 × 0·29 × (t − 16) = (t − 16) × 19·32

Total heat absorbed = (t − 16) × 37·51

Equating, we get—

(t − 16) 37·51 = 49,338

t = 1,330° C. { = Maximum temperature attainable, if reaction (4) = 0.

Stage (4).—Reaction proceeding (at 1,330° C.) on the lines of the equation—

$$2H_2S + SO_2 + H_2O + 12N = 3S + 3H_2O + 12N.$$

Sulphuretted hydrogen = 26·94 grms.

= 26·94 × $\frac{32}{34}$ = 25·35 grms. sulphur.

Sulphur dioxide = 25·33 grms.

= 25·33 × $\frac{1}{2}$ = 12·66 " "

38·01 Total.

Aqueous vapour from (3) = 8·42

Add ditto produced (4) = 26·94 × $\frac{18}{34}$ = 14·26 } = 22·68 total.

Then, we have for reaction at 1,330° C.—

Heat brought in by reacting gases— Calories.

Sulphur dioxide .. = 25·33 × 0·1544 × 1,330 = 3·91 × 1,330

Sulphuretted hydrogen .... = 26·94 × 0·2123 × 1,330 = 6·53 × 1,330

Aqueous vapour .. = 8·42 × 0·92 × 1,330 = 7·75 × 1,330

Nitrogen .... = 66·6 × 0·29 × 1,330 = 19·32 × 1,330

Total = 37·51 × 1,330

Heat produced by oxidation of the sulphuretted hydrogen to water vapour .... = 49,888 calories

water vapour = 57,400 × $\frac{26·94}{34}$ = 45,480 "

+ 95,368 "

Less heat required to decompose the sulphuretted hydrogen—

= 4,740 × $\frac{26·94}{34}$ = 3,756

Ditto sulphurous acid...... } = 71,970 × $\frac{25·33}{64}$ = 28,490 = − 32,246

Net heat evolved = 63,122

As before, let t' be final temperature,
Then—

To raise aqueous vapour from 0° C. to t' heat required—
$= t' \times 0·84 \times 22·68$ .... $= t' \times 19·05$

Ditto nitrogen—
$= t' \times 0·283 \times 66·6$ .... $= t' \times 18·85$

Ditto sulphur—
To raise from 0° C. to 316° C. and vaporise....... $= 452 \times 38·01 =$ $+ 17,200$
Vapour to $t'°$ from 316°
$= (t' - 316) \times 38·01 \times 0·08 = t' \times 3·04 - 960$

Total heat required $= t' \times 40·94 + 16,240$

Equating, we get—

$$t' \times 40·94 + 16,240 = 63,122$$

$$t' = \frac{46,882}{40·94} = 1,150° \text{ C.*} \quad 2,100° \text{ F.}$$

Maximum temperature attained if (3), (4) occur simultaneously.

The calculations in Table I. proceed entirely on the lines of practical working; the following example is given to illustrate the method by which the results are reached, see also J., 1903, page 464 :—

EXAMPLE.—TABLE I., WORK A.

1. On the lines of equation (1), p. 577.
2. On the lines of equations (3), (4), p. 577.

1. Reacting mixture (16° C. moist)—

		Permanent Gases.	
H_2S	= 11·7		
CO_2	= 50·5	CO_2	= 50·5
O	= 7·2	N	= 28·9
N	= 28·9	Aqueous vapour	= 1·4
Aqueous vapour......	= 1·7		80·8
Entering......	= 100·0		

Whence, per 100 litres of reacting mixture (16° C. 766 mm.)—

Entering—

Grms.

$$\text{Nitrogen} \ldots = 28·9 \times 1·255 \times \frac{273}{289} = 34·3$$

$$\text{Oxygen} \ldots = 7·2 \times 1·430 \times \frac{273}{289} = 9·7$$

$$\text{Carbon dioxide} \ldots = 50·5 \times 1·966 \times \frac{273}{289} = 93·8$$

$$\text{Sulphuretted hydrogen} \ldots\ 11·7 \times 1·523 \times \frac{273}{289} = 16·8$$

$$\text{Water vapour} \ldots = 1·7 \times 0·805 \times \frac{273}{289} = 1·3$$

Leaving (hot chamber)—

$$\text{Sulphur as } H_2S = \frac{3·6}{15·432} \times \frac{1}{28·32} \times 80·8 = 0·67$$

Calculated as H_2S = 0·71

$$\text{Sulphur as } SO_2 = \frac{8·35}{15·432} \times \frac{1}{28·32} \times 80·8 = 1·54$$

Calculated as SO_2 = 3·08

And sulphuretted hydrogen—
Entering................. = 16·80
Leaving................. = 0·71

$$\text{Reacting to free sulphur} = 16·09 \times \frac{16}{34} = 7·6 \text{ grms. oxygen.}$$

Calculated as sulphur...	= 15·15		
Reacting to SO_2.........	= 1·54	= 1·5	
Net free sulphur........	= 13·61	9·1	calculated from products.†
		9·7	entering kiln, see above.

Whence, per combustion of 100 litres of moist reacting mixture (16° C.)—

Heat evolved—

$$\text{Sulphuretted hydrogen to free sulphur} \ldots = \frac{16·09}{34} \cdot 52,660 = 24,920$$

$$\text{Free sulphur to sulphur dioxide} = \frac{1·54}{32} \times 71,970 = 3,464$$

Total.............. 28,384

Products—
Free sulphur......... = 13·6 grms.
Sulphur dioxide....... = 3·1 „
Sulphuretted hydrogen = 0·7 „

$$\text{Water} = \frac{16·1}{34} \times 18 = 8·5 + 1·3 \text{ carried} = 9·8 \text{ grms. total.}$$

Assume that the whole of the sulphur is in the form of vapour—

Then—

Rise of temperature $= (t - 16)°$ C.

Nitrogen absorbs $= (t - 16) \times 34·3 \times 0·259 = (t - 16) \times 8·88$.

Carbon dioxide absorbs $= (t - 16) \times 93·8 \times 0·313 = (t - 16) \times 29·36$.

Water absorbs $= (t - 16) \times 9·8 \times 0·604 = (t - 16) \times 5·92$.

Sulphur—

	Per Grm.
To heat solid from 16° to 115° = 0·18 × 100 =	18·0
To melt to liquid at 115°................. =	9·4
To heat liquid to 316° = 30 × 201......... =	60·3
To vaporise liquid at 316° .... =	362·0
	450 approx.

Whence, in converting 13·6 grms. of solid sulphur at 15·6° into vapour at 316, 450 × 13·6 = 6,120 calories are absorbed.

To raise 13·6 grms. of sulphur vapours from 316° to $t°$ $= (t - 316) \times 0·08 \times 13·6 = (t - 316) \times 1·09 = (t - 16) \times 1·09 - 344$.

Sulphur dioxide absorbs $(t - 16) \times 0·1544 \times 3·1 = (t - 16) \times 0·48$.

Sulphuretted hydrogen absorbs $(t - 16) \times 0·2423 \times 0·7 = (t - 16) \times 0·17$.

Equating, we get—

$$(t - 16)\{8·88 + 29·36 + 5·92 + 1·09 + 0·48 + 0·17\} + 6,120 - 344 = 28,384.$$

$$t = 508° \text{ C.} \quad 916° \text{ F.}$$

2. Maximum temperature attained in kiln calculated, on the lines of the equations (3), (4). p. 577.

(3) $3H_2S + 3O + 12N = 2H_2S + SO_2 + H_2O + 12N$
(Evolution of heat).

(4) $2H_2S + SO_2 + H_2O + 12N = 3S + 3H_2O + 12N$
(Absorption of heat).

It is assumed first, that (3) proceeds to completion, the oxygen in the reacting mixture reacting to form the full equivalent of SO_2, further, that no free sulphur is produced at this stage of the kiln reaction; secondly, that residual H_2S and SO_2 in the exit gases result from the failure of reaction (4) to complete itself.

Stage (3).

Assuming that the oxygen present produces its full equivalent of sulphur dioxide, we have (see above)—

$$\text{Sulphur dioxide produced} = \frac{2}{3} \times 9·7 \times \frac{64}{32} = 12·93 \text{ grms}$$

$$\text{equivalent to } \frac{34}{64} \times 12·93 = 6·87 \text{ grms. } H_2S.$$

	Grms.
Total sulphuretted hydrogen entering	= 16·80
Reacting to sulphur dioxide............	= 6·87
Sulphuretted hydrogen available for reaction (4) =	9·93

---

* NOTE.—The same final temperature (1150° C.) is reached if the calculation is made on the lines of equation (1), see p. 577, in which oxidation to sulphur and water is represented as occurring in one stage.

† See remarks, p. 586.

Whence, per combustion of 100 litres of moist reacting mixture (15·6° C.).

Heat evolved by reaction (3)—

Sulphur dioxide produced yields $71{,}970 \times \frac{12{\cdot}93}{64} = 14{,}540$ calories.

Less sulphuretted hydrogen decomposed

$= 4{,}740 \times \frac{6{\cdot}87}{34} = 957 - 13{,}583$

Water vapour produced yields $57{,}400 \times \frac{6{\cdot}87}{34} = 11{,}595$

Total heat evolved................. = 25,178

Products—

	Grms.
Sulphur dioxide.......	12·93
Sulphuretted hydrogen	9·93
Aqueous vapour.......	4·93 ($= 18 \times \frac{6{\cdot}87}{34} + 1{\cdot}3$ carried).

Then—

Rise of temperature = $(t - 16)$ C.

Sulphur dioxide absorbs	$12{\cdot}93 \times 0{\cdot}1544 \times (t - 16)$	$= (t - 16) \times 1{\cdot}99$
Sulphuretted hydrogen	$9{\cdot}93 \times 0{\cdot}2423 \times (t - 16)$	$= (t - 16) \times 2{\cdot}40$
Aqueous vapour ..	$4{\cdot}93 \times 0{\cdot}62 \times (t - 16)$	$= (t - 16) \times 3{\cdot}06$
Carbon dioxide....	$93{\cdot}8 \times 0{\cdot}322 \times (t - 16)$	$= (t - 16) \times 30{\cdot}20$
Nitrogen..........	$34{\cdot}3 \times 0{\cdot}261 \times (t - 16)$	$= (t - 16) \times 8{\cdot}95$
		$(t - 16) \times 46{\cdot}60$

Equating, we get—

$$(t - 16) \times 46{\cdot}60 = 25{,}178$$

$$\left.\begin{aligned} t &= 556^{\circ}\ \text{C.} \\ &\ \ 1{,}033^{\circ}\ \text{F.} \end{aligned}\right\} = \text{Maximum attainable if reaction (4)} = 0.$$

Stage (4) $2H_2S + SO_2 + H_2O + 12N = 3S + 3H_2O + 12N$.

Sulphuretted hydrogen available from (3)........................ = 9·93 grms.
Less ditto escaping in exit gases — 0·71 „

Net reacting = 9·22 = 8·7 grms. sulphur.

Sulphur dioxide available from (3) = 12·93 grms.
Less ditto escaping = 3·08 „

Net reacting = 9·85 = 4·9 grms. sulphur.

Total sulphur = 13·6 „ „

Water from (3) $4{\cdot}9 +$ water produced $\frac{18}{34} \times 9{\cdot}2 = 9{\cdot}8$ grms. total.

Then we have for reaction (4) at 556° C.

Heat brought in by reacting gases—

Sulphur dioxide	$= 12{\cdot}93 \times 0{\cdot}1544 \times 556.$
Sulphuretted hydrogen	$= 9{\cdot}93 \times 0{\cdot}2423 \times 556.$
Aqueous vapour	$= 4{\cdot}9 \times 0{\cdot}62 \times 556.$
Carbon dioxide	$= 93{\cdot}8 \times 0{\cdot}322 \times 556.$
Nitrogen	$= 34{\cdot}3 \times 0{\cdot}261 \times 556.$

Total $= 556 \times 46{\cdot}60 = 25{,}910$

Heat produced by oxidation of hydrogen to water vapour $= 57{,}400 \times \frac{9{\cdot}22}{34} = 15{,}565 = +\ 41{,}475$

Heat required to decompose the sulphuretted hydrogen $= 4{,}740 \times \frac{9{\cdot}22}{34} = 1{,}285$

Ditto sulphurous acid $= 71{,}970 \times \frac{9{\cdot}85}{64} = 11{,}080 = -\ 12{,}365$

Net heat evolved = 29,110

As before, let t' = final temperature.

Then—

To raise residual sulphuretted hydrogen to t'...............	$= t' \times 0{\cdot}2423 \times 0{\cdot}7 = 0{\cdot}17t'$
Ditto sulphur dioxide	$= t' \times 0{\cdot}1544 \times 3{\cdot}1 = 0{\cdot}48t'$
To raise aqueous vapour to t'	$= t' \times 0{\cdot}604 \times 9{\cdot}8 = 5{\cdot}92t'$
Do. carbon dioxide	$= t' \times 0{\cdot}313 \times 93{\cdot}8 = 29{\cdot}36t'$
Do. nitrogen	$= t' \times 0{\cdot}259 \times 34{\cdot}3 = 8{\cdot}88t'$
To raise sulphur to 316° C. and vaporise	$= 13{\cdot}6 \times 450 = 6.120$

To raise sulphur vapour from 316° C. to t'

$= (t' - 316) \times 0{\cdot}08 \times 13{\cdot}6 = -\ 0{\cdot}344 + 1{\cdot}09t'$

Total heat required $= 5{,}776 + 45{\cdot}90t'$

Equating, we get—

$$t' \times 45{\cdot}90 + 5{,}776 = 29{,}110$$

$$t' \times 45{\cdot}90 = 23{,}334$$

$$\left.\begin{aligned} t' &= 508^{\circ}\ \text{C.} \\ &\ \ 946^{\circ}\ \text{F.} \end{aligned}\right\} = \text{Maximum temperature if equations (3), (4) occur simultaneously.}$$

The theoretical maximum temperature according to this hypothesis must lie between the values 508° C. and 556° C. = 946° F. and 1,033° F.

Calculation of Air Supply to Claus Kiln treating Saturator Gases.

Let saturator gas entering kiln contain, per 100 volumes

$$\begin{cases} CO_2 = x. \\ H_2S = y. \\ \text{Air} = 100 - (x + y).^{*} \end{cases}$$

Let V volumes of air enter kiln per 100 volumes of saturator gas;

V′ = volume of exit gases after reaction has spent itself.

Let 100 volumes of exit gases contain

$$\begin{cases} CO_2 = x' \\ H_2S = y' \\ SO_2 = z' \\ N = 100 - (x' + y' + z'). \end{cases}$$

Suppose y (the volume of H_2S entering per 100 volumes of gas) to consist of three parts—

y_1 = volume of H_2S that passes through the kiln unchanged.

y_2 = volume of H_2S that reacts with half its volume of oxygen to form sulphur and water. Thus—

$H_2S + O = H_2O + S$, where decrease in volume due to reaction $= 1{\cdot}5y_2$.

y_3 = volume of H_2S that reacts with one and a half times its volume of oxygen to form SO_2 and water. Thus—

$H_2S + O_3 = H_2O + SO_2$, where decrease of volume due to reaction $= 1{\cdot}5y_3$.

Now,

$$V' + 1{\cdot}5y_2 + 1{\cdot}5y_3 = 100 + V.$$

$$\therefore V = V' - 100 + 1{\cdot}5\,(y_2 + y_3).$$

Further,

Since CO_2 is unchanged in its absolute amount in passing through the kiln—

$$\frac{x}{x'} = \frac{V'}{100},\ \text{whence}\ V' = 100\,\frac{x}{x'}$$

Further, we have—

$$y = y_1 + y_2 + y_3,\ \text{whence}\ (y_2 + y_3) = y - y_1,$$

and—

$$\frac{y_1}{y'} = \frac{V'}{100}\ \text{because}\ y_1\ \text{passes unchanged through the kiln.}$$

Replacing $\frac{V'}{100}$ by $\frac{x}{x'}$, we get $y_1 = y'\frac{x}{x'}$

and—

$$(y_2 + y_3) = y - y'\frac{x}{x'}.$$

Finally, replacing V′ by $100\frac{x}{x'}$, and $(y_2 + y_3)$ by $y - y'\frac{x}{x'}$, in the general equation, we get—

$$V = \frac{x}{x'}100 - 100 + 1{\cdot}5\left(y - y'\frac{x}{x'}\right).$$

$$= 100\left(\frac{x - x'}{x'}\right) + 1{\cdot}5\left(\frac{x'y - xy'}{x'}\right).$$

In this equation—

$$1{\cdot}5\left(\frac{x'y - xy'}{x'}\right)$$

represents the reduction of volume due to chemical reaction, while

$$100\left(\frac{x - x'}{x'}\right)$$

is the expression for the volume of air admitted to the kiln per 100 volumes of gas, if such reduction of volume be

---

[*] See footnote, p. 578.

neglected, which may be done when saturator gas is very weak, as in the Granton experiments, mentioned in our paper in 1903.

Calculation of the Relation of the Volume of Reacting Mixture entering to that of the Exit Gases leaving the Chance-Claus Process Kiln, both measured at Atmospheric Pressure and Temperature.

Let v' volumes leave per 100 volumes of reacting mixture entering.

y = volume per cent. of H_2S in ditto.

y' = volume per cent. of H_2S in the exit gases.

As before, we suppose y to consist of 3 parts $= y_1 + y_2 + y_3$, where—

y_1 = residual H_2S leaving in exit gases;

y_2 = volume of H_2S reacting to form sulphur and water:—

$H_2S + O = H_2O + S$; reduction of volume $= 1\cdot5y_2$.

y_3 = volume of H_2S reacting to form sulphur dioxide and water:—

$H_2S + O_3 = H_2O + SO_2$; reduction of volume $= 1\cdot5y_3$.

Then we have—

$$y_1 : y' :: v' : 100, \text{ whence } y_1 = \frac{v' \times y'}{100}.$$

Now volume of gases entering = volume of gases leaving + reduction due to reaction,

Hence—

$$100 = v' + 1\cdot5\,(y_2 + y_3).$$

Also—

$$y = y_1 + y_2 + y_3 \text{ and } (y_2 + y_3) = y - y_1.$$

Wherefore—

$$100 = v' + 1\cdot5\,(y - y_1).$$

Replacing in the equation, y_1 by $\frac{v'\,y'}{100}$,

We have—

$$100 = v' + 1\cdot5\left(y - \frac{v'\,y'}{100}\right).$$

Whence—

$$v'\left(1 - \frac{1\cdot5y'}{100}\right) = 100 - 1\cdot5y$$

$$v' = 100\,\frac{(100 - 1\cdot5y)}{(100 - 1\cdot5y')}$$

Or, if v'' leave per 1 cb. ft. entering, the equation becomes—

$$v'' = \frac{(100 - 1\cdot5y)}{(100 - 1\cdot5y')}$$

In conclusion, we desire to acknowledge the advantage we have received from discussion of the thermochemical reactions with Dr. Affleck, who has been of great assistance, by reason of the independent investigations on which he is indeed still engaged, not only in developing, but in initiating the hypothesis set out on page 577.

Discussion.

Mr. J. **Haydn Morris** said that in quite a number of different Claus kilns he had found a considerable quantity of ammonia in the shape of sulphate and sulphite of ammonia, and it was very interesting to him to know that it was due in many cases to conversion of the hydrocyanic acid into ammonia. It had struck him that it might be possible to construct a Claus kiln in which the formation of ammonia would be impossible—a kiln in which the contact substance and the temperature could be regulated so that the cyanide would be completely decomposed into nitrogen and there would be no ammonia formed at all. He had also found in the Claus kilns a considerable amount of sulphur which was insoluble in carbon bisulphide, and it would be interesting to know under what conditions this amorphous sulphur was formed and how the condition of the sulphur varied. In some cases he had found as much as 15 per cent. of amorphous sulphur in the product. He further wished to know whether Mr. Carpenter had had results from two different works where Claus kilns had been in operation, whether in each case the cyanides had been proved to be going in, and whether in both cases the ammonia had been formed. It seemed to him that if the results of several works were taken, and the cyanides were proved to be going in, it would then show that they all worked in the same way, and in each case were converted into ammonia.

Mr. **Arthur Carey** asked, in reference to the very small yield of flowers of sulphur in the chamber in the instance he had quoted, *viz.* 4 per cent., whether the 4 per cent. of the total sulphur was collected in the chamber, or was the sulphur which was supposed to be made in the chamber and deposited there. It was a very difficult matter to determine whether the sulphur which was deposited from these gases was really carried in the form of vapour from the Claus kiln itself, or was formed by the continued reaction between the residual sulphur dioxide and hydrogen sulphide. He had seen a number of analyses from time to time of the exit gases from Claus kilns both before and after they had travelled a long distance in flues. They knew from the necessity for periodical cleaning that sulphur was deposited in those flues, but there was a very small drop, if any, to be noticed in the sulphur content of the gases as shown by analysis.

Mr. **Herbert Potter** inquired whether, in the experiments mentioned with the small kiln in regard to the mixture of cyanides and sulphuretted hydrogen, varying quantities of air were used. In some works the kiln was too big for the work, and he had noticed considerable difference in the smell of the exit gasea from the oxide purifier; in one or two cases the smell of cyanides was noticeable. He wondered if the quantity of air would materially affect the conversion of the cyanide, for when the kiln was too large more air was admitted in order to maintain the heat.

Mr. R. H. **Clayton** inquired whether Mr. Carpenter had any experience of Walter Feld's method of analysis for cyanides in gas liquors. It was a simple method, and he had found it give good and accurate results. As regards the practical working of the Claus kilns, what had been the highest maximum yield that had been obtained from the hydrogen sulphide in the waste gases from ammonia plant?

Mr. **Eustace Carey** asked if the author, in his allusion to pyrometers, was referring to electrical pyrometers, where heat was measured by the resistance to an electric current. His experience some years ago with electrical pyrometers was not fortunate, but probably they were much improved now, and he would be glad to know if they were reliable and lasting.

Mr. W. H. **Coleman** asked if Mr. Carpenter found that the condensing space required for the Claus process in a gas works was very much greater than at alkali works. The large proportion of carbon dioxide would seem to demand it.

Mr. R. **Forbes Carpenter**, in answer to Mr. Morris, said that the influence upon conversion of cyanogen into ammonia of different contact materials in the Claus kiln was a subject on which the authors were not yet in a position to speak; the apparatus for the trials had had to be specially made. No experiments had as yet been made. As regards the works tests, experiments in Works A. and C. had been concluded before the gas liquor used had been tested for cyanide; in Work A. this was absent; its amount in the liquor used at Work C. was ascertained only after the conclusion of experiments at Work B. In reply to Mr. Arthur Carey, the reaction among the gases in the cool sulphur chamber, which he would fin described in the text of the paper, was ascertained by series of concurrent inlet and exit tests corrected to standar volume as compared with that of inlet gases to the kiln. While in a vitriol chamber it was impossible, as Dr. Hunter had shown, to accurately determine by such analysis what amount of acid was actually made in that chamber, in the present case it was possible, by filtering out the sulphur suspended in the gases, to arrive at correct figures for sulphuretted hydrogen and sulphur dioxide (in the absence of ammoniacal compounds), and so to reach a figure for work done in the cool chamber. In the small Claus kiln experiments they had not desired the presence of air; it was impossible entirely to exclude it, and, as explained, the in-leakage of air in the last experiment had markedly increased the rate of flow of gases through the contact material; but in this last experiment, where sulphuretted hydrogen was present, as in Claus kiln conditions, they could see by the jump up in percentage conversion the protective effect of this gas on hydrocyanic acid and ammonia, both of which air would tend to destroy at the temperature used. As explained to Mr. Morris, fresh apparatus was being prepared. They had not tried the Feld method of estimating cyanides mentioned by Mr. Clayton. They had no figures to communicate as to highest yield of sulphur in gas liquor works plants, nor could they give figures as to comparative condensing space required in these and Chance-Claus plants.

MR. WALTER F. REID IN THE CHAIR.

THE OLDEST DOCUMENT IN THE HISTORY OF GUNPOWDER.

BY OSCAR GUTTMANN, M.INST.C.E., F.I.C., F.C.S.

The so-called ancient records concerning the invention of gunpowder should be approached with great caution, since manuscripts of doubtful date and origin which had been nadequately translated were used to serve various nations nd individuals as proofs of their claim to this invention. Only such documents present a special interest, which urnish information about the time preceding 1354, and as here is no doubt that even the Arabs did not shoot up to 1313, although they knew gunpowder-like mixtures since 280, we are limited in our investigation to within a eriod of 40 years.

I have shown in another place, that an Arabian manucript in the St. Petersburg Library, which was published y Reinaud and Favé, is of no importance, since, apart rom other objections, its date is very doubtful. The oftited passage in the Indian "Gentoo Laws" also becomes alueless when correctly translated, and the description of ities and of the composition and manufacture of gunowder, as published by Prof. Gustav Oppert from the Sukraniti,"* is doubtless of more recent origin than he upposes. Oppert had before him only copies 200 years ld of a lost original, and the learned Indian, Praphulla handra Ray, peremptorily denies† that the Indians knew unpowder in the 14th century.

The following are the only existing unimpeachable ocuments:—

1. The accounts of King Edward III's private wardrobe om 1344 to 1347, and the accounts of the same King's great wardrobe from 1345 to 1349, in both of which there are entries of payments for gunpowder, and also sulphur and saltpetre for the King's guns.

2. The accounts of the town of Aix-la-Chapelle of 1346, showing some expenditure for an iron gun and saltpetre for same.

3. A document at the town library of Tournay, giving an account of experiments with a gun in 1346 by Pierre de Bruges.

4. The accounts, published in Muratori, Vol. 24, of Aimone di Challant, Sire di Fenis, Guardian of Lanzo in Northern Italy from 1347 to 1348, according to which Master Hugonino di Chatillon in 1347 made 4 bronze guns for the Marquess of Monferrato, in the Aosta valley, each of which weighed about 45 lbs., was fired by means of gunpowder, and threw leaden balls with large, iron-bound arrows.

5. The accounts dating 1342 for the artillery of Rihoult Castle, published in the "Mémoires de la Société des Antiquaires de la Morinie," tome 5. The guns threw wooden arrows, bound with iron, and centred by means of copper discs. The price of the powder was about 30*s.* per pound.

6. A document in the Paris National Library, according to which 5 iron and 5 bronze cannon were bought in 1339 for the defence of the town of Cambray, for which Estienne Marel supplied saltpetre and sulphur, but in such small quantities only (for the sum of 11 livres 4 sous) that at the existing prices of that time barely 3 pounds of powder would work out per cannon.

7. A document in the same library, according to which Guillaume du Moulin from Boulogne acknowledges the receipt on the 11th July 1338 from Thomas Fouque-, guardian of the galley-house at Rouen, of "one iron pot for shooting fire-arrows, 48 iron-bound and feathered arrows, one pound of saltpetre, and half-a-pound of live sulphur for making powder for shooting the said arrows." This would hardly give 20 grms. of powder to each arrow. Hitherto there was a general disinclination to regard these arrow-shooting guns favourably, but I am now in a position to give a picture of one.

In Prof. Oppert's above-mentioned book I found a footnote, which drew attention to a manuscript in Oxford dating from 1336, and I therefore endeavoured to get particulars and later on to inspect it myself. To my surprise the manuscript proved to bear the date 1326. It is written by Walter de Millemete, is entitled "De Officiis Regum," and is kept in Christchurch library. It is beautifully illuminated. I have only been able to obtain the right of reproduction for the new edition of my book on Explosives, the authorities of Christchurch jealously guarding any further publication. The manuscript begins as follows:—

"Hic incipiunt rubrice capitulorum huius libri de nobilitatibus sapienciis et prudenciis regum editi ad honorem illustris domini Edwardi dei gracia Regis anglie incipientis regnare Anno domini ab incarnacione Milesimo Tricentesimo Vicesimo Sexto."

Translation.—"Here begin the lists of the chapters of this book about the noble origin and the prudence of kings, edited in honour of the illustrious Lord Edward, by God's grace King of England, who began to reign in the year of our Lord, 1326." (This is old reckoning; King Edward entered his reign in the year 1327 of the new.)

The contents of the book in no way refer to the history of the invention of gunpowder, but only deal with the duties and qualities of kings. It must have been begun in the reign of Edward II., because it contains pictures of him as king, and no doubt it was originally intended as a present to him. The very elaborate and rich illuminations must have taken a long time, probably more than a year, since such fine work could only be done in the summer months, so that it was very likely already begun in 1325.

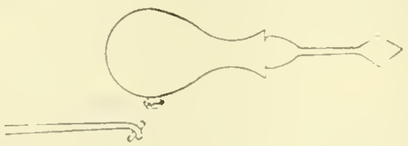
There is on the last page of the manuscript a richly adorned frame surrounding the text, and on its lower part the reproduction of a bottle-shaped gun resting on a wooden

---

[*] On the Weapons, Army Organization, and Political Maxims of e Ancient Hindus. Madras, 1880.

[†] Praphulla Chandra Ray, History of Hindu Chemistry. London, 03.

trestle. The shape of the bottle resembles an antique urn (see sketch). It is closed by means of an arrow, which has a ball on its lower extremity, and a warrior in full armour is in the act of firing this gun by means of an



incandescent rod, intending to burst the lock of a castle-gate. This gives us on the one hand an authentic and the oldest date for the use of gunpowder, and on the other hand, it is a most interesting illustration of the earliest guns, and the manner in which they were used. The gradual progress towards the use of the ball from the end of the arrow, only, and as is known, in the way of ball-shaped common stones, is so far only conjecture.

I am indebted for the photograph of this interesting page to the kindness of the trustees of the Wake Trust, and for the information concerning it to the late Prof. York Powell and Prof. Webb, to whom I herewith tender my sincere thanks.

Now only we can believe a passage in John Barbour's life of Robert Bruce, King of Scotland, which was written in 1375, and has hitherto been considered a fable. Barbour wrote of the year 1327 :—

> "Twa noweltys that dai thai saw,
> That forouth in Scotland had bene nane.
> Tymmris for helmys war the tane,
> That thaim thoucht than off grete bewte,
> And alsua wondre for to se;
> The tothyr *crakys* war *off wer*,
> That thai befor herd nevir er."

So much appears now certain, that the knowledge of the propelling force of gunpowder-like mixtures must have come about between 1313 and 1325. I am of opinion that Berthold Schwarz invented the guns, only the date of their invention must be put back much further than 1353, as written on his monument at Freiburg.

MR. J. CARTER BELL IN THE CHAIR.

THE IGNITION OF CLAYS IN KILN GASES.

BY ARTHUR HOPWOOD, A.R.C.Sc., A.I.C.

Introduction.—In view of the importance of the behaviour on ignition of clays and clayey mixtures in the manufacture of ceramic bodies, it is necessary to have the fullest possible knowledge of the deportment of clays when ignited in the presence and absence of the various gases which result from the combustion of fuel and pass through the ovens, or kilns, during the firing process. The combustion of fuel in clayware kilns being variable and always imperfect, it follows that the gaseous product derived from the fuel and air is a variable mixture of nitrogen, oxygen, carbon dioxide, carbon monoxide, hydrogen, steam, ammonia, and hydrocarbons more or less contaminated with sulphur and compounds of sulphur derived from the impurities present in the fuel. (*Cf.* E. Orton, Transactions of the American Ceramic Society, Volume V., page 405, 1903.) In consequence, this paper deals with the behaviour of clays of known nature when ignited alone, and in presence of the principal gases which pass through clayware kilns.

Occurrence and Nature of the Clays.—Thirty clays were selected for investigation which occur at the various places mentioned below, the figures indicating the number of different kinds taken from each place :—

Red Tile Clays.—Tunstall, 6; Ruabon, 2; Accrington, 1.

Common Brick Clays.—Burslem, 1; Hanley, 1; Tunstall 1.

Fireclays.—Ruabon, 3; Stourbridge, 2; Burslem, 1; Hanley, 1; Goldendale, 1; Tunstall, 1; Coatbridge, 1.

Stoneware Clays.—Burslem, 1; Ruabon, 1.

Ball Clays.—Newton Abbot, 1; Torrington, 1; Corfe Castle, 1.

China Clays.—St. Austell, 3.

The Tunstall and Ruabon red tile clays are red bodies; the Accrington shale clay and all the common brick, fire, stoneware, and ball clays are grey bodies; while the Cornish china clays are white in colour. On analysis, the Cornish china clays and the Tunstall red tile clays were found to contain only traces of organic matter; while the Accrington, common brick, fire, stoneware, and ball clays were found to contain moderate or large amounts. The china and ball clays contain small, the fireclays and stoneware clays moderate, and the red tile and common brick clays large amounts of iron. The china clays and the Tunstall red tile clays are the only ones which are free from sulphides.

Behaviour of the Clays on Ignition.—The behaviour of the clays on ignition was ascertained by heating the coarsely powdered clays to a bright red heat for three hours in a combustion tube 30 inches long. When the clays were being heated in absence of external gases the tube was closed at one end, and when in the presence of one of the kiln gases one of the open ends was connected with a gasholder, or generating apparatus, supplying a current of the requisite gas.

The behaviour of the clays was studied in the following gases, *viz.*, nitrogen, carbon dioxide, steam, air (limited supply and in excess), oxygen, hydrogen, carbon monoxide, ammonia, marsh, and olefiant gases.

The china clays and the Tunstall and Ruabon red tile clays when ignited alone, or in presence of nitrogen, carbon dioxide, and steam, left dark white or brown residues respectively; while the common brick, stoneware, ball, fire, and Accrington clays left greyish black residues. The darkening or blackening was found to be largely due to carbon modified more or less by ferrous oxide, magnetite, and occasionally ferrous sulphide. The residues on being refired in a muffle furnace became lighter in colour, leaving white, ivory, stone-yellow, buff, pale red, or bright red bodies in accordance with their derivation from china, ball, stoneware, fire, common brick, or red tile clays. We therefore observe that all clays darken when heated alone, or in presence of nitrogen, carbon dioxide, and steam, but they only blacken when they contain moderate or large amounts of organic matter. This darkening, or blackening, disappears on oxidation, and consequently clay burners can convert bricks having black carbonaceous interiors into good normal bricks by refiring them in a kiln freely supplied with air.

The china clays and the Tunstall and Ruabon red tile clays when heated in a *limited supply* of air left white and bright red bodies respectively along the whole length of the tube; while the commom brick, stoneware, ball, fire, and Accrington clays left residues differently coloured in different parts of the tube: the residues at the end of the tube where the air entered were ivory, stone-yellow, buff, pale red, or bright red bodies in accordance with their derivation from ball, stoneware, fire, common brick, or Accrington clays: the residues at the middle of the tube were always dark grey bodies; while those at the end farthest away from the entering air were always black bodies identical with those obtained from the corresponding clays by ignition in absence of external gases. The china, ball, stoneware, fire, common brick, and red tile clays when ignited in *excess* of air or oxygen left white, ivory, stone-yellow, buff, pale red, and bright red bodies respectively along the whole length of the tube. It follows that white, ivory, yellow, and red claywares made from clays containing little organic matter do not require much air for the development of their normal colorations, but more air is required as the percentage of organic matter is greater. In consequence, clay-burners should observe that highly carbonaceous clays are liable to yield claywares having black interiors unless a liberal supply of air passes through the kiln during the firing process.

The china clays when heated in hydrogen, carbon monoxide, ammonia, methane, and ethylene left dark white bodies; the Tunstall and Ruabon red tile clays left dark blue bodies; while the common brick, stoneware, ball, fire, and Accrington clays left greyish black bodies. The darkening or blackening was found to be mainly due to carbon, ferrous oxide, and magnetite, occasionally modified by ferrous sulphide and finely divided iron. The residues obtained by igniting the clays in marsh and olefiant gases were darker in colour and contained a little more carbon than the corresponding ones obtained by ignition in hydrogen: indicating partial decomposition of the marsh and olefiant gases and subsequent deposition of carbon in the mass of the clay. The residues on being refired in a muffle furnace became gradually lighter in colour, eventually leaving white, ivory, stone-yellow, buff, pale red, or bright red bodies in accordance with their derivation from china, ball, stoneware, fire, common brick, or red tile clays. It follows that all clays darken when heated in reducing clayware kilns, but the darkening is only appreciable when they contain considerable quantities of iron, or organic matter. The blue or black colorations readily change on oxidation, and consequently clay-burners making blue bricks must not allow air to enter their kilns in the last stage of the process, as the bricks would acquire an undesirable brown tinge.

Conclusion.—Dr. H. A. Seger (Notizblatt, 1876, page 278) ascertained the colour of the residues left by four German clays when ignited in a Roses' crucible in currents of several of the gases present in clayware kilns. The residues obtained by Seger from these German clays were similar to those I obtained from similar English clays containing little carbonaceous matter; so that the behaviour on ignition of different varieties of the same kind of clay appears to be universally uniform.

New York Section.

Meeting held at Chemists' Club, on April 22nd, 1904.

DR. VIRGIL COBLENTZ IN THE CHAIR.

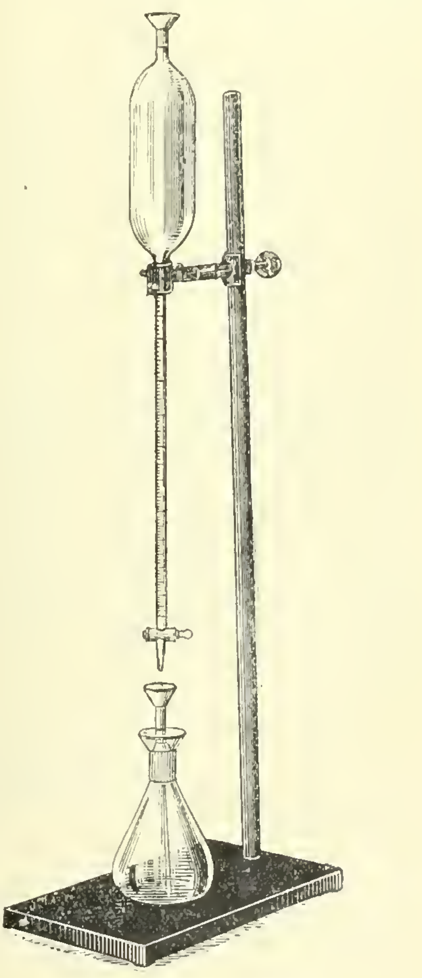
AN APPARATUS FOR THE DIRECT DETERMINATION OF THE SPECIFIC GRAVITY OF CEMENT.

BY DANIEL D. JACKSON.

It is a well-known fact among chemists who have had extensive work to do in connection with the specific gravity of cement that the test as ordinarily applied is subject to grave inaccuracy and is consequently of doubtful value. Accurate determinations with the pyknometer or specific gravity bottle are more troublesome and time consuming than is practical for routine work. Le Chatelier's apparatus, which is the one most extensively used, has of necessity a graduated tube of such large calibre that an accurate reading is impossible. It is also very difficult to work with this instrument under even conditions of temperature without consuming a large amount of time for each determination. This same objection holds true with all the other forms of apparatus employed for this purpose.

There is apparently little appreciation of the fact that even slight changes in temperature make a very considerable error in the result and, that whatever instrument is used, if the temperature of the liquid changes more than half a degree F. during the determination, it must be brought back to its original point before making the reading, or a temperature correction must be employed. The use of the temperature correction is decidedly to be preferred as it is fully as accurate and much more rapid. This conclusion being granted, it is then not necessary that the instrument should be one connected piece of glassware. By making it in two separate parts we are allowed a graduated tube of much smaller calibre, thus greatly increasing the accuracy of the determination.

Description of New Apparatus.—In the accompanying illustration is shown a simple form of apparatus designed by the author for the accurate and rapid determination of the specific gravity of cement. Above is suspended a burette, with graduations, about 9 in. (23 cm.) long and with an inside diameter of about $\frac{1}{4}$ in. (0·6 cm.). This is connected with a glass bulb, approximately $5\frac{1}{2}$ in. (13 cm.) long and $1\frac{3}{4}$ in. (4·5 cm.) in diameter. The Erlenmeyer flask below is of heavy glass, and contains a ground-glass stopper which is hollow, and has a neck of the same bore as the burette. The flask has a capacity of exactly 200 c.c. up to the graduation on the neck of the stopper.



SPECIFIC GRAVITY APPARATUS.

In order that the work may be more rapid, the burette is not graduated in c.c., as in other instruments of this nature, but is made to read directly in specific gravity. The manufacturer* of the instrument makes the glass bulb of such a size that from the mark on the neck at the top to the mark on the burette just below the bulb, the capacity is exactly

---

* Emil Greiner, 78, John Street, N.Y. City.

180 c.c. If 50 grms. of cement are taken, this mark represents a sp. gr. of 2·50—

$$\begin{array}{rll} & 200 & \text{(capacity of flask).} \\ - & 180 & \quad ,, \quad \text{bulb to first graduation.} \\ \hline = & 20 & \text{volume displaced by 50 grms. of cement.} \end{array}$$

$$\frac{50}{20} = 2 \cdot 50 \text{ sp. gr.}$$

The burette is graduated for every 0·05 in sp. gr., and five equidistant marks are placed between each of these accurate graduations. In this way the instrument is made to read with accuracy to 0·01 in sp. gr.

The following table gives the calculations used in the original graduation of the instrument :—

Table for Graduating Apparatus for the Determination of the Specific Gravity of Cement.

Specific Gravity.	Reading.	Displacement.	Specific Gravity.	Reading.	Displacement.
	c.c.			c.c.	
2·50	180·00	20·00	2·86	182·52	17·48

Method of Determination.—To determine the specific gravity of a cement by means of this instrument—

1. Weigh out accurately, to 0·1 grm., 50 grms. of the dry sample and pour it into the unstoppered Erlenmeyer flask.

2. Fill the bulb and burette with kerosene, leaving just space enough to take the temperature by introducing a thermometer through the neck. Remove the thermometer and add sufficient kerosene to fill exactly to the mark on the neck, drawing off any excess by means of the burette.

3. Run into the flask about one-half of the kerosene in the bulb to remove air bubbles. Run in more kerosene until any adhering cement is carefully washed from the neck of the flask and the liquid is just below the ground glass.

4. Place the hollow ground-glass stopper in position and turn it to fit tightly. Run in kerosene exactly to the 200-c.c. graduation on the neck, making sure that no air bubbles remain in the flask.

5. Read the specific gravity from the graduation on the burette and then the temperature of the oil in the flask, noting the difference between the temperature of the oil in the bulb before the determination and the temperature of the oil in the flask after the determination.

6. Make a temperature correction to the reading of the specific gravity by the use of the subjoined table. For the convenience of those using the centigrade thermometer the table of corrections on next page has been compiled.

It was thought possible that the variation in the different brands of kerosene might be sufficient to cause an error in the determination. A collection of various good and bad

kerosenes was made and the co-efficient of expansion of each sample was determined. The differences in expansion found were entirely within the limit of error of the determination.

With the instrument herein described the time required to make a determination is about ten minutes, and the accuracy is to 0·01. No Portland cement should be accepted which is below 3·05 in specific gravity.

Nottingham Section.

Meeting held at Burton-on-Trent, on April 27th, 1904.

MR. J. T. WOOD IN THE CHAIR.

THE GLAZING OF CERTAIN KINDS OF SILICIOUS PIG IRON, AND ITS CAUSE.

BY O. F. HUDSON, A.R.C.S.,

Lecturer in Metallurgy in the University of Birmingham.

Cast iron is, essentially, iron containing more than 2 per ent. of carbon, but, as made in the blast furnace, it contains n addition to the carbon varying, and often considerable, mounts of other impurities. Commercial cast iron, howver, although it cannot be considered as simply an alloy f iron and carbon, depends for its characteristic properties pon the amount and mode of existence of the carbon, the ther impurities being of importance principally according o their influence on the relation between the iron and the arbon. Carbon exists in cast iron mainly in two forms, s graphite, or combined with iron as the carbide Fe_3C. Vhen the carbon is all or almost all present as graphite the on is soft and grey, and when it is all or almost all resent in the combined state the iron is hard and white. n their effect upon the condition of the carbon in cast iron licon and sulphur are of the utmost importance in deterining the grade and quality of the iron. The effect of licon is to produce a grey soft iron by its tendency to use the separation of graphite and to reduce the amount f combined carbon. Sulphur, on the other hand, tends to ake the iron white, because it has the effect of keeping e carbon in the combined state (Turner, J. I. & S. I., 886, p. 163). In ordinary cases the silicon in pig iron aries from 0·5 per cent. to 4 per cent., but silicon pig is ade in the blast furnace with as much as 10—18 per cent. licon. Pig iron with 4—5 per cent. silicon is widely used the foundry as a "softener," and is preferred, at any rate this country, to ferrosilicons with higher percentages of silicon for this purpose (Turner, Metallurgy Iron and Steel, p. 196). Such silicious iron was, however, looked upon by many with suspicion, as it did not give uniformly satisfactory results, and was in consequence not recommended for use in mixtures intended to give iron of the best quality (Gjers, in discussion on paper by C. Wood, J. I. & S. I., 1885, p. 464).

It is well known that some kinds of silicious pig iron frequently have a peculiar, glistening, and close-grained fracture, and in that condition is known as "glazed" pig. It is also a matter of common knowledge that two samples of silicious iron may be obtained of approximately the same composition, but the one open grained and the other glazed, the difference being due apparently to no well-defined cause. In addition the glazed iron is of less value than the opened grained variety, especially as a softener in the foundry. In view, therefore, of these facts it was thought that some attempt to explain the cause of this glazing of silicious pig iron would be of interest.

It is stated in Phillips and Bauerman's "Treatise on Metallurgy" that (p. 127) "glazy" or "glazed" iron is metal containing 5—7 per cent. silicon. Also (p. 225) "that such iron is produced when the furnace is in the highest working condition, i.e., when lightly burdened, and developing a maximum temperature in the hearth with highly heated blast." Sir Lowthian Bell ("Manufacture of Iron and Steel," pp. 162—163) gives the following analyses of glazed Cleveland pig:—

—	I.	II.
Silicon	5·13	5·13
Sulphur	0·17	0·23
Phosphorus	1·12	1·12
Manganese	0·77	0·56
Combined carbon	0·79	0·71
Graphite	2·59	2·68

and states that it is generally due to excessive heat in the furnace, and that raising the burden or lowering the temperature of the blast, preferably the latter, prevents its formation.

In Turner's "Metallurgy of Iron and Steel," p. 197, it is pointed out that silicious irons with upwards of 4 per cent. silicon, although of the same ultimate chemical composition, may be obtained sometimes grey and soft, and at others glazed and brittle. It is mentioned that it has been suggested that the glazed appearance may be due to some variation in the condition of the silicon. It is also stated (p. 105) that glazed iron is commonly made in blowing in the furnace when the first few charges are of light burden.

The peculiar fracture of glazed iron is explained in Sexton's "Metallurgy of Iron and Steel," p. 537, on the authority of Stead, as being due to the fact that "in high silicon irons the metal between the graphite flakes is easily fractured, the lines of weakness being the cleavage planes of the crystal grains." It is also stated that the larger the percentage of phosphorus the less silicon is required to make the iron glazed, instancing the fact that Cleveland iron with 1·5 per cent. P is glazed with 4 per cent. silicon, while hematite iron requires as much as 7 per cent. silicon to make it glazed. The reasons for this action of phosphorus are given as :—

(1) 1·5 per cent. phosphorus combines with 8·5 per cent. iron which cannot combine with carbon, and the graphite is therefore less than in hematite metal.

(2) The phosphorus compound is itself brittle, and the fracture has a more easy track through it.

The experiments described in this paper were made on samples of Northamptonshire pig iron kindly supplied by Mr. J. N. Kidner of the Islip Iron Co., Thrapston, Northamptonshire. Four pieces of pig iron were supplied, in the first place, of which the following are the descriptions :—

1. Ordinary, No. 2 Foundry : A good iron.
2. Silicious Foundry : A good iron.
3. Glazed iron : Not satisfactory.
4. Silicious iron, not glazed : Not satisfactory.

Samples 1 and 2 had coarse, open, grey fractures, while samples 3 and 4 had close-grained grey fractures. The fractures of samples 3 and 4 were, to the unpractised eye, almost identical, although only sample 3 was described as "glazed." Analyses were made of the four samples with the following results :—

——	1.	2.	3.	4.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Silicon	3·81	4·48	4·01	3·87
Sulphur	0·054	0·048	0·14	0·14
Manganese	0·66	0·45	0·64	0·45
Phosphorus	1·26	1·212	1·64	1·59
Combined carbon	0·07	0·07	0·16	0·20
Graphite	2·69	2·68	2·54	2·56

Three other samples of pig-iron were subsequently supplied by Mr. Kidner, and they were analysed for silicon and sulphur.

——	I.	II.	III.
	Per Cent.	Per Cent.	Per Cent.
Silicon	4·10	3·98	4·15
Sulphur	0·060	0·033	0·122

Samples I. and II. were open grained, and sample III. was glazed.

Mr. Kidner, some 10 years ago, when a student at Mason College, Birmingham, made analyses of samples of open and glazed Northampton iron, of which the following record has been kept :—

——	Open.	Glazed.
	Per Cent.	Per Cent.
Silicon	4·2	4·2
Sulphur	0·05	0·10
Manganese	0·40	0·38
Phosphorus	1·42	1·48
Combined carbon	0·03	0·03
Graphite	2·82	2·57

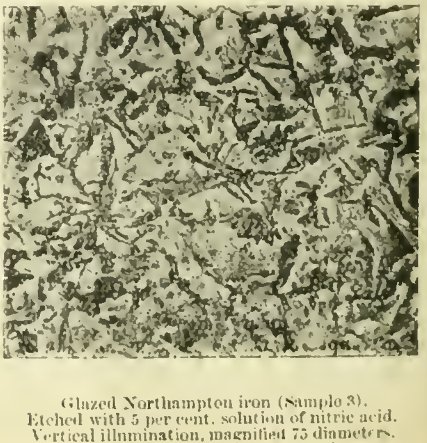
No conclusions, however, were drawn from these results at the time.

On considering these analyses it will be seen that glazed iron contains from two to three times the amount of sulphur that is present in the similar open-grained irons, a fact that would account for the unsatisfactory properties of the glazed iron. That the combined carbon is not appreciably increased in amount is due to the very high percentage of silicon in these irons. In a foundry mixture, however, where the percentage of silicon would be only, say, 1·5 per cent. a small increase in sulphur would cause a marked increase in the amount of combined carbon, with a corresponding difference in the expected properties of the casting.

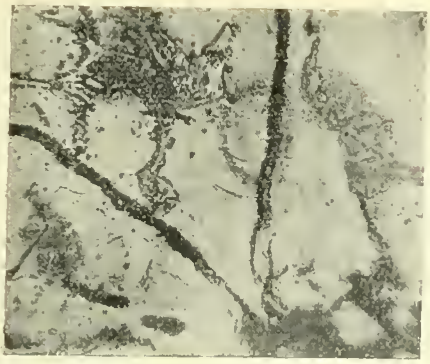
As an extreme example of glazing accompanied by high sulphur, Prof. Turner in his paper on "Silicon and Sulphur in Cast Iron" (J. I. & S. I., 1888, I., 41) refers to a specimen of glazy white iron which contained : silicon, 4·17 per cent. ; sulphur, 0·446 per cent. ; and which on remelting with blast furnace slag parted with more than half its sulphur, and gave silicon, 3·94 per cent. ; sulphur, 0·186 per cent.

The samples from the Islip Iron Co. were examined microscopically. The structure in all cases consists of three distinct constituents—graphite, silico-ferrite, *i.e.*, iron containing silicon, and phosphide eutectic or the eutectic of iron and phosphide of iron (Stead, "Iron and Phosphorus," J. I. & S. I., 1900, II., p. 120). The structures of samples 1 and 2 are similar to each other, but distinct from those of samples 3 and 4, which are also in themselves alike.

Open-grain Northampton iron (Sample 1).
Etched with 5 per cent. solution of nitric acid.
Vertical illumination, magnified 75 diameters.
Reduced by about one-third in reproduction.

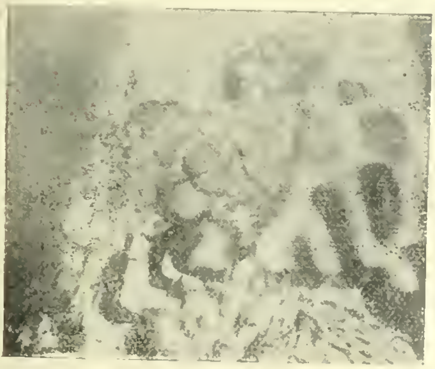


Glazed Northampton iron (Sample 3).
Etched with 5 per cent. solution of nitric acid.
Vertical illumination, magnified 75 diameters.
Reduced by about one third in reproduction.



Open-grained Northampton iron (Sample 1).
Etched with 5 per cent. solution of nitric acid.
Vertical illumination, magnified 300 diameters.
Reduced by about one-third in reproduction.

Glazed Northampton iron (Sample 3).
Etched with 5 per cent. solution of nitric acid.
Vertical illumination, magnified 300 diameters.
Reduced by about one-third in reproduction.



Open-grained Northampton iron (Sample 1), showing the ultimate cubical structure of the silico-ferrite.
Etched with 5 per cent. solution of nitric acid.
Vertical illumination, magnified 1,800 diameters.
Reduced by about one-third in reproduction.

amples 1 and 2 show large plates of graphite surrounded y silico-ferrite, and enclosing large areas, usually discon-ected, of phosphide eutectic. In samples 3 and 4 the raphite plates are much smaller, while the phosphide utectic appears to have a somewhat greater tendency to orm a continuous network. As has been pointed out, all ne analyses show that glazing is accompanied by high ulphur, and the microscope shows in addition that the raphite in glazed iron is very much smaller than in iron which is not glazed. The effect of sulphur in cast iron is to cause an increase in the amount of combined carbon, and to prevent the separation of graphite; but, as is seen from the analyses, the high percentage of silicon very nearly neutralises the effect of the sulphur as far as the amount of combined carbon is concerned. It is quite conceivable, however, that the sulphur may be the cause of the smallness of the graphite in glazed pig. Under favourable conditions a flake of graphite once formed continues to rapidly grow in size by further deposition of graphite on the small flake as nucleus, so that such an iron contains very coarse graphite. Under less favourable conditions when the iron is subject to some influence restraining the formation of graphite, *i.e.*, the influence of sulphur, the graphite, although it may be formed in equal quantity, will be of smaller size. In the same way the restraining influence of quick cooling leads to the formation of small graphite and in consequence a fine-grained fracture.

In some of the analyses given there is distinctly more phosphorus in the glazed than in the open samples. This increase of phosphorus in itself would probably have very little effect on the separation of the graphite (Stead, "Iron and Phosphorus," J. I. & S. I., 1900, II.), but the phosphorus compound being white and brittle might very well have an important influence in giving the distinctive fracture of glazed iron. It would seem probable, however, that the size of the graphite flakes is the determining factor in producing the glazed appearance, as in an open-grained iron with coarse graphite the fracture would have a greater tendency to pass along the large graphite plates instead of through the other part of the metal, whether silico-ferrite or phosphorus eutectic.

In a paper read before the Staffordshire Iron and Steel Institute in January 1904, Professor Turner describes some experiments made to determine the size of the graphite in cast iron. A comparatively large quantity (about 250 grms.) in the form of small lumps was taken in each case. The iron was then completely dissolved by hydrochloric acid and the residue oxidised with hot dilute nitric acid and extracted with caustic potash to remove silica. The graphite after being completely freed from iron and silica was then dried at 120° C., weighed and subdivided according to size by sieving.

The following results were obtained with No. 1 Northampton iron and with glazed Northampton iron.

—	No. 1.		Glazed.	
	Per Cent. of Original Pig.	Per Cent. of Total Graphite.	Per Cent. of Original Pig.	Per Cent. of Total Graphite.
Graphite left on 30 sieve.......	0·83	27·6	0·095	4·87
Graphite left on 60 sieve.......	1·37	45·5	0·341	17·23
Graphite left on 90 sieve.......	0·28	9·3	0·726	36·70
Passed through 90 sieve.......	0·53	17·6	0·815	41·20
	3·01	100·0	1·978	100·0

It will be noted that in the case of No. 1 Northampton iron, 73·1 per cent. of the graphite was too coarse to pass through the 60 sieve, while 77·9 per cent. of the graphite from the glazed iron was fine enough to do so—facts which very clearly illustrate the difference in size.

Cooling curves of the four samples from the Islip Iron Company were also taken (by the kind permission of Dr. T. K. Rose) in the laboratory of the Royal Mint. The curves gave four points of retardation of cooling, thus:—

—	R. I.	R. II.	R. III.	R. IV.
	° C.	° C.	° C.	° C.
Sampl 1	1128	1113	946	840(?)
" 2	1122	1114	935	868
" 3	1115	1091	955	852
" 4	1107	1093	935	837

Retardation I. is small and represents the commencement of solidification. Retardation II. is large and extends through a comparatively wide range of temperature (40 — 50° C.) It represents the solidification of the eutectic of graphite and iron (with silicon). Retardation III. is very sharp and distinct, and represents the solidification of the phosphide eutectic (Stead, J. I. & S. I., 1900, II., p. 116). Retardation IV. is faint in all cases.

Pure alloys of iron and carbon have an eutectic of 4·3 per cent. carbon with a melting point of 1130° C., but the irons examined, although only containing some 2·75 per cent. carbon are seen from the cooling curves to be of practically the eutectic composition. This, as is pointed out by Howe ("Iron and Steel and Other Alloys," p. 216), is the effect of silicon, and silicon in this respect may be considered as being equivalent to a certain amount of carbon (1 per cent. Si = 0·43 per cent. C). In the two close-grained irons (samples 3 and 4), the second retardation occurs at a distinctly lower temperature than in the open grained irons. This may be due to increase in phosphorus and sulphur as it is only in these two constituents that important differences are noted. In this connection it is interesting to note that Osmond and Werth, in a sample of Thomas pig iron containing 1·98 per cent of phosphorus, found that a retardation of cooling occurred at 1060°—1070° C. (Annales des Mines, 1888, July—Aug.).

The conclusions that may be drawn from the results given are :—

(1) The glazing of certain kinds of silicious irons is caused principally by an increase in the percentage of sulphur.

(2) The difference in the appearance of the fractures is due to the small size of the graphite plates in the case of glazed iron.

The author wishes to record his thanks to Prof. Turner for advice and suggestions in connection with this paper.

DISCUSSION.

Mr. G. J. **Ward** demurred to the statement that glazed iron was of less value than grey. It had given satisfactory results when the silicon was not used in excessive quantities. A badly grained glazed pig was invariably fine, but No. 2 iron might show signs of glazing. As to the effect of the sulphur in the case of the glazing, he was inclined to think that the author had confused cause and effect. Wedding, in his standard book on iron, said on page 171, "It seems certain that free SiO_2, when accompanied by no other mineral which can form slag with it, such as $CaCO_3$, tends to the production of iron rich in silicon, especially when the temperature is very high and there is much carbon present." The glazed iron was made when they had too high a burden, when the temperature of the blast was high, and by excess of fuel, and when they had got an acid slag. There was undoubtedly a tendency for the sulphur to get into the iron when the slag was acid, and these high sulphurs were due to the same cause as the glazing, and not the glazing due to the extra sulphur. Allen, of Sheffield, had given the following figures for Stanton glazed iron, silicon 4·50 per cent., sulphur 0·046 per cent. Percy in his experiments remelted pure kidney ore (69 per cent. Fe) with fine sand charcoal, heating strongly in covered crucible for 1½ hours. The resultant iron was hard, brittle, light grey, strongly crystalline, with aggregates of light flakes, in other words glazed iron. Turner, on page 198 "Metallurgy" expressed the opinion that bright crystals were silicides of carbon or of iron, and Carnot and Goutal (this J., 1898, 1150) said silicon irons containing a little manganese treated with 5 per cent. cold sulphuric acid leave a residue which consists of carbon, silicon hydroxide, and different combinations of iron and silicon. The hydroxides of iron and silicon are removed by potassium hydroxide. The manganese and iron are removed by sulphuric acid. The residue contains 19·75 to 19·86 per cent. of silicon and 79·63 to 79·84 per cent. of iron. $SiFe_2$ was a compound prepared by Moissan in an electric furnace. Glazed iron was, of course, rotten, and quickly broken, but he did not understand the argument that this was due to the smallness of the graphite flakes; No. 1 iron with large graphite was not nearly so strong as No. 4 with fine graphite. As to the effect of the phosphorus, if foundry iron were made in a blast furnace, all the phosphorus went into the pig, and the two samples of No. 1 iron must have been made from a somewhat different ore to the glazed. Whether this would increase the tendency to make glazed iron he did not know, but the author's statement about hæmatite iron pointed in that direction. His personal opinion was that glazed iron was due to the presence of $FeSi_2$, not to sulphur.

Mr. F. J. R. **Carulla** commented on the lightness of the samples of graphite extracted from pig iron which were exhibited. Including graphite, pig iron contained not far from 10 per cent. of substances other than iron, and taking into account their much lower specific gravity than that of iron, the volume of these impurities might be as much as 20 per cent. This fact might help one to understand the apparently great amount of impurity made visible by the photo-micrographs. The circumstance that sulphur influenced the size of the graphite in cast iron would seem an interesting point in connection with large castings, in which, owing to the necessarily slow cooling, the graphite would in any case be present in the large form. The small form of the graphite in chilled castings would possibly explain their being so much stronger than those that were not chilled.

Mr. O. F. **Hudson**, replying to the discussion, said that, so far as he had had to do with it, close-grained glazed iron such as was examined in connection with this paper always contained high sulphur. That glazing occurred with an acid slag was a fact worth noting, as such a slag favoured the production of iron high in sulphur. With regard to the weakness of glazed iron it was true that strong iron also contained low graphite, but in that case the metallic portion of the iron was comparatively strong, whereas in glazed iron it was brittle. He could throw very little light upon the question of the solubility of carbon in the sulphur in iron. The influence of sulphur on the carbon in cast iron was very powerful; it might be considered as having from 10 to 15 times the effect of silicon, and hence the importance that must be attached to small variations in the percentage of sulphur.

MR. JAS. E. BEDFORD IN THE CHAIR.

THE "DALITE" LAMP FOR COLOUR-MATCHING.

BY WALTER M. GARDNER AND A. DUFTON.

A new form of colour-matching lamp, the joint invention of Mr. A. Dufton and himself, was shown by Prof. Walter M. Gardner. It consists of an electric arc lamp surrounded by glass specially prepared to absorb the rays which the lamp emits in excess of those present in normal daylight. The variation in the apparent hues of objects due to illumination by lights of varying character is well known, and is of particular importance in connection with the accurate matching of colours, such as is required in dyeing, printing, painting, &c. The generally flat and lifeless appearance of pictures in artificial light is also due to this cause. In connection with chemical work the difficulty of performing, in artificial light, titrations in which coloured indicators are used is a matter of common experience. Hitherto no artificial light has been available in which all colours have the same appearance as when viewed in daylight, though the different forms of artificial light vary greatly in this respect. The greatest colour changes are brought about by ordinary gas or lamp light, or the incandescent electric light, all of which contain a large excess of yellow rays. while the violet end of the spectrum is almost entirely absent. The incandescent oil and incandescent gas light contain all the spectral rays, but the yellow is in considerable excess. The acetylene light is somewhat similar in character, the statement that this light affords a perfect colour-matching illumination being quite erroneous. The light produced by burning magnesium ribbon has a spectrum more nearly approximating to that of daylight. The light from electric arc lamps varies considerably in character, according to the kind of lamp used. In each case a portion of the light emanates from the glowing carbons, and this portion contains a considerable excess of red and yellow rays. Another portion of the light emanates from the arc itself, and this contains a considerable excess of violet and ultra-violet rays. The proper balancing of these separate portions of an electric arc light is of great importance in view of the production of a true artificial daylight effect, but in any case the light will contain an excess of rays from the red end of the spectrum. The problem involved in the production of a light suitable for colour work of all kinds does not consist merely in the production of a white light; such, of course, could be obtained by a combination of any two complementary lights, *e.g.*, red and green, but it s obvious that when viewed by a white light thus con-tituted many colours would appear unreal. For example, a blue or violet would appear black.

A perfect colour-matching light must contain all the pectral hues which are present in daylight, and in the same roportion. Taking an electric arc lamp of a special type s the most convenient basis, the spectrum of the light was carefully compared with that of normal daylight, and it was thus determined what rays were in excess. Means were hen devised for cutting off these rays, and eventually he problem was solved by the production of a special lass having the necessary absorption. The light of this olour-matching lamp, which is known as the "Dalite" amp, is precisely of the same character as that of good aylight from a north sky, and has the advantage over rdinary daylight of being perfectly uniform and unchangeble; whereas daylight itself varies not only from day to ay but frequently from minute to minute.

The lecture was illustrated by means of a set of coloured ntern slides; absorption spectra and many other colour fects being shown on the screen.

Meeting held at Bradford on April 18th, 1904.

MR. JAMES E. BEDFORD IN THE CHAIR.

STABILITY OF STANDARD SOLUTIONS OF POTASSIUM PERMANGANATE AND AMMONIUM OXALATE.

BY WALTER M. GARDNER AND E. NORTH.

A statement is often found in standard text books on analysis that a solution of potassium permanganate gradually becomes weaker on exposure to light, by slow decomposition of the salt; and that it is necessary on this account to re-standardise the solution at frequent intervals. In the course of some recent work involving the use of this reagent (see this J., 1903, 731), we found occasion to doubt the accuracy of this statement, and have, therefore, made experiments extending over a period of twelve months. These have established the fact that, both in the solid state and in solution, pure permanganate retains its strength if kept in well-stoppered bottles, even when exposed to light.

On March 30th, 1904, a solution of permanganate prepared from the specially purified salt described in the paper above referred to, was made decinormal by weighing, and the accuracy of the solution was confirmed by titration of pure ammonium oxalate and pure ferrous ammonium sulphate. On October 28th, 1903, *i.e.*, seven months afterwards, the factor of the solution was found by titration to be 0·997, and on April 15th, 1904, the same solution gave precisely the same factor. A similar N/10 solution of permanganate was prepared on October 28th, 1903, from the same lot of solid recrystallised permanganate of potash preserved during the seven months in a closely stoppered bottle. The solid permanganate had retained its original strength, and the second solution restandardised on April 15th, 1904, after an interval of six months, was again found to have the factor 0·997. The above results show that a solution of pure permanganate may be considered to retain its original strength for all practical purposes for at least 12 months if pure water is used in its preparation and the solution kept in a closely stoppered bottle; and it is not necessary to keep such a solution in the dark.

Similar experiments to test the stability of solutions of ammonium oxalate showed that in seven months in a closely stoppered bottle, the strength had diminished from 100 per cent. to 86·28 per cent., which agrees closely with the result previously obtained, and noted in our previous paper, that such a solution may be considered for practical purposes to be permanent for about a week, as it deteriorates at the rate of about 1 per cent. per fortnight. In the solid condition, we have determined that pure ammonium oxalate and pure ferrous ammonium sulphate retain their original strength undiminished for at least 12 months.

I.—PLANT, APPARATUS AND MACHINERY.

Air Compressors; Causes of Explosions in ——. E. Goffe. J. Mech. Eng. Assoc., Witwatersrand, 1904; through Eng. and Mining J., 1904, **77**, 686—687.

The author gives a detailed description of two cases of explosions in two-stage air compressors. He concludes that the principal cause of such explosions is the accumulation of dust in the interior of the valve-chambers, pipes, and receivers, which dust absorbs the excess of lubricating oil. The mixture produced in decomposing gives off explosive gases, which, under favourable circumstances, become ignited.—A. S.

English Patents.

Drying Machines; Cylindrical ——. J. R. Hatmaker, London. From J. A. Merrett, Paris. Eng. Pat. 13,907, June 22, 1903.

The invention refers to machines composed of one or more revolving heated cylinders upon which liquid materials are distributed in a layer or film, for the purpose of evaporating their contained water. The special improvement consists in the arrangement of the stripping knife, by means of which materials which are injured by overheating can be quickly and entirely removed from the surface of the cylinder. Parallel with the smooth drying cylinder of the machine a pivoted back-plate is arranged to serve as support to the stripping knife. This back-plate is mounted in bearings adjustable to the exact distance desired from the axis of the cylinder, and is held in position by means of screw-bolts freely attached to a fixed bar which forms part of the framework of the machine. The stripping edge of the knife is adjusted by set-screws arranged in a cover-plate, which is itself secured to the back-plate by which the stripping knife is carried.—A. G. L.

Filters. F. D. Marshall, Copenhagen. Eng. Pat. 15,948, July 18, 1903.

Rows of solid bars with doubly-inclined upper surfaces are arranged in the filtering mass, to divide it into prismatic layers, which become arched between two laterally adjacent supporting bars.—W. H. C.

Heating Substances in Retorts; Apparatus for Use in ——. C. W. Stanton, Mobile. Eng. Pat. 4139, Feb. 18, 1904

Describes the application of the device of Eng. Pat. 5791 of March 9, 1904 (this J., 1904, 538), to stills or metallurgical retorts.—W. H. C.

Furnaces. P. Jensen, London. From the White-Mylin Furnace Co., Brooklyn. Eng. Pat. 6855, March 21, 1904.

An outer horizontal metal cylinder, provided with a water jacket and a refractory lining is combined with an inner concentric cylinder of refractory material, perforated on its lower side and forming the combustion chamber. On the top of the outer cylinder is a circular opening, with sheet-iron covers, through which the fuel and air are fed to the furnace, and at one end of the cylinder is a door for the purpose of cleaning out ashes, &c. The inner chamber has an outlet for the hot gases at one end and a jet for producing and regulating the draught at the other. The heat generated in the combustion chamber can either be utilised there for heating crucibles, &c., or can be led to a steam boiler or other external means of utilisation.—W. H. C.

French Patents.

Minerals [Coal, &c.]; Washing of ——. M. Evrard. Fr. Pat. 337,234, Dec. 5, 1903.

The minerals are fed from a chute on to a bed, along which they are moved by an endless chain provided with scoops and passing over two rollers. Underneath the bed are a number of semi-cylindrical hollow cells, standing in the wash water, and connected through their lower ends with a pipe leading to a pump. Air is forced from the pump into the cells, and projected into the wash water, producing efficient stirring.—L. F. G.

Liquids under Pressure; Bottling ——. Filter u. Brautech. Masch. Fab. vorm. L. A. Enzinger. Fr. Pat. 338,188, Oct. 29, 1903.

A containing vessel is filled, half with the liquid and half with compressed air; at the bottom of the vessel is a tubular orifice, which fits over the neck of the bottle to be filled. A sliding tube works up and down vertically through this orifice, and is provided with openings in such positions that, when the tube is first depressed, compressed air is admitted to the bottle, and when it is lowered still further, the liquid runs into the bottle until it covers the opening by which the air has escaped. The sliding tube is then raised, thereby delivering the liquid which remains in it into the bottle until, at the highest point, all orifices are closed and the bottle can be removed.—J. F. B.

Hydraulic Press for Pasty Masses. Maschinenfabrik St. Georgen b. St. Gallen. L. von Süsskind, Ltd. Fr. Pat. 338,287, Dec. 3, 1903.

The mass to be compressed is placed in a chamber provided with a removable bottom, and pressed by the actio of a hydraulic press into a mould co-axial with it, latera motion being prevented by causing projections of the chamber to engage in guides fixed to the mould. The hydraulic press is single acting, the return stroke bein accomplished by the weight of the ram and platform whilst the mould is moved into position by means of a bel and screw-gearing.—L. F. G.

Calcium Chloride; Process and Apparatus for Employing —— *as a Drying Agent.* Comp. des Usines Nouvelle J. Yberty et Cie. Fr. Pat. 338,133, Dec. 28, 1903.

Mountain-flax, pumice-stone, or coke, is impregnate with calcium chloride and dried. The lumps are the placed on shelves arranged in parallel rows in a cupboar the substances to be dried being placed on similar parall shelves placed between the calcium chloride shelves. A is circulated over the calcium chloride, and then over t substances, drying them. The calcium chloride trays c be readily removed to be reheated when necessary.
—L. F. G.

Condensing and Aspirating Fumes; Apparatus for ——. R. McKnight. Fr. Pat. 338,154, Dec. 29, 1903. Under Internat. Conv., Jan. 5, 1903.

See U.S. Pat. 737,003 of 1903; this J., 1903, 1038.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Sulphur; Forms in which —— *occurs in Coal; their Calorific Values and their Effects upon the Accuracy of the Heating Powers, Calculated by Dulong's Formula.* E. E. Somermeier. J. Amer. Chem. Soc., 1904, **26**, 555—568.

By a number of determinations with two samples of pyrites, each containing 53·2 per cent. of sulphur, the author found that the calorific value of pyrites as determined in the Mahler calorimeter is 2637 cals. per grm., which is equivalent to 4957 cals. per grm. of sulphur as pyrites. Owing, however, to the different products of combustion of pyrites when burnt in a calorimeter and when burnt in air, 2042 cals. per grm. of sulphur must be deducted from the value found by means of the calorimeter. Thus, 4957—2042 or 2915 cals. represents the heat of combustion in air of 1 grm. of sulphur as pyrites, and consequently the value given in Dulong's formula, 2250 cals., is about 665 cals. too low, or 6·6 cals. for each 1 per cent. of sulphur present as pyrites. The oxygen being determined by difference in the ultimate analysis of the coal, the author calculates that if no allowance be made for the oxygen taken from the air to form ferric oxide with the iron of the pyrites, the results for hydrogen given by Dulong's formula will be 16·2 cals. too high for each 1 per cent. of sulphur as pyrites. Thus by applying Dulong's formula in the usual way, the net error will be 16·2 cals. − 6·6 cals., or 9·6 cals. too high for each 1 per cent. of sulphur as pyrites.—A. S.

Ethane; The Slow Combustion of ——. W. A. Bone and W. E. Stockings. Proc. Chem. Soc., 1904, **20**, 106—107.

(1) The proportions of ethane and oxygen most favourable to chemical change are equimolecular (1 : 1), although interaction takes place nearly as rapidly in mixtures containing ethane and oxygen in the ratio of 2 : 1. At all temperatures, ethane is oxidised much more rapidly than is methane, other conditions being equal.

(2) When ethane is treated with proportions of oxygen insufficient to oxidise the whole to carbon monoxide and steam, there is no preferential combustion either of hydrogen or carbon. In the absence of secondary phenomena, the interaction is always marked by a diminution in the pressure of the cold products without any deposition of carbon or liberation of free hydrogen.

(3) The combustion proceeds in several well-defined stages, among which the following have been distinguished:

(i) A primary oxidation to acetaldehyde and steam.

(ii) A further rapid oxidation of the acetaldehyde to formaldehyde, carbon monoxide, and steam.

(iii) The final oxidation of formaldehyde to carbon monoxide, carbon dioxide, and steam, which may best be considered as due to two simultaneous interactions (i) $CH_2O + O_2 = CO_2 + H_2O$, (ii) $2CH_2O + O_2 = 2CO + 2H_2O$.

(4) The combustion of the hydrocarbon may be accompanied by the following secondary phenomena:

(i) Hydrogen or methane, or both, may appear in the products without any liberation of carbon, as the result of he purely thermal decompositions of formaldehyde and cetaldehyde vapours respectively, the latter giving rise to methane and carbon monoxide, whilst the former yields ydrogen and carbon monoxide, although its decomposition s a more complex process than that of acetaldehyde.

(ii) Small quantities of ethylene and hydrogen may ppear in the products as the result of the thermal decomposition of ethane.

(iii) If the heat liberated during the initial stages of oxidation is sufficient to raise the temperature of the intercting gases to the ignition point, an explosion takes ace, during which the excess of hydrocarbon, and probably so of aldehyde vapours, is decomposed, carbon and hydrogen being liberated together with some acetylene and ethylene. There is no liberation of carbon below the ignition point.

(5) Although ethyl alcohol has not been detected among the oxidation products of ethane, its absence may be explained by the fact that it is oxidised far more rapidly than is ethane under similar conditions.

(6) The view taken of the mechanism of the combustion of ethane is supported by the experiments on ethyl alcohol and acetaldehyde.

English Patents.

Fuels; Artificial or Composite ——. G. C. Marks, London. From The International Fuel Co., Rutland. Eng. Pat. 3781, Feb. 15, 1904.

A mixture is made of coal dust or waste (bituminous or anthracite) with hydraulic cement and sea-water or a solution of common salt. Potassium carbonate and sodium benzoate may be added. It is claimed that the chlorine renders the combustion complete.—W. H. C.

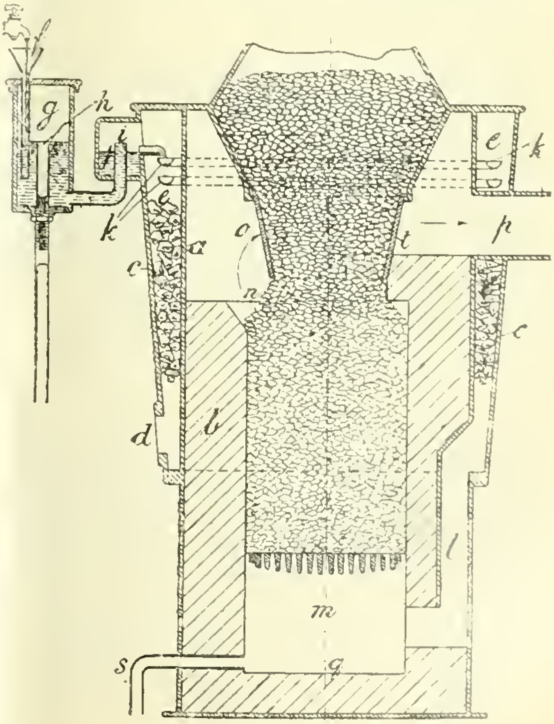
Cement [for Coal Briquettes]; Process of Making a Binding Agent or ——. L. Weiss. Eng. Pat. 4939, Feb. 29, 1904. IX., page 607.

Coke; Process and Apparatus for Quenching and "Bleaching" ——. W. P. Thompson, Liverpool. From E. A. Moore, Philadelphia. Eng. Pat. 6527, March 17, 1904.

See U.S. Pats. 755,154 and 755,155 of 1904; this J., 1904, 436.—T. F. B.

[Suction] Gas Generators. J. E. Dowson, London. Eng. Pat. 13,476, June 16, 1903.

The generator has two concentric casings, *a* and *c*, the space between which may be filled with pieces of iron or the like, which serve to heat the air supply drawn in at *d* by the suction of the gas engine. Water enters the chamber *g*, which has an adjustable overflow *h* and outlet *i*. The level in *g* can be regulated so that no water flows from *i* until the engine sucks. At each suction, water flows from



i into j, and then into gutters k or the like arranged in the upper part of the space e. By this means the quantities of air and steam drawn into the producer are regulated automatically by the requirements of the gas engine. The hot air, mixed with the steam, flows down the passage l to the space m, and thence up through the fuel, the gas produced being drawn off from n through the circular passage o and the pipe p. Any excess of water flowing on to the floor q is drawn off by the pipe s. The lower part of the fuel container, t, may be formed of a loose piece, to facilitate renewals.—H. B.

Gas-Retort Furnace. A. Deegen, Wittstock. Eng. Pat. 22,946, Oct. 23, 1903.

By means of flues arranged in the bottom part of the furnace, the lower air current required for the combustion is heated; and for the upper air supply, horizontal zigzag passages are formed in the pillars which support the arch of the furnace. These passages may be lined with boxes or pipes to prevent the access of cold air through cracks in the setting.—H. B.

Gas Producers. F. W. Paul, Harrogate. Eng. Pat. 14,893, July 4, 1903.

The producer is provided with orifices at different heights, throug hwhich the fuel is fed, and with blast-inlet and gas-outlet pipes both at top and bottom, to enable the direction of the blast to be reversed at will. In addition to the usual water-sealed ash-pit below, the producer is fitted at its upper end with a luted discharge, formed by a dome-shaped top, the lower edge of which rests in an annular water-pan surrounding the upper part of the producer. Thus the ashes which are carried up by the feeding of fuel from below fall over into the water-pan.—H. B.

Gas; Manufacture of ——. J. Y. Johnson, London. From Deutsche Continental Gasgesellschaft, and J. Bueb, Dessau. Eng. Pat. 15,147, July 8, 1903.

To obtain a higher yield of gas and a better utilisation of the heat in the distillation of coal, the carbonisation is conducted in vertical retorts and in two stages, during the first of which the distillation is effected as usual until the greater part of the coal has been carbonised, whereupon steam is passed up in a vertical direction from the bottom of the retort.—H. B.

Wood-Gas; Manufacturing ——. B. Loomis and H. Pettibone, New York. Eng. Pat. 6302, March 15, 1904.

A layer of coke is placed on the grate of a gas generator, which has a valved outlet pipe at its base. A charge of wood is placed on top of the coke and ignited, air being drawn downwards through the generator, so that the coke is brought to incandescence, and effects the reduction of the steam and carbon dioxide formed. In practice it is well to have two generators connected together by a pipe at the top. In order to prevent the coke from becoming choked with ash, &c., the outlet valve and the air inlet at the top of the generator are shut, and a blast of steam is injected upwards through the coke, thus cleaning it; the resulting gases are then drawn down through the incandescent fuel in the second producer, water-gas being thus produced.
—T. F. B.

Producer-Gas; Manufacturing ——. B. Loomis and H. Pettibone, New York. Eng. Pat. 6303, March 15, 1904.

Low-grade producer gas, obtained from peat, sawdust, garbage, pulverised fuel, or the like, is passed through a body of incandescent coal or coke, whereby a high-grade gas is produced. Steam, generated by the waste heat of the gases, is blown occasionally through the incandescent coal or coke to break up the clinker, the water-gas formed being mixed with the high-grade gas. The apparatus consists preferably of two generators, charged with the superior fuel, connected with each other and with two generators or fire-boxes, in which the inferior fuel is burned, the rich gas being cooled in a tubular economiser.
—H. B.

United States Patents.

Fuel; Smokeless ——. T. Weeple, Oakland. U.S. Pat. 759,783, May 10, 1904.

Soft coal is boiled with water in a tank, whereby it disintegrates and volatile matters are eliminated; it is then drained and dried.—L. F. G.

Carburetted Water-Gas; Apparatus for Manufacturing ——. W. R. Addicks, Brookline. U.S. Pat. 758,882, May 3, 1904.

The apparatus consists of a generator, a carburetter, and a fixing chamber arranged in series as usual. The oil supply for the carburetter is heated by flowing through a horizontal zigzag pipe, arranged within the pipe or flue which conducts the carburetted gas from the fixing chamber to the hydraulic main.—H. B.

Gas-Producer; Water-Seal ——. W. H. Holcroft, Assignor to E. V. Holcroft, Chester. U.S. Pat. 759,179, May 3, 1904.

A water-sealed producer is provided, within the ash-pit, with a blast-box having a closed top and sides, and having channels, open at the bottom, for the passage of the blast, the channels being submerged in the water of the seal.
—H. B.

Gas Condensing [Catalytic] Bodies; Process of Producing ——. A. Tissier, Paris. U.S. Pat. 759,406, May 10, 1904.

See Eng. Pat. 18,035 of 1900; this J., 1901, 1100.—T. F. B.

French Patent.

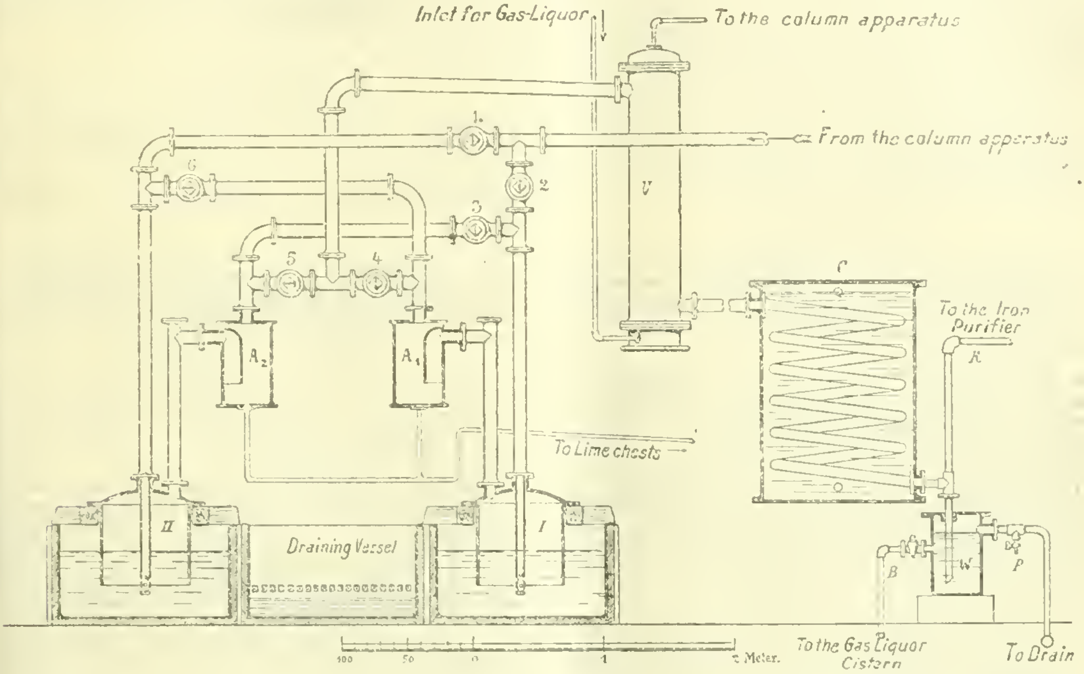
Alcohol; Carburisation of ——. F. Hache. First Addition, dated Dec. 18, 1903, to Fr. Pat. 334,783 of Aug. 22, 1903 (this J., 1904, 112).

Alcohol is mixed with the light hydrocarbons obtained by distilling crude petroleum, and with a smaller quantity of crude petroleum, and distilled, a little toluene or similar hydrocarbon being first added to the mixture. An alcohol of higher calorific power is thus obtained.—L. F. G.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Ammonium Sulphate [from Gas-Liquor]; Continuous Apparatus for the Manufacture of ——. M. Rosenkranz. J. Gasbeleucht., 1904, **47**, 459—460.

The accompanying diagram represents an apparatus for the manufacture of ammonium sulphate which has the advantage of being continuous in operation, and of retaining the last traces of ammonia in the gas coming from the liquor stills. The saturators are in duplicate, and the arrangement of cocks is such that either can be used alone or both employed in series. Starting with fresh acid in I and II, all the cocks are shut except 2 and 4; the ga then passes from I to the catch-vessel A_1, direct to th liquor heater V, &c. But as soon as a sample taken at I shows that some ammonia is escaping retention, cock 4 i shut, 5 and 6 opened (in the method actually shown by th sketch), so that the gas is compelled to bubble through th fresh acid in II. This goes on till the liquid in I is con pletely neutralised, when the cocks are altered to bring I alone into service. The crystals in I are then taken o and thrown into the common drainer; a new charge o acid is introduced, and I becomes ready to follow II by th time that the latter is approaching exhaustion. Thus th liquor distillation does not have to be interrupted every ti a saturator needs refilling. Should either I or II requ repair, any ammonia passing W may be recovered b causing the gas to pass through B into the liquor sto The number of cast-iron cocks in the apparatus is a defe for they become corroded and need frequent lubrication; but the economy in ammonia compensates for this. The author states that by the use of this plant he has increased his output from 0·63 or 0·65 kilo. of ammonium sulphate per 100 kilos. of coal to over 0·85 kilo.; while his daily make has increased from 312 to 502 kilos. per 24 hours.



he apparatus described by Feldmann (this J., 1903, 206) s mentioned.—F. H. L.

Distillation of Immiscible Liquids. E. Charabot and J. Kocherolles. XXIV., page 628.

English Patent.

eating Substances in Retorts; Apparatus for Use in ——. C. W. Stanton. Eng. Pat. 4139, Feb. 18, 1904. I., page 600.

IV.—COLOURING MATTERS AND DYESTUFFS.

-Substituted o-Nitrobenzaldehydes [*Indigo Derivatives*]. F. Sachs and E. Sichel. Ber., 1904, **37**, 1861—1874.

.4-Dinitrobenzaldehyde was converted by the authors
to its oxime, which yields on reduction *p*-amino-*o*-nitro-
nzaldoxime. F. Sachs and R. Kempf have already
own (this J., 1903, 1238) that on treatment with iron
loride and hydrochloric acid this yields *p*-chloro-*o*-nitro-
nzaldehyde. The authors obtain the hitherto unknown
romo-*o*-nitrobenzaldehyde in a similar manner by treat-
p-amino-*o*-nitrobenzaldoxime with ferric sulphate and
drobromic acid. They also obtain substituted indigos
m both the *p*-chloro- and *p*-bromo-*o*-nitrobenzaldehydes
condensing with acetone in presence of trisodium phos-
ate and heating the lactic-acid ketone so obtained with
lium carbonate solution. The dibromo-indigo obtained
this way closely resembles the similarly prepared
hloro derivative, and is much less blue than the product
ained by brominating indigo. Both *p*-chloro- and
romo-*o*-nitrobenzaldehyde are converted by the action
ight into the corresponding nitrosobenzoic acids. They
reduced by titanium chloride in hydrochloric acid
tion to the corresponding halogenaminobenzaldehydes.
-Dinitrobenzaldehyde yields with the same reagent
nino-*p*-nitrobenzaldehyde.—E. F.

Dinitrophenylethers of 3-chloro-4-aminophenol and of 4-aminophenol. F. Reverdin and A. Dressel. Ber., 1904, **37**, 1516—1519.

1.2.4-Chlorodinitrobenzene and 3.4-chloroaminophenol react in alcoholic solution in presence of sodium acetate to form the dinitrophenylether of *m*-chloro-*p*-aminophenol $C_6H_3(NH_2)Cl.O.C_6H_3(NO_2)_2$. In absence of sodium acetate chlorohydroxydinitrodiphenylamine is formed. If the 3.4-chloroaminophenol be replaced by its isomeride, the 2.4-derivative, a chlorohydroxydinitrodiphenylamine, is formed, whether sodium acetate is present or not. The dinitrophenyl ether of *m*-chloro-*p*-aminophenol is readily diazotised, and can then be coupled with the ordinary components, forming dyestuffs which are bright in shade but not fast to alkali. Dyestuffs of similar character are obtained from a sulphonated derivative of the dinitrophenyl ether. The dinitrophenyl ether of *p*-aminophenol was obtained by acting on acetylaminophenol with chlorodinitrobenzene and saponifying the product. This substance can be diazotised in the usual manner, and then yields azo-dyestuffs which are rather more stable to alkali than those obtained from the dinitrophenyl ether of *m*-chloro-*p*-aminophenol, but not sufficiently so to be of practical interest. Azo dyestuffs obtained from the sulphonic acid of this dinitrophenyl ether are quite unstable to alkali.
—E. F.

Triphenylmethane Dyestuffs, fast to Alkalis. C. Lauth. Comptes rend., 1904, **138**, 1220—1221.

The leuco bases obtained by the reduction of the products of condensation of *m*-nitro-benzaldehyde with dimethyl- or diethylaniline were heated with various reagents capable of substituting an acidic group for one of the hydrogen atoms of the amino group. The products obtained by the action of acetyl chloride or acetic anhydride and of benzene sulphonic chloride are described. These products, when converted into disulphonic acids and oxidised, yield blue dyestuffs fast to alkalis, similar to "Patent Blue."
—J. F. B.

3.8-Diaminodiphenazone. F. Fichter and P. Dieterle. Z. Farben- u. Textil-Chem., 1904, **3**, 157.

This compound is produced by the electrolytic reduction of dinitrobenzidine. If the latter be reduced with sodium sulphide, the phenazone-oxide is formed, which, on treatment with stannous chloride and hydrochloric acid, yields the diaminodiphenazone,

$$NH_2.C_6H_3.N:N.C_6H_3.NH_2,$$

which crystallises from water and alcohol in red needles. It combines readily with aldehydes; *e.g.*, heated with benzaldehyde in alcoholic solution, it gives dibenzylidenediaminodiphenazone, yellow plates m.p. 210° C. If the phenazone be diazotised and treated with sodium naphthionate, a dark red precipitate is formed which dyes cotton from a bath containing sodium carbonate in a shade of a more carmine colour than Congo Red. The nitrogen bridge in the ortho position to the bond coupling the two benzene nuclei increases the substantive character no more than the sulphone, imino, or methylene groups.—A. B. S.

English Patents.

Phenyl-glycine-carboxylic Acid Nitrile, and Intermediate Products relating thereto; Manufacture of—— [*Indigo*]. J. Y. Johnson. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. Eng. Pat. 14,676, July 1, 1903.

Anthranilic acid is warmed with aqueous formaldehyde solution. Equimolecular proportions of the two substances react to form a solid which is insoluble in dilute sodium carbonate solution. On treating this compound with hydrocyanic acid or a metallic cyanide, the nitrile of phenylglycinecarboxylic acid is formed. On treating the above-described solid condensation product of anthranilic acid and formaldehyde with a sulphite or bisulphite, the so-called bisulphite compound of methylene-anthranilic acid is formed, and can be converted, by treatment with a cyanide, into the nitrile of phenylglycinecarboxylic acid.—E. F.

Disazo Colouring Matters [*Azo Dyestuffs*]; *Manufacture of* ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. Eng. Pat. 10,536, May 8, 1903.

See U.S. Pat. 741,936 of 1903; this J., 1903, 1241.—T. F. B.

Dyestuffs of the Triphenylmethane Series; Manufacture of ——. H. E. Newton, London. From The Farbenfabr. vorm. F. Bayer and Co., Elberfeld. Eng. Pat. 13,192, June 12, 1903.

See U.S. Pat. 738,227 and Fr. Pat. 332,926 of 1903; this J., 1903, 1125 and 1290.—T. F. B.

United States Patents.

Glucoside Dye, and Process of Making same. F. J. Oakes, New York. U.S. Pat. 759,008, May 3, 1904.

Vegetable matter containing glucosides is extracted with water, carbon dioxide being injected "under such conditions as to ensure chemical combination." When logwood is thus extracted, haematoxylin carbonate is obtained as a reddish-brown crystalline substance, soluble in water, giving a neutral solution. It is oxidised to haematin carbonate "by application of atmospheric air."—T. F. B.

Azo Dye; Blue ——, *and Process of Making same.* K. Jagerspacher and T. Kröber, Assignors to Soc. Chem. Ind. in Basle, Basle. U.S. Pat. 759,284, May 10, 1904.

See Eng. Pat. 14,113 of 1903; this J., 1903, 1051.—T. F. B.

Tetrazo Dye [*Azo Dyestuff*]; *Violet* ——, *and Process of Making same.* K. Jedlicka, Assignor to Soc. Chem. Ind. in Basle. U.S. Pat. 759,613, May 10, 1904.

See Eng. Pat. 28,033 of 1903; this J., 1904, 319.—T. F. B.

Rhodamine Dye [*Pyrone Dyestuff*]; *Red Basic* ——, *and Process of Making same.* A. Bischler, Assignor to Basle Chemical Works, Basle. U.S. Pat. 759,657, May 10, 1904.

See Eng. Pat. 2738 of 1904; this J., 1904, 367.—T. F. B.

Azo Dyestuff; Red ——. P. Julius, Ludwigshafen, and S. Haeckel, Mannheim, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. U.S. Pat. 759,716, May 10, 1904.

By diazotising *o*-chloro-*p*-toluidine sulphonic acid and coupling with β-naphthol, a red dyestuff is obtained. Its sodium salt is soluble with difficulty in hot water, and its barium, calcium, aluminium, and lead salts are scarlet insoluble powders.—T. F. B.

French Patent.

Indigo; Purification of Natural or Synthetic ——. Badische Anilin und Soda Fabrik. Fr. Pat. 338,311, March 16, 1903.

See Eng. Pat. 7395 of 1903; this J., 1904, 248.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Mercerised Cotton; Increased Affinity of —— *for Dyestuffs and Mordants.* W. Schaposchnikoff and W. Minajeff. Z. Farben- u. Textil-Chem., 1904, **3**, 163—167. (See also this J., 1903, 903.)

Pieces of mercerised and unmercerised cotton were dyed in the same bath with a direct dyestuff containing several sulphonic groups, *e.g.*, Diamine Blue 3 B. The amount of dyestuff taken up was found by means of a sulphur estimation of the dyed patterns. The result showed that the unmercerised cotton required about 50 per cent. more dyestuff than the mercerised in order to dye it the same depth. Mercerised cotton absorbs about 40 per cent. more tannic acid than unmercerised. The results with chrome mordants were contradictory, but in the case of iron and manganese the unmercerised cotton took up more mordant than the mercerised.—A. B. S.

Calico Printing; Photographic Preparation of Rollers for ——. J. Wolkoff. Z. Farben- u. Textil-Chem., 1904, **3**, 158—163.

The photographs which have been taken through a ruled screen or grating are printed on to a chrome-gelatin paper which is then transferred to a carefully cleaned metal roller (molette). The paper and unaltered gelatin are removed by washing, which leaves the gelatin, rendered insoluble by exposure, on the roller. The latter is then etched with weak solution of ferric chloride until the weakest shadow are engraved to the correct depth. The roller is then wel cleaned, and the portions sufficiently engraved are coate with a varnish to protect them from further action. Th engraving process is repeated until the various shadows ar etched to their proper depth. In working with the three colour process it is important that the engraving on th three rollers be in the correct proportions to one anothe It is also possible that the three rollers may wear awa unevenly during the printing, and so alter the relativ amounts of the different colours in the picture.—A. B. S.

Hyposulphites [*Hydrosulphites*]: *Electrochemical Prep ration of* ——. K. Elbs and K. Becker. XI. A., page 61

English Patents.

Silk, Artificial; Manufacture of ——. E. Thiele, Barme Eng. Pat. 16,588, July 28, 1903.

See Fr. Pat. 334,507 of 1903; this J., 1901, 59.—T. F. B.

Dyeing under Pressure, Apparatus for ——. L. Dé Reims. Eng. Pat. 25,555, Nov. 23, 1903. Und Internat. Conv., Dec. 2, 1902.

See Fr. Pat. 326,806 of 1902; this J., 1903, 905.—T. F.

Printing Patterns upon Piece Goods, Paper, and the like. E. Schoening and The Carl Schoening Eisengiesserei und Werkzeugmaschinenfabrik Act.-Ges., Berlin. Eng. Pat. 10,802, May 12, 1903.

A "PATTERNING" roller serves to remove in parts the uniformly-spread layer of colour or ink from a smooth-surfaced printing roller. The two rollers then print upon the webs of tissue or sheets of paper which are continuously passed round the printing cylinders with which they are in contact. The "patterning" roller may be employed to transfer colour or ink to the colour- or ink-coated printing roller, and thus to modify in parts the intensity or shade of colour applied by the latter.—E. B.

White Discharges in Printing Fabrics and Discharges therefor; Process for Producing ——. O. Imray. From Farbw. vorm. Meister, Lucius und Brüning, Hoechst-on-the-Maine. Eng. Pat. 13,827, June 20, 1903.

A MIXTURE of a hydrosulphite-aldehyde compound as described in Eng. Pat. 5867 of 1903 (this Journal, 1904, 369), strong caustic alkali and a thickening agent is applied to the fabric. On steaming the fabric this acts as a powerful discharge, even towards mordant and basic dyestuffs such as Alizarin Red or a Safranine-azo-dyestuff.—E. F.

United States Patent.

Cotton-Seed Hulls or Cotton Waste; Process of Treating ——. H. F. Bockmeyer, Assignor to A. O. Granger, Cartersville. U.S. Pat. 759,800, May 10, 1904.

COTTON-SEED hulls, ground to a comminuted condition, cotton waste, &c., are first treated with a one to two per cent. solution of an alkali with live steam passing through the mixture. The material is drained, washed, and treated with chlorine gas in the presence of a one per cent. solution of a free alkali, until the agitated mass is decolorised and bleached. The material, after draining and washing, is subjected to the action of oxalic acid, or a reagent capable of reacting with the excess of chlorine present, and is then given a final washing.—B. N.

French Patents.

Hydrosulphite Compounds [with Aldehydes]; Process for Making ——, and their Use in Dyeing and Printing. Cie. Paris. Coul. d'Aniline. Fr. Pat. 338,385, March 20, 1903.

EE Eng. Pat. 5687 of 1903; this J., 1904, 369.—T. F. B.

Dyeing; New Process and Apparatus for ——. H. L'Huillier. Fr. Pat. 338,113, Dec. 12, 1903.

ULPHIDE dyestuffs which easily oxidise in the air, thus iving uneven results, are dyed in an atmosphere of some iert gas. The apparatus consists of a closed dye vessel onnected at the top with a gas generator, and at the bottom ith a reservoir which contains the dye solution. Steam used to clear the apparatus of air, and to force the dye olution from the reservoir into the dye vat. The gas to be ed is then drawn into the vat and remains there until the eration is finished. Indigo and similar dyestuffs can be ed by this process. The air is displaced by coal gas ring the dyeing, then oxygen is passed in to oxidise the ıcindigo.—R. S.

yeing Cotton Thread Several Colours; Process for ——. Soc. Anon. Teinturerie Clément Marot. Addition, dated Dec. 22, 1903, to Fr. Pat. 337,027, Nov. 26, 1903; this J., 1904, 440.

us addition states that first the outside only of the bbin is dyed with a mordant dyestuff and then the inside h a direct dyestuff, the latter being partially bleached l reduced as before. Textile fibres other than cotton, h as wool, silk, jute, ramie, &c., can also be dyed by this thod.—R. S.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

English Patent.

Printing Patterns upon Piece Goods, Paper, and the like. S. Schoening and The Carl Schoening Eisengiesserei u. Werkzeugmaschinenfabrik Act.-Ges. Eng. Pat. 10,802, May 12, 1903. V., next col.

VII.—ACIDS, ALKALIS, AND SALTS.

Hypophosphorous Acid; Preparation and Properties of ——. C. Marie. Comptes rend., 1904, **138**, 1216—1217.

Two methods of preparation are described:—(1) A solution of 300 grms. of barium hypophosphite, purified by precipitation by alcohol, are dissolved in 2 litres of boiling water and treated with a slight excess of boiling dilute sulphuric acid. The clear liquid is separated and the exact point of complete precipitation is established. The liquid is rapidly concentrated down to about 25 per cent. of acid by boiling, it is then filtered, and evaporation is continued under decreased pressure at 80°—90° C. in an atmosphere of carbon dioxide until the weight remains practically constant. The acid solidifies in a freezing mixture and melts at 12°—15° C.

(2) Sodium hypophosphite is powdered, dried at 100° C., and treated in a dry flask with the calculated quantity of concentrated sulphuric acid whilst cooling. After two days the mixture is treated with absolute alcohol (about 2 litres for 300 grms. of sodium salt), the sodium sulphate is filtered off and the solution is evaporated as above. By fractional crystallisations and thorough drying over phosphoric anhydride, the melting point of hypophosphorous acid may be raised to 26·5° C. The decomposition of hypophosphorous acid by heat takes place in two stages: At 130°—140° C. it is rapidly decomposed, forming phosphorous acid and phosphoretted hydrogen $3H_3PO_2 = 2H_3PO_3 + PH_3$. Towards 160°—170° C. the phosphorous acid is itself decomposed into phosphoric acid and phosphoretted hydrogen.—J. F. B.

Sodium Thiosulphate; Oxidation of ——. E. Sedlaczek. Phot. Corr., 1904, **41**, 158; Chem.-Zeit., 1904, **28**, Rep. 144.

POTASSIUM permanganate oxidises sodium thiosulphate to polythionic acids; whether in acid, neutral, or alkaline solution, the same amount of permanganate is used, but the nature of the ultimate products depends on the time during which they remain in contact with the precipitated manganese peroxide. Sodium silver thiosulphate gives with permanganate in neutral solution neither silver sulphide nor sulphate; in acid solution the silver is completely oxidised to sulphate.—J. T. D.

Potassium Thiocyanate; Action of ——, on Metallic Oxides at a high Temperature. J. Milbauer. Listy chemické, 1904, **5**, 113; Chem.-Zeit., 1904, **28**, Rep. 130.

THE following compounds were obtained by heating metallic oxides with pure potassium thiocyanate to temperatures between 200° and 1,200° C.:—From lead oxide: crystalline lead sulphide. Cupric oxide: crystalline cuprous oxide and $K_2Cu_8S_6$. Bismuth oxide: bismuth sulphide and $K_2Bi_2S_4$. Cadmium oxide: amorphous cadmium sulphide, and pearly flakes, probably $K_2Cd_3S_4$. Stannic oxide: stannic sulphide and potassium thiostannate. Molybdic oxide: molybdenum sulphide and potassium thiomolybdate. Trimanganic tetroxide: amorphous green manganous sulphide; once, at a very high temperature, flesh-coloured $K_2Mn_3S_4$. Chromic oxide: crystallised Cr_2S_3 and $K_2Cr_2S_4$. Ferric oxide: crystallised ferrous sulphide and $K_2Fe_2S_4$. Nickel oxide: $K_2Ni_{11}S_{16}$. Cobalt oxide: $K_2Co_{11}S_{10}$. Uranium oxide: uranium oxysulphide.—J. T. D.

Ammonium Sulphate [from Gas Liquor]; Continuous Apparatus for the Manufacture of ——. M. Rosenkranz, III., page 602.

Ferrous Salts; Conversion of —— into Ferric Salts for Volumetric Determination, or for Separation of Iron with Manganese. L. L. de Koninck. XXIII., page 624.

Carbon Dioxide; Rapid Method for the Volumetric Determination of ——. T. Macara. XXIII., page 625.

English Patents.

Zinc Hydrosulphite Difficultly Soluble in Water; Process for Producing Solid ——. C. Bollé, Manchester. From Chem. Fabr. Grünau, Landshoff und Meyer, Act.-Ges., Grünau. Eng. Pat. 9360, April 25, 1903.

See Fr. Pat. 331,095 of 1903; this J., 1903, 1130.—T. F. B.

Nitre-Cake; Utilisation of ——, and the Manufacture of Useful Products therefrom. G. E. Davis, Salford. Eng. Pat. 14,749, July 2, 1903.

Aluminous material, such as clay or bauxite, is added to a hot concentrated solution of nitre-cake, and the mixture is heated and agitated by high pressure steam. On cooling, a solid mass is formed, suitable for use in sewage precipitation, &c. But usually, the product is purified by solution filtration, and separation of the excess of sodium sulphate by crystallisation, after which, by suitable treatment, sodium alum is obtained.—E. S.

Magnetic Oxide of Iron; Production of Black ——. C. L. Parker, London. Eng. Pat. 6775, March 21, 1904.

Ferrous carbonate, in the form of spathic iron ore or otherwise, is subjected to a low red heat in air-tight vessels furnished with safety valves, for from 12 to 24 hours, when the vessels are allowed to cool thoroughly before being opened. The product is stated to be black magnetic iron oxide intimately mixed with carbon.—E. S.

Oxygen; Manufacture of —— by Means of Liquid Air. G. Claude, Paris. Eng. Pat. 16,298, July 23, 1903.

See Fr. Pat. 328,245 of 1903; this J., 1903, 950.—T. F. B.

United States Patent.

Sulphuric anhydride; Process of making [Contact Substance] ——. G. Lunge, Zurich, and G. T. Pollitt, Stanford le Hope, Assignors to Ver. Chem. Fabr. in Mannheim. U.S. Pat. 758,844, May 3, 1904.

The gases derived from roasting pyrites are passed, with air, over burnt pyrites, for which is afterwards substituted "new contact substance containing throughout a greater percentage of arsenic than fresh-burnt ore, formed by mixing the contact substance removed with fresh-burnt pyrites." The use of a contact substance consisting of a "metallic oxide" or of ferric oxide containing "5 per cent. or more of arsenic in all its parts" is also claimed.
—E. S.

French Patents.

Hydrochloric Acid and Sulphuric Acid; Process for the Production and Simultaneous Separation of ——. Consortium fur Elektrochem. Ind. First Addition, dated Dec. 16, 1903, to Fr. Pat. 335,496 of Aug. 24, 1903. See this J., 1904, 252.

Correction of a verbal error in the main patent.—E. S.

[Aluminous] Ores; Utilising Natural —— [for Production of Aluminium Sulphate]. F. Jooss. Fr. Pat. 338,387, March 21, 1903.

Certain more or less complex native aluminium silicates, which may contain calcium and magnesium, &c., but are practically free from iron, are digested with (for instance) sulphuric acid at a temperature above 125°—130° C. in order to dissolve the bases whilst leaving the silica in an insoluble condition. The solution of aluminium sulphate obtained may be purified by known means.—E. S.

Zinc Waste containing Ammonium Chloride; Utilising ——, Enriching such Waste, and Recovering the Ammonium Chloride. J. Celak and L. de Szczytnicki. Fr. Pat. 338,221, Nov. 26, 1903.

The zinc waste, containing, besides impurities, zinc oxide and zinc and ammonium chlorides, is powdered, mixed with milk of lime, and heated in a vessel with a condenser attached. The ammonia expelled is, preferably, conducted into solution of calcium chloride, which solution, when saturated, is treated with carbon dioxide under pressure. The solution of ammonium chloride thus obtained is freed from calcium carbonate, and is concentrated to obtain the crystallised salt. The zinc waste, deprived of ammonium salts as described, and now associated with calcium chloride, is washed free from the latter (which is utilised as stated) and dried for extraction of zinc metallurgically.—E. S.

Alkali Sulphates; Treatment of Native ——. E. Hildt. Fr. Pat. 338,328, Dec. 18, 1903.

The native sodium sulphate usually associated with calcium sulphate is dried, powdered, mixed with coke dust, and heated for some hours to about 800° C. in special inclined steel retorts fitted with travelling screws and various adjuncts, with arrangements for collection of the volatile products. Calcium and sodium sulphides are thus produced, with evolution of carbon dioxide. The double sodium and calcium sulphate similarly heated, but not mixed with carbon, is exposed to the passage of sulphuretted hydrogen, and yields the same fixed products, but with evolution of sulphur vapour and of sulphur dioxide, which are collected. The sodium and calcium sulphides produced by either or both of these processes, treated with water and carbon dioxide under pressure (obtained as described) supplies the hydrogen sulphide which is utilised in the second process; and the sodium bicarbonate obtained as one of the main products of the present process may be transformed into sodium carbonate by known methods.—E. S.

Zinc Sulphide; Chemical Production of ——, and Electro-Chemical Formation of Barium Hydroxide by the Simultaneous Regeneration of the Soluble Salt of Zinc. J. B. and A. Candau, jun. Fr. Pat. 338,322, Dec. 21, 1903.

Solution of barium sulphide is treated with zinc chloride to obtain barium chloride in solution and a precipitate of zinc sulphide. The filtered solution of barium chloride is electrolysed with the use of zinc anodes, to obtain in the anode compartments solution of zinc chloride, and in the cathode compartments, of barium hydroxide. The process is claimed for obtaining "all the metallic sulphides."
—E. S

Chloride of Calcium; Process and Apparatus for Employing —— as a Drying Agent. Comp. des Usines Nouvelle J. Yberty et Cie. Fr. Pat. 338,133, Dec. 28, 1903. I page 600.

VIII.—GLASS, POTTERY, ENAMELS.

Crystalline Glazes and their Application to the Decorati of Pottery. W. Burton. J. Soc. Arts, 1904, **52**, 595-601.

The author regards a glaze as a mixture in which th various silicates present play much the same part as th separate metals in a metallic alloy. With the same ultima composition, however, the particular silicates form depend largely on the temperature and duration of firin The glaze is also capable of acting on the material of t pottery, dissolving certain constituents; in any piece pottery there is an intermediate layer between the glaze a the clay, formed by their interaction. The more strong marked this layer is the less is the glaze liable to the defect known as "crazing" or cracking. If, during the firing, the glaze has become saturated with certain substances, *e.g.*, ferric oxide, either present in the clay or intentionally added to the glaze, these will tend to crystallise out on cooling, giving rise to crystalline glazes resembling the mineral aventurine. By allowing suitably shaped vessels to cool slowly, the natural flow of the glaze tends to arrange the crystals in lines, with their long axes in the direction of the lines of flow, a striated effect being produced. Similar effects are also produced with chromium and uranium oxides, the crystals produced being small hexagonal plates. The crystalline glazes produced on the hard-fired porcelains and stonewares made on the Continent, on the other hand, consist of ordinary felspathic glazes to which frits, consisting of trisilicates of zinc, or of zinc and potassium, have been added. On cooling, some of the silicates formed during the firing at approximately 1350° C., probably silicates of zinc, or of zinc and aluminium, separate out as radiating needle-like or starry groups of different colours. By adding copper oxide to the glaze, white effects are produced; cobalt oxide gives a "Cyanine" blue, and ferric oxide a yellow bronze colour, to the crystals. The author has applied the well-known property of leadless glazes of becoming opalescent or milky to the manufacture, at the comparatively low temperature of 1000° C. to 1030° C., of opalescent glazes of all colours and showing different striations; a certain amount of lead frit is added, as otherwise these glazes tend to bubble and blister in the fire. By combining these opalescent glazes with the crystalline glazes of the Continental type, he has also been able to obtain groups of starry crystals on a finely streaked, opalescent, and coloured background.—A. G. L.

English Patents.

Regenerative Steel Furnaces, Glass and Heating Furnaces, and the like. H. W. Henderson. Eng. Pat. 10,866, May 13, 1903, X., page 609.

Glass; Furnaces for the Manufacture of ——. R. W. Orrock, Hackney Wick. Eng. Pat. 13,110, June 11, 1903.

For finishing the necks of glass bottles and the like, a small fire-clay crucible is fitted to a glass tank furnace in any part where it will get sufficiently hot. One end of the crucible is built into a hole made in the side wall of the furnace or in the flues, and in this end of the crucible two small holes are left, into which is placed the neck of the bottle to be finished. Two separate flues are also constructed, one of which is brought over, and the other under, or one on each side of, an annealing chamber attached to the furnace.
—A. G. L.

Glass-ware; Manufacturing ——. J. I., C. V., F. J., P. R. and F. L. Arbogast, all of Pittsburgh. Eng. Pat. 20,679, Sept. 25, 1903. Under Internat. Conv., Sept. 30, 1902.

See U.S. Pat. 756,558; this J., 1904, 490.—A. G. L.

Earthenware Bodies, Hollow; Process of, and Hydraulic Appliances for, Producing ——. E. D. Delattre, Budel. Eng. Pat. 7766, April 2, 1904.

Earthenware crucibles, retorts, &c., are made by subjectng the clay to a preliminary compression within a suitable ylinder or vessel, whereby air is completely excluded from he cylinder and all fissures in the material are closed, after hich the said material is perforated by a compressor iston whilst still under the maximum pressure to which it as subjected during the preliminary compression. For rticles, such as zinc retorts, which are made from two ifferent superimposed materials, two concentric cylinders re employed, an annular space being provided between the vo cylinders to contain the one material, whilst the other placed inside the inner cylinder. The press for carrying at the process is also claimed.—A. G. L.

Enamelling Metallic Articles [Electro-plating]. W. Kenyon and S. Hobson, Sheffield. Eng. Pat. 14,219, June 27, 1903.

The interior surface of a hollow article is first electroplated with copper or gold, after which the enamel is applied as usual.—A. G. L.

Gilding [Glass, Porcelain, &c.] Surfaces. F. Herrmann, Rheingau. Eng. Pat. 14,910, July 4, 1903.

Coherent and reflecting layers of gold are produced on glass, porcelain and like surfaces by first covering the surface with a dilute alkaline solution of a gold salt containing a feeble organic reducing agent, to deposit an extremely thin and invisible film; and afterwards, by means of a gold solution and a strong reducing agent, depositing the final reflecting layer. A design may be formed by removing parts of the first very thin film of gold deposited, before depositing the second layer. The layer of gold produced as described may be transferred by aid of an adhesive material.
—E. S.

United States Patent.

Glass; Method of Blowing ——. M. J. Owen, Assignor to The Toledo Glass Co., both of Toledo. U.S. Pat. 759,742, May 10, 1904.

A mould is inserted into the molten glass, which is drawn into the mould by suction so as to form a finished portion and a body or blank, which is then blown in a mould to the finished shape whilst still plastic from its initial heat.—A. G. L.

French Patent.

Filter-Press Applicable to Earths and Clays. Mme. Vivien (*née* C. M. L. C. C. Forest). Fr. Pat. 338,176, Aug. 18, 1903.

The wet mass is placed on a fine cloth, metallic or otherwise, which is supported on a metal or wooden grating, and the air is exhausted underneath the cloth. A number of such filters may be combined, in any position, after the manner of a filter-press.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

English Patents.

Refractory Articles; Manufacture of ——. J. Bach, Riga. Eng. Pat. 4478, Feb. 23, 1904.

Pure aluminium hydroxide is mixed with 12 per cent. of quartz or 8 per cent. of fire-clay. The mixture is moulded, pressed, and burnt.—A. G. L.

Cement [for Coal Briquettes, Artificial Stone, &c.]; Process of Making a Binding Agent or ——. L. Weiss, Buda-Pesth. Eng. Pat. 4939, Feb. 29, 1904.

The binding agent, which is to be used for making coal-briquettes, artificial stone, &c., is made by decomposing mixed salts of calcium and magnesium in about equal proportions with sulphuric acid, or using the waste sulphates of calcium and magnesium produced in the carbonic acid industry, separating the solid from the liquid portions by pressing, drying the solid residue, igniting a portion of it at a red heat, grinding the ignited and the unignited portions together, and then mixing the product either with the liquid pressed out from the mixed sulphates, or with water or steam. This cement hardens within a few hours. The mixed sulphates may also be mixed with water and burnt magnesia or burnt dolomite added without any further treatment. Or a very thin solution of the mixed sulphates may be used alone as a binding agent.—A. G. L.

Cement and other Analogous Materials; Preparing and Burning ——. Levie Frères, Cronfestu. Eng. Pat. 7028, Mar. 23, 1904. Under Internat. Conv., March 30, 1903.

An intimate mixture is made of the material to be burnt with an inexpensive fuel, such as inferior coal-dust. The mixture may be directly placed in the kiln after drying, without other fuel if a "running" kiln is used; with an "intermittent" kiln a layer of large coal is first placed on the floor of the kiln.—A. G. L.

United States Patents.

Portland Cement Clinker, &c.; Method of Burning ——. T. A. Edison, Llewellyn Park. U.S. Pat. 759,356, May 10, 1904.

See Eng. Pat. 1404 of 1903; this J., 1903, 555.—T. F. B.

Portland Cement Clinker, &c.; Apparatus for Burning ——. T. A. Edison, Llewellyn Park. U.S. Pat. 759,357, May 10, 1904.

See Eng. Pat. 4735 of 1902; this J., 1903, 367.—T. F. B.

French Patent.

Drying Apparatus [Bricks, &c.] J. W. Aregood. Fr. Pat. 338,203, Nov. 17, 1903.

The bricks are placed on trucks standing on rails inside the drying chambers. These are provided with sliding doors at the back, and hinged doors in front, and communicate by channels in the sole, with a main air channel, constructed so as to decrease in width from the first to the last chamber. Hot air from the brick furnace, mingled with fresh air, is blown into the main air channel, the admission into each drying chamber being regulated by a damper.—L. F. G.

X.—METALLURGY.

Steel and Iron Castings; Influence of Varying Casting Temperatures on the Properties of ——. P. Longmuir. Iron and Steel Inst., May 1904.

Cast-Iron.—Preliminary experiments showed the great influence which casting temperature exercised on the tenacity of cast-iron. Starting with a metal cast at a very high temperature, the tenacity gradually rises as the temperature falls, until a "fair" casting temperature is reached; from this point the tenacity falls with the casting temperature. The influence of casting temperature remains very clearly marked after annealing. The following were some results obtained with iron as cast:—

Iron.	Casting Temperature.	Max. stress in Tons per Sq. In.
	° C.	
White	1,320	10·7
	1,230	15·9
	1,120	12·1
Grey	1,400	9·7
	1,350	14·1
	1,245	10·6

Other specimens of cast-iron of varying compositions gave similar results to the above.

Steel.—Mild steels are not easily overheated in the crucible furnace, and no striking example of excessive casting temperature was obtained, although the influence is quite apparent, and similar to that in the case of cast-iron. Steel poured at "fair" to "low" temperatures showed a decrease of elasticity as the casting temperature decreased, and very large decreases in the elongation and contraction of area. A sample of steel high in sulphur gave results quite comparable with those from a steel of normal composition. No correlation has at present been established between casting temperature and density of iron and steel. The results of a microscopic examination tend to show that the influence of casting temperature is exerted on the crystal junctions, since a "fair" casting temperature favours a stronger type of internal cohesion. (See also this J., 1903, 1089.)—T. F. B.

Pig-Iron; Manufacture of —— from Briquettes at Herräng. H. Louis. Iron and Steel Inst., May 1904.

The Herrang mining property is situated on the Baltic coast of Sweden, about 60 miles north of Stockholm. The ore consists of a somewhat granular magnetite, containing 35 to 40 per cent. of iron as magnetite, 1 to 1·5 per cent. of sulphur, and usually less than 0·005 per cent. of phosphorus. The ore is broken, crushed wet, and the magnetite removed in a magnetic concentrator; it is then stored for a week, and stamped into briquettes of 6 × 6 × 3 ins., and weighing about 10 lb. each, in drop presses. There are two such presses, requiring 3 h.p. each, and turning out 8—12 briquettes per minute. The briquettes are loaded on cars, which hold about 15 cwt. each, and are then burnt in a long horizontal furnace. This process has the result of removing practically all of the sulphur, the finished briquettes containing about 63 per cent. of iron, 0·01 per cent. of sulphur, and 0·002 per cent. of phosphorus. The briquettes are then broken into pieces of a size convenient for the blast furnace, where they are smelted for high-class pig-iron, charcoal being the fuel used. The waste gases from the blast furnace fire the briquetting furnace, and supply gas engines which furnish the blast and also drive dynamos, which furnish the power for the concentrating works and for the mines.—T. F. B.

Iron-Carbon Alloys; Range of Solidification and Critical Ranges of ——. H. C. H. Carpenter and B. F. E Keeling. Iron and Steel Inst., May 1904.

The authors determined the exact melting points of iron and iron-carbon alloys, ranging from pure iron to white iron containing 4·5 per cent. of carbon; and also investigated all the evolutions of heat in the alloys from the beginning of solidification down to 500° C. The results obtained confirm, broadly speaking, those set out in Bakhuis-Roozeboom's paper (this J., 1900, 1016, 1154), but indicate that Roozeboom's diagram (this J., 1900, 1017, Fig. 2) should be modified as follows:—(1) The melting point of iron is about 1,505° C.; (2) A B is a smooth curve, slightly convex upwards; (3) *a* B is not a horizontal line, but rises from *a* to B; (4) S E may be represented quite as well by a straight line as by a curve; (5) P K is not a straight line, but rises from P to K. The authors also state that probably the diagram will be amplified in certain parts when the equilibrium between the various phases has been more fully studied, *viz.*, on account of:—(1) The small evolutions of heat observed at about 796° C. with alloys containing from 0·8 to 4·5 per cent. of carbon; (2) The slow thermal change at about 600° C. found over the whole range of alloys; (3) The evolutions of heat observed at about 900° C. with the alloys containing 3·87 and 4·50 per cent. respectively of carbon.—A. S.

Troostite. H. C. Boynton. Iron and Steel Inst., May 1904.

The view most generally held as to the nature of troostite appears to be that it is an intermediate or transitory form between martensite and pearlite. The author concludes, however, from a micrographic examination of a steel containing 0·51 per cent. of carbon, that troostite is a form of iron, free from carbon, probably β-iron, which separates from the martensite on cooling, and which, during the retardation, is converted into ordinary ferrite or α-iron. The fact that in the slow cooling of over-saturated carbon steel, the author could detect no formation of troostite is in accord with this view. Osmond and Le Chatelier have stated that troostite may be found in an over-saturated steel but in the author's opinion they have mistaken sorbite for troostite.—A. S.

Constituents of Steels; Classification in Chemistry, an its Application to the ——. H. Le Chatelier. Rev Metall., 1904, **1**, 207—225.

The author shows that, apart from chemical compositio the constituents of steels may be regarded from thre quite distinct points of view, and allow of three differe methods of classification:—(1) The homogeneous constituents or phases, corresponding to the minerals containe in rocks; (2) the constituents of aggregation, correspondin to the rocks themselves; and (3) the constituents structure, corresponding to the somewhat vague distinctio sometimes drawn between rocks of amorphous, crystalli and schistose texture.—A. S.

Irons and Mild Steels; Modes of Deformation and of Rupture of ——. F. Osmond and C. Frémont. Rev. Metall., 1904, **1**, 198—206.

The authors discuss the practical conclusions to be deduced from their previous work on this subject (this J., 1903, 1350).
—A. S.

Gold; Melting Point of ——. D. Berthelot. Comptes rend., 1904, **138**, 1153—1156.

By the help of formulæ which he had previously worked out, the author has calculated the values on the absolute scale of temperature of the determinations of the melting point of gold made by himself (1898), Holborn and Day (1900), and Jacquerod and Perrot (1904). They work out respectively to 1065°·6, 1064°·3, and 1067°·4 C. The two later determinations do not differ from the author's figure by so much as the probable error ($\pm$ 2°) which he estimated at the time to attach to his determination.
—J. T. D.

Copper Ores; Smelting of poor —— containing Sulphur, Arsenic, and Antimony by the Bessemer Process, without Fuel. A. Torkar. Oesterr. Z. Berg- u. Hüttenw., 1904, **52**, 175. Chem.-Zeit., 1904, **28**, Rep. 142.

A basic-lined cylindrical furnace is used, into which the ore, mixed with acid flux, is continually fed through a rotating cylinder, in which it undergoes preliminary heating by the waste gases of the furnace. The slag is removed continuously through an overflow pipe, and the enriched ore also overflows continuously into a smelting hearth adjoining the cylindrical converter. Provision is made for a thick covering of slag above the bath, and the wind is brought in underneath this slag over the surface of the bath. The heat generated by the combustion of the ore is then sufficient to keep the process going, even with ores so poor that they will not pay for any preliminary preparation.
—J. T. D.

Tin-Aluminium Alloys. H. Pécheux. Comptes rend., 1904, **138**, 1170—1171.

A filed rod of tin-aluminium alloy, plunged in cold water, gives off for some minutes bubbles of gas, composed of hydrogen and oxygen in explosive proportions. An unfiled od, or a filed rod of either component, is without action, hough the unfiled rod of alloy will act on boiling water. The filed rod of alloy, in faintly acid solution of copper r zinc sulphate, becomes covered with a deposit of copper r zinc, whilst bubbles of oxygen are given off. The author upposes that the metals are truly alloyed only at the urface, and that filing lays bare an almost infinitely umerous series of junctions of the two metals, which, eated by the filing, act as thermo-couples.—J. T. D.

Tin; Assay of ——, and Solubility of Cassiterite. J. H. Collins. XXIII., page 624.

English Patents.

rmour Plates and Projectiles; Manufacture of ——. F. C. Fairholme and J. E. Fletcher, Sheffield. Eng. Pat. 1850, Jan. 26, 1903.

he object of the invention is to produce armour plate and er steel articles having one side or portion very hard, d the other side or portion of a softer or tougher character. Articles made of certain steel alloys, such as those with chromium and tungsten, are strongly heated, cooled rapidly, as by an air-blast, re-heated to a certain lower temperature than before, and cooled more slowly; in this condition they can be readily worked. Then the face or side of the shaped article to be hardened is strongly heated and rapidly cooled, as in the preceding first operation, whilst the other face or side is treated as in the second operation. In some cases the face or portion of the article to be hardened is heated in contact with carbon, boron, tungsten, molybdenum, or vanadium; or with an alloy of chromium, molybdenum, and carbon, followed by the described treatment.—E. S.

Steel; Manufacture of ——. J. Vernon, Newton Stewart. Eng. Pat. 1966, Jan. 27, 1903.

A mixture of ferro-manganese with small proportions of aluminium, broken glass, porous earth, and kelp, is placed in the ladle before the steel is tapped into it, the object being to act on the steel mechanically and chemically, to increase its density, and remove impurities.—E. S.

Regenerative Steel Furnaces, Glass and Heating Furnaces, and the like. H. W. Henderson, Glasgow. Eng. Pat. 10,866, May 13, 1903.

The invention relates to means for the admission and regulation of gas and air to furnaces in such manner as to be capable of alternate reversal. The entering gas passes through a mushroom or similar lift valve (having spindle and counterpoise) into a chamber, the top of which is fitted with two semicircular hinged lids, provided with fire-clay flanges. The chamber has a hinged lower door and a side trap-door for the removal of soot, and the gas passing these traverses one or other of a pair of oppositely inclined flues, into a vertical chamber, having hinged soot-doors, which also act as safety-valves for exit of air, the chamber being provided with a "duplex mushroom valve," covering a port in a lower casing to the main gas flue. Air is admitted through another similar valve, suitably placed in reference to the gas and regenerative chambers. The duplex-shaped mushroom valves may be formed hollow, means for filling them with water or other liquid being described. Dampers are also made hollow and are similarly cooled. The arrangements for the circulation of the gases throughout, and for discharge of the waste gases, after utilising their heat, are described and shown in detail, as well as means to prevent destruction of the gas-valves when the furnaces are not working.—E. S.

Iron and Steel; Manufacture of —— from Chromic Pig Iron or the like. O. Massenez, Wiesbaden. Eng. Pat. 14,361, June 27, 1903.

See Addition, of July 1, 1903, to Fr. Pat. 329,132 of 1903; this J., 1903, 1353.—T. F. B.

Scrap Sheet Steel; Treating ——, and Recarbonising the same. H. B. Atha, East Orange. Eng. Pat. 2187, Jan. 28, 1904.

Scrap sheet steel is prepared for remelting in an open-hearth furnace, by intimately mixing it with finely-divided carbon, and making up the mixture into bundles or sacks; or the carbon is placed in bags, which are compressed into bundles with the steel; or the scrap is treated with the carbon diffused in a liquid, so that the carbon may adhere to the scrap on withdrawing the liquid; or the scrap and carbon are combined in other ways. The mixture of steel scrap and carbon thus formed into bundles or parcels, is heated, with or without additional unprepared steel scrap, to a sufficiently high temperature to occasion absorption of the carbon.—E. S.

Furnaces for Melting Metal. A. H. Oakley, Millbury. Eng. Pat. 14,646, July 1, 1903.

The crucibles containing the metal to be melted are set in covered ovens placed in succession on the same level, and communicating with one another and with a horizontal flue leading to the stack. In a recess in the transverse wall in front of the ovens a combination of open, triangular, superposed iron troughs is placed, communicating by vertical overflow pipes, into which troughs oil, or other liquid fuel, is fed in regulated quantity. The oil is ignited in the troughs, and the flames are carried by the air draught into a mixing chamber, from the top of which additional air is admitted, regulated by a sliding cover, and the heated gases pass downward into the lower part of the first oven, thence into the upper part of the second oven, and downwards from the same into the flue.—E. S.

Zinc and other Sulphides; Extracting —— from their Ores. G. C. Marks, London. From G. D. Delprat, Broken Hill. Eng. Pat. 27,132, Dec. 11, 1903.

Ores of zinc, lead, and silver sulphides, in a finely-divided state, are fed into a bath of solution of sodium chloride, to which a certain small proportion, varying according to the nature of the ore, of dilute sulphuric acid is added. The scum, carrying sulphides, which rises to the surface, is skimmed, or brushed, or arranged to flow off. Compare Eng. Pat. 19,783 of 1903; this J., 1903, 1247.—E. S.

Alloys or Compounds; Metallic ——. A. Jacobsen, Hamburg. Eng. Pat. 27,516, Dec. 15, 1903.

See Fr. Pat. 338,415 of 1903; following these.—T. F. B.

Cupels; Manufacture of ——. The Morgan Crucible Co., Ltd., and J. C. Fox. Eng. Pat. 1695, Jan. 22, 1904. XXIII., page 623.

Heating Substances in Retorts: Apparatus for use in ——. C. W. Stanton. Eng. Pat. 4139, Feb. 18, 1904. I., page 600.

United States Patents.

Iron or Steel; Process of Producing —— direct from Ore. W. M. Brown and D. Reynolds, Albany. U.S. Pat. 759,590, May 10, 1904.

A mixture of granulated iron oxide with granulated carbonaceous matter, is heated, with continuous agitation, by waste products of combustion only, until the ore is reduced and the iron carbonised. A flux is then added, and the mixture is heated "from an initial source of heat," until the iron is fused. The "waste products of combustion" used in the first part of the process are derived from the "initial source of heat."—E. S.

[Precious] Metals; Method of Recovering —— from Solutions. J. Anderson, Prescott, Assignor to M. Scanlan, Whitehills. U.S. Pat. 759,493, May 10, 1904.

Gold and silver are recovered from solutions containing iron or copper by addition of lime, with thorough agitation. —E. S.

Copper Ores; Process of Treating ——. C. H. Rider, St. Louis. U.S. Pat. 759,191, May 3, 1904.

Crushed copper ore and a solvent (which may be composed of water, sodium chloride, and nitric acid) are placed in a series of closed vessels, so connected that the gases liberated may pass from the top of each vessel to the bottom of the next vessel of the series, and the last vessel is connected to the first of a second series of similar connected vessels on a lower level, charged with the clear solution of the ore derived from the former vessels, the copper from such solutions being precipitated, for instance, by metallic iron, the operation being aided by the continuous passage of the gases therethrough, and back, through valved connections, to the first series of vessels. —E. S.

Copper-bearing Ores; Method of Treating —— with Cyanide Solutions. L. E. Porter, Los Angeles, Assignor to J. J. Seeman, Barstow. U.S. Pat. 759,220, May 3, 1904.

The ore is subjected to the action of an alkaline cyanide solution, and in case precious metals are present, these are precipitated by zinc, and separated from the solution, which is then treated with an acid. The copper cyanide thus precipitated is removed, and the solution of hydrocyanic acid is neutralised by an alkaline hydroxide, to produce an alkali cyanide for re-use. The copper cyanide precipitate, mixed with solution of an alkaline hydroxide, is electrolysed to recover an alkaline cyanide solution, with separation of metallic copper.—E. S.

Copper Ores; Reduction of ——. E. P. Clark, New York, Assignor to E. Baltzley, Glen Echo. U.S. Pat. 759,670, May 10, 1904.

The powdered ore is washed with water containing sulphuric acid and ferrous sulphate, to extract the soluble contents. The residue is then "oxidised," after which it is leached as before.—E. S.

Lead-bearing Ores; Process of Treating ——. C. H. Rider, St. Louis. U.S. Pat. 759,192, May 3, 1904.

The apparatus used is identical with that described in U.S. Pat. 759,191 (see preceding abstract but two). "Water and nitric acid" are named as used to act upon the finely-divided lead ore. The precipitating agent specified is sodium bicarbonate; and the gases generated are circulated as in the previous case. White lead is precipitated in the second series of receptacles.—E. S.

Separating Apparatus [for Ores] Magnetic ——. T. A. Edison, Llewellyn Park. U.S. Pat. 759,358, May 10, 1904.

See Eng. Pat. 14,355 of 1900; this J., 1901, 998.—T. F. B.

Metallic Chromium; Method of Making ——. A. K. Eaton, Assignor to H. M. Eaton, New York. U.S. Pat. 759,424, May 10, 1904.

A reducing agent, such as powdered animal charcoal, and a suitable binding substance, are made up into solid cakes with "the chromite of a readily volatilisable base," such as zinc chromite, and the cakes are heated so as to volatilise the zinc or other volatile base and leave metallic chromium.—E. S.

Alloy. S. Kneppel, Scranton. U.S. Pat. 759,617, May 10, 1904.

The alloy is composed of from 5 to 7 parts of aluminium, 1 part of zinc, and 2 parts of "Babbitt" metal; the latter containing 96 parts of tin to 8 parts of antimony and 4 parts of copper, all by weight.—E. S.

Metals; Apparatus for Separating —— from their Crushed Ores or Materials containing same. W. N. Turner, Ipswich. U.S. Pat. 759,775, May 10, 1904.

See Eng. Pat. 12,778 of 1903; this J., 1904, 493.—T. F. B.

French Patents.

Steel and Iron; Manufacture of ——. B. Talbot and P. Gredt. Second Addition, dated Dec. 1, 1903, to Fr. Pat. 324,448 of Sept. 15, 1902. See this J., 1903, 559 and 634.

Pig iron containing too much phosphorus for the Bessemer process, and insufficient phosphorus for the Thomas basic treatment, is not completely removed after each treatment in the converter, but to the phosphatic slag there is added a new portion of the ore to be converted. Thus, the silicon in the cast-iron is, to a certain extent, replaced by phosphorus from the slag, whereby the metal becomes fitted for the Thomas process. The yield of steel is increased by the presence of iron oxide in the slag. (See also U.S. Pat. 747,662 of Dec. 22, 1903; and U.S. Pat. 749,115 of Jan. 5, 1904; this J., 1904, 66 and 119.)—E. S.

Cementation; Processes of ——. C. Lamargese. Fr. Pat. 338,199, Nov. 16, 1903.

Plates or other articles of iron or steel are cemented by heating them in contact with a mixture of carbon produced from the bark of the wild pine tree (or from other resinous substances) and of finely-divided silica. Or, less advantageously, a mixture of ordinary wood charcoal with lamp black and silica may be used.—E. S.

Metals; Obtaining New Combinations of ——. A. Jacobsen. Fr. Pat. 338,415, Dec. 21, 1903.

An alloy is formed by fusing together, in quantities proportional to their atomic weights, copper, aluminium, zin and silicon. The silicon may be replaced by nickel or by silicious earth. To form a bronze, variable proportions of either of the stated combinations is fused with copper and aluminium.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*A.*)—ELECTRO-CHEMISTRY.

Anodes of Tin, Antimony, and Bismuth; Behaviour of ——. K. Elbs and H. Thümmel. Z. Elektrochem., 1904, **10**, 364—367.

Tin, when used as anode in solutions of sodium chloride, sodium sulphate, hydrochloric and sulphuric acids under varying conditions of temperature, concentration, and current density, always enters into solution chiefly as the divalent salt. With antimony, only sodium chloride and hydrochloric acid are suitable electrolytes, and in these cases the metal passes in the trivalent form into solution. Bismuth behaves similarly to antimony and gives trivalent salts.—R. S. H.

Hyposulphites [*Hydrosulphites*]; *Electrochemical Preparation of* ——. K. Elbs and K. Becker. Z. Elecktrochem., 1904, **10**, 361—364.

The authors have attempted to make use of electrolysis for the reduction of bisulphites—

$$2NaHSO_3 + 2H = Na_2S_2O_4 + 2H_2O.$$

Dilute solutions can be prepared with a good yield, but for concentrated solutions the chemical reduction with zinc is preferred. The chief cause of the low yield with more concentrated solutions is ascribed to the formation of thiosulphates, $Na_2S_2O_4 + 2H = Na_2S_2O_3 + H_2O$. The claims of A. R. Frank (Ger. Pat. 125,207; this J., 1902, 51), are said to be incorrect, since neither the calcium nor magnesium salts could be prepared in the solid state by electrolysis as proposed. The electrolytic process for hyposulphites, when applied directly to the indigo vat, is said to be advantageous, since here the hyposulphite, as soon as formed, reduces the indigo, and can be constantly regenerated at the cathode. —R. S. H.

Oxide of Zinc; [*Electrolytic*] *Manufacture of* ——. H. H. Lake, London. From Synd. pour l'Exploitation des Inventions du Prof. Oettli. Eng. Pat. 12,719, June 5, 1903.

See Fr. Pat. 328,491 of 1903; this J., 1903, 1007.—T. F. B.

Electrode Mass; Process for the Production of a Porous, Hard ——, *Insoluble in Alkalis, from Metallic Oxides, or Metallic Powders.* G. A. Wedekind and H. P. R. L. Pörschke, Hamburg. Eng. Pat. 20,313, Sept. 21, 1903.

See Fr. Pat. 337,276 of 1903; following these.—T. F. B.

Generation of Electric Energy; Process of and Apparatus for the ——. H. J. Keyzer, Amsterdam. Eng. Pat. 3913, Feb. 16, 1904.

An iron vessel is provided with several vertical iron partitions, between which porous carbon electrodes are supported. The latter have flanged heads, which abut against each other and are insulated from the iron portion of the apparatus. Openings in the lower parts of the iron partitions allow of the circulation of the electrolyte, the latter consisting of a saturated solution of potassium or sodium hydroxide or carbonate, preferably mixed with about 1 per cent. of a metallic salt, such as ferrous or ferric chloride. The cell is closed by a lead ring, cast round the heads of the carbon electrodes, and an insulated hood-like cover, the ring and outer iron vessel being connected to binding screws for the transmission of the current. In the middle of the covering hood is an admission pipe for Dowson gas, or other suitable gas containing hydrocarbons, mixed with about 95 per cent. of air or oxygen, and admitted sufficiently hot to boil the electrolyte. The gas passes down vertical channels in the carbon electrodes, permeates the pores, and meets there the electrolyte, which enters from the outer surface of the carbon. The resulting oxidation of the hydrocarbons generates electric energy, and the products of the oxidation, principally steam, are again introduced, after condensation, into the electrolyte.—B. N.

United States Patents.

Accumulating and Using Electrical Energy; Method of ——. A. G. Betts, Troy. U.S. Pat. 759,065, May 3, 1904.

Lead peroxide and lead are deposited respectively on the two electrodes from an electrolyte consisting of a solution of a readily soluble lead salt of a non-oxidising and non-oxidisable acid, such as lead fluosilicate, electrical energy being subsequently generated by redissolving the active materials in the electrolyte. The electrodes are of insoluble material, one or both of which may be of graphite or artificial graphite. The charging current may be passed at certain times in one direction, and at other times in the opposite direction, and air or oxygen is introduced into the electrolyte from time to time.—B. N.

Battery; Electric Storage ——. A. G. Betts, Troy. U.S. Pat. 759,066, May 3, 1904.

The electrolyte consists of a solution of lead fluosilicate with or without copper fluosilicate, and the electrodes are of graphite with numerous small surfaces arranged at angles one to another, or with laterally-extending surfaces arranged to catch and hold any detached active material. A conductive receptacle may also be arranged for this purpose, and the receptacle maintained in circuit during the discharge of the battery; or the electrode may comprise a plate of insoluble conductive material between plates of insulating material, each plate having apertures corresponding in location but smaller in the insulating plates, so as to form pockets for the purpose of retaining the active material. Air is introduced into the electrolyte near the bottom of the cell.—B. N.

Battery. J. Noble and E. L. Anderson, St. Louis. U.S. Pat. 759,740, May 10, 1904.

The battery consists of a carbon cathode, a non-decomposable or aluminium anode, an electrolyte evolving nitrogen peroxide, such as nitric acid, and a condenser containing coke or similar material to receive the gases evolved in the cell. Means may be provided for heating the battery. —A. G. L.

Gases; [*Electrical*] *Apparatus for the Treatment of* ——. H. Pauling, Gelsenkirchen. U.S. Pat. 758,775, May 3, 1904.

A hollow rotating shaft, forming one of the electrodes, projects into a funnel-shaped electrode, which communicates at one end with a means for sucking air through the funnel, the other end of the latter being closed by a lid which embraces the shaft. The portion of the shaft enclosed in the funnel is covered with insulating material, and a tubular projection is attached at right angles to one end of the shaft and passes through to the outer surface of the insulating material.—B. N.

Gaseous Media from Air; [*Electrical*] *Method of Generating* ——. J. N. Alsop, Owensboro. U.S. Pat. 758,883, May 3, 1904.

The invention relates to a method of generating gases from air, by continuously and alternately bringing into contact and separating two electrodes connected with a source of electricity. The electrodes are worked in two sets, the arc in one set being short-circuited at predetermined intervals by the contact of the electrodes of the second set. Simultaneously with the separation of the electrodes, the potential of the current is automatically increased, and each is short-circuited while at its maximum density and before the same is appreciably diminished.—B. N.

Gaseous Mediums from Air; [Electrical] Apparatus for Generating ——. J. N. Alsop, Owensboro. U.S. Pat. 758,884, May 3, 1904.

On a frame is mounted a "walking-beam," to each end of which is attached a "pitman" carrying one or more vertical electrodes, and so arranged that the movement of the beam gives a reciprocating motion to the electrodes. The electrodes in each set are connected in series, and the two sets in parallel, so that the contact of one set of electrodes with the lower stationary electrodes short-circuits the other set. Each movable electrode is capable of automatic adjustment, the electrodes being attached by a piston rod to a piston, and the latter is surrounded by a movable cylinder attached to the "pitman." Oil passes from the under to the upper side of the piston and thus permits the piston to settle in the cylinder for the purpose of making contact as the carbon is consumed. A self-induction coil is interposed in the circuit of the electrodes, and each pair of electrodes is surrounded by a casing provided with an air inlet, the casings being connected to a conduit leading to an air pump for withdrawing the gases.—B. N.

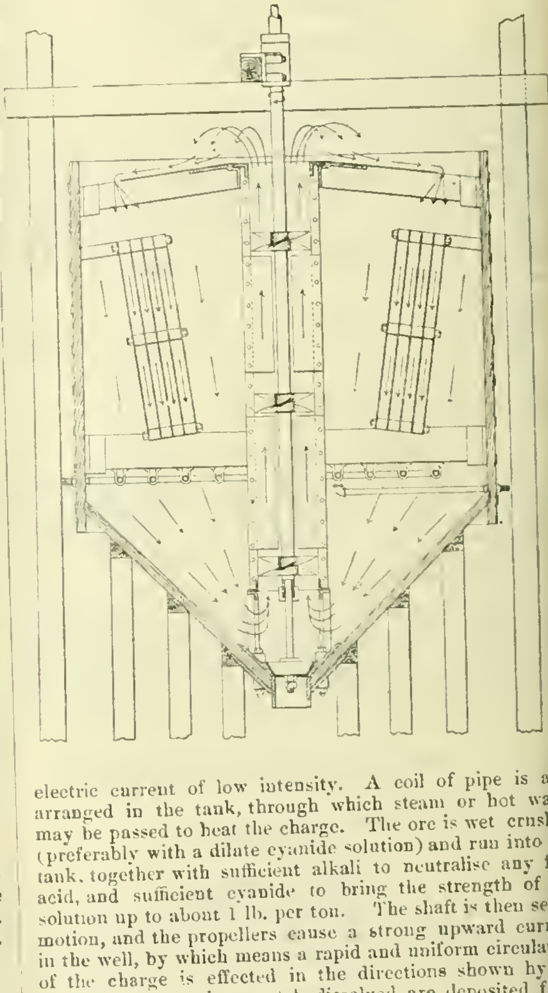
(*B.*)—ELECTRO-METALLURGY.

Hendryx Cyanide Process; The ——. C. M. Fassett. Eng. and Mining J., 1904, **77**, 723—724.

The apparatus (see figure) in which the extraction and deposition of the gold and silver are carried on in one operation, consists of a cylindrical tank having a conical bottom. A circular well or tube extends through the centre of the tank nearly from top to bottom, and is supported by braces from the side of the tank. At the top the well is connected to a circular apron, which is inclined slightly downwards towards the side of the tank. A hollow shaft, provided with a driving pulley at the top and carrying the screw propellers, passes through the centre of the well. The stem of the discharge valve at the bottom of the tank extends through the hollow shaft, and is operated by a hand-wheel located above the driving pulley. Outside the well, and between the apron and the bottom of the tank, anode and cathode plates are arranged, being supported from the side of the tank and connected to a source of electric current of low intensity. A coil of pipe is als arranged in the tank, through which steam or hot wate may be passed to heat the charge. The ore is wet crushe (preferably with a dilute cyanide solution) and run into th tank, together with sufficient alkali to neutralise any fre acid, and sufficient cyanide to bring the strength of th solution up to about 1 lb. per ton. The shaft is then set i motion, and the propellers cause a strong upward curre in the well, by which means a rapid and uniform circulatio of the charge is effected in the directions shown by t arrows. The precious metals dissolved are deposited fro the solution on the cathodes. It is claimed that the extra tion of gold and silver can be made in much less time a at a much smaller cost than by the usual methods, a that the process is perfectly adapted to the treatment tailings and slimes.—A. S.



Gold; Solubility of —— in certain Oxidising Agen V. Lenher. J. Amer. Chem. Soc., 1904, **26**, 550—55

Gold is readily attacked in many reactions in which oxyg is formed, particularly on the application of heat. Thus goes into solution when heated with sulphuric acid (phosphoric acid) and nitric acid, telluric acid, the hig oxides of lead, manganese, and chromium, or nickelic oxi Gaseous oxygen and acid are without action. An oxygen will attack gold in presence of strong sulphu acid. Operating with a current of 0·3—0·4 ampère resistance of 5 volts, an anode of sheet gold, and a platin crucible as cathode, it was found that when the acid hot, the gold was readily dissolved and then deposited the cathode. Using phosphoric acid or dilute sulph acid, no solution took place, an incrustation of gold o being left on the anode. This is also the case when solutions of neutral salts, *e.g.*, nitrates and sulphates of potassium and sodium, are electrolysed. With caustic alkalis a little gold passes into the solution, perhaps owing to the formation of an aurate.—E. H. T.

United States Patents.

Electrolytic Apparatus. H. S. Blackmore. Mount Vernon, N.Y. U.S. Pat. 759,798, May 10, 1904.

The layer of liquid-metal forming the cathode in the electrolytic cell communicates with a feeding chamber containing the metal, the height of the column in the chamber being balanced by the weight of the cathode and superposed electrolyte in the electrolytic cell. The height of the column in the chamber controls, by means of a float, the supply of metal from a reservoir, and a saturator maintains the electrolyte at uniform density. An outlet, near the surface of the cathode, carries the alloy from the electrolytic cell to a reservoir, in which the metal is covered by an independent body of electrolyte communicating with the electrolyte in the electrolytic cell, and then to an oxidising vessel, thus preventing any possibility of short-circuiting between the cathode and the alloy in the oxidising vessel. The alloy passes by a tortuous passage through the oxidising vessel, the latter being provided with an outlet for the alloying metal, the outlet having a float-valve controlled by the height of the oxidising liquid. The height of the latter is maintained uniform by an inlet and outlet, for the oxidising liquid and oxidised product, adjacent to but above the outlet and inlet for the alloying metal and alloy respectively.—B. N.

Electrolytic Apparatus. H. S. Blackmore. Mount Vernon, N.Y. U.S. Pat. 759,799, May 10, 1904.

Light-metal compounds are electrolysed in a containing vessel divided into two compartments by a tube-like partition, provided at its open lower end with a diaphragm of loose granular material. In the inner compartment is the anode and electrolyte, and in the other is a molten or liquid-metal cathode, supporting and in contact with the diaphragm, but the upper surface of the cathode is above its surface of contact with the diaphragm. Means are provided for removing the light metal from the alloy or amalgam as it rises to the upper surfaces of the cathode, the depleted portion of the cathode returning into contact with the diaphragm. An oxidising agent is injected beneath the surface of the alloy, and a layer of granular material, electronegative in relation to the oxidisable metal, and in contact with the alloy, serves to distribute the reagent, an oxidising electrolyte being maintained in contact with the granular material and the alloy. In extracting an alkali metal from the liquid alloy, sodium hydroxide is injected; the resulting product is removed, treated with water, and again returned into contact with the alloy.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Olives; Preservation of —— *before Expression.* H. Mastbaum. Chem. Rev. Fett- u. Harz-Ind., 1904, **11**, 39—42, 64—69, 89—91.

The total proportion of oil in olives dried in the air diminishes, at first slowly, and then more rapidly, so that after five months it is only about two-thirds of the original quantity. The acidity of the oil shows a steady increase. The diminution of oil is considered as possibly due to a species of "intercellular respiration" but "chemical reaction may also play a part." Olives kept in running water are well preserved, but the quality of the oil is inferior, the acidity increasing by about 1 per cent. for each month. The result of keeping the olives in brine or in a vessel from which air is excluded is shown by the following experimental results:—

Method of Keeping.	Water.	Oil.	Oil in dry Substance.	Acidity of Oil.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
In brine	60·34	16·81	42·38	4·03
Air excluded, no salt used	53·51	19·61	42·19	5·81
Air excluded, salt used	53·09	20·12	42·90	5·21

The odour and flavour of the oil obtained from olives preserved by the two latter processes were superior to those of oil from olives kept in brine.—C. A. M.

Melon-Seed Oil. G. Fendler. Z. Unters. Nahr. u. Genussm., 1903, 1025.

The kernels of Togo melon seeds contain 5·8 per cent. of water and 43·8 per cent. of a yellow, almost tasteless oil which has the following characters:—M. pt., 5·5° C.; congealing pt., 5° C.; m. pt. of fatty acids, 39° C.; congealing pt. of fatty acids, 36° C.; acid value, 4·81; saponification value, 193·3; iodine value, 101·5. It appears to be suitable for dietetic use.—J. O. B.

Acrocomia Vinifera [*Nicaraguan Coyol Palm*]; *Fatty Oil of Seeds of* ——. G. Fendler. Z. Unters. Nahr. u. Genussm., 1903, 1025.

The kernels of the seeds yield 6·55 per cent. of water and 48·66 per cent. of a yellow pleasant-tasting oil. At about 15° C. the oil separates in feathery crystals and ultimately becomes solid. It has the following characters:—Sp. gr. at 25° C., 0·9136; m. pt., 25° C.; congealing pt., 17° C.; acid value, 1·69; saponification value, 246·2; iodine value, 25·2; Reichert-Meissl value, 5·0. The portion which first crystallises out has the m. pt. 34° C., when recrystallised from alcohol. The liberated fatty acids melt at about 54° C. and probably contain myristic acid.

—J. O. B.

Aleurites Moluccana; Fatty Oil from the Seeds of ——. G. Fendler. Z. Unters. Nahr. u. Genussm., 1903, 1025.

The kernels of the seeds of *Aleurites moluccana* from the Cameroons, contain 3·65 per cent. of water and 64·4 per cent. of fat; the residue free from fat contains 60·62 per cent. of albuminoids. The oil obtained by extraction with ether is strong-smelling, acrid, and yellow; it is sparingly soluble in alcohol. It dries quickly in a thin layer, and should be useful as a drying oil for varnishes. It has the following characters:—Sp. gr. at 15° C., 0·9254; congealing pt., – 15° C.; m. pt. of fatty acids, 18° C.; congealing pt. of fatty acids, 15·5° C.; acid value, 0·97; saponification value, 194·8; iodine value, 114·2; Reichert-Meissl value, 1·2.—J. O. B.

Rhus Glabra; Fixed Oil of the Seeds of ——. G. B. Frankforter and A. W. Martin. Amer. J. Pharm., **76**, 151. Pharm. J., 1904, **72**, 681.

The seeds free from husks yielded on extraction with ether, 9·1 per cent. of a light-yellow oil of pleasant taste and peculiar odour. Sp. gr., 0·9203 at 20° C, and 0·9312 at 0° C.; *n* = 1·48228 at 15° C. and 1·48821 at 0° C.; saponification value, " 190—200 "; and iodine value, 85·96 —87·86. The oil contains about 0·696 per cent. of an unsaponifiable alcohol, probably a cholesterol. The husks of the seeds after being freed from tannin and calcium acid malate by treatment with water, yielded, on extraction with ether, 8·5 per cent. of a black semi-solid oil, of sp. gr. 0·933 at 35° C. and 0·9412 at 20° C.; iodine value, 87·2; and saponification value, 179·7. From this oil, by treatment with acetone, 80 per cent. of a yellow oil was separated, a black semi-solid oily residue being left.

—A. S.

Fats; Enzymic Action of Plant Seeds on ——. S. Fokin. Chem. Rev. Fett- u. Harz-Ind., 1904, **11**, 48—49, 69—71.

Of the seeds of 60 plants belonging to 30 families examined, more than half effected the hydrolysis of 10 to 16 per cent. of fat, but this hydrolysis was not produced by the same seeds when old and was therefore not attributed by the author to the presence of an enzyme. When seeds contain an enzyme there is a quantitative relationship between the yield of fatty acids and the amount of seed employed. Thus in the case of castor seeds the yield of fatty acids liberated increases with the proportion of seed used, but in the case, *e.g*, of fresh *Cynoglossum* seeds, the amount of fatty acids liberated from an oil remained the same (30 per cent.), whether the seeds were used in the proportion of 24 or 100 per cent. Of all the plants examined only two answered this requirement of an enzyme, *viz.*, celandine (*chelidonium majus*) and *linaria*. Compared with the seeds of the castor oil plant and celandine, the seeds of *linaria vulgaris* contain but little enzyme, 20 to 30 parts only having the same lipolytic action as 4 to 5 parts of castor seeds. A yield of 90 per cent. of fatty acids was obtained from sunflower oil by the action of 46·7 per cent. of crushed linaria seeds with dilute acetic acid. The author suggests that lipolytic activity may be invariably accompanied by the presence of an alkaloid.

Characteristics of Vegetable Oils Examined.—The following results were obtained :—

Oil from Seeds of	Yield of Oil.	Sp. Gr. at 20° C.	Iodine Value.	Saponification Value.	Fatty Acids.			
					Solidification Point.	Sp. Gr. at 20° C.	Iodine Value.	Acid Value.
	Per Cent.				° C.			
Xantium "strumarium" (in husks)	14·2	..	142·0	..	9—10	..	..	193·8
" " "	..	0·912	132·2	185·4	..	..	..	..
Xantium strumarium (decorticated)	28·0	..	..	..	..	..	147·9	..
Tilia parvifolia (decorticated)	26·6	0·925	125·9	184·8	9—18 [m. pt. 17—26].	..	136·3	197·0
Delphinium elatum	36·6	0·921	..	..	..	0·8915	108·2	191·8
Evonymus verrucosus	43·64	0·959	..	..	22—23	0·912	110·6	198·5
Galeopsis ladanum	40·4	0·927	..	..	..	..	147·0	..
Leonurus cardiaca	23·0	0·923	..	..	..	..	133·7	..

All six oils contained linolic acid, whilst linolenic acid was detected in the oil of *Galeopsis ladanum*. The author concludes that the presence of a lipolytic enzyme is not the characteristic property of any particular families of plants. (See also this J., 1904, 259.)—C. A .M.

Castor Seeds; Hydrolysing Power of ——. M. Nicloux. Comptes rend., 1904, **138**, 1175—1177.

The author finds that the substance possessed of lipolytic properties contained in castor seeds is the "cytoplasma" (Comptes rend., 1904, **138**, 1112), to the exclusion of all other parts of the seed. Whether the cytoplasma is endowed with specific properties, or whether it secretes a soluble ferment, is a matter for further investigation.—A. S.

Ethyl Butyrate; Hydrolysis of —— by Lipase. J. H. Castle, M. E. Johnston, and E. Elvove. XXIV., page 628.

English Patent.

Fat and other Substances; Apparatus for Extracting —— by Means of Vapours or Volatile Solvents. O. Schneider, Nürnberg. Eng. Pat. 8897, April 20, 1903.

This apparatus, specially intended for the continuous extraction of bones, &c., comprises an extractor and a connected distillation vessel. The cylindrical extractor consists of an outer shell and an inner perforated compartment for the material. It has a perforated false bottom beneath the inner chamber, whilst a compartment below the false bottom (with which it communicates by means of a protected opening) contains a heating arrangement. The vaporised solvent enters the extractor through a pipe from the top of the distillation vessel, and passes through the material, and the condensed liquid runs back into the distillation vessel through another pipe below the false bottom.—C. A. M.

French Patents.

Press; New Form of —— [for Olive and Seed Oils]. Lèbre Frères. Fr. Pat. 338,066. Dec. 24, 1903.

The apparatus consists of a circular bed with channels and exit tube for the escape of the oil and an upper arm fixed, *e.g.*, to a wall. A central screw rod is fixed in the lower bed, whilst the corresponding upper part of the screw rod is fixed, pointing downwards, in the upper horizontal arm, a small space being left between the points of the two. The plates of the press are perforated in the centre to allow of their being passed over the lower screw rod, and have ledges round their circumference to retain the expressed material, whilst the top plate and a collar are carried by the upper screw rod, and can be brought down by means of a lever.

—C. A. M.

Fat; Apparatus for Extracting —— by Means of Carbon Tetrachloride. P. Bernard. Fr. Pat. 338,354, Dec. 24 1903.

The dried crushed material is fed into a cylindrical steam-jacketed extractor where it meets an ascending column o carbon tetrachloride. The solvent charged with fat passe into adjoining vessels where it is evaporated, condensed and stored in a tank until again put into circulation. Th extracted oil is passed through a filter below the evaporatio vessel.—C. A. M.

Oils; Apparatus for Washing —— by Decantation. V. Coq. Fr. Pat. 338,356, Dec. 22, 1903.

The mixture of oil and aqueous impurities obtained, e.g in the expression of olives, is introduced into a vess surrounded by a concentric chamber containing water. Th oil falls from a tap in the bottom, and meets a fine spra of water from the outer chamber, and both fall into vessel below, where they are separated by decantation. Th outlet for the separated oil is controlled by a float of suc density that it floats in a mixture of oil and water, bu sinks in pure oil.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

United States Patents.

Pigment, and Method of Producing it from Ferrous Liquors. A. S. Ramage, Cleveland. U.S. Pat. 758,687, May 3, 1904.

Air is blown through concentrated ferrous sulphate liquor, and the solution is neutralised, basic ferric sulphate being precipitated; the solution is now diluted, and air is again injected, and the solution neutralised, precipitating basic ferric hydroxide. These precipitates, when mixed together, dried, and calcined, form a golden-yellow pigment.—T. F. B.

Lead-Bearing Ores; Process of Treating ——. C. H. Rider. U.S. Pat. 759,192, May 3, 1904. X., page 610.

English Patent.

Varnish Substitute; Manufacture of an Improved —— from Rosin Oil. R. Blume, Magdeburg. Eng. Pat. 14,987, July 6, 1903.

See Fr. Pat. 333,602 of 1903; this J., 1903, 1358.—T. F. B.

(*C.*)—INDIA-RUBBER, &c.

French Patent.

India Rubber; Regeneration of ——. M. Pontio. Fr. Pat. 338,018, Oct. 16, 1903.

The rubber is digested with a suitable solvent, the insoluble constituents are separated by filtration or in a centrifugal machine, and the solution is evaporated under reduced pressure. The residue is treated with acetone, boiled, the acetone decanted, and alcoholic soda added. After boiling and decanting, the rubber is treated a second time with boiling alcohol, decanted again and boiled with water, finally, it is treated with superheated steam to remove the last traces of alcohol and water.—J. K. B.

XIV.—TANNING; LEATHER, GLUE, SIZE.

United States Patent.

Chrome Tanning Bath. C. A. O. Rosell, New York. U.S. Pat. 759,831, May 10, 1904.

The tanning liquor contains an inorganic reducing sulphur salt of chromium and consists essentially of chromium thiosulphate and chromium sulphite, or of chrome alum, a thiosulphate and a sulphite.—R. L. J.

French Patents.

Tanning Materials; Apparatus for the Cold Extraction of ——. A. Lautard. Fr. Pat. 338,360, Dec. 23, 1903.

A series of extractors, made of heavy glass, are connected with a powerful exhaust pump. Large movable lids are placed on rubber seatings, and close automatically under he external pressure. The liquors are sucked from one vessel to the next, and ammonia vapour is introduced as a lecolorising agent. Mechanical details are given.
—R. L. J.

Cork-Leather; Manufacture of ——. L. Couher. Fr. Pat. 338,205, Nov. 17, 1903.

A suitable textile fabric is coated, on one or both sides, vith gelatin mixed with more or less glycerin according to he degree of suppleness required, and containing formaldeyde (1—5 per cent.) or chromic acid (1—3 per cent.). ork-dust is sprinkled on the sticky surface or surfaces and he whole compressed till solid between heated metal plates. urther coats of cement and cork may be superimposed to ive required thickness. Alternatively, a solid block of ork-dust with glycerin-gelatin cement is prepared and liced into sheets.—R. L. J.

Leather, Artificial; Manufacture of ——. G. Gautier. Addition, dated Dec. 19, 1903, to Fr. Pat. 310,726 of May 11, 1901. See this J., 1902, 1405.

Animal fibres (raw leather, parchment, &c.) or vegetable fibres are combined with "Volta" leather (prepared by the process described in the main patent) by warming the surfaces to be united and treating them with a special animal glue, then submitting the block to pressure.
—J. K. B.

XV.—MANURES, Etc.

Phosphate, Wolter. P. Wagner. Bied. Centr., 1904, **33**, 301—302; from Illust. landw. Zeit., 1903, 959.

Wolter phosphate is prepared by fusing a mixture of crushed phosphorite (100 parts), sodium bisulphate (70 parts), calcium carbonate (20 parts), sand (22 parts), and coal (6—7 parts). The melt is granulated by being poured into cold water, and the dried substance is then finely ground. As regards the solubility of the phosphate, it was found that when 2·5 grms. of the substance are agitated with 1 litre of 0·5 per cent. citric acid solution for 10 minutes, 97 per cent. of the phosphoric acid is dissolved. Under the same conditions only 80 per cent. of the phosphoric acid of basic slag dissolved in the citric acid solution. The author considers that the phosphoric acid of Wolter phosphate is hardly slower in its action than the water-soluble phosphoric acid in superphosphate; and the results of vegetation experiments showed that the effect of two samples of the phosphate was 72 and 94 respectively, as compared with superphosphate = 100. The new phosphate is stored without difficulty and is not hygroscopic.
—N. H. J. M.

Phosphoric Acid of Tricalcium Phosphate; Action of Sterile Organic Substances and those occurring in Fermentations on the Solubility of ——. A. Stalström. Centr.-Bl. Bakter u. Parasitenk., **11**, 724—732; Chem. Centr., 1904, **1**, 1323.

The results obtained by the author confirm the view that organic substances are capable of exerting a solvent action on minerals, and that this power depends upon biological activity. The kind of fermentation set up depends upon the nature of the organic substances: with peat, peat litter, dung, or "bouillon," an ammonia and carbon dioxide fermentation is caused; with milk, sour milk, and milk-sugar a lactic fermentation; and with peat together with milk-sugar a butyric fermentation. In the case of the ammonia and carbon dioxide fermentation, the solvent action on tricalcium phosphate is very small, but it is quite distinct in the case of the lactic and butyric fermentations. Sterile organic substances have no solvent action on tricalcium phosphate.—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Experiment Station Laboratory, Louisiana; Results of Investigations at the ——. C. A. Browne, jun. The Louisiana Planter and Sugar Manufacturer, Jan. 14, 1904, 47—51.

Among the non-sugar constituents of the cane are the insoluble carbohydrates which make up the fibre of the cane and constitute a complex including cellulose, lignin, and hemicellulose. To the latter group belong the so-called gums of the cane. The cane gums are mixed pentosans which make up about one-fourth of the weight of the dried fibre and contain both *xylan* and *araban*. By inversion with acids about four parts of xylose were obtained to one of arabinose. *Galactan* is only found in small quantities. The percentage of gums in the cane-juice is usually not more than 0·2 per cent. Foreign canes often show more, as also do the juice from old canes or those which have remained a long time in the "windrows." The hemicelluloses of sound cane while comparatively insoluble in cold water are appreciably dissolved if heat be applied. Of the enzymes or natural ferments of the cane the presence of invertase in the green parts of the stalk has an important bearing on the "windrowing" of the cane, since the rapid deterioration of the cane when "windrowed" with the tops on is accounted for by the invertase there present. The very rapid coloration which takes place when the green top of the cane is cut through near the apex and exposed to the air is caused by *oxidase*. This coloration is also produced, but less rapidly, in the ripe portions of the stalk. The discoloration which occurs when cane is injured by the borer may result from the oxidising action of this ferment, since Dodson has shown that sterilised canes do not develop this colour. The darkening of cane-juice after milling is produced in the same way, but is soon arrested by sulphuring. The destruction of the enzymes by heat before milling is hardly practicable in actual work. The presence of both oxidase and reductase in the cane finds a parallel in the pepsin and anti-pepsin in the stomach. The author is inclined to believe that the oxidising ferments have the function of protecting the plant, when injured, from infection by moulds, bacteria, &c., through the formation of germicidal products, the deleterious effects of these upon the plant itself being prevented by the action of the reducing enzymes. Analysis of the juice from the green tops of the cane shows that there is nearly twice as much sucrose late in the evening as in the early morning, assimulation being suspended during the night, whereas the process of inversion by the invertase still goes on. Towards the bottom of the stalk the sucrose is re-formed. At very early stages of growth the juice shows a minus reading due to the preponderance of invert sugar; somewhat later the juice becomes inactive, although about 1 per cent. of sucrose is present. Then the rotation becomes positive until, as the cane matures, the polariscopic reading and true percentage of sucrose coincide, when the polarising power of dextrose and levulose neutralise one another. If circumstances are favourable for complete ripening, which is not usual in Louisiana, the levulose will almost completely disappear, when the polariscopic reading will slightly exceed the content of sucrose, owing to the predominating rotatory power of the dextrose. Probably no fermentation product gives the sugar-maker so much trouble as the gum dextran. A small amount of this substance renders cane-juice exceedingly viscid, so that successful clarification and boiling become almost impossible. The high polarising power of the gum, three times that of sucrose, also introduces an error into the analytical work unless the dextran is first precipitated with alcohol before polarising.—L. J. de W.

Diffusion Juice; Cold Liming of ——. Aulard. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1057—1062.

Prangey and de Grobert state that the proportion of lime being reduced to the minimum necessary to secure good filtration, the purification of the juice is better in proportion as the time of contact is shortened, provided that the temperature is sufficiently raised. This is in direct contradiction to the method favoured by the author, who claims that he obtains juice of a higher purity and a minimum of molasses by liming cold and maintaining the contact for at least an hour. Sellier is of opinion that limed juice should not be heated beyond 80° C. to avoid risk of redissolving part of the precipitated albumin.—L. J. de W.

Water; Rate of Diffusion of —— through a Semi-permeable Membrane [Molecular Weight of Dextrin]. J. Šebor. XXIV., page 628.

French Patents.

Sugar; Extraction of —— from Plants. G. Tauer. Fr. Pat. 338,039, July 31, 1903.

Beetroots and sugar cane are protected from the action of the air, during the process of their reduction by chopping, rasping or crushing, by submerging the working level of the reducing machinery below the surface of a circulating mass of crude juice, heated to a temperature between 45° and 97° C. (preferably 85° C.). The reduced matter, as it falls into the heating juice, is conveyed to an immersed screen, whence it is elevated and transported to the diffusers or presses.—J. F. B.

Massecuites [Sugar]; Process and Apparatus for Boiling ——, with Circulation. H. Roy. Fr. Pat. 337,227, Dec. 1, 1903.

A vacuum pan of the usual shape is provided with a circulating system in such a manner that syrup can be withdrawn from near the surface of the boiling mass by means of a pipe adjustable to a suitable height; the syrup is then mixed with fresh feed-syrup and passed, by means of a centrifugal pump, through a re-heater and back into the vacuum pan at the bottom, where it is mixed with the coarse granulated mass by means of a stirring apparatus. In this way the pan can be fed with syrups at a higher degree of concentration than usual, since the re-heater prevents the formation of fine grain.—J. F. B.

Sugar and Saccharine Products; Denaturing ——. C. Dutordoir. Fr. Pat. 338,294, Dec. 9, 1903.

The denaturing of sugar for fiscal purposes is effected by the addition to 100 parts of sugar of sodium chloride, 4—8 parts, powdered oil cake [*e.g.* linseed] 2 parts and yellow ochre 0·25 part. The product, whilst still suitable for cattle food, cannot be purified for human consumption.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Amylase; Action of Heat and Acidity on ——. P. Petit. Comptes rend., 1904, **138**, 1231—1233.

An infusion of malt in water made faintly alkaline by sodium carbonate gives a filtrate, the diastatic activity of which may be increased by the addition of minute quantities of lactic acid. If the acid be added gradually a turbidity appears when the acidity reaches a certain point and increases with increase of acid but re-dissolves when a certain excess of acid has been added. If this precipitate be collected, washed with acidulated water and dried *in vacuo* it turns brown and dissolves, but only partially, in dilute alkali or acid. The solutions of this substance liquefy and saccharify starch paste. If the substance be dissolved in N/50 sodium carbonate solution in presence of phenolphthalein the alkaline reaction disappears and additions of more soda have to be made repeatedly as the substance dissolves. It would appear that the alkali displaces the amylase fro an insoluble combination with lactic acid. If an infusio of malt faintly acid, be neutralised exactly with sodiu carbonate and if increasing quantities of lactic acid b added to portions of it and these be heated for 10 minute at the temperature of the boiling water-bath, a decreas of the acidity takes place, due to the heating, whic increases the higher the proportion of acid initially adde The change in acidity takes place according to a consta law expressed by the equation $y = 0{\cdot}4 - 0{\cdot}337x$, whe x = the initial acidity, and y = the change in acidity. progressive formation of a turbidity and finally a coagulatio take place parallel with this decrease in acidity. The coag ations produced in aqueous infusions of malt on heating a due to the excess of acidity of the infusions, and if t acidity be reduced by successive additions of sodium ca bonate no coagulation or turbidity is produced on heating. —J. F. B.

Starch; Coagulation of ——. A. Fernbach and J. Wol J. Fed. Inst. Brewing, 1904, **10**, 216—237.

The authors communicate certain observations in additi to those previously recorded (this J., 1903, 1302; and 19 124), relative to the enzyme *amylo-coagulase*. The pe liarities of all these reactions may be traced to the f that two antagonistic enzymes, coagulase and diastase, t part simultaneously, and if the diastase be allowed predominate no coagulation may occur. Conditions wh favour the diastase are elevated temperatures and dil starch solutions, but if these be allowed for, it may stated that the first signs of coagulation appear earlier greater the quantity of malt extract employed. Coag tion is easier the lower the temperature at which the st has been rendered soluble and the shorter the dura of the process of heating under pressure. If the coag tion has proceeded rapidly, it first appears as a turbi which subsequently forms clots like those of curdled

If coagulation has been very slow a powdery white precipitate is deposited. With a 2 per cent. solution of starch, coagulation may take place at 8° C., but not at 22° C., but with a 4 per cent. solution coagulations are readily produced at 15°—25° C., the lower temperatures are, however, always more favourable. Like diastase, the amylo-coagulase is very sensitive to the influence of traces of free acids and alkalis, but it is less sensitive than diastase to caustic soda, and the addition of 80 mgrms. per litre of that alkali to the solutions acts as a restrainer of the diastase and consequently assists the coagulation. By this means, for instance, the proportion of starch coaguluted, was raised from 14·4 per cent. without caustic soda to 24·1 per cent. with caustic soda, at 15° C. Owing to diastatic activity, it frequently happens that increased proportions of malt infusion cause a decrease in the quantity of starch coagulated. The coagulated substance dissolves readily in boiling water and separates again partially on cooling. A portion of the coagulated matter consists of amylo-cellulose and resists hydrolysis by malt extract at 67° C. Although the activity of the coagulase in solution is destroyed by heating at 63° C. for 5 minutes, it resists the action of heat in the dry state and is normally present in kilned and cured malts.—J. F. B.

Potatoes; Bad Attenuations shown by Certain Sorts of ——. G. Heinzelmann. Z. Spiritusind., 1904, **27**, 193—194.

The author describes the procedure adopted for the analysis and examination of a batch of Silesian potatoes which had the reputation of giving poor attenuations in the distillery, the gravity of the fermented mashes being sometimes as high as 5° Balling. Fermentation experiments showed that the potatoes were perfectly normal and yielded as much alcohol as could be expected from the quantity of starch present. A very valuable means for checking cases of suspected bad attenuations is afforded by the re-fermentation of the residual extract of the fermented mashes. —200 c.c. of filtered fermented mash are half neutralised and evaporated on the water-bath to a syrupy consistency; the residue is diluted again to 200 c.c. and sown with 4 grms. of pure yeast at 28° C. After 24 hours the alcohol produced is determined by distillation, and the results are calculated per 100 c.c. of mash. If the mash showed a deficiency of diastase the same determination should also be carried out, with the addition of 100 c.c. of water and 100 c.c. of malt extract (100 grms. of green malt to a litre of water) to the syrupy extract, and the results should be corrected for the quantity of alcohol yielded by the malt extract. (See also this J., 1904, 263.) In good distillery practice the residual extract should not yield more than 0·2—0·3 per cent. by volume of alcohol calculated on the mash. Further experiments showed that the proportion of unfermentable extract is increased by steaming the potatoes at higher pressures. The mashes produced, on the one hand, by steaming for 1 hour at 2 atmospheres, and on the other at 4 atmospheres, showed final gravities of 0·2° and and 0·9 Balling respectively. The poor attenuation, in the latter case, was, however, only apparent, since the yield of alcohol was the same in both cases. When high final gravities are obtained, the fermented mashes should be analysed in the manner described above, and if no fault is indicated in the efficiency of the yeast, the potatoes should be steamed at lower pressures.—J. F. B.

Malt; The Ready-formed Sugars of ——. A. R. Ling and T. Rendle. J. Fed. Inst. Brewing, 1904, **10**, 238—263.

In a previous paper Ling (this J., 1898, 478) pointed out that the extraction of the ready formed sugars of malt by cold water involves an incipient saccharification of the starch by the diastase and the appearance of maltose and other conversion products in the extract. The soluble carbohydrates of malt include cane sugar, invert sugar, maltose (doubtful), pentoses and gummy substances. They are formed chiefly during flooring, but considerable metabolism goes on during withering and in the earlier stages of kilning. This metabolism consists in the production of reducing sugars from the starch, and the conversion of these reducing sugars into cane sugar; it is attended by an energetic growth of the aerospire whilst the rootlet dies away. The authors propose to extract the soluble carbohydrates of malt by means of a dilute solution of caustic potash, soda or ammonia, sufficiently powerful to inhibit all diastatic action :—25 grms. of ground malt are digested for three hours at the ordinary temperature with 250 c.c. of a solution containing 15 c.c. of N/20 caustic potash solution in excess of the amount which is necessary to neutralise the acidity of the malt. The extract is filtered through a dry filter, filtration being assisted by the addition of purified kieselguhr or fuller's earth. The total soluble matter, which includes the soluble albuminoids as well as the carbohydrates, is determined in a portion of the filtrate either directly by drying or indirectly from the specific gravity (divisor, 3·86). The total reducing sugars are determined volumetrically in 25 c.c. of the filtrate diluted to 100 c.c. In absence of any precise information as to their nature, although some of them are certainly unfermentable, the whole of the reducing sugars are expressed in terms of invert sugar. For the determination of the cane sugar 25 c.c. of the original filtrate are mixed with 10 c.c. of N/2 hydrochloric acid, the solution is slowly raised to boiling and maintained in ebullition for one minute, the mixture is cooled, neutralised by 10 c.c. of N/2 caustic soda solution, and diluted to 100 c.c. The cupric-reducing power is then determined and the proportion of cane sugar is calculated. All results are expressed in terms of the dry malt. The authors give tables showing the results of a full examination of 42 samples of malt, together with all available information regarding the method of their preparation. The majority of the samples had not been "forced," *i.e.*, they had been germinated on the cool system with limited amounts of sprinkling liquor. Depletion of the endorsperm adjacent to the acrospire was taken as the indication of "forcing." Although in a general manner the proportion of soluble carbohydrates and the sum of the ready-formed sugars tend to increase under "forcing" conditions, no definite limits can be fixed for any of these constituents by which "forcing" can be diagnosed. The proportions in which they exist in malt are the resultants of a large number of factors, some of which, *e.g.*, respiration, whether aërobic or anaërobic, tend to reduce the amount of soluble carbohydrates. In very pronounced cases of "forcing," the sum of the proportions of cane sugar and reducing sugar may amount to over 12 per cent., but in more moderate cases, such as are usually met with, the proportion of these sugars may be no higher, and sometimes even less, than in malts which have not been forced. Pneumatic malts appear to contain somewhat smaller amounts of soluble carbohydrates, other than cane sugar and invert sugar, than floor malts. The amount of soluble carbohydrates of malt probably varies according to the kind of barley and its condition.—J. F. B.

Mashing Heats. H. W. Harman. Brewers' J., 1904, **40**, 351—352.

The control of the behaviour of different worts towards yeast, which is obtained by varying the mashing heats, depends upon the quantity and the type of the maltodextrins produced by the conversion of the starch. At 158° F. the liquefaction of the starch by the diastase is most rapid and complete; a temperature of 130° F. is most favourable for the production of free maltose, and below 145° F. no considerable percentage of maltodextrins is produced. From 145° F. to 150° F. low-type maltodextrins are formed in small but increasing quantities, whilst above 150° F. the production of maltodextrins is considerable in amount, but no great change of type results until a temperature of 156°—158° F. is reached, when the higher and more stable maltodextrins are formed. A mixture of malt and flaked maize saccharifies far more rapidly if mashed at 148° F., and raised in 15 minutes to a temperature of 158° F., than if mashed at 150° F. all through. The diastase does better work, even though partially crippled, at 158° F., at which temperature the starch is readily convertible, than a more energetic diastase at a lower temperature, less favourable to the liquefaction of the starch.
—J. F. B.

Fermentation Gas; Wittemann's Collecting and Carbonating System for ——. J. Steinemann. Hantke's Letters on Brewing, 1904, **3**, 223—229.

The collecting and carbonating plants form two independent systems. No changes in the mashing and fermentation processes are involved. One brew out of every six or seven is fermented under a pressure of 3—5 lb. in two closed storage tuns. The wort is run into the closed tuns the first morning after pitching, and fermentation is allowed to continue for 6—8 hours with the valves open in order to expel the air. The tuns are then closed, and when the pressure has reached 4 lb. the compressor pump is started. In about 24 hours sufficient gas will have been collected for the carbonation of 2,000 barrels of beer. The pitching temperature is 8·8° to 9·4° C., and this rises to 12·5° C. during the fermentation under pressure. After sufficient gas has been collected, the fermenting wort is preferably returned to the open tuns. The gas is compressed by the pump to a pressure of 250 lb. In the purifiers the compressed gas is saturated with water, both entering from above, the gas is passed on to the storage cylinders, and the separated water is used for cooling the compressor. The circulating water removes objectionable volatile acids, whilst "through the cooling the hop ether is retained in the carbonic acid." The stored carbon dioxide cools down to the temperature of the cellar in about 24 hours, and a further cooling is obtained in its expansion at the time of carbonating. The aroma of the gas depends on the quality of the beer, and the best, strongly-hopped brews are selected for providing the gas. In the carbonator the beer, entering at 0·6°—0° C., is cooled by the gas to −0·6° C. For bottled beers carbonation is effected at 8—9 lb. pressure, for draught beers at 10—12 lb. The beer should be carbonated direct from the chip-cask, and should not be more than three weeks old. Young beers so treated are more aromatic than "kräusened" beers. Beers stored for 2—3 months are not suitable for carbonation; they should be treated with 2—6 per cent. of "Kräusen."—J. F. B.

Alcoholic Fermentation; Production of Sulphuretted Hydrogen in ——. M. E. Pozzi-Escot. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1071—1073.

Hydrogenases or reductases are present in yeast in abundance, and when sulphur, a sulphate, or sulphite is added to a liquid undergoing alcoholic fermentation, sulphuretted hydrogen is formed. This direct fixation of hydrogen is not limited to sulphur, but extends to all the metalloids of this family, and even to phosphorus and arsenic. While sucrase will diffuse through parchment during the whole course of the fermentation, the reducing diastase only appears towards the end when about one-tenth of the sugar is left.—L. J. de W.

Potable Spirits used by the Native Population of India; Analyses of ——. H. H. Mann. Analyst, 1901, **29** 149—152.

The results are given of the examination of numerous samples of these spirits, which the author divides into four classes:—Those derived from *mahua* (the flowers of *Bassia latifolia*); those obtained from rice; those from the refuse of sugar manufacture; and those representing imported foreign low-grade spirit. All the samples were very dilute, only two exceeding 25 degrees under proof. Large quantities of volatile and fixed acids were present, and the percentage of fusel oil was extremely high in nearly all cases. Furfural was present in all the spirits, except one. The imported spirits were highly sweetened. The fusel oil was estimated by Röse's method, and as this process has recently been severely criticised (this J., 1902, 815), the author hopes shortly to repeat the determinations, and also to investigate the physiological action of the quantity of both furfural and aldehydes in the spirits (this J., 1992, 96—102).—W. Grain; Process and Apparatus for Drying, Desiccating, and Roasting Germinated and Non-Germinated ——. O. Imray, London. From Brau. Gross-Crostitz, Leipzig. Eng. Pat. 6975, March 22, 1904.

In order to obviate the troubles arising from the condensation of moisture on the upper walls of the drying chamber, as in the apparatus described in Eng. Pat. 26,473 of 1901, the apparatus is so arranged that two-thirds of the moisture is removed by heated currents of air introduced at the top of the chamber, and withdrawn, together with the moisture, at the bottom. The drying may then be completed by currents of air ascending through the chamber. The moisture in the saturated air is condensed in a mixing chamber below the apparatus. The condensation of moisture on the outside of the drying chamber is prevented by surrounding the latter with heating or cooling pipes. Heating or cooling pipes are also arranged in the air-supply channel instead of inside the chamber as before. —J. F. B.

Malt; Apparatus for Making —— and Treating other similar Materials. H. J. Sulzen, Sacramento. Eng. Pat. 1797, Jan. 23, 1904.

The apparatus for turning and aerating malt on the germinating floor is mounted on a carriage propelled by a motor, and provided with steering gear. At the bottom of the carriage in front are situated a number of ploughs, which turn and lift the grain, delivering it to a series of spiral conveyors, which raise it to the summit of the carriage. In its upward course the grain in the elevators is subjected to a blast of air from a fan situated below the perforated walls of the conveyors. At the summit, the malt may be treated with a spray of water if desired. It then falls on to a series of alternate shelves and shakers, from which it is discharged through an adjustable door at the back of the carriage.—J. F. B.

Wort [Raw Grain] for Brewing or Distilling; Preparation of ——. F. B. Aspinall, Blackheath. Eng. Pat. 9106, April 22, 1903.

Raw grain is disposed in layers or columns, freely accessible to water, but protected from heat other than that conveyed by the water. The receptacles containing the layers of grain, so arranged that there is room for the expansion of the latter, are placed in a digestor, in which the grain is boiled with water under pressure until the water is saturated with "liquefied starch." The boiling is repeated with changes of water until the whole of the starch is extracted; the bulk of the albuminoid matter remains in the grain. —J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A.*)—FOODS.

Phosphorus Compound in Wheat Bran; Nature of i Principal ——. A. J. Patten and E. B. Hart. Am Chem. J., 1904, **31**, 564—572.

The authors find that nearly the whole of the solul phosphorus in wheat bran exists in the form of a ma nesium-calcium-potassium salt of a phospho-organic acid. The free acid is probably identical with Posternak's anhydro-oxymethylene-diphosphoric acid, $(OH)_2PO.O.CH_2.O.CH_2.O.PO(OH)_2$. The alkali salts of this acid are readily soluble in water, the calcium and copper salts are slightly soluble, and the barium and strontium salts are but sparingly so. The acid or its salts have already been isolated from the seeds of red fir, peas, beans, pumpkin, red and yellow lupin, and also from the potato and other tubers and bulbs.—A. S.

Palm of Madagascar; Alimentary Pith from a ——. R. Gallerand. Comptes rend., 1904, 138, 1120—1121.

The pith is obtained from the *Satranabe* palm, *Medemia nobilis*, which grows abundantly in Ambongo. After being dried, ground, and sifted, it is used as a food by the natives. The specimen of the meal examined contained 13·3 per cent. of water. The dry material contained:—Starch, 66·833; cellulose, 12·939; albuminoids, 10·538; fat, 1·037; and mineral matter, 8·2 per cent. The meal is thus richer in albuminoid matter than potatoes, manioc, sweet potatoes, and yams, which contain 6·23, 3·30, 3·85, and 7·24 per cent. respectively of nitrogenous substances. —A. S.

Caseïn; Hydrolysis of ——. Z. H. Skraup. Ber., 1904, 37, 1596—1597.

From the products of the hydrolysis of caseïn the author has isolated *diaminoglutaric acid* and *diaminoadipic acid*. He has also separated several hydroxyamino acids, including mono- and diamino derivatives of di- and tribasic acids. Amongst these are described:—*Hydroxyaminosuccinic acid*, m. pt. 320 C.; an acid, $C_8H_{16}N_2O_6$, m. pt. 243° C., which is named provisionally *dihydroxydiaminosuberic acid*: an acid, $C_9H_{16}N_2O_7$, occurring in characteristic rystals, melting at 192° C., and yielding a sparingly soluble opper salt and a well-crystallised hydrochloride; this acid eceives the name of *caseanic acid*; it is apparently a nonohydroxy tribasic acid; finally an acid, $C_{12}H_{16}N_2O_5$, ermed *caseïc acid*, which is dibasic and yields a copper alt which is very sparingly soluble in cold water and eadily turns violet. Caseïc acid occurs in two modiications, one melting at 226° C., feebly dextro-rotatory and rystallising in fairly well formed prisms, the other melting t 246° C., optically inactive and crystallising in very ndistinct prisms; both forms apparently yield the same opper salt and hydrochloride.—J. F. B.

Butter; Distinction of Natural from Artificial ——. A. Quartaroli. XXIII., page 625.

ard; Detection of Cocoanut Oil in ——. F. Morrschöck. XXIII., page 625.

Melon-Seed Oil. G. Fendler. XII., page 613.

English Patent.

eat Extract; Manufacture of a ——. A. R. da S. Braga, Sao Paulo. Eng. Pat. 7895, April 5, 1904.

quantity of meat and some finely-divided fruit of the paw family (*carica papaya*) are mixed with a little water ightly acidulated with hydrochloric acid, and digested at temperature of 50° to 70° C., until disintegrated, when the ixture is boiled. After cooling, straining, and removing lid fat, the liquid is evaporated and mixed with a suitable antity of glycerin to form either a liquid or pasty meat tract.—W. P. S.

United States Patent.

Flour; Process of Treating —— [Electrically]. N. Alsop, Owensboro. U.S. Pat. 759,651, May 10, 1904.

E Eng. Pat. 14,006 of 1903; this J., 1903, 1062. —T. F. B.

French Patent.

Foodstuffs; Process for the Partial or Complete Suppression of the Products of Decomposition of ——, formed by Micro-Organisms. H. Frings, jun. Fr. Pat. 338,333, Dec. 19, 1903.

This invention is based on the facts that, while saccharomycetes can flourish in presence of a certain quantity of hydrogen peroxide, *mycelium* and the schizomycetes cannot develop under the same conditions; and also that, with a sufficient quantity of hydrogen peroxide, the growth of the saccharomycetes is also stopped. Hydrogen peroxide is, then, added to fruit, wines, beer, meat, &c., in very small quantities (*e.g.*, 0·03 per cent. for wines) to partially or completely prevent the development of micro-organisms. Instead of hydrogen peroxide, compounds which produce it, such as metallic peroxides or percarbonates, may be used.—T. F. B.

(*B.*)—SANITATION; WATER PURIFICATION.

Sewage; The Organic Colloids of ——. W. Biltz and O. Kröhnke. Ber., 1904, 37, 1745—1754.

Samples of town sewage were submitted to dialysis in parchment tubes immersed in distilled water, and the oxidisable matter was determined at intervals in the undiffused residue by means of permanganate. The speed of diffusion of the putrescible matters was generally slow, and slackened down towards the end of the period of observation until the permanganate value of the residue remained practically constant. The inorganic salts, *e.g.*, chlorides, diffused with extreme rapidity. The results showed that one-half to one-third of the total oxidisable matter of the sewage exists in the form of practically undiffusible colloids. Electrical tests of the convective migration of the oxidisable matters of the sewage showed that these tended to concentrate at the anode, and belong therefore to the class of negatively charged colloids (see this J., 1904, 459). Precipitation tests with the partially diffused sewage showed that the colloids were almost completely precipitated by colloidal solutions of ferric hydroxide and zirconium hydroxide in absence of electrolytes. The precipitations followed the law of optimum proportions enunciated *loc. cit.* In the chemical precipitation of sewage by ferric salts, the influence of the positive colloidal hydroxide is assisted by that of the electrolyte. The primary action in the biological purification of sewage is a mechanical one, due to the production of "adsorption compounds" between the colloids of the sewage and the gelatinous slimy layer of bacterial growths. Similar precipitations are produced by fungoid growths in solutions of inorganic colloids; they also appear to play a part in the sedimentation which takes place in the septic tank and in the "auto-purification" of rivers.—J. F. B.

Cellulose; Decomposition of —— by Aerobic Micro-Organisms. C. van Iterson, jun. Centr.-Bl. Bakter. u. Parasitenk., 11, 689—698. Chem. Centr., 1904, 1, 1338.

Cellulose can be brought into solution by the action of denitrifying non-sporulating bacteria, with restricted access of air. The presence of considerable quantities of soluble organic matter, prevents the nitrification process, but cellulose is without influence, if the aeration be good. The conjoint action of nitrification and denitrification processes must play an important part in the destruction of cellulose in the self-purification of waters and soils and the biological purification of effluents. Cellulose is also decomposed by aerobic, non-sporulating bacteria, of which a brown pigment-bacterium (*Bac. ferrugineus*) is the most important. This bacterium is particularly active in symbiosis with a yellow micrococcus, which by itself is inactive. In nutritive solutions in which the cellulose is decomposed by the aerobic bacteria of mud or garden soil, spirilla-cultures are always formed abundantly. The property of attacking cellulose is a general one among the fungi, and is due to an enzyme, which the author names *cellulase*. One of the causes of the formation of humus colouring matters is the production of pigments from cellulose by the action of bacteria and fungi. The nature of the anaerobic decomposition of cellulose may be of two kinds: In absence of potassium nitrate, carbon dioxide and hydrogen or methane, together with acetic and butyric acids, are formed; whilst in presence of potassium nitrate, the cellulose is decomposed by denitrifying bacteria, with formation of nitrogen, carbon dioxide, and water.—A. S.

English Patents.

Town Refuse such as is at present sent to Destructors; Separation or Treatment of ——. G. E. H. Rawlins and G. W. Douglas, both of Waterloo. Eng. Pat. 14,897, July 4, 1903.

The refuse is passed into a solution of such specific gravity that most of the carbonaceous matter will float therein, whilst most of the mineral matter will sink. The carbonaceous matter is removed by an elevator which dips just below the surface of the solution, and the mineral matter by a second elevator reaching to the bottom of the tank. After leaving the elevator, the carbonaceous matter is washed and dried. The salts used for making the solution are cheap ones, such as sodium chloride, calcium chloride, sodium sulphate, and the like.—W. P. S.

Sewage and like Waters; Process and Apparatus for Disinfecting ——. G. Porion, Arques. Eng. Pat. 7383, March 28, 1904.

The sewage or water is aerated or oxidised by means of rapidly revolving paddle-wheels placed across the channel through which the sewage flows. The paddles dip just below the surface and project a thin film of the sewage or water into the air. A weir maintains a constant level in the channel. The paddle-wheels may be mounted on a raft, together with suitable driving machinery, for use in rivers and reservoirs.—W. P. S.

Settling or Filtering Tanks [*Water Softening*] *and the like.* F. J. Farrell, London. Eng. Pat. 10,682, May 11, 1903.

The invention relates to a settling or filtering tank having a series of plates or trays arranged to slope downwards from each side of the tank towards a clear space in the centre. These trays form, between their ends and the end plates of the tank, oppositely arranged wedge-shaped recesses. The water to be treated enters the recess having its apex at the top, and its flow is diverted through or over the trays by means of centrally arranged baffle plates. The precipitate or sludge falls through the still water in the central space to a gutter at the bottom of the tank, where it is periodically drawn off. The clear water passes over a sill at the top of the tank, and, if desirable, may be filtered as it leaves.—W. P. S.

(*C.*)—DISINFECTANTS.

Ammonium Fluoride and Rubber Hose. E. Bidtel. Hantke's Letters on Brewing, 1904, **3**, 238—239.

Acid ammonium fluoride is the best disinfectant for rubber hose. The behaviour of the nearly chemically pure salt differs considerably from that of the technical salt. Pure vulcanised Para rubber is employed for lining the vessels in which the solutions of the salt are concentrated. This rubber resists the action of the hot concentrated solutions of acid ammonium fluoride for 3—4 years. With solutions of the technical salt, however, the rubber loses its elasticity, becomes brittle, and cracks, and the entire surface turns dark in colour. This is due to the fact that the technical fluoride, prepared in lead vessels, contains 2—3 per cent. of lead, which desulphurises the rubber. Other inferior qualities of rubber are always more or less attacked by the acid fluoride. For brewery purposes, therefore, pure rubber hose and pure acid ammonium fluoride should always be used. (See this J., 1904, 265.)—J. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Pulp Boards for Beer Filtration. Wochenbl. f. Papierfab., 1904, **35**, 1546.

The pulp employed in filters for beer and wine is a long-fibred, "free"-beaten cotton half-stuff. When filtration was first introduced in the brewing industry, sheets of filter pulp were employed, which were used until they became clogged, and were then discarded. Later, on account of the expense, the pulp was supplied in blocks 40 cm. square and 3—5 cm. thick; these blocks were pulped up in water and distributed on the sieves of the filter to any desired thickness. After use the pulp was washed, sterilised, and dried. Owing to improper treatment in manufacture and irrational drying in thick blocks, the pulp frequently presented difficulties in the disintegration previous to use. There has lately, therefore, been a tendency to replace the thick blocks by sheets of thin cardboard, weighing 200—400 grms. per square metre, ready for use, which are prepared on the Fourdrinier paper machine at a far less cost than the blocks. The whole art of preparing a filtering pulp which disintegrates readily and uniformly in water, lies in maintaining the fibres in the same condition as they exist in the rags, with a minimum of chemical and mechanical treatment. For this reason the raw material should consist of knitted white cottons [cellular shirtings] which require very little beating. Strong bleaching should, above all, be avoided, since this tends to the production of a "wet" half-stuff, which resists the desired disintegration in water.

—J. F. B.

Cellulose; Decomposition of —— *by Aerobic Micro-organisms.* C. van Iterson, jun. XVIII. B., page 619.

United States Patent.

Viscose; Manufacture of Filaments or Films from ——. C. N. Waite, Lansdowne, Assignor to General Artificial Silk Co., Delaware. U.S. Pat. 759,332, May 10, 1904.

"Residual constituents such as sulphur and caustic soda" are removed from viscose threads by steaming, under tension, in an atmosphere containing sulphur dioxide.

—T. F. B.

Casein; Treatment of ——. L. A. Dreyfus, New Brighton. U.S. Pat. 759,808, May 10, 1904.

The "insoluble properties of casein" are improved by heating it in the presence of acid (*e.g.*, sulphuric acid), with or without the addition of a mineral base, for a period of 24 hours, more or less.—R. L. J.

French Patents.

Paper [*from Sawdust*]; *Process and Machine for Manufacture of* ——. C. Pfeifer. Fr. Pat. 338,330, Dec. 19, 1903.

Wood sawdust is screened and thoroughly steeped in water; the material is then pumped into a refiner, in which it is subjected to a milling process. From the refiner it passes through a cylindrical-strainer and thence to a special cylindrical mill. This mill has a conical form and the grinding being and outer cylinder are constructed of stone, the object edges to beat the fibres to a mucilaginous consistency. After the pulp has passed through the conical portion of the mill, it is further ground by a portion of the cylindrical roller set with emery stones, before being finally ejected.—J. F. B.

Papier-Maché Articles; Process of Making ——. C Gaertner. Addition, dated Dec. 23, 1903, to Fr. Pat 337,480, Nov. 19, 1903.

See Eng. Pat. 27,339 of 1903; this J., 1904, 453.—T. F. B

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Ceriсsulphuric Acid; Salts of —— *with the Rare Eart Elements.* B. Brauner. Z. anorg. Chem., 1904, **39** 261—295.

When concentrated sulphuric acid and water react o ceric oxide and the products are crystallised, a yellow a a red salt result. The former is normal ceric sulphat $Ce(SO_4)_2.4H_2O$, and its crystal-constants have be measured by the author. The red salt is the hydrog cerous salt of the complex tetrabasic cericsulphuric ac

$Ce^{iv}(SO_4)_4Ce'''H.12H_2O$. This salt can be produced synthetically by adding solution of cerous sulphate to excess of ceric sulphate solution containing sufficient free sulphuric acid to form the complex acid. If the solution contain no more sulphuric acid than is just sufficient to prevent hydrolysis of the ceric sulphate, a bright orange salt, possibly normal cerous cericsulphate, $Ce_4'''[Ce^{iv}(SO_4)_4]_3.44H_2O$, is formed, usually, however, in admixture with other products. The cerous cerium in the red salt can be replaced by other rare earth elements, such as lanthanum and the didymiums. These other salts can also be formed synthetically from cerisulphuric acid and the sulphates of lanthanum, praseodymium, or neodymium; they are isomorphous with the cerous salt.—J. T. D.

Chloroform; Electrolytic Preparation of —— from Acetone.
J. E. Teeple. J. Amer. Chem. Soc., 1904, **26**, 536—543.

The conditions necessary for the successful preparation of chloroform by the electrolysis of a chloride in presence of acetone are: a temperature below 25° C., absence of alkali, a high current density at the cathode and a low one at the anode. A solution containing 120 grms. of sodium chloride in 700 c.c. of water, and 25 c.c. of acetone, was electrolysed The anode consisted of platinum foil of 75 sq. cm. area, a platinum wire forming the cathode. To obtain information as to the course of the reaction, portions of the liquid were pipetted off at different intervals and analysed for total alkali and free hypochlorite. The current efficiency (*i.e.*, he ratio of the amount of chloroform formed to that calculated from the current passed through) was 80—90 per cent. uring the first few minutes, but fell very rapidly as the lkalinity of the liquid increased. If, during the electroysis, acid be added to neutralise the alkali, then the fficiency is 80 per cent. for the first 8 ampère-hours. The lkalinity may be observed by the addition of trinitrobenzene o the bath, this being colourless in an acid, and red in an lkaline, solution. A good yield of chloroform is obtained y the action of chlorine upon calcium hydroxide solution ontaining acetone. This suggests that the electrolysis of a alcium chloride solution in presence of acetone would be e best method of making chloroform, provided that the igh resistance of the deposits on the anode could be vercome.—E. H. T.

Anethol; Contribution to our Knowledge of ——.
P. Hoering. Ber., 1904, **37**, 1542—1560.

N experimental and theoretical study of anethol; more pecially of the bromine compounds.—A. S.

ohimbine: Composition of ——, and its Relation to Yohimboaïc Acid. L. Spiegel. Ber., 1904, **37**, 1759—1766.

HE author has repeated the purification and analysis of himbine, and has established beyond a doubt that the rmula of the hydrated base is $C_{22}H_{30}N_2O_4$, and that this es 1 mol. of water under certain conditions, yielding *hydroyohimbine*, $C_{22}H_{25}N_2O_3$, m. pt. 234° C., which exists such in the salts of yohimbine. Examination of the mmercial hydrochloride showed that this is indeed a single bstance. The nitrate crystallises readily from water, and lts at 276° C. *Yohimboaïc acid*, which is identical with *yohimbine*, $C_{20}H_{26}N_2O_4$ (this J., 1903, 228), is a monosic acid. This acid, when esterified with methyl alcohol presence of hydrogen chloride, yields yohimbine hydrooride. Yohimbine is not, however, simply the methylic er of yohimboaïc acid. Esterifications of this acid with thyl, ethyl, and propyl alcohols showed that two alkyl oups are taken up, and that 1 mol. of water is split off all three cases.—J. F. B.

squiterpenes; Action of Paraformaldehyde on ——.
P. Genvresse. Comptes rend., 1904, **138**, 1228—1229.

E sesquiterpenes, like the terpenes, form molecular mpounds with formaldehyde, having an alcoholic function. imolecular proportions of paraformaldehyde and sesquipene are heated in a Pfungst tube for 10 hours at 180 00° C. The excess of the reagents is removed by illation with steam, and the alcoholic residue is exted and rectified. The products give, on analysis, results corresponding to the formula $C_{16}H_{26}O$. Compounds are described obtained in this manner from *caryophyllene*, *clovene*, and *cadinene*; they are all odourless and lævorotatory. The acetic ester of the product obtained from caryophyllene is also described.—J. F. B.

Terpenes and Essential Oils. **66** *and* **67**. O. Wallach.
Annalen, 1904, **332**, 305—351.

The 66th communication relates to the addition products of unsaturated compounds with nitrogen trioxide and nitrosyl chloride. It is divided under the following headings:—(1) Compounds of the anethol series, (2) compounds of the isosafrol series, and (3) compounds of the methylisoeugenol series. The 67th communication is entitled "A new case of optical isomerism," and treats of optically isomeric derivatives of cyclomethylhexanone.—A. S.

Patchouli Oil: A New Adulterant. W. H. Simmons.
Chem. and Druggist, 1904, **64**, 815.

The author points out that, in addition to cedarwood and cubeb oils, the usual adulterants of patchouli oil, apparently an ester or an oil containing an ester is also now employed for adulteration. Two samples of patchouli oil recently examined gave the following figures:—Sp. gr. at 15° C./15° C., 0·9948 and 0·9937; optical rotation, $\alpha_D = -38° 30'$ and $-49° 30'$; refractive index at 20° C., 1·5175 and 1·5110; saponification value, 58 and 18·5; solubility in 90 per cent. alcohol, 1 in 0·75 and 1 in 0·5.
—A. S.

Monodora Myristica Seeds; Essential Oil of ——.
H. Thoms. Ber. Pharm., **14**, 24; Pharm. J., 1904, **72**, 617.

The seeds of *Monodora myristica*, Duval, a native of Western Africa, yield, when subjected to steam distillation, 7 per cent. of an essential oil of very pleasant odour, and having a yellow colour with greenish fluorescence. The oil is lævo-rotatory, $\alpha_D = -64° 16'$. It contains *l*-limonene and a terpene alcohol, $C_{10}H_{16}O$, probably identical with myristicol; but no myristicin or other phenolic esters such as are present in nutmeg or mace oil (see this J., 1903, 1255).—A. S.

Essential Oil of Ilex Paraguayensis [Paraguay Tea Oil].
H. Haensel's Report, April 1904, 21.

The yield from the dried compressed maté leaf was 0·975 per cent. The oil is solid at the ordinary temperature, of a dark green colour, and possesses the characteristic odour and flavour of maté. It melts at about 26·5° C., and has the following characters:—Sp. gr. at 15° C., 0·8875; opt. rot., α_D^{20} + 3·73°; acid value, 61; saponification value, 91. The oil is acid in reaction, readily soluble in 96 per cent. alcohol, but only sparingly so in 80 per cent. alcohol.
—J. O. B.

Pinene; Action of Nitrosyl Chloride on ——.
W. A. Tilden. Proc. Chem. Soc., 1904, **20**, 122.

Pinene nitrosochloride having been shown by von Baeyer to have the double formula $(C_{10}H_{16}.NOCl)_2$, it occurred to the author that the unsatisfactory yield of this compound by the usual processes might be improved by using a mixture of equal quantities of *d*- and *l*-pinenes, which is optically inactive. Whereas previously the yield of nitrosochloride from ordinary *d*-pinene was about 32 per cent. of the pinene, and the product from the more highly rotatory pinene obtained from French turpentine was still less, the employment of a mixture prepared so as to be optically inactive gives 55 per cent. The melting point of pure pinene nitrosochloride is not 103°, as originally given, but 115° C. (*circa*). For the regeneration of pinene from the nitrosochloride, methylaniline is recommended in preference to aniline, as there is no violent action, and the yield of pinene is greater.

Mercuric Chloride; Delicate Reaction for —— [in Calomel and other Mercurous Preparations]. A. Moulin. XXIII., page 623.

C.C-Dialkylbarbituric Acids; Process for the Production of ——. C. E. Merck. Fr. Pat. 338,183, Oct. 16, 1903.

C.C-Dialkylbarbituric acids are obtained by heating the corresponding dialkylmalonyl chlorides with urea, hydrochloric acid being evolved, thus:— $R_2C(COCl)_2 + CO(NH_2)_2 = 2HCl + R_2C:(CO.NH)_2:CO$. Dimethylbarbituric acid is prepared by heating 5 parts of dimethylmalonyl chloride with 2·66 parts of urea for 10 hours on the water-bath, and then for 2 hours, at 130° C., on the oil-bath. (See also Eng. Pats. 1945, 1944, 1664, and 2054 of 1903; this J., 1903, 818, 880, and 923).—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Sodium Thiosulphate; Oxidation of ——. E. Sedlaczek. VII., page 605.

Calico Printing; Photographic Preparation of Rollers for ——. J. Wolkoff. V., page 604.

English Patents.

Photographs on Linen or other Fabrics or Substances; Production of ——. O. Fulton, Chiswick, and W. M. Gillard, Twickenham. Eng. Pat. 11,219, May 16, 1903.

A closely woven fabric is stiffened by means of a dilute solution of celluloid, dried, and coated on both surfaces with a sensitive emulsion (silver, platinum, bichromate, &c.). The object of this treatment is to produce a "duplex" photograph, *i.e.*, a photograph on each surface of the fabric, whereby "the effect of density is produced by transmitted light, and the effect of brilliancy by light reflected from the photograph produced."—T. F. B.

Photographic Printing Paper or the like; Process for Preparing ——. I. Hoffsümmer, Düren. Eng. Pat. 3855, Feb. 16, 1904.

Instead of preparing paper (for receiving emulsions) by treatment with "zapone," (a solution of cellulose in amyl alcohol, &c.) as described in Eng. Pat. 25,390 of 1903 (this J., 1904, 337), cellulose acetates may be employed in a similar manner.—T. F. B.

French Patent.

Photographs in Colours; Process for Obtaining ——. Dr. Riebensahm and Posseldt, Ges. m. beschr. H. Fr. Pat. 338,170, Dec. 29, 1903.

A finely-divided pigment is thoroughly incorporated with a silver halide emulsion, and the mixture spread on paper in the usual manner. After exposure under a reversed negative, the paper is developed in the usual manner, washed, and immersed for 10 or 15 minutes in a 5 per cent. solution of potassium bichromate. By this treatment, a quantity of the gelatin, corresponding to the reduced silver of the image, is rendered insoluble. The paper having been washed and the excess of bichromate neutralised with alkali, the film is transferred to a support, developed by means of hot water, and fixed with "hypo (sodium thiosulphate)." By this means permanent photographs in any desired colour may be obtained.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Nitrocellulose; Study of ——. II. C. Haeussermann. Ber., 1904, **37**, 1624—1625. (See this J., 1904, 36.)

The aqueous distillate obtained when nitrocellulose is boiled with caustic alkali was treated with dilute sulphuric acid and distilled. The portion coming over first was treated with potassium carbonate, and the oil which separated was distilled *in vacuo* at a temperature not rising above 40° C. In this way a colourless mobile liquid was obtained, which yielded iodoform with alkali and iodine dissolved in potassium iodide solution, but did not reduce ammoniacal silver nitrate solution. The residue consisted of a red resinous substance insoluble in water. The distillate appears to consist of the oxime-like compound of an aldehyde or ketone; it contains 5·4 per cent. of nitrogen, 56 per cent. of carbon, and 10 per cent. of hydrogen. A distillate capable of yielding iodoform is obtained from both fibrous and amorphous nitrocellulose, and also from other nitrated carbohydrates, *e.g.*, nitro-inulin, nitrostarch, nitrolactose and nitroglucose (this J., 1898, 271), and the nitro-amyloid obtained by Lunge and Weintraub by allowing nitric acid to drop into a solution of cellulose in sulphuric acid (Z. angew. Chem., 1899, 448; this J., 1899, 705).—A. S.

Explosions Produced by Ferrosilicon. A. Dupré and M. B. Lloyd. Iron and Steel Inst., May 5, 1904.

In December last 48 drums of ferrosilicon were landed at Liverpool, and, after being left on the quay until January 12, were removed to Bootle. While the drums were being placed in a warehouse, one violently exploded, as also did another shortly afterwards. The ferrosilicon was then transferred to wooden barrels, in the ends of which holes were bored to prevent accumulation of inflammable gas. Notwithstanding these precautions, however, a third explosion occurred in one of the barrels on January 21. The ferrosilicon contained: silicon, 59·40; iron, 36·85; manganese, 0·08; aluminium, 2·73; calcium, 0·14; magnesium, 0·17; carbon, 0·218; sulphur, traces; and phosphorus, 0·056 per cent. The authors found that 4 kilos. of the powdered ferrosilicon, when moistened with water, gave off an inflammable gas consisting mainly of phosphoretted hydrogen, in sufficient quantity to render explosive 64 litres of air. The explosions were therefore probabl caused by water having got into the interior of the drums the gas evolved forming with the air in the drums a explosive mixture which could be fired by the heat produce by the friction of the hard lumps against each other whe the drums were moved about, or possibly by the spontaneous ignition of some phosphoretted hydrogen contained in "pocket" in the material and liberated suddenly by th breaking of a lump. It is suggested that in future th drums be filled up with paraffin oil of high flashing poin or that the material be submerged in water until all actio has ceased. The drums should be water-tight and not liabl to become insecure under the ordinary conditions transport.—A. S.

English Patent.

Explosives. J. Führer, Vienna. Eng. Pat. 3301, Feb. 10, 1904.

On account of the large number of calories developed oxidation, it is proposed to use silicon in certain explosive The following composition is given: Ammonium nitra (73 per cent.), charcoal (2·5 per cent.), dinitrotolue (14·5 per cent.), and silicon (10 per cent.).—G. W. McD

United States Patent.

Pyrotechnical Compositions; Process for Making ——. M. Magnard, Salaise. U.S. Pat. 759,387, May 10, 1904.

Five kilos. of gum-arabic are mixed with 5 kilos. of magnesium carbonate, 5 litres of water are added, and the mixture is heated to 50° C.; 1 kilo. of white phosphorus is then added, and the mixture allowed to cool to 25° C. under continuous agitation, when 2·5 kilos. of red ochre and 3 kilos. of potassium chlorate are put in. The product resulting is then powdered.—L. F. G.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Pyrometers suitable for Metallurgical Work. Report by R. A. Hadfield, J. E. Stead, and B. H. Brough. Iron and Steel Inst., May 1904.

A description, with illustrations, of a number of pyrometers is given. In the *Baird and Tatlock pyrometer* the electromotive force developed by the difference in temperature of two similar thermo-electric junctions opposed to one another, is measured. *Bristol's recording air pyrometer* consists of a porcelain bulb connected by a capillary tube to a recording pressure-gauge. It allows of the measurement of temperatures of high ranges and gives continuous records on a moving chart. In the *Callendar and Griffiths' thermometers* the increase in resistance of a platinum wire with rise of temperature is observed. The principle on which the *Le Chatelier pyrometer* is based, is the conversion of heat into an electric current and the determination of the electromotive force of the current produced. By the *Mesuré and Nouel optical pyrometer* the temperature of incandescent bodies is measured by observation of the luminous tint of the light emitted by them. The *Roberts-Austen pyrometer* is of the recording electrical type. The *Rosenhain-Chalmers optical pyrometer* measures the temperature of a hot body by comparing the intensity of the light emitted by the body with that of the light given out by a comparison body at a known temperature. The *Siemens electric pyrometer* is a platinum resistance thermometer. In the *Siemens water-pyrometer*, the degree of heat imparted to a known volume of water by a metal cylinder which has been exposed to the temperature to be measured, is determined. The *Uehling pneumatic pyrometer* is based upon the laws governing the flow of air through small apertures; it is combined with an autographic recorder. By the *Wanner optical pyrometer* the temperature is measured by determining the quantity of light radiated from he hot body. A comparison is made, by polarisation, of he rays of the temperature to be measured with the rays of a known temperature emitted by an electric lamp. The *Wiborgh thermophones* consist of small cylinders which explode with a sharp crack at the end of an interval of ime corresponding to the temperature of the furnace. A list of English patents relating to pyrometry and a bibliography of the subject are also given.—A. S.

English Patents.

Lids or Covers for Crucibles. J. H. R. Appleyard, Huddersfield, and W. Cranfield, Halifax. Eng. Pat. 14,242, June 27, 1903.

Covers for porcelain or other crucibles are constructed with he interior surface of the lid convex or inclining downards, from the outer upper-edge to the centre. By this ethod of construction anything that splashes up, on to the d gravitates to the centre, and falls back into the crucible, stead of running down to the edge and being lost.
—W. H. C.

Cupels; Manufacture of ——. The Morgan Crucible Co., Ltd., and J. C. Fox, Battersea. Eng. Pat. 1695, Jan. 22, 1904.

He base or underside of the cupel is hollowed out, so that e litharge may penetrate the mass, flowing laterally, and not reach the floor of the oven on which the cupel rests, as it is liable to do with a cupel having the usual flat base.
—E. S.

French Patent.

Alcovinometer [Alcoholometer]; Capillary ——. Soc. L. Legrand et Lafaverge. Fr. Pat. 338,291, Dec. 3, 1903.

For the determination of alcohol in wines advantage is taken of the height to which the wine ascends in a capillary tube starting from a constant level. The wine is placed in a receiver up to a constant level determined by a needle-point. The containing vessel and capillary tube are made in one piece, which is levelled on an adjustable stand; when the vessel has been filled with wine, the latter is forced up the capillary tube by pressure on a piece of rubber tubing, the height at which the column stands is then read off and corrected for temperature.—J. F. B.

INORGANIC—QUALITATIVE.

Mercuric Chloride; Delicate Reaction for —— [*in Calomel and other Mercurous Preparations*]. A. Moulen. L'Union Pharm., 1904, **45**, 147—148.

A reagent is prepared by dissolving 2 grms. of diphenylcarbazide in 100 c.c. of 90 per cent. alcohol, and 10 c.c. of 50 per cent. acetic acid. When solution is complete, the volume is made up to 200 c.c. A few drops of this reagent are added to the aqueous solution to be tested, followed by a few c.c. of 10 per cent. sodium acetate solution. In the presence of mercuric chloride a characteristic blue colour is produced. The presence of 1 part in 1,000,000 can be readily detected by this reaction. It is specially applicable for the detection of mercuric salt in calomel, in wash waters from other mercurial preparations, and in mercurous iodide.
—J. O. B.

INORGANIC—QUANTITATIVE.

Gelatinous Precipitates; Filtration and Ignition of ——. M. Dittrich. Ber., 1904, **37**, 1840—1842.

The filtration of gelatinous precipitates, and especially of those which, like aluminium and ferric hydroxides, become slimy on heating, can be considerably accelerated by adding to the precipitate, before filtration, filter-paper shaken up with water so as to form a pulp. One filter-paper of 7—11 cm. diameter, according to the quantity of precipitate, is usually sufficient. The filtration and washing can then be carried out very quickly. In the ignition, care must be taken that the whole of the filter-paper is completely burnt, this generally requiring repeated careful and cautious shaking, so as to change the position of the mass. The ignited precipitate then consists, not of hard lumps, but of an extremely fine powder. Ferric hydroxide precipitates, treated in this way, may be placed in the crucible in the wet state and ignited without any fear of reduction taking place. When it is required to dissolve a precipitate and re-precipitate it, the filter-paper and precipitate are placed in the original beaker, in which they are boiled with moderately concentrated acid until the precipitate is dissolved and the filter paper converted into a coarse pulp; the precipitant is then added and the liquid filtered. In the separation of ferric hydroxide and alumina by fusion with caustic soda, the fine division of the precipitate by the filter pulp makes it extremely ready of attack by the soda. The grinding of ignited precipitates in an agate mortar, in order to treat them with various reagents, is also obviated.
—T. H. P.

Bleaching Powder; New Method for the Technical Analysis of ——. U. Roberto and F. Roncali. L'Ind. Chimica, **6**, 93—95; Chem. Centr., 1904, **1**, 1294.

The method is based upon the fact that when chlorine water is added to an aqueous solution of hydrazine sulphate, nitrogen is evolved, in accordance with the equation—

$$N_2H_4.H_2SO_4 + 2Cl_2 = N_2 + 4HCl + H_2SO.$$

100 c.c. of water, 2—3 grms. of hydrazine sulphate and 30 c.c. of dilute sulphuric acid are introduced into a

300—400 c.c. flask, and the latter is closed with a double-bored cork carrying a funnel-tube and a gas-outlet tube. 10 grms. of the bleaching powder are well mixed with water and the whole made up to 1 litre. The hydrazine sulphate solution is heated to boiling, and after the air is expelled from the flask, 100 c.c. of the bleaching powder solution (= 1 grm. of the sample) are introduced through the funnel-tube, followed by 30—40 c.c. of water, the solution in the flask being kept boiling. The nitrogen is collected in the usual way, and from the volume corrected to 0° C. and 760 mm. pressure, the percentage of available chlorine is calculated.—A. S.

Iron and Zirconium; Separation of —— by Means of Nitroso-β-naphthol. G. von Knorre. Z. angew. Chem., 1904, **17**, 641—647, 676—678.

Iron and zirconium in chloride solutions containing oxalic acid can be quantitatively separated by means of nitroso-β-naphthol, if the solution be strongly acidified with hydrochloric acid, and then heated to boiling before precipitating the iron. The method was carried out as follows. 50 c.c. of ferric chloride solution (= 0·1131 grm. of ferric oxide) and 100 c.c. of zirconium chloride solution (= 0·309 grm. of zirconium dioxide) were mixed together, and 20 c.c. of N/1 oxalic acid solution added, followed by 5 c.c. of hydrochloric acid of sp. gr. 1·12; the solution was then treated with 10 c.c. of 90 per cent. acetic acid, heated to boiling, and the iron precipitated by a hot solution of 1·5 grms. of nitroso-β-naphthol in 10 c.c. of acetic acid. The precipitate was filtered off cold, washed, dried, ignited, and weighed as ferric oxide. In the filtrate the zirconium can be precipitated by ammonia, either directly, or preferably after destroying the organic matter by boiling with potassium chlorate and hydrochloric acid. In most cases, however, it would be better to precipitate in a fresh portion of the original solution the iron and zirconium together by ammonia and determine the zirconium by difference. In the case of sulphate solutions, the precipitation of zirconium is not completely prevented by oxalic acid, but the separation can be readily effected in presence of tartaric acid. The solution containing iron and zirconium is treated with tartaric acid, a slight excess of ammonia is added to dissolve the precipitate produced, the clear liquid diluted to about 200 c.c., slightly acidified with hydrochloric acid, 10—20 c.c. of acetic acid added, the solution heated to boiling and the iron precipitated, whilst stirring, with a hot solution of nitroso-β-naphthol in acetic acid. The procedure is then the same as described above. (See also this J., 1889, 819; 1892, 713; 1893, 711; and 1897, 67.)—A. S.

Ferrous Salts; Conversion of ——, into Ferric Salts for Volumetric Determinations or for Separation of Iron with Manganese. L. L. de Koninck. Bull. Soc. Chim. Belg., 1904, **18**, 90—92.

A solution of pure ferrous chloride, completely oxidised by means of bromine, is decomposed on heating, a basic salt being precipitated. After boiling the solution, with or without the addition of hydrochloric acid, the presence of a ferrous salt can be detected on addition of potassium ferricyanide. Thus ferric bromide, in solution, is dissociated by boiling, even in presence of hydrochloric acid or a chloride; the author concludes that the use of bromine as an oxidising agent for ferrous salts should be avoided when an excess of bromine is undesirable in the solution.

—T. F. B.

Cupric Salts; Precipitation of —— by Potassium Hydroxide. L. L. de Koninck. Bull. Soc. Chim. Belg., 1904, **18**, 89—90.

The presence of a large excess of alkali nitrate does not, as is stated in several works on analytical chemistry, prevent the complete precipitation of cupric salts by potassium hydroxide; the solvent action attributed to the nitrate is probably due to the use of a large excess of alkali in the precipitation or to the presence of organic matter in the reagents used.—T. F. B.

Cyanogen; Volumetric Determination of ——. J. McDowall. Chem. News, 1904, **89**, 229.

The author recommends, for the rapid determination of cyanides, *e.g.* in the valuation of potassium cyanide for gold extraction, titration with a standardised solution of copper sulphate to which excess of ammonia has been added. The presence of chlorides has no influence on the results.—A. S.

Silver [in Silver Alloys]; Proposed Modification of Volhard's Method of Determining ——. C. Hoitsema. Z. angew. Chem., 1904, **17**, 647—650.

Rose (this J., 1904, 470) has proposed to alter Volhard's method by adding directly sufficient standardised thiocyanate solution to precipitate nearly the whole of the silver, then filtering, adding the iron indicator and finishing the titration with the clear filtrate. The author finds that whilst the sensitiveness of the final reaction is considerably increased by the alteration, the accuracy is, in certain cases impaired. For example, in six tests with 1000, 1001, 1002, 1003, 1004, and 1005 mgrms. respectively of pure silver, after adding to the solution 100 c.c. of standard thiocyanate solution (1 c.c. = 10 mgrms. of silver), and filtering, the amounts of dilute thiocyanate solution required to produce a yellow colour in the filtrate were 0, 1, 3, 7, 14, and 20 drops, instead of there being a regular increase of 20 drops (= 1 mgrm. of silver) in each case. In other tests, also variable results were obtained, and these are shown by the author to be due to the "adsorption" by the silver thiocyanate precipitate of soluble silver salts and also of the soluble thiocyanate. The author concludes that Rose's proposed modification may give rise to false results and should therefore not be used.—A. S.

Tin. Assay of ——, and Solubility of Cassiterite. J. H. Collins. Inst. Min. Metall., May 19, 1904.

For practical purposes on the mine, the author recommends vanning; for scientific determinations the old Ecole des Mines method of reducing by fusion with potassium cyanide and weighing as metallic tin, due precautions being taken when lead, bismuth, arsenic, antimony, &c., are present. In the assay of "black tin" by the direct fusion method, he deprecates a previous cleansing by boiling with acid, cassiterite not being altogether insoluble under such treatment. The results of a number of experiments on the solubility of different forms of native oxide of tin in dilute sulphuric and hydrochloric acids in presence of metallic zinc are then recorded, and the author concludes that it is only the "wood-tin" varieties which are in any important degre soluble—some varieties being almost completely solubl under the conditions named.—J. H. C.

Copper; Quantitative Electrolytic Precipitation of —— T. W. Richards and H. Bisbee. J. Amer. Chem. Soc 1904, **26**, 530—536.

Among the conditions upon which the rapid deposition o the copper depends are the area of the cathode and the concentration of the solution. The best conditions are thu obtained by employing a thin film of the liquid between tw large surfaces, such as the annular space between two concentric platinum crucibles or dishes, separated by a suitabl device made of thin glass rod. As the electrolysis proceed the current density can be automatically diminished b employing a single storage cell without resistance. copper solution was used for the experiments, and it w found that the time of deposition was approximately i versely proportional to the concentration.—E. H. T.

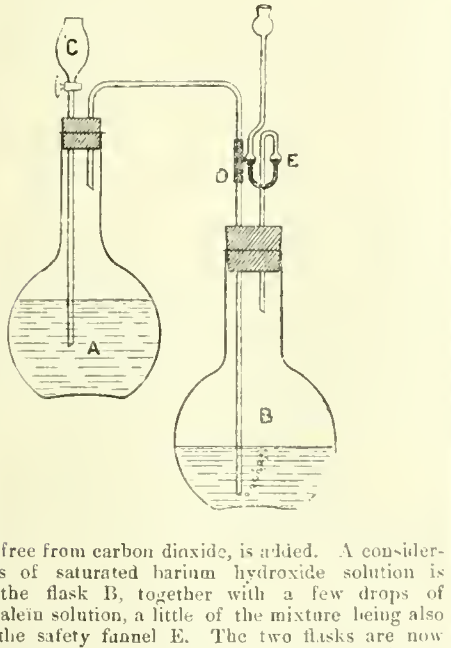
Lead; [Determination of ——] in Citric and Tartar Acids. C. T. Bennett. Chem. and Druggist, 1904, **6** 815.

According to A. H. Bennett, the results obtained in t colorimetric determination of lead by means of sodiu sulphide are slightly higher when distilled water is used f the preparation of the standard colours than when pu solutions of ammonium citrate or tartrate are employed, originally proposed by Warington. The author finds t

although a slight difference is discernible when the proportion of lead is greater than about 20 parts per million, the discrepancy is practically negligible with smaller amounts. If, therefore, when the amount of lead is greater than 20 parts per million, the solution be diluted before being tested, the great drawback to Warington's method, viz., the impossibility of obtaining commercially samples of citric and tartaric acids quite free from lead, may be overcome.
—A. S.

Carbon Dioxide; Rapid Method for the Volumetric Determination of ——. T. Macara. Analyst, 1904, **29**, 152—153.

The process is based on the fact that barium carbonate behaves like an alkali towards Methyl Orange. A known quantity of the substance (equivalent to not more than 2·5 grms. of calcium carbonate) is placed in the flask A, and water, free from carbon dioxide, is added. A considerable excess of saturated barium hydroxide solution is placed in the flask B, together with a few drops of phenolphthalein solution, a little of the mixture being also placed in the safety funnel E. The two flasks are now onnected, hydrochloric acid is added by the funnel C, and he contents of A gradually raised to boiling, the flask B eing vigorously shaken meanwhile. When all carbon lioxide has passed over, the flasks are disconnected, dilute ydrochloric acid is added to the contents of B through a unnel attached at D until all free barium hydroxide has een neutralised, 2 or 3 c.c. of barium hydroxide are added o make the solution again alkaline, and the flask is well haken. The contents of E and B are now mixed, eutralised exactly with N/10 hydrochoric acid, and the arium carbonate titrated with N/10 hydrochloric acid after dding Methyl Orange as indicator. Should sulphides, lphites, chlorine, bromine, or nitrites be present in the ıbstance, the usual precautions must be taken by adding opper sulphate or chromate to the evolution flask. With e latter, sulphuric acid must be used instead of hydroloric acid.—W. P. S.



ulphur; Forms in which —— occurs in Coal; their Calorific Values and Effects on the Accuracy of the Heating Powers, calculated by Dulong's formula. E. E. Somermeier. II., page 601.

ORGANIC—QUALITATIVE.

utter; Distinction of Natural from Artificial ——. A. Quartaroli. Staz. sperim. agrar. ital., **37**, 18—23. Chem. Centr., 1904, **1**, 1373—1374.

RELLI and Carcano (Staz. sperim. agrar. ital., **25**, 77) oposed to detect adulteration of butter by determining s molecular weight from the lowering of its freezing-point in benzene solution according to Raoult's method, but were unable to detect additions of less than 25 per cent. of margarine. The author obtains better results by the following method depending on the same principle. 30 grms. of the sample are melted at 60° C. in a dry porcelain dish, and filtered through a dry filter, 5—6 c.c. of the filtrate are made up to nearly 50 c.c. with acetic acid, the mixture is allowed to stand for 24 hours in a hermetically-closed flask, then filtered rapidly, and the cryoscopic determination made immediately in a Beckmann's apparatus. The results given in the following table show that whilst the lowering of the freezing point scarcely varies in direct proportion to the amount of margarine present, yet the presence of 10 per cent. of the latter can be detected.

Lard; Detection of Cocoanut Oil in ——. F. Morrschöck. Z. Unters. Nahr.- u. Genussm., 1904, **7**, 586—587.

The results of the experiments given show that pure lard is only slightly soluble in 95 per cent. alcohol. This soluble portion has a considerably higher iodine value (70) than the original lard; it has a + refraction, but the saponification value does not appreciably alter. The presence of a small quantity of cocoanut oil in the lard distinctly alters the composition of the fraction soluble in alcohol. The saponification value is increased, compared with that of the original mixture, the iodine value is lower, and the refraction is negative. The alcohol-soluble portion of a mixture containing 10 per cent. of cocoanut oil had an iodine value of 46·56, against 54·65 for the original mixture; a saponification value of 221·6 against 204·2, and a refraction of − 3·4 compared with − 1·9.
—W. P. S.

Quinine, Detection of ——, by J. J. André's [Thalleioquin] Reaction. E. Léger. J. Pharm. Chim., 1904, **19**, 281—284, 434—435.

It is shown that the green colour-reaction obtained with salts of quinine in the presence of ammonia and free bromine or chlorine depends entirely upon the amount of the latter present. It is, therefore, necessary to employ a definite quantity of bromine solution to obtain a positive reaction. By adding 1 drop only of saturated bromine water to 10 c.c. of the quinine solution, agitating, then adding 1 drop of ammonia, without shaking, a green zone is formed at the line of contact, with a dilution of 1 : 20,000 of quinine. The Swiss and Italian Pharmacopœias adopt this test to indicate the amount of quinine in the "total alkaloids" of the official cinchona bark. The 0·5 grm. which the 10 grms. of bark should yield, is directed to be dissolved in 100 c.c. of water by the aid of a little acetic acid. If the bark meets the official requirement of containing 1 per cent. of quinine, this will give a 1 : 1000 solution. The bromine reagent is directed to consist of 1 c.c. of freshly prepared saturated bromine water and 99 c.c. of distilled water. To 10 c.c. of this reagent, 1 c.c. of the alkaloidal solution is added, then 5 or 6 drops of ammonia. A green colour should be produced. If instead of employing the bromine reagent of the strength indicated, one of half the strength be employed, a green colour may be obtained with 0·5 c.c. of the alkaloidal solution almost as intense as with the official quantity. The colour reaction depends, therefore, not on the amount of quinine present, but on the dilution of the bromine reagent. Other tests confirmed the view that the reaction is useless for quantitative purposes.—J. O. B.

ORGANIC—QUANTITATIVE.

Quinine; Determination of ——, in Mixtures with other Cinchona Alkaloids. E. Léger. J. Pharm. Chim., 1904, **19**, 427—434.

It is found that, although quinine may be precipitated from a solution of cinchona alkaloids as basic tartrate by means of solution of Rochelle salt, and the precipitate does not carry down the other bases, the same is not the case with cinchonidine, precipitated as tartrate under similar conditions. This precipitate is found to be largely contaminated with the other alkaloids. Consequently the method of Oudemans alone, based on the polarimetric reading of the solution of the tartrates is inapplicable to the case of the determination of quinine in "total alkaloids," although it gives very accurate results with quinine and cinchonidine only. The method of Carles also, in which the crystallised quinine sulphate is weighed as such, gives good results with barks rich in quinine and poor in cinchonidine; but is unsatisfactory with those in which the cinchonidine is in preponderance. The author proposes to combine the two methods. In the first place, the basic sulphates of quinine and conchinidine are obtained in a crystalline form, employing a saturated solution of quinine sulphate, instead of water, as the solvent of the sulphates of the other alkaloids; these sulphates of quinine and cinchonidine are then converted into tartrates in a cold saturated solution of quinine and cinchonidine tartrates. The rotation of the mixed tartrates is then determined as in Oudemans method. The details of the process are as follows. The total alkaloids in the form of basic sulphates are treated in a conical flask with a boiling mixture of 5 c.c. of water and 75 c.c. of aqueous solution of quinine sulphate saturated in the cold. The mixture is then heated over the naked flame to complete solution, and set aside for 24 hours to crystalise. In this manner the sulphates of quinine and cinchonidine are separated, whilst the sulphates of the other bases remain in the mother liquor of saturated quinine sulphate. The crystalline sulphates are collected on a tared filter comprising a funnel, a perforated porcelain disc, and a round flannel filter pad, drained by a vacuum, washed with saturated solution of quinine sulphate and finally with 2 c.c. of distilled water. After draining, the crystalline cake of sulphates is first dried in the air, then at 30° C. The funnel, the disc, and the flannel pad are dried and weighed as well as the crystals. The crystalline mass is then powdered, 0·7 grm. weighed off into a conical flask, treated with 40 c.c. of saturated solution of tartrates of quinine and cinchonidine previously heated to boiling, and the mixture heated until solution is complete. To the hot solution 2 c.c. of solution of sodium-potassium tartrate, containing 0·35 grm. per c.c., are added. After 24 hours, the crystalline precipitate of double tartrates is collected on two counterpoised filters, and washed, first with saturated solution of quinine and cinchonidine tartrates, then with 5 c.c. of water. The filters are then drained and pressed between bibulous paper, the contents withdrawn, the filters and tartrates dried separately in the air until constant, then weighed. The index of rotation is then determined as in Oudeman's method according to his formulæ—

$$215{\cdot}8 \times x + 131{\cdot}3\,(100 - x) = 100 \times \alpha m$$

in which αm = the observed rotation of the mixed tartrates. Hence—

$$x = \frac{100\,\alpha m - 13130}{215{\cdot}8 - 131{\cdot}3}$$

in which 215·8 is the rotatory index of quinine tartrate, and 131·3 that of cinchonidine tartrate. The quantity of quinine tartrate TQ in the mixed tartrates TM will be therefore—

$$TQ = \frac{TM\,(100\,\alpha m - 13130)}{100\,(215{\cdot}8 - 131{\cdot}3)}$$

and the corresponding amount of quinine Q will be—

$$Q = \frac{324 \times TM\,(100\,\alpha m - 13130)}{408 \times 100\,(215{\cdot}8 - 131{\cdot}3)}$$

324 being the mol. wt. of quinine and 408 that of quinine tartrate. With mixtures of quinine, cinchonidine and cinchonine sulphates the method has afforded very accurate results.—J. O. B.

Methyl Alcohol; Determination of ——, in Formaldehyde. R. Gnehm and F. Kaufler. Z. angew. Chem., 1904, **17**, 673—676.

Ninety grms. of the sodium salt of sulphanilic acid are dissolved in 35 c.c. of boiling water, and rapidly cooled, with agitation. To the magma, 20 c.c. of the formaldehyde are added and occasionally shaken during 3—4 hours; the aldehyde is thus fixed. Next 30—35 c.c. are distilled over, made up to 50 c.c., and weighed in a pycnometer, thus obtaining the specific gravity of the methyl alcohol; this specific gravity must be known to four places of decimals, and the temperature must therefore be carefully adjusted or allowed for. Traces of a body, not formaldehyde, which reduces ammoniacal silver nitrate, are always found in the distillate. The maximum error observed in applying this method was 0·5—0·6 grm. in 100 c.c.—W. A. C.

Formaldehyde and Trioxymethylene; Determination of ——. C. Kleber. Pharm. Rev., **22**, 94. Pharm. J., 1904, **72**, 682.

A concentrated solution of sodium bisulphite is treated with sodium hydroxide solution till all odour of free sulphurous acid has disappeared, and is then diluted until 30 c.c of it exactly neutralise 50 c.c. of N/1 sodium hydroxide solution. Formaldehyde and trioxymethylene act towards this solution as alkalis. 5 c.c. of the formaldehyde solution, or 2 grms. of trioxymethylene with a few c.c. of water, are titrated, in presence of phenolphthalein, with the bisulphite solution, until the red colour is destroyed, and does not reappear on warming.—A. S.

Tartaric Acid; New Method for Determination of ——. H. Ley. Pharm. Zeit., 1904, **49**, 149.

The method is based on the complete insolubility of zinc tartrate in alcohol and in acetic acid, so that by their employment the precipitation of hydrated carbonate or other basic compounds of zinc is avoided.

Tartaric Acid.—A few decigrms. of the acid are dissolved in water or alcohol; the solution is gently warmed, then treated with alcoholic solution of zinc acetate in excess; after standing for some time in the warm, from 100 to 150 c.c. of alcohol, and 5 c.c. of 50 per cent. acetic acid are added and the mixture is kept for about 10 minutes on the water-bath. After cooling, the precipitate is collected, washed with alcohol, dried, calcined, redissolved in a little nitric acid, again calcined, and weighed as zinc oxide.

Potassium Acid Tartrate.—With pure cream of tartar the process is conducted as above, the first solution, however being obtained by heating with the smallest possible quantit of water, which is then precipitated with aqueous zinc acetat solution. In crude argol the whole of the tartaric aci must first be converted into potassium tartrate, by digestin with potassium carbonate, a few drops of phenolphthalei being used as indicator to avoid excess of alkali. Th solution thus obtained is made up to a known volume, an after standing, an aliquot part is taken for the determinatio which is then conducted as described above. The metho may be applied to the determination of tartaric acid i wines, but the tannin present must be first eliminated b treatment with animal charcoal.—J. O. B.

Morphine in Opium; Determination of ——. I Schidrowitz. Analyst, 1904, **29**, 144—148.

The following method is described, being based to certain extent on the process given in the Pharmacopœ Germanica IV. Six grms. of powdered opium are mix into a cream with 6 c.c. of water, and then transferred to 100 c.c. Erlenmeyer flask, which has previously be counterpoised. The weight of opium and water is th made up to 54 grms. After shaking the contents of t flask for 1 hour, the whole is poured on a filter. Exac

42 grms. of the filtrate are shaken for half a minute with 2 grms. of a solution of sodium salicylate containing 50 grms. per 100 c.c. and again filtered. 36 grms. of filtrate are collected, 15 c.c. of ether are added, and then 5·2 c.c. of ammonia solution prepared by mixing 17 grms. of ammonia (sp. gr., 0·960) with 83 grms. of water. The whole is vigorously shaken for 10 minutes and allowed to stand for 24 hours, when the ether is poured on a filter, 15 c.c. of fresh ether are added to the flask, cautiously shaken, and again poured on the filter together with the aqueous portion. The greater part of the crystals remain in the flask and are washed with 3 quantities of 5 c.c. of water saturated with ether. Of each 5 c.c., 3 c.c. are used to rinse the flask, and 2 c.c. run directly on the filter. The filter and its contents are then pressed between blotting-paper, and the greater part of the crystals returned to the flask. The filter and flask are dried at 55° C., when the crystals remaining on the filter are readily transferred to the flask The crystals are now dissolved in 25 c.c. of N/10 sulphuric acid, and the excess of acid titrated back with N/10 alkali, using Methyl Orange as indicator. The amount of morphine in the sample is then calculated from the equation—

$x \times 0{\cdot}7575 + \frac{1}{13}(x \times 0{\cdot}7575) =$ per cent. of morphine where $x =$ the number of c.c. of N/10 acid used.

Test analyses are given which show that the method is accurate.—W. P. S.

Nux Vomica, Ignatius Beans, Ipecacuanha, and Cinchona Bark; [*Alkoloidal*] *Assay of* ——. E. Léger. J. Pharm. Chim., 1904, **19**, 479–484.

Nux Vomica: First Method.—An amount of the powdered drug, equivalent to 12 grms. of the dry substance, is agitated for 5 minutes, with a mixture of 20 c.c. of chloroform and 100 c.c. of ether, sp. gr., 0·721. 5 c.c. of a mixture of equal volumes of solution of ammonia and distilled water are then added, and the mixture is well agitated occasionally for 3 hours; 80 c.c. of the liquid are filtered off (corresponding to 8 grms. of the original powder), and shaken out successively with 25, 15, and 10 c.c. of a solution of 2 c.c. of hydrochloric acid in 48 c.c. of water. The acid extracts are mixed, the alkaloids liberated with a slight excess of dilute ammonia, and shaken out twice with 50 c.c. of the above ether-chloroform mixture; the bulked alkaloidal solutions are washed with 2 c.c. of water, and the solvent is then distilled off in a small tared flask, the residue dried at 100° C. and weighed. The amount of alkaloids thus found should be about 2·5 per cent.

Second Method.—A modified Prollius's extraction menstruum, consisting of solution of ammonia 4 c.c., absolute alcohol 16 c.c., ether sp. gr. 0·721, 130 c.c., may be employed instead of the ether-chloroform mixture. In this case, 180 c.c. are taken for the 12 grms. of powder operated n. After macerating for 12 hours, 150 c.c. are filtered off, nd distilled in two portions from a small flask. The esidue is dried, first on the water-bath, then at 100° C., n the drying oven; then dissolved in 12 c.c. of a mixture f hydrochloric acid 1 c.c. and water 14 c.c. by heating he rubber-corked flask on the water bath and well agitating fter the fatty matter has melted. When the solution is cold, his adheres to the sides of the flask. The acid liquid is ltered through a small paper, 10 c.c. of the filtrate are endered alkaline with ammonia, and the alkaloids shaken ut with three successive 20 c.c. of chloroform. The bulked hloroform extracts are washed with 2 c.c. of water, then istilled; the residue dried at 100° C. and weighed. The eight × 12 gives the percentage of alkaloids.

Ignatius Beans.—The equivalent of 12 grms. of the dry aterial is weighed off, and treated as described under x vomica by the first method. Ignatius beans are somemes richer in alkaloids than nux vomica, G. Sandor *ahresbericht der Pharm.*, **1896**, 135), having found 1 to 3·22 per cent.

Ipecacuanha: First Method.—Similar to the first method r nux vomica, but adding 2 c.c. of solution of ammonia d 8 c.c. of water to the ether-chloroform extraction fluid; aceration is conducted for one hour only, after which the wdered drug is aggregated by the addition of 10 c.c. of ter; 100 c.c. of liquid, equivalent to 10 grms. of drug, are filtered off. The amount of total alkaloids should not fall below 2 per cent.

Second Method.—Similar in all respects to the second method for *nux vomica*.

Cinchona Bark.—The method is based on Portes' modification of the Prollius method. A weight of powdered bark equivalent to 6 grms. of dry material is macerated for 1 hour with 6 c.c. of solution of ammonia, and 24 c.c. of 90 per cent. alcohol; 120 c.c. of ether (sp. gr., 0·721) are then added and maceration continued for 6 hours with occasional agitation. 120 c.c. of filtrate are collected (equivalent to 4·8 grms. of the dry drug), distilled to dryness in several small portions, and the perfectly dry residue dissolved in 12 c.c. of a mixture of hydrochloric acid, 1 c.c. in water 14 c.c. The acid alkaloidal solution is passed through a small filter, and 10 c.c. of the filtrate are rendered alkaline with 2 c.c. of solution of ammonia, and 2 c.c. of water, and the liberated alkaloids shaken out with three successive 20 c.c. of chloroform. The bulked chloroformic extracts are washed with 2 c.c. of water filtered, then distilled from a small tared flask, and dried to constant weight at 100° C. and weighed. The weight × 25 = the percentage of total alkaloids.
—J. O. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radioactivity and Matter. C. Winkler. Ber., 1904, **37**, 1655—1662.

The author discusses the question whether the so-called radio-active elements are elements, or whether radio-activity is not a purely physical process, somewhat similar to the magnetism of magnetite. He considers that the question will be satisfactorily answered only when larger quantities of the radio-active substances have been isolated and subjected to a more thorough chemical examination.—A. S.

Emanium. An Emanating Substance. F. Giesel. Ber., 1904, **37**, 1696—1699.

The emanation obtained from pitchblende (this J., 1903, 322) has been further investigated. The anhydrous chloride or bromide phosphoresces, the spectrum being discontinuous, and containing 3 lines lying between red and bluish-green. The glass in which the substance is preserved is coloured violet, whilst paper is turned brown and disintegrates. The activity of the solid reaches a maximum about 1 month after its separation from solution, and the emission of β-rays diminishes the longer the solid has been kept in solution, and the more dilute the solution. These properties point to the presence of a new element, which is named "Emanium" and which appears to belong to the rare earths. The scintillations produced on a Sidot's fluorescent screen are much brighter and larger than those produced by radium. A spinthariscope containing emanium is therefore more effective than one containing radium or polonium.—L. F. G.

Silicon; Apparent Volatilisation of —— *in Hydrogen.* A. Dufour. Comptes rend., 1904, **138**, 1169—1170.

In vacuum tubes containing arsine, the metallic arsenic deposited by the discharge is displaced, when the discharge is taking place, by a simple process of distillation, and deposits on the coolest part of the tubes; by artificial cooling it can be made to deposit at any desired part of the tube. With silicon hydride, however, this is not the case; the silicon deposits always in the Faraday's dark space. The author considers that the silicon is not volatilised, but converted by the free hydrogen into silicon hydride, which is decomposed at that particular part of the tube.—J. T. D.

Aluminium, Mercuric Chloride, and Benzene; Reaction between ——. W. Gulewitsch. Ber., 1904, **37**, 1560—1564.

If a mixture of 10 grms. (1 mol.) of aluminium turnings, and 151 grms. ($1\frac{1}{2}$ mols.) of mercuric chloride, be covered with 15 grms. of benzene, the mass becomes heated, and the benzene boils. The reaction is allowed to continue under a reflux condenser and another 43 grms. of benzene (2 mols. in all) are added. The mixture evolves hydrochloric acid, and is vigorously shaken towards the end of the reaction. A reddish-brown layer of liquid is produced, which, on filtering from metallic mercury, deposits transparent, yellow, six-sided plates on standing over sulphuric acid. The crystals are hygroscopic, and their composition is $C_6H_6.AlCl_3.HgCl$.—L. F. G.

Distillation of Immiscible Liquids. E. Charabot and J. Rocherolles. Bull. Soc. Chim., 1904, **31**, 533—544.

IN general the proportion in which an immiscible liquid distils with water is expressed by

$$\frac{P}{P^1} = \frac{M.F}{M^1.F^1}$$

where P is the weight of condensed liquid, M its molecular weight, and F its vapour-tension at the common boiling point, P^1, M^1, and F^1 being the corresponding functions of water. The authors' experiments show that P/P^1, if less than unity, increases as the boiling point is raised by pressure, whilst if greater than unity it diminishes under the same circumstances. When steam is passed into a less volatile immiscible liquid, the relation $\frac{P}{P^1} = \frac{M.\phi}{M^1.h}$ holds good, where ϕ is the vapour-tension of the liquid corresponding to the observed temperature of the mixed vapours, and h is the pressure. Hence, in steam distillation (as, for instance, of essential oils), the proportion of oil in the distillate can be raised, (1) by heating the still from outside and thus increasing ϕ; (2) by applying a vacuum and thus diminishing h.—W. A. C.

Water; Rate of Diffusion of ——, through a Semi-permeable Membrane. [*Molecular Weight of Dextrin*]. J. Sebor, Z. Elektrochem., 1904, **10**, 347—353.

THE rate of diffusion of water into a sugar-solution contained in a copper ferrocyanide cell is found to be, disregarding a moderate experimental error, directly proportional to the osmotic pressure; the experiment consumes much less time than Pfeffer's familiar measurement of the ultimate pressure. Applying this method, the molecular weight of dextrin is found to correspond to $(C_6H_{10}O_5)6{\cdot}3$. Further, the molecular weight of freshly-dissolved glucose remains the same whilst its rotation is simultaneously decreasing towards constancy; hence the bi-rotation of glucose cannot be due to the existence and breaking down of complex molecules.
—W. A. C.

Alkoli Fusion of Sulphonic Acids; Introduction of —— into Technology. H. Wichelhaus. Chem. Ind., 1904, **27**, 234.

H. BRUNCK has stated that Graebe and Liebermann in their process for the manufacture of alizarin, were the first to introduce into technology the sulphonating process, and the alkali fusion of sulphonic acids. The author points out, however, that he, in conjunction with L. Darmstädter, patented on Jan. 12, 1869, the preparation of α-naphthalene-sulphonic acid and of α-naphthol from the same, by fusion with alkali; and that a German firm intimated their willingness to carry out the process on the manufacturing scale on Mar. 22, 1869. Graebe and Liebermann's second patent for the manufacture of alizarin, in which the use of anthraquinone-sulphonic acids and the fusion of the same with alkali are claimed, was taken out on June 25, 1869.
—A. S.

Ethyl Butyrate; Hydrolysis of ——, by Lipase. J. H. Castle, M. E. Johnston, and E. Elvove. Amer. Chem. J., 1904, **31**, 521—550.

A CLEAR solution of the lipase was prepared by macerating 1 grm. of fresh hog liver with powdered glass or coarse white sand and 75 c.c. of water. The mixture was heated to 35° C., 5 c.c. of $N/_{10}$ butyric acid added gradually, and the whole made up to 100 c.c. with water. The heavy precipitate produced, was filtered off on a folded filter, a perfectly clear filtrate being obtained, usually of a faint yellowish colour. 5 c.c. of the clear solution when allowed to act upon 0·26 c.c. of ethyl butyrate at 40° C., will hydrolyse from 5 to 6·25 per cent. (or about 0·0145 grm.) of the ester. The solution loses only 7 per cent. of its lipolytic activity in five months, the very small amount of acid present exercising a preservative action on the enzyme. If the clear solution be filtered through a Pasteur-Chamberland filter, the filtrate possesses no enzymic activity. Experiments with clear solutions of the lipase which had been previously neutralised with standardised caustic soda solution, showed that small amounts of free acid (hydrochloric and butyric) greatly inhibit the action of the enzyme, whilst larger amounts completely destroy the ferment. Between 0° and 40° C., the rate of hydrolysis was increased by rise of temperature, being, on the average, 1·69 times greater for a rise of 10° C. Lipase appears to be a true catalytic agent, in that it suffers no permanent alteration while effecting the hydrolysis of the ethyl butyrate. The degree of hydrolysis effected by lipase is, within certain limits, independent of the concentration of the ethyl butyrate. From a comparison of the hydrolysing action of lipase, hydrochloric acid, and sodium hydroxide, the authors conclude that lipase as a hydrolysing agent more nearly resembles sodium hydroxide than it does hydrochloric acid.—A. S.

Ferment Actions. L. Liebermann. Ber., 1904, **37**, 1519—1524.

THE effect of hydrogen or nitrogen gas on a colloidal platinum solution is, in general, to diminish the amount of active oxygen it contains, but in some cases, and more especially immediately after nitrogen has been passed through such a solution, the latter exhibits a considerably increased activity for the catalysis of hydrogen peroxide. This the author considers to be due to an alteration brought about in the molecular structure of the colloidal platinum, possibly by increasing the smallest particles o platinum and so the surface of the latter. Colloidal platinum solutions containing 6—8 mgrms. of metal per 100 c.c., or boiling for half an hour or longer, become greatly diminishe in activity, which, however, they gradually recover whe cold; if such a boiled solution be allowed to cool i contact with air or oxygen, its catalytic activity is appreciably greater than if the cooling take place in nitrogen o hydrogen. These and similar results lead to the conclusio that oxygen plays an important part in the catalysis hydrogen peroxide by colloidal platinum, and the autho assumes that the latter possesses the power of rendering th molecular oxygen of the air active, and that this activ oxygen initiates the catalysis, which then proceeds witho requiring any source of oxygen other than the hydroge peroxide itself.

In studying the action of animal and vegetable enzym in catalysing hydrogen peroxide, the author has made u of an apparatus by means of which the pressure of t oxygen evolved, is measured by a mercury manomete These catalases, or the solutions containing them, nev contain active oxygen, nor have they the power of renderi active, oxygen led into them. In most cases, howev they are capable of taking up active oxygen (ozone) although, as a rule, for only a short time—and of retaini it in such a manner that it can be detected in the soluti At ordinary temperatures, air, oxygen, hydrogen, a nitrogen are practically without action on the cataly power of these enzymes, but when these are heated, t presence of oxygen or air lowers the temperature at whi they are destroyed. The action of these enzymes diff from platinum-catalysis in this, that here a direct action the enzyme on hydrogen peroxide undoubtedly takes pla as no active oxygen is required to initiate the reaction. may hence be assumed that an intermediate oxide peroxide of the enzyme is formed which reacts rea with hydrogen peroxide and carries on the catalysis. F tissue yields an extraordinarily active catalase, w causes brisk effervescence when added to a 3 per c solution of hydrogen peroxide.—T. H. P.

Reductases of Yeast; Conversion of Nitrobenzene Aniline by Philothion and ——. M. E. Pozzi- Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 10 1075.

THE author, in reply to the criticism of Abelons and Gé maintains that the hydrogenising and reducing fermen yeast are capable of converting nitrobenzene into an

Beer or wine yeast pressed, but not dried, is distributed in a mixture of alcohol and water of about 40° C., and left for 30—40 hours, with occasional agitation; it is then filtered. The clear amber-coloured filtrate, with a few drops of nitrobenzene, is introduced into a flask and shaken from time to time for 24 hours, when the odour has almost disappeared. The liquid does not give the reaction of aniline until the alcohol has been distilled off in a hydrochloric acid solution and the residue treated with an excess of baryta and distilled with steam. The action is increased in the presence of sulphur.—L. J. de W.

Chromous Tartrate; Crystalline ——. G. Baugé.
Comptes rend., 1904, **138**, 1217—1220.

Moist chromous acetate is treated with a cold, boiled solution of tartaric acid (1 : 3) in an atmosphere of carbon dioxide. The acetate rapidly dissolves, giving a blue liquid. The flask is immersed in a bath of boiling brine, and a blue powder is deposited, whilst aqueous acetic acid distils off The blue deposit is filtered off, whilst still maintaining the atmosphere of carbon dioxide, washed with boiled water and dehydrated with alcohol, and finally with ether. The salt has a pale blue colour and crystallises in the form of microscopic prismatic crystals. It has a density of 2·33 at 15° C., and is insoluble in water. Analysis indicated the formula $C_4H_4CrO_6$. Chromous tartrate is very readily oxidised, and reduces ammoniacal silver nitrate. In contact with a concentrated solution of an alkali carbonate, in absence of air, it is converted into a double carbonate of chromium protoxide. In dilute solutions, containing a large proportion of carbonate relatively to tartrate, the saline oxide of chromium ($Cr_3O_4.4H_2O$; see this J., 1899, 305) is produced quantitatively on boiling.—J. F. B.

ERRATUM.

This J., 1899, 305, abstract of Baugé's article on "A New Hydrate of Chromous Oxide," *for* "$CrCr_3O_4$" throughout the abstract *read* "Cr_3O_4."

Camphor Group; Metallo-organic Syntheses in the ——.
G. Oddo. Ber., 1904, **37**, 1569—1572.

For the preparation of dicamphor and dicamphoquinone from bromocamphor, magnesium powder gives better results than sodium, which was previously proposed:—184·8 grms. of bromocamphor, 19·2 grms. of magnesium powder and 800 c.c. of dry toluene are mixed in a large flask under a reflux condenser and heated in an oil-bath. When the reaction begins it is very violent for the first 10 minutes, and the flask must be cooled. After the reaction has subsided, the contents of the flask are boiled for 24 hours; the mixture is then treated with ice and acidified with dilute sulphuric acid. The volatile constituents are removed by distillation with steam for four hours, and the residue is recrystallised from dilute alcohol (yield 37·2 per cent.). The dicamphoquinone is extracted from this product by means of a mixture of light petroleum spirit and benzene, and the dicamphor is eparated from the residue by treatment with dilute acetic acid.—J. F. B.

Ethane; Action of Ozone on ——. W. A. Bone and J. Drugman. Proc. Chem. Soc., 1904, **20**, 127.

The authors have obtained ethyl alcohol by the interaction of ethane and ozone at 100° C. Two experiments have been carried out as follows: ethane and ozonised air (the latter ontaining about 2½ per cent. of ozone) were separately led nto the top of a vertical, wide glass tube, about 18 inches ong, packed with glass beads and heated by a steam jacket. The proportions of the gases were so regulated that the ethane was always present in large excess, under which conditions the zone entirely disappeared as the mixture slowly descended he tube. The gases were then drawn through a series of ooled glass worms containing water for the absorption of soluble intermediate products. Each experiment extended ver 3 or 4 days, during which about 5 litres of ethane and 13 o 15 litres of the ozonised air passed through the apparatus. Subsequent examination of the liquid from the coolers showed that it contained ethyl alcohol, acetaldehyde, and traces of formaldehyde. At temperatures where ethane begins to react with oxygen with appreciable velocity, the alcohol is oxidised so many times faster than the ethane that it is practically impossible actually to detect its formation.

Prizes.

Butter; Detection of Adulterating Matters in ——.
Bd. of Tr. J., May 26.

The "Bulletin Commercial" (Brussels) of 14th May states that the Berlin Association of Butter Merchants is offering the following prizes:—

(1) 150*l.* for the best method of detecting the presence of palm fats in butter.

(2) 50*l.* for the best method of detecting the presence of lard in butter.

(3) 50*l.* for the best method of detecting the presence of palm fats in lard.

The methods must be of a nature which will allow them to be carried out in the course of one day in laboratories established for the purpose, and must be able to detect the presence of 15 per cent. of adulterating matter. The fee for each analysis must not exceed 6*s.*

New Books.

Elements of Water Bacteriology with Special Reference to Sanitary Water Analysis. By Samuel Cate Prescott and C. E. Amory Winslow, Lecturers in the Massachusetts Institute of Technology. John Wiley and Sons, New York, U.S. America. 1904. Price 5*s.* 6*d.* net. Chapman and Hall, Ltd., London.

Small 8vo volume containing 118 pages of subject-matter, an appendix of 9 pages, a list of references (bibliography) of 14 pages, and indexes of authors and subject-matter (20 pages). The following subjects are treated of:—I. Bacteria in Natural Waters. II. Quantitative Bacteriological Examination of Waters. III. Interpretation of preceding. IV. Determination of the Number of Organisms developed. V. Isolation of Specific Pathogens from Water. VI. Isolating the Colon Bacillus. VII. and VIII. Significance of and Presumptive Tests for *B. Coli* in Water. IX. Other Intestinal Bacteria. X. Significance and Applicability of the Bacteriological Examination.

Gas Works, their Construction and Arrangement, and the Manufacture and Distribution of Coal Gas. Originally written by Samuel Hughes, C.E. Ninth Edition, revised, with Notices of Recent Improvements, by Henry O'Connor, Assoc. M. Inst. C.E. Crosby Lockwood and Son, 7, Stationers' Hall Court, Ludgate Hill. 1904. Price 6*s.*

Small 8vo volume, containing frontispiece, preface, and 410 pages of subject-matter, with 75 illustrations.

The leading subjects treated of are as follows:—I. Historic Sketch. II. Chemistry of Gas-Lighting. III. Composition of Coal Gas. IV. Coal used in Gas Making. V. Carbonisation. VI. General Construction. VII. Retorts and Retort Settings. VIII. The Hydraulic Main and Valves. IX. The Exhauster. X. Purification of Gas. XI. Gas Holders. XII. Station Meter. XIII. The Photometer. XIV. The Governor, Regulator, Pressure Gauge, and Pressure Register. XV. Residual Products. XVI. Distribution. XVII. Consumers' Meter. XVIII. Burners and Glasses. XIX. Applications of Gas for Heating, Cooking, &c. XX. Explosions. XXI. Light Production. XXII. Controlling Influences, affecting Quality and Volume. XXIII. Public Lighting. XXIV. General Remarks (Naphthalene Removal; Mond Gas; Coke Ovens; and Acetylene Gas). XXV. The Sliding Scale.

Trade Report.

I.—GENERAL.

NATAL; IMPORT TRADE OF ——. GERMAN AND UNITED STATES COMPETITION WITH THE UNITED KINGDOM.

Bd. of Trade J., May 19, 1904.

The Board of Trade have received from Port Natal the following statement, showing the value of certain imports into Natal, by sea, in 1903, from Germany and the United States of America, comprising goods which might have been supplied by British manufacturers:—

Goods.	Germany.	United States of America.
	£	£
Ale and beer	17,400	1,400
Apothecary-ware	9,100	3,700
Candles	600	5,000
Cement	32,300	..
Cottons—piece, printed and dyed	12,000	1,000
Earthenware	12,500	1,100
Glass—bottles	4,000	300
„ window	2,700	..
Glassware	11,000	1,500
Malt	14,000	..
Medicines	1,400	10,300
Milk—condensed	3,600	8,800
Oilman's stores	800	9,400
Oils—other than paraffin and linseed, &c.	1,300	29,000
Painter's colours	500	5,000
Paper—		
Printing	6,600	4,000
Wrapping and brown	2,800	..
Perfumery	2,100	1,200
Soap	1,300	2,100
Spirits (not including perfumed)	3,500	2,700

SWITZERLAND; TRADE OF —— IN 1902.

Foreign Office Annual Series, No. 3150.

Switzerland imported "chemicals" to the value of 1,497,600*l.* in 1903, as compared with 1,434,400*l.* in 1902; "glass, pottery, and porcelain" amounted to 455,600*l.* in 1903 and 412,800*l.* in 1902.

JAVA; TRADE OF —— IN 1903.

Foreign Office Annual Series, No. 3163.

The following table shows the exports of some articles from Java and Madura during the year 1901-3:—

Articles.		1901.	1902.	1903.
Copra	Tons	27,220	43,781	15,155
Cinchona bark—				
Private	Lb.	13,076,016	13,682,335	14,087,143
Government	„	825,570	1,026,266	879,736
Gum dammar	Cwts.	26,272	35,451	37,400
Gutta-percha	Lb.	179,112	52,360	22,848
Hides	Pieces	550,404	529,499	500,664
Indigo	Lb.	1,411,310	1,128,664	1,297,274
India rubber	„	39,168	34,408	60,928
Quinine suphate	Oz.	1,032,800	794,400	766,800
Sugar (all kinds)	Tons	676,795	808,457	869,295
Tin—				
Private	„	4,296	4,105	3,436
Government	„	14,697	10,339	15,381

Cinchona Bark.—Although the total exports are somewhat larger than those of 1902, the average unit price obtained at 10 auctions held in Amsterdam was slightly better, *viz.*, 7·06 against 6·90 c. (5 c. = 1*d.*), while at the 12 London auctions an average price of 1⅜*d.*, or the same as in 1902, was realised.

Copra.—From the official returns, it appears that the greater part was shipped to Port Said for Marseilles or Amsterdam, the bulk probably going to the former port.

Indigo.—The increase in the indigo production may be ascribed partly to the larger acreage which, on account of the more favourable prices paid for the article during the previous year, was brought under cultivation, and partly to the propitious weather experienced while the crop was in the ground. Good prices were paid at the Samarang auctions for the first eight months of the year, but latterly results were less satisfactory. The bulk of the production during the year found its way to Japan, and this outlet appears to have taken the place of the Amsterdam market, which hitherto absorbed the greater part of the Java product.

Prospects for the coming season are not so bright, as buyers for Japan have withdrawn from the market, and planters have been forced to commence consigning their indigo to the Amsterdam market, which is over-stocked, apparently with the cheaper artificial indigo.

The prices obtained were much more satisfactory than in the preceding year, the lowest point reached being the equivalent of 7*s.* 3*d.* per cwt., as against 6*s.* 2*d.* per cwt. in 1902.

Notwithstanding the low values of the last two years, only five mills in Java have been compelled to close.

Petroleum.—The imports of petroleum during 1903 were slightly in excess of those of 1902. Of American oil only some 675,000 cases were brought in, against 813,898 and 1,344,085 cases in 1902 and 1901 respectively. This was no doubt due to the large stocks in hand at the close of 1902. No reliable statistics are available for Russian and other brands, but the number of cases imported probably showed an increase over the previous year.

The quantity of oil produced locally during the past three years was as follows:—

—	1901.	1902.	1903.
	Cases	Cases.	Cases.
Java, Wonokromo	478,290	293,947	407,853
Java, Blora	1,201,466	1,265,583	1,169,823

Sugar.—The production of sugar exceeded that of any previous year, the total reaching nearly 35,000 tons in excess of the year 1902. The results obtained, however, in the various divisions of the island were very dissimilar. In East Java, where the long dry monsoon was regarded as likely to prove unfavourable to the production, heavy rains fell early in the year, entirely altering the aspect of affairs, and the quantity produced was 500,507 tons, as against 463,364 tons in 1902 and 436,032 tons in 1901. The increase in production amounted to about 8 per cent., although the area planted for 1903 was about 1 per cent. less than in 1902.

In Mid Java heavy rains fell at frequent intervals during the milling season, and although the crop was the largest so far produced, being 228,604 tons as compared with 222,546 tons in 1902 and 182,833 tons in 1901, the percentage of sugar in the cane was very disappointing.

In West Java, where the weather was also unfavourable, the crop obtained from practically the same area as in the previous year amounted only to 153,907 tons, while in 1902 and 1901 the figures were 162,111 and 147,477 tons respectively.

ALKALI, &C. WORKS BILL [No. 202].

Ordered by the House of Commons to be Printed, May 17th, 1904.

A Bill to consolidate and amend the Alkali, &c. Works Regulation Acts, 1881 and 1892. Presented by Mr. Walter Long. (See also this J., 1903, 1022, *seq.*)

[N.B.—*Amendments of substance in the existing law are underlined.*]

PART I.

Alkali Works and Alkali Waste.

1.—(1) Every alkali work shall be carried on in such manner as to secure the condensation, to the satisfaction of the chief inspector, of the muriatic acid gas evolved in such work, to the extent of ninety-five per centum, and to such an extent that in each cubic foot of air, smoke, or chimney gases, escaping from the works into the atmosphere, there is not contained more than one-fifth part of a grain o muriatic acid.

(2) The owner of any alkali work which is carried on in contravention of this section shall be liable to a fine not exceeding, in the case of the first offence, fifty pounds, and in the case of every subsequent offence one hundred pounds.

2.—(1) In addition to the condensation of muriatic acid gas as aforesaid, the owner of every alkali work shall use the best practicable means for preventing the escape of noxious or offensive gases by the exit flue of any apparatus used in any process carried on in the work, and for preventing the discharge of such gases into the atmosphere, whether directly or by a chimney or other outlet, and for rendering such gases where discharged harmless and inoffensive, subject to the qualification that, on the basis of the amount of acid gas per cubic foot, no objection shall be taken under this section by an inspector to any muriatic acid gas in the air, smoke, or gases discharged into the atmosphere by a chimney or other outlet where the amount of such acid gas in each cubic foot of air, smoke, or gases so discharged does not exceed the amount limited by the last preceding section.

(2) If the owner of any alkali work fails, in the opinion of the court having cognisance of the matter, to use such means, he shall be liable to a fine not exceeding, in the case of the first offence, twenty pounds, and in the case of every subsequent offence, fifty pounds, with a further sum not exceeding five pounds for every day during which any such subsequent offence has continued.

3.—(1) Every work of whatever description in which ny liquid containing acid or any other substance capable of liberating sulphuretted hydrogen from alkali waste or rainage therefrom is produced or used shall be carried on n such manner that the liquid shall not come in contact vith alkali waste, or with drainage therefrom, so as to cause nuisance.

(2) The owner of any work which is carried on in conravention of this section shall be liable to a fine not xceeding, in the case of the first offence, fifty pounds, and n the case of every subsequent offence, one hundred ounds, with a further sum not exceeding five pounds for very day during which any such subsequent offence has ontinued.

(3) On the request of the owner of any such work as is entioned in this section the sanitary authority of the istrict in which such work is situate shall, at the expense f such owner, provide and maintain a drain or channel r carrying off such liquid as aforesaid produced in such ork into the sea or into any river or watercourse into hich the liquid can be carried without contravention of e Rivers Pollution Prevention Act, 1876, as amended any subsequent enactment; and the sanitary authority all for the purpose of providing any such drain or channel ve the like powers as they have for providing sewers, hether within or without their district, under the Public ealth Act.

(4) Compensation shall be made to any person for y damage sustained by him by reason of the exercise by sanitary authority of the powers conferred by this section, d such compensation shall be deemed part of the penses to be paid by the owner making the request to e sanitary authority under this section.

4.—(1) Alkali waste shall not be deposited or discharged thout the best practicable means being used for effectually eventing any nuisance arising therefrom.

(2) Any person who causes or knowingly permits any ali waste to be deposited or discharged in contravention this section, shall be liable to a fine not exceeding, in case of the first offence, twenty pounds, and in the case every subsequent offence, fifty pounds, with a further n not exceeding five pounds for every day during which such subsequent offence has continued.

5. Where alkali waste has been deposited or discharged, er before or after the commencement of this Act, and plaint is made to the chief inspector that a nuisance is asioned thereby, the chief inspector, if satisfied of the existence of the nuisance, and that it is within the power of the owner or occupier of the land to abate it, shall serve a notice on such owner or occupier requiring him to abate the nuisance; and if such owner or occupier fails to use the best practicable and reasonably available means for the abatement thereof, he shall be liable to a fine not exceeding twenty pounds, and if he does not proceed to use such means within such time as may be limited by the court inflicting such fine he shall be liable to a further penalty not exceeding five pounds for every day after the expiration of the time so limited during which such failure continues.

PART II.

Sulphuric Acid, Muriatic Acid, and other specified Works.

6.—(1) Every sulphuric acid work as defined in Paragraph (1) of the First Schedule to this Act shall be carried on in such manner as to secure the condensation, to the satisfaction of the chief inspector of the acid gases of sulphur or of sulphur and nitrogen, which are evolved in the process of the manufacture of sulphuric acid in that work, to such an extent that the total acidity of those gases in each cubic foot of residual gases after completion of the process, and before admixture with air, smoke, or other gases does not exceed what is equivalent to four grains of sulphuric anhydride.

(2) Every muriatic acid work as defined in paragraph (8) of the First Schedule to this Act shall be carried on in such manner as to secure the condensation to the satisfaction of the chief inspector of the muriatic acid gas evolved in such work, to such extent that in each cubic foot of air, smoke or chimney gases escaping from the work into the atmosphere there is not contained more than one-fifth part of a grain of muriatic acid.

(3) The owner of any sulphuric acid work or of any muriatic acid work which is carried on in contravention of this section shall be liable to a fine not exceeding, in the case of the first offence, fifty pounds, and in the case of every subsequent offence, one hundred pounds.

7.—(1) The owner of any work specified in the First Schedule to this Act (herein-after referred to as a scheduled work) shall use the best practicable means for preventing the escape of noxious or offensive gases by the exit flue of any apparatus used in any process carried on in the work, and for preventing the discharge of such gases into the atmosphere, whether directly or by a chimney or other outlet, and for rendering such gases where discharged harmless and inoffensive, subject to the qualification, that on the basis of the amount of acid gas per cubic foot no objection shall be taken under this section by an inspector—

- (*a*) To any muriatic acid gas in the air, smoke, or gase discharged into the atmosphere by a chimney or other outlet, where the amount of such acid gas in each cubic foot of air, smoke, or gases so discharged does not exceed the amount limited by the last preceding section:
- (*b*) To any acid gases in the air, smoke, or gases discharged into the atmosphere by a chimney or other outlet receiving the residual gases from any process for the concentration or distillation of sulphuric acid where the total acidity of such acid gases (including those from the combustion of coal) in each cubic foot of air, smoke, or gases so discharged, does not exceed what is equivalent to one grain and a half of sulphuric anhydride.

(2) If the owner of any such work fails, in the opinion of the court having cognizance of the matter, to use such means, he shall be liable to a fine not exceeding, in the case of the first offence, twenty pounds, and in the case of every subsequent offence, fifty pounds, with a further sum not exceeding five pounds for every day during which any such subsequent offence has continued.

8.—(1) An inspector may inquire whether, in any works in which aluminous deposits are treated for the purpose of making cement, herein-after called cement works, means can be adopted at a reasonable expense for preventing the discharge from the furnaces or chimneys of such works into the atmosphere of any noxious or offensive gas evolved in such works, or for rendering such gas where discharged harmless or inoffensive.

(2) Where it appears to the Local Government Board that such means can be adopted at a reasonable expense, the Board may by order require the owners of such works to adopt the best practicable means for the purpose, and may by the order limit the amount or proportion, in the case of cement works, of any noxious or offensive gas which is to be permitted to escape from such works into the chimney or into the atmosphere, and may also by the order extend to such works such provisions of this Act relating to scheduled works as they think fit.

(3) An order made under this section shall be provisional only, and shall not be of any validity until confirmed by Parliament, but when so confirmed shall have full effect, with such modifications as may be made therein by Parliament; and the expression "this Act" when used in this Act shall be deemed to include an order so confirmed, so far as is consistent with the tenor of that order.

(4) The Board shall take such steps as they may think fit for giving notice to persons interested of the provisions of any order made by them under this section before any Bill for confirming the same is introduced into Parliament.

(5) An order made under this section may impose fines for a breach of its provisions of like amount as any fines imposed by this Act for offences against this Act.

(6) An order made under this section may be repealed, altered, or amended by any subsequent order made under this section, and confirmed by Parliament.

PART III.

(i) *Registration of Works.*

9.—(1) An alkali work, a scheduled work, or a cement work, shall not be carried on unless it is certified to be registered.

(2) The work shall be registered in a register containing the prescribed particulars, and the register shall be conducted and the certificates issued in the prescribed manner.

(3) A certificate of registration, if issued at a time when a previous certificate is in force, shall be in force for one year after the time when that certificate ceases to be in force, and if issued at a time when no previous certificate is in force shall be in force until the following first day of April.

(4) An application for a certificate of registration of a work may, in the case of the first registration of that work, be made at any time, and an application for any subsequent certificate in respect of that work shall be made in the month of January or February.

(5) A certificate of registration shall be issued on application being made in the prescribed manner by the owner of the work, if the conditions of registration are complied with, and one of the conditions, in the case of the first registration of an alkali or scheduled work, or the registration of such a work if the work has been closed for a period of twelve months previously, shall be that the work is at the time of registration furnished with such appliances as appear to the chief inspector or, on appeal, to the Local Government Board to be necessary in order to enable the work to be carried on in accordance with such of the requirements of this Act as apply to the work:

Provided that the Local Government Board may dispense with the last-mentioned condition in the case of works erected before the commencement of this Act which were not before the commencement of this Act required to be registered.

(6) *There shall be charged upon every such certificate a stamp duty of five pounds in the case of an alkali work, and of three pounds in the case of any other work, and the Commissioners of Inland Revenue shall issue stamped forms of certificate for the purpose.*

(7) Written notice of any change which occurs in the ownership of a work or in the other particulars stated in the register shall, within one month after such change, be sent by the owner to the Local Government Board, and the register and the certificate shall be altered accordingly in the prescribed manner without charge and without the issue of a new certificate. If such notice is not sent as so required the work shall not be deemed to be certified to be registered.

(8) The owner of a work which is carried on in contravention of this section shall be liable to a fine not exceeding five pounds for every day during which it is so carried on.

(ii) *Inspection.*

10.—(1) The Local Government Board may, with the approval of the Treasury as to numbers and salaries or remuneration, appoint such inspectors (under whatever title they may fix) as the Board think necessary for the execution of this Act, and may assign them their duties and award them their salaries or remuneration, and shall constitute a chief inspector, and may regulate the cases and manner in which the inspectors are to execute and perform the powers and duties of inspectors under this Act, and may remove such inspectors.

(2) Notice of the appointment of every such inspector shall be published in the London Gazette, and a copy of the Gazette shall be evidence of the appointment.

(3) *The salaries or remuneration of the inspectors, and such expenses of the execution of this Act as the Treasury may sanction, shall be paid out of moneys provided by Parliament.*

(4) A person holding the office of chief inspector or inspector shall not be employed in any other work except with the sanction of the Local Government Board.

11. A person who—

(*a*) acts or practises as a land agent; or

(*b*) is engaged or interested directly or indirectly in any work to which this Act applies, or in any patent for any process or apparatus carried on or used in any such work, or in any process or apparatus connected with the condensation of acid gases, or with the treatment of alkali waste, or with preventing the discharge into the atmosphere or rendering harmless or inoffensive any noxious or offensive gas, or otherwise with any of the matters dealt with by this Act; or

(*c*) is employed in or about or in connexion with any work to which this Act applies, or in any other chemical work for gain,

shall be disqualified to act as an inspector under this Act.

12.—(1) For the purpose of the execution of this Act, an inspector may at all reasonable times by day and night, without giving previous notice, but so as not to interrupt the process of the manufacture,

(*a*) enter and inspect any work to which, in the opinio of the Local Government Board, any of the pro visions of this Act applies; and

(*b*) examine any process causing the evolution of an noxious or offensive gas, and any apparatus fo condensing any such gas, or otherwise preventin the discharge thereof into the atmosphere, or fo rendering any such gas harmless or inoffensiv when discharged; and

(*c*) ascertain the quantity of gas discharged into th atmosphere, condensed or otherwise dealt with and

(*d*) enter and inspect any place where alkali waste treated or deposited, or where any liquid co taining acid or any other substance capable liberating sulphuretted hydrogen from alkali was or drainage therefrom is likely to come in contact with alkali waste or drainage therefro and

(*e*) apply any such tests and make any such experimen and generally make all such inquiries, as seem him to be necessary or proper for the executi of his duties under this Act.

(2) The owner of any such work shall, on the demand of the chief inspector, furnish him within a reasonable time with a sketch plan, to be kept secret, of those parts of such work in which any process causing the evolution of any noxious or offensive gas or any process for the condensation of such gas or preventing the discharge thereof into the atmosphere, or for rendering any such gas harmless or inoffensive when discharged, is carried on.

(3) The owner of every such work and his agents shall render to every inspector all necessary facilities for an entry, inspection, examination, and testing in pursuance of this Act.

(4) Every owner of a work in which such facilities are not afforded to an inspector as are required by this Act, or in which an inspector is obstructed in the execution of his duty under this Act, and every person wilfully obstructing an inspector in the execution of his duty under this Act, shall be liable on conviction under the Summary Jurisdiction Acts to a fine not exceeding ten pounds.

13. The chief inspector shall, on or before the first day of March in every year make a report in writing to the Local Government Board of the proceedings of himself and of the other inspectors under this Act, and a copy of such report shall be laid before both Houses of Parliament.

14.—(1) If any sanitary authority apply to the central authority for an additional inspector under this Act, and undertake to pay a proportion of his salary or remuneration, not being less than one half, the Local Government Board may (if they see fit), with the sanction of the Treasury, appoint an additional inspector under this Act, to reside within a convenient distance of the works he is required to inspect; and such inspector shall have the same powers and be subject to the same power of removal and the same regulations and liabilities as other inspectors under this Act.

(2) The proportion of salary or remuneration aforesaid shall be paid at the prescribed times into the Exchequer, and shall be a debt due from the sanitary authority to the Crown.

(iii) *Special Rules.*

15.—(1) The owner of an alkali work or of a scheduled work may, with the sanction of the central authority, make special rules for the guidance of his workmen who are employed in or in connexion with any process causing the evolution of any noxious or offensive gas, or in or in connexion with the condensation or other treatment of that gas, and may annex fines to any violation of such rules, so that the fine for any offence do not exceed two pounds.

(2) A printed copy of the special rules in force under this section in any work shall be given by the owner of that work to every person working or employed in or about that work who is affected thereby.

(3) Any fine incurred under this Act in respect of an offence against a special rule may be recovered in accordance with the Summary Jurisdiction Acts.

(iv) *Procedure.*

16. In calculating the proportion of acid to a cubic foot of air, smoke, or gases, for the purpose of this Act, such air, smoke, or gases shall be calculated at the temperature of sixty degrees of Fahrenheit's thermometer, and at a barometric pressure of thirty inches.

17. The following regulations shall have effect with respect to the recovery of fines for offences under this Act other than fines recoverable summarily:—

(1) Every such fine shall be recovered by action in the county court having jurisdiction in the district in which the offence is alleged to have been committed:

(2) The action shall be brought, with the sanction of the central authority, by the chief inspector, or by such other inspector as the Local Government Board may in any particular case direct, within three months after the commission of the offence, and for the purposes of such action the fine shall be deemed to be a debt due to such inspector:

(3) The plaintiff in any action for a fine under this Act shall be presumed to be an inspector authorised under this Act to bring the action, until the contrary is proved by the defendant:

(4) The court may, on the application of either party, appoint a person to take down in writing the evidence of the witnesses, and may award to that person such remuneration as the court thinks just; and the amount so awarded shall be deemed to be costs in the action:

(5) If either party in any action under this Act feels aggrieved by the decision or direction of the court in point of law, or on the merits or in respect of the admission or rejection of any evidence, he may appeal from that decision to the High Court.

(6) Subject to the provisions of this section, all the enactments, rules, and orders relating to proceedings in actions in county courts, and to enforcing judgments in county courts, and appeals from decisions of judges of county courts, shall apply as if the action related to a matter within the ordinary jurisdiction of the court.

18.—(1) In any proceeding under this Act in relation to a fine for an offence other than an offence against a special rule—

(*a*) It shall be sufficient to allege that any work is a work to which this Act applies, without more; and

(*b*) It shall be sufficient to state the name of the registered or ostensible owner of the work, or the title of the firm by which the employer of persons in such work is usually known.

(2) A person shall not be subject to a fine under this Act for more than one offence in respect of the same work or place in respect of any one day.

(3) Not less than twenty-one days before the hearing of any proceeding against an owner to recover a fine under this Act for failing to secure the condensation of any gas to the satisfaction of the chief inspector, or for failing to use the best practicable means as required by this Act, an inspector shall serve on the owner proceeded against a notice in writing stating, as the case requires, either the facts on which such chief inspector founds his opinion, or the means which such owner has failed to use, and the means which, in the chief inspector's opinion, would suffice, and shall produce a copy of such notice before the court having cognisance of the matter.

(4) A person shall not be liable under this Act to an increased fine in respect of a second offence, or in respect of a third or any subsequent offence, unless a fine has been recovered within the preceding twelve months against such person for the first offence, or for the second or other offence, as the case may be.

19. All fines recovered under this Act, other than those recovered summarily, shall be paid into the Exchequer.

20. The owner of a work in which an offence under this Act other than an offence against a special rule has been proved to have been committed shall in every case be deemed to have committed the offence, and shall be liable to pay the fine, unless he proves to the satisfaction of the court before which any proceeding is instituted to recover such fine, that he has used due diligence to comply with and to enforce the execution of this Act, and that the offence in question was committed, without his knowledge, consent, or connivance, by some agent, servant, or workman, whom he shall charge by name as the actual offender; in which case such agent, servant, or workman shall be liable to pay the fine, and proceedings may be taken against him for the recovery thereof and of the costs of all proceedings which may be taken either against himself or against the owner under this Act:

Provided that it shall be lawful for the inspector to proceed against a person whom he believes to be the actual offender, without first proceeding against the owner, in any case where the inspector is satisfied that the owner has used all due diligence to comply with and to enforce the provisions of this Act, and that the offence has been committed by that person without the knowledge, consent, or connivance of the owner.

21. Any notice, summons, or other document required or authorised for the purposes of this Act to be delivered to or served on or sent to the owner of any work, may be served by post or by delivering the same to the owner, or at his residence or works; and the document shall be deemed to be properly addressed if addressed to the registered address of an owner, or, when required to be served on or sent to the owner of any works, if addressed to the owner of the works at the works, with the addition of the proper postal address, but without naming the person who is the owner.

22.—(1) Where complaint is made to the central authority by any sanitary authority, on information given by any of their officers, or any ten inhabitants of their district, that any work (either within or without the district) to which this Act applies is carried on, or that any alkali waste is deposited or discharged (either within or without the district) in contravention of this Act, and that a nuisance is occasioned thereby to any of the inhabitants of their district, the central authority shall make such inquiry into the matters complained of, and after the inquiry may direct such proceedings to be taken by an inspector as they think just.

(2) The sanitary authority complaining shall, if so required by the central authority, pay the expense of any such inquiry.

23.—(1) Where a nuisance arising from the discharge of any noxious or offensive gas or gases is wholly or partially caused by the acts or defaults of the owners of several works to which any of the provisions of this Act applies, any person injured by such nuisance may proceed against any one or more of such owners, and may recover damages from each owner made a defendant, in proportion to the extent of the contribution of that defendant to the nuisance, notwithstanding that the act or default of that defendant would not separately have caused a nuisance.

(2) This section shall not authorise the recovery of damages from any defendant who can produce a certificate from the chief inspector that in the works of that defendant the requirements of this Act have been complied with and were complied with when the nuisance arose.

(v) *Miscellaneous.*

24. Any expenses incurred by a sanitary authority under this Act shall be defrayed as general expenses incurred by the authority in the execution of the Public Health Act.

25. In determining any matter which under this Act is to be determined by the chief inspector, the chief inspector may found his opinion on facts disclosed by his own examination, or by an examination by any other inspector.

26.—(1) For a period of three years after the commencement of this Act paragraph (*b*) of section seven of this Act shall apply where the process for the concentration of sulphuric acid is that known as the over-heat pan process, as if in that paragraph two grains of sulphuric anhydride were substituted for one grain and a half of sulphuric anhydride.

(2) For the purposes of this section "the over-heat pan process" means the process in which the concentration of sulphuric acid is effected by the passage of the heated gases resulting from the combustion of fuel over the surface of the acid.

27.—(1) In this Act, unless the context otherwise requires,—

The expression "alkali work" means every work for—

(*a*) the manufacture of sulphate of soda or sulphate of potash, or

(*b*) the treatment of copper ores by common salt or other chlorides whereby any sulphate is formed,

in which muriatic acid is evolved:

The expression "noxious or offensive gas" includes the following gases and fumes:—Muriatic acid; sulphuric acid; sulphurous acid, except that arising solely from the combustion of coal; nitric acid and acid-forming oxides of nitrogen; sulphuretted hydrogen; chlorine, and its acid compounds; fluorine compounds; cyanogen compounds; bisulphide of carbon; chloride of sulphur; fumes from cement works; fumes containing copper, lead, antimony, arsenic, zinc, or their compounds; fumes from tar works:

The expression "owner" includes any lessee, occupier, or any other person carrying on any work to which this Act applies:

The expression "best practicable means," where used with respect to the prevention of the escape of noxious and offensive gases, has reference not only to the provision and the efficient maintenance of appliances adequate for preventing such escape, but also to the manner in which such appliances are used and to the proper supervision, by the owner, of any operation in which such gases are evolved:

The expression "prescribed" means prescribed by the Local Government Board:

The expression "Local Government Board" means the Local Government Board established by the Local Government Board Act, 1871:

The expression "central authority" means as regards England the Local Government Board, as regards Ireland the Local Government Board for Ireland, and as regards Scotland the Secreta ry for Scotland:

The expression "sanitary authority" means any local authority entrusted with the execution of the Public Health Act:

The expression "the Public Health Act" means, as regards England, the Public Health Act, 1875, or in the case of London the Public Health (London) Act, 1891; and as regards Scotland, the Public Health (Scotland) Act, 1897; and as regards Ireland, the Public Health (Ireland) Act, 1878, and includes any enactment amending those Acts.

(2) Nothing in this Act shall be construed as exempting any work from any of the provisions of this Act applicable to the work as being a work of a certain class or description by reason only that the work is subject to other provisions of this Act as being a work of some other class or description.

28. In the application of this Act to Scotland—

(*a*) references to the Secretary of Scotland shall be substituted for references to the Local Government Board, and references to the Edinburgh Gazette shall be substituted for references to the London Gazette;

(*b*) the court of the sheriff or sheriff substitute of the county in which the offence is committed shall be the county court, and may award costs to either party, and may sentence the offender to imprisonment for any period not exceeding six months, unless the fine and costs be previously paid; and any decision or sentence of such sheriff or sheriff substitute shall be subject to review and appeal according to law.

29. Nothing in this Act shall legalise any act or default that would, but for this Act, be deemed to be a nuisance, or otherwise be contrary to law, or deprive any person of any remedy by action, indictment, or otherwise, to which he would have been entitled if this Act had not passed.

30. The Acts specified in the Second Schedule to this Act are hereby repealed to the extent mentioned in the third column of that Schedule:

Provided that—

(*a*) Nothing in this Act shall affect any certificate special rule, or notice issued, made, or serve before the commencement of this Act in pursuance of any enactment so repealed, but every such certificate, special rule, and notice shal continue in force as if issued, made, or served i pursuance of this Act; and

(*b*) Nothing in this Act shall affect the tenure of offic of any inspector appointed under any enactmen so repealed, but every such inspector shall hol office as if appointed under this Act; and (*c*) Nothing in this Act shall affect any liability of a sanitary authority incurred under any enactment so repealed to pay any proportion of the salary or remuneration of an additional inspector.

31.—(1) This Act may be cited as the Alkali, &c. Works Regulation Act, 1904.

(2) It shall come into operation *on the first day of January nineteen hundred and five.*

SCHEDULES.

First Schedule.

List of Works.

(1) Sulphuric acid works, that is to say, works in which the manufacture of sulphuric acid is carried on by the lead chamber process, namely, the process by which sulphurous acid is converted into sulphuric acid by the agency of oxides of nitrogen and by the use of a lead chamber.

(2) Sulphuric acid (Class II.) works, that is to say, works in which the manufacture of sulphuric acid is carried on by any process other than the lead chamber process, and works for the concentration or distillation of sulphuric acid.

(3) Chemical manure works, that is to say, works in which the manufacture of chemical manure is carried on and works in which any mineral phosphate is subjected to treatment involving chemical change through the application or use of any acid.

(4) Gas liquor works, that is to say, works (not being sulphate of ammonia works or muriate of ammonia works) n which sulphuretted hydrogen or any other noxious or offensive gas is evolved by the use of ammoniacal liquor in any manufacturing process, and works in which any such iquor is desulphurised by the application of heat in any process connected with the purification of gas.

(5) Nitric acid works, that is to say, works in which the manufacture of nitric acid is carried on, and works in which itric acid is recovered from oxides of nitrogen.

(6) Sulphate of ammonia works and muriate of ammonia works, that is to say, works in which the manufacture of lphate of ammonia or of muriate of ammonia is carried on.

(7) Chlorine works, that is to say, works in which hlorine is made or used in any manufacturing process.

(8) Muriatic acid works, that is to say—

(*a*) Muriatic acid works, or works (not being alkali works as defined in this Act) where muriatic acid gas is evolved either during the preparation of liquid muriatic acid or for use in any manufacturing process;

(*b*) Tin-plate flux works, that is to say, works in which any residue or flux from tin-plate works is calcined for the utilisation of such residue or flux, and in which muriatic acid gas is evolved; and

(*c*) Salt works, that is to say, works (not being works in which salt is produced by refining rock salt otherwise than by the dissolution of rock salt at the place of deposit) in which the extraction of salt from brine is carried on, and in which muriatic acid gas is evolved.

(9) Sulphide works, that is to say, works in which sul-uretted hydrogen is evolved by the decomposition of tallic sulphides, or in which sulphuretted hydrogen is d in the production of such sulphides.

(10) Alkali waste works, that is to say, works in which ali waste, or the drainage therefrom, is subjected to any emical process for the recovery of sulphur or for the lisation of any constituent of such waste or drainage.

(11) Venetian-red works, that is to say, works for the manufacture of Venetian-red, crocus, or polishing powder, by heating sulphate or some other salt of iron.

(12) Lead-deposit works, that is to say, works in which the sulphate of lead deposit from sulphuric acid chambers is dried or smelted.

(13) Arsenic works, that is to say, works for the preparation of arsenious acid, or where nitric acid or a nitrate is used in the manufacture of arsenic acid or an arseniate.

(14) Nitrate and chloride of iron works, that is to say, works in which nitric acid or a nitrate is used in the manufacture of nitrate or chloride of iron.

(15) Bisulphide of carbon works, that is to say, works for the manufacture of bisulphide of carbon.

(16) Sulphocyanide works, that is to say, works in which the manufacture of any sulphocyanide is carried on by the reaction of bisulphide of carbon upon ammonia or any of its compounds.

(17) Picric acid works, that is to say, works in which nitric acid or a nitrate is used in the manufacture of picric acid.

(18) Paraffin oil works, that is to say, works in which crude shale oil is refined.

(19) Bisulphite works, that is to say, works in which sulphurous acid is used in the manufacture of acid sulphites of the alkalis or alkaline earths.

(20) Tar works, that is to say, works where gas tar or coal tar is distilled or is heated in any manufacturing process.

(21) Zinc works, that is to say, works in which, by the application of heat, zinc is extracted from the ore, or from any residue containing that metal.

Second Schedule.

Repeals.

Session and Chapter.	Short Title.	Extent of Repeal.
44 & 45 Vict. c. 37.	The Alkali, &c. Works Regulation Act, 1881.	The whole Act.
47 & 48 Vict. c. clvii.	The Local Government Board's Provisional Order Confirmation (Salt Works) Act, 1884.	The whole Act.
55 & 56 Vict. c. 30.	The Alkali, &c. Works Regulation Act, 1892.	The whole Act.

X.—*METALLURGY.*

Radium Minerals in Quebec.

Halifax Mercantile Maritime Merchant and Commercial Review. U.S. Cons. Rep., No. 1948, *May* 9, 1903.

Minerals containing radium have been discovered in the Province of Quebec. The ore from which radium and oxide of uranium have been extracted was taken from a white-mica mine about 18 miles from Murray Bay, in Charlevoix County. White-mica deposits exist at several points in Quebec and Eastern Ontario, and these will be developed in future by an electric company, which hitherto has imported its mica supplies from India.

XIII. C.—*INDIA-RUBBER, Etc.*

Rubber in Ceylon.

F. J. Holloway. India-Rubber J., 1904, **27**, 471—472.

It has been found that the Para rubber tree will yield rubber in paying quantities when grown on different soils, on hill sides up to 2,700 ft. in elevation. The only soil on which the tree yielded no rubber was a blue sandy soil with sandstones below the surface. It does not yield well, however, on very stiff soil. The best temperature for cultivation lies between 74° and 94° F., with a rainfall of from 80 to 150 ins. The best yields of rubber per acre of soil cultivated were obtained by planting about 15 ft. by 15 ft. apart, giving about 200 trees per acre.—A. S.

XVI.—SUGAR, STARCH, Etc.

Starch; Cassava —— in Jamaica.

Bd. of Trade J., May 26.

In its issue of 26th March, the Jamaica *Daily Telegraph* refers to the efforts that are being made in that island to establish an export business in cassava starch, and more particularly to the trial shipment that had been made by a firm, who had started a factory for the manufacture of this starch at Longville, Clarendon. This firm has just received a report from Manchester on the result of the tests to which the cassava starch made at their factory has been subjected. The results of the trial have been very satisfactory, and they have been asked to send at the earliest opportunity 50 tons, for which a price of 10*l.* per ton in Bristol is offered.

It is stated that the manufacturer has succeeded in making a starch to suit the finishers of high-class goods in Manchester, who at present use, for their finer processes, wheat starch which costs, on an average, 27*l.* per ton.

The cultivation at Longville consists of about 50 acres, which will be ready for starch-making this season. The capacity of the plant is about 150 tons per annum.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 11,430. May. Apparatus for mixing substances together in regular proportions. May 18.
„ 11,454. Stansfield. Condensing machines. May 18.
„ 11,533. Henderson. Determination and control of the temperature of furnaces, &c. May 19.
„ 11,680. Wollaston. Apparatus for controlling the flow of liquids. May 21.
„ 11,752. McKenna (Holst and Fleischer). *See under* XVII.
„ 11,797. Murray. Gas or air compressors. May 24.
„ 11,839. Cautley. Hydro-extractors. May 24.
„ 11,854. Matkol. Filters. [U.S. Appl., July 3, 1903.]* May 24.
„ 11,945. Crosfield and Markel. Apparatus for precipitating and separating solids from water and other liquids. May 25.
„ 11,979. Sellenscheidt. Filters. May 26.
„ 12,145. Lennox. Evaporator for evaporating the liquid in brewers' wash, sewage, waste or spent dyes, and the like, and concentrating the solids in the same. May 28.
„ 12,161. Dall. Centrifugal separators. [Appl. in Denmark, May 28, 1903.]* May 28.
[C.S.] 12,297 (1903). Rawson. High pressure filter. June 1.
„ 15,148 (1903). Cebulla. Gas kilns. May 26.
„ 16,760 (1903). Lebedinsky. Filters. June 1.
„ 16,936 (1903). Macfarlane. Centrifugal machines. May 26.
„ 27,287 (1903). Wetter (Boellinghaus). Filtering apparatus. May 26.

II.—FUEL, GAS, AND LIGHT.

[A.] 11,268. Schweich. Gas producers.* May 16.
„ 11,685. Brooks. Manufacture of peat fuel. May 21.
„ 11,719. Hills and Schill. Construction and working of producer gas generators. May 21.
„ 11,917. Warburton. Process for obtaining producer gas and electrical energy from peat. May 25.
„ 11,948. Guilbaud. Apparatus for generating gas.* May 26.
„ 11,984. Darby. Cleaning blast furnace and other gases. May 26.
[C.S.] 15,645 (1903). Kent. Process for making gas. June 1.
„ 16,853 (1903). Welsbach. *See under* X.
„ 26,776 (1903). Abel (Siemens und Halske Act.-Ges.). Manufacture of incandescence bodies for electric glow lamps. June 1.
„ 1676 (1904). Blondel. Manufacturing electrodes for arc lamps. June 1.
„ 3901 (1904). Thompson (Hoberecht). Means for economising fuel and preventing smoke. May 26.
„ 7979 (1904). Boutillier. Gas producers for poor gas free from tarry matters. May 26.
„ 9376 (1904). Bildt. Apparatus for the continuous feeding and distributing of material in gas producer furnaces and the like. June 1.
„ 9483 (1904). Mackenzie (Cie. des Charbons et Briquettes de Blanzy and de l'Ouest). Ovens for the manufacture of smokeless briquettes. June 1.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 12,122. Weyl. Distillation of coal tar. [Ger. Appl., May 27, 1903.]* May 27.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 11,317. Schmitt. Method and apparatus for recovering sulphur colouring matters from dye liquids and washing liquids. May 17.
„ 11,863. Ellis (Chem. Fabr. vorm. Sandoz). Manufacture of green sulphur dyes. May 24.
[C.S.] 12,120 (1903). Johnson (Kalle and Co.). Manufacture of disazo colouring matters. June 1.
„ 15,515 (1903). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of yellow sulphurised colouring matters. May 26.
„ 16,995 (1903). Johnson (Badische Anilin und Soda Fabr.). Manufacture of new azo dyestuffs and of products to be used in the said manufacture. June 1.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 11,317. Schmitt. *See under* IV.
„ 11,397. Hannau. *See under* XIII. B.
„ 11,450. Johnson (Badische Anilin und Soda Fabrik). Production of blue to blue-black shades on wool. May 18.
„ 11,736. Bernhardt. Potash leaching apparatus for raw wool. May 21.
„ 12,145. Lennox. *See under* I.
[C.S.] 15,358 (1903). Grime. Dyeing of cotton cloth. May 26.

[C.S.] 18,599 (1903). Chischin. Method of fixing or protecting designs impressed on fabrics. June 1.

,, 28,508 (1903). Boult (Horton). *See under* XII.

,, 9510 (1904). Gaisman. Elastic fabrics. June 1.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 11,237. Blackman. Formation of an acid or electrolyte from water. May 16.

,, 11,256. Wood Smith. Purification of natural salts such as alkaline carbonates, chlorides, sulphates, and nitrates. May 16.

,, 11,891. Brindley. Manufacture of ferric sulphate from scrap iron or steel. May 25.

[C.S.] 13,419 (1903). Thompson (Wischin). Manufacture of sulphuric anhydride. June 1.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 11,243. Jones. Glazing and enamelling kilns. May 16.

[C.S.] 9033 (1904). Rowart and Francq. Apparatus for the manufacture of sheet glass. May 26.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 11,218. Wulf. Manufacture of floor covering. May 16.

,, 11,258. Stöffler. Fireproof quartz bricks or blocks. [Ger. Appl., May 16, 1903.]* May 16.

,, 11,398. Hargreaves. *See under* XIII. B.

,, 11,441. Bates and McTierard. Paving materials. May 18.

,, 11,523. Stöffler. Manufacture of lime and sand bricks or blocks. [Ger. Appl., Oct. 31, 1903.]* May 19.

,, 11,565. Draenert. Manufacture of bricks, building blocks, &c., and apparatus therefor May 19.

,, 11,765. Liversedge. Pavements. May 21.

,, 11,803. Marlow. Manufacture of tiles, bricks, &c. May 24.

,, 11,830. Kauffmann and Medberg. Manufacture of artificial stone for paving, decorative, and other purposes. May 24.

,, 11,997. Hadlington. Brick and like kilns. May 26.

[C.S.] 16,301 (1903). Lambert. Building blocks or slabs. May 26.

,, 21,947 (1903) Hocke. Manufacture of Portland cement. May 26.

X.—METALLURGY.

[A.] 11,386. Johnson. Improvements whereby scrap or refuse metal can be used up in manufactures. May 18.

,, 11,437. Clark (Goldschmid). Process of and apparatus for refining ores. May 18.

,, 11,527. Sulman and Picard. Treatment of complex sulphide ores. May 19.

,, 11,579. Ackland. Apparatus for and method of calcining ore or other material. May 20.

,, 11,733. Martin. Casting pig iron and other metals. May 21.

,, 11,743. Martin. Filtering apparatus for the extraction of liquid from finely crushed minerals, &c. May 21.

,, 12,020. Jenkins. Magnetic ore separators. May 26.

,, 12,098. Engels. Process for treating steel and armour plates. [Ger. Appl., March 24, 1904.]* May 27.

,, 12,117. Abelspies. Ore concentrating apparatus. May 27.

[C.S.] 14,295 (1903). Edison Ore-Milling Syndicate, Ltd. (Edison). Electro-magnetic separators. May 26.

,, 15,849 (1903). Tomellini. Method for soldering aluminium. May 26.

,, 16,853 (1903). Welsbach. Manufacture of metallic alloys having pyrophoric action, and their application to the purposes of ignition and illumination. June 1.

,, 26,775 (1903). Abel (Siemens und Halske Act.-Ges.). Manufacture of incandescence bodies for electric glow lamps. June 1.

,, 8994 (1904). Wedge. Process of preparing iron pyrites for desulphurisation. May 26.

,, 9445 (1904). Orbison. Melting furnaces. June 1.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 11,237. Blackman. *See under* VII.

,, 11,470. Atkins. Poles or electrodes of electrolytic apparatus, &c. May 18.

,, 11,917. Warburton. *See under* II.

,, 11,920. Bruno. Manufacture of electrodes for electric accumulators.* May 25.

,, 12,061. Cie. Franc. de l'Ozone. *See under* XVIII. B.

[C.S.] 9531 (1903). Round and Round. Electro-depositing metals. June 1.

,, 11,145 (1903). Calandri. Accumulator electrodes. May 26.

,, 12,312 (1903). Carolan (Gen. Electric Co.). Manufacture of materials suitable for electric insulating purposes. June 1.

,, 28,780 (1903). Eimer. Electric furnaces or ovens. May 26.

,, 3912 (1904). Soc. Anon. l'Ind Verrière et ses Dérivés. Apparatus for regulating the intensity and heating effect of electric currents. May 26.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 11,436. Fischer. Manufacture of resin soap. May 18.

,, 11,553. Wilson. Refining of linseed oil. May 19.

,, 11,638. Bamberg. Hydrolysis. May 20.

,, 11,966. Jones (Tailfer). Treating or maturing linseed oil. May 26.

[C.S.] 28,508 (1903). Boult (Horton). Manufacture of dyeing soap. May 26.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(*B.*)—RESINS, VARNISHES.

[A.] 11,397. Hannan. Method of rendering linoleums, floor-cloths, &c., non-combustible. May 18.

,, 11,398. Hargreaves. Manufacture of varnishes and paints for waterproofing and like purposes, also for indurating building materials. May 18.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 11,249. Amidon. Apparatus for treating hides, skins, and sides of leather. [U.S. Appl., Jan. 28, 1904.]* May 18.

,, 11,581. Lippert and Schlosser. Quick tanning process for chrome leather. May 20.

,, 11,885. Southworth. Process for treating raw hide. May 25.

XV.—MANURES, ETC.

[A.] 11,421. Crone, Taylor, Williams, and Lewis. Manufacture of fertilisers. May 18.

[C.S.] 8949 (1904). Bell. Fertiliser and insecticide. May 26.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 11,752. McKenna (Holst and Fleischer). Malting and drying drums. May 21.

„ 12,069. Boord. Production of absolute alcohol. May 27.

„ 12,145. Lennox. *See under* I.

[C.S.] 6742 (1904). Kuhn. Process and apparatus for the manufacture of effervescent wines. May 26.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A*.)—Foods.

[A.] 11,899. Richardson. Bleaching wheat and other cereals. May 25.

„ 12,113. Schröder. Sterilisation of food and other substances. May 27.

[C.S.] 7896 (1904). Braga. Process for the manufacture of meat preparations. *May 26.

(*B*.)—Sanitation; Water Purification.

[A.] 11,900. Bordigoni. The bacterial or septic tank treatment of sewage. May 25.

„ 11,945. Crosfield and Markel. *See under* I.

„ 12,061. Cie. Franc. de l'Ozone. Apparatus for the sterilisation of water by means of an electric current. [Fr. Appl., Nov. 20, 1903.]* May 27.

„ 12,145. Lennox. *See under* I.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 11,259. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new derivatives of barbituric acid. May 16.

„ 11,349. Morgan. Manufacture of certain organic compounds of thorium. May 17.

„ 11,747. Imray (Meister, Lucius und Brüning). Manufacture of new perfumes and of intermediate products therefor. May 21.

„ 11,991. Boissiere and Faucheux. Manufacture of cream of tartar, tartaric and citric acids and secondary products. May 26.

„ 12,091. Newton (F. Bayer & Co.). Manufacture of pyrimidine derivatives. May 27.

[C.S.] 15,782 (1903). Imray (Meister, Lucius und Brüning). Manufacture of a new therapeutical compound. May 26.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 11,192. Croft. Method of preparing photographic printing paper in the gum bichromate process. May 16.

„ 12,125. Southey. Photographic materials. May 28.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 11,427. Luck. Manufacture of explosives. May 18.

„ 11,428. Luck. Manufacture of explosives. May 18.

Printed and Published by Eyre and Spottiswoode, East Harding Street, London, E.C., for the Society of Chemical Industry.—P 7.

JOURNAL OF THE

Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.
ISSUED TWICE A MONTH.

No. 12.—Vol. XXIII. JUNE 30, 1904. No. 12.—Vol. XXIII.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum:
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each; 1902 *et seq.*, 1/9 each.

The Society of Chemical Industry.

Hon. Local Secretary:
H. Schweitzer, 40, Stone Street, New York, U.S.A.

The following take office in Sept. next:—*Chairman:* C. F. Chandler. *Committee:* V. Coblentz, A. H. Elliott, E. G. Love, H. A. Metz, F. Schniewind, and C. B. Zabriskie.

Nottingham Section.

Chairman: J. T. Wood.

Vice-Chairman: S. F. Burford.

Committee:

L. Archbutt.
F. J. R. Carulla.
R. M. Caven.
F. Stanley Kipping.
G. D. Lander.
H. B. Mayfield.
J. O'Sullivan.
J. M. C. Paton.
A. L. Stern.
G. J. Ward.
J. White.

Hon. Treasurer: S. J. Pentecost.

Hon. Local Secretary:
S. R. Trotman, King's Walk Chambers, Parliament Street,
Nottingham.

The following takes office in Sept. next:—*Committee:* J. Golding.

Scottish Section.

Chairman: *T. L. Patterson.*

Vice-Chairman: *D. J. Playfair.*

Committee:

H. Bumby.
D. B. Dott.
Thos. Ewan.
J. Arnold Fleming.
W. Frew.
G. H. Gemmell.
Jas. Hendrick.
Jas. Hope.
H. Ingle.
D. S. Jerdan.
W. G. Johnston.
J. Falconer King.
J. G. F. Lawson.
J. S. Macarthur.
J. McCulloch.
M. A. Parker.

Hon. Secretary and Treasurer:
Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

The following take office in Sept. next:—*Chairman:* R. Thomson. *Vice-Chairman:* J. S. Macarthur. *Committee:* W. Curphey, L. Dobbin, Robt. Hamilton, T. L. Patterson, and D. Playfair.

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.
J. F. Elliott.
F. B. Guthrie.
L. Meggitt.
J. Morison.
A. A. Ramsay.
J. A. Schofield.
R. Greig Smith.
H. G. Smith.
T. Steel.

Hon. Local Secretary:
T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S

Yorkshire Section.

Chairman: *Jas. E. Bedford.*

Vice-Chairman: G. W. Slatter.

Committee:

C. S. Bedford.
E. A. Brotherton.
John W. Cobb.
W. M. Gardner.
A. J. Murphy.
H. R. Procter.
F. W. Richardson.
Geo. Ward.
H. A. Watson.
Thorp Whitaker.
J. B. Wilkinson.

Hon. Local Secretary and Treasurer:
T. Fairley, 17, East Parade, Leeds.

The following take office in Sept. next:—*Chairman:* R. Procter. *Committee:* W. Ackroyd, J. E. Bedford, F. Bra B. A. Burrell, and A. Smithells.

N.B.—The names in *italics* are those of members of Committee who retire from their respective offices at the end of the current se

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who propose to attend the meeting are requested to inform the General Secretary, as soon as possible, by what steamer they will travel. The principal boats will be met on arrival at New York by a representative of the Reception Committee, who will escort the guests to the Hotel Seville, Madison Avenue and 29th Street, which will be the Society's Headquarters in New York. A similar system will be observed at all the other cities visited by the special train. A revised programme appeared in the March 31st issue.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Wm. H. Nichols has been nominated to the office of President under Rule 8; Dr. Edw. Divers, Prof. W. R. Eaton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. Parker have been nominated Vice-Presidents under Rule 8; and Sir Wm. Ramsay has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the Annual General Meeting at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

HONOUR LIST, JUNE 24TH, 1904.

His Majesty has been pleased to confer a Baronetcy of the United Kingdom on Mr. W. J. Goulding, Dublin; and the honour of Knighthood on Prof. Jas. Dewar, F.R.S., and Dr. Thos. Stevenson.

DUTY-FREE ALCOHOL.

The Council of the Society of Arts has awarded to Mr. Thomas Tyrer the Society's Silver Medal for his paper on "The Need of Duty-free Spirit for Industrial Purposes," and the presentation of the Medal will take place at the opening meeting of the Society's session in November next.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye laws the Society has the right of priority of publication for three months of all such papers. nfringement of this Bye-law renders papers liable to be ejected by the Publication Committee, or ordered to be bstracted for the Journal, in which case no reprints can e furnished to the author.

List of Members Elected

23rd JUNE 1904.

ack, J. Wyclif, 20, Mardale Crescent, Edinburgh, Analytical Chemist.

oyce, Framroze H., City of Bombay Manufacturing Co., Ltd., 39, Hornby Road, Bombay, India, Technical Chemist.

Carter, A., Cuba Street, Petone, Wellington, New Zealand, Works Manager.

Hayman, Jack V. J., Semper Aurea, Burwell, Cambridge, Chemist.

Hermsdorf, Dr. Walter, Salzstrasse 69, Chemnitz, Saxony, Chemist.

Hildebrand, Charles C., 113, Metoxan Avenue, Ridgeway, Pa., U.S.A., Chemist.

Johnson, Cedric, Field House, Winnington, Northwich, Chemical Engineer.

Kane, Richard W. H., 88, Kimmersitch Street, Burton-on-Trent, Mechanical Engineer.

Kniffen, Frederick, Indian Head, Md., U.S.A., Chemist.

Kunz, Dr. George F., c/o Tiffany and Co., 11–15, Union Square, New York City, U.S.A., Gem Expert.

Lorimer, John H., 280, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Textile Machinist and Merceriser.

Meads, Charles J., Bel Air, Dartmouth, Inland Revenue Officer.

O'Brien, Claude H., c/o Fiji Sugar Co., Suva, Fiji, Chemist.

Schwitter, Martin, Tin City, Cape Prince of Wales, Alaska, U.S.A., Chemist and Assayer.

Southall, A. W., Lower Priory, Birmingham, Manufacturing Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Adgate, Matthew, l/o Syracuse; retain Journals.

Allen, Richard F., l/o Baltimore Avenue; 1241, South 47th Street, Philadelphia, Pa., U.S.A.

Bowes, Harry, l/o Higher Crumpsall; 40, Radford Street, Blackley, Manchester.

Buchanan, D. G., l/o Glasgow; c/o Gibbs & Co., Iquique, Chile.

Campbell, Ashley, l/o Sydney; c/o Colonial Sugar Refining Co., Yarraville Refinery, Melbourne, Vic., Australia.

Cargill, Jno. T.; Journals to c/o Burmah Oil Co., Rangoon, Burmah.

Carhart, Dr. C., l/o Keyport; c/o Mr. Berk Talley, Rama, Nicaragua.

Carlsson, Hugo, l/o Cape Breton; 42, Smålandsgatan, Stockholm, Sweden.

Christie, Jno., l/o Pitsea; c/o The New Explosives Co., Ltd., Stowmarket, Suffolk.

Crane, Jasper E., l/o Boston; c/o The Arlington Co., Arlington, N.J., U.S.A.

Cunningham, Edw., l/o Kilby Street; c/o S. Cabot, 141, Milk Street, Boston, Mass., U.S.A.

De Blois, W. H., l/o Camden; c/o General Chemical Co., Syracuse, N.Y., U.S.A.

Ellis, A. W., l/o Brixton Hill; Public Analyst's Laboratory, Town Hall, Southwark, S.E.

Ermen, F.; Journals to c/o Walter Ermen, 14, Park Road, Eccles, Manchester.

Garrigues, W. E., l/o Broadway; 66, Beaver Street, New York City, U.S.A.

Hübner, Julius, l/o Crumpsall; Ash Villa, Cheadle Hulme, Cheshire.

Ingalls, Walter R., l/o Lynn; 52, Broadway, New York City, U.S.A.

Jacoby, A. H.; Journals to c/o American Dyewood Co., 156, William Street, New York City, U.S.A.

Knapp, R. E., l/o Ann Arbor; 1219, 8th Street, Evansville, Ind., U.S.A.

Levy, A. G.; Journals to 45, Warrington Crescent, Maida Vale, W.

We have compared the above Statement with the Vouchers, Counterfoils of the Receipts issued, and other records, and are of opinion it correctly exhibits the Cash transactions of the Society for the year 1903. The amounts of the Metropolitan 3 per cent. Consolidated, 3 per cent. New Zealand, and 3 per cent. New South Wales Stocks have been confirmed by the Chief Accountant to the Bank of England. Certificates for the remaining investments have been inspected, and the Bank Balances have been certified to us by the Bankers.

23, St. Swithin's Lane, London, E.C.,
21st April 1904.

Meeting held at Burlington House, on Monday, June 6th, 1904.

MR. WALTER F. REID IN THE CHAIR.

THE LOSS OF NITRE IN THE CHAMBER PROCESS.

BY J. K. H. INGLIS.

The question of the loss of nitre in the chamber process has long been the subject of discussion and investigation; but no very satisfactory solution of the question has as yet been obtained. The difficulty in the investigation is threefold. Not only does the total amount of nitrous gases lost amount to only a fraction of a per cent. of the flue gases, but endless complications arise (*cf.* Carpenter and Linder, this J., Dec. 1902) when the flue gases are treated with aqueous absorbents so that an interpretation of the analysis is very difficult. The third difficulty is that no means have been devised for detecting small quantities of nitrous oxide, which many authorities believe is formed in the chambers and causes the "chemical loss" as opposed to the "mechanical loss," due to incomplete absorption in the Gay Lussac tower.

Sir W. Ramsay, in his researches on the "Gases of the Atmosphere," found that fractional distillation of liquefied gases at low temperatures gave in many cases a satisfactory separation; and he, therefore, kindly suggested to me that I should attempt analysis of the flue gases by that method. This paper gives a preliminary account of some of the results that have been obtained; but the experiments have not yet been brought to a conclusion.

The flue gases may consist of nitrogen, oxygen, nitric oxide, nitrogen peroxide, nitrous oxide, sulphur dioxide, carbon dioxide, and possibly sulphuric acid vapour. The gases, nitrous oxide, carbon dioxide, and sulphur dioxide, were first of all prepared and it was found that they could be almost completely separated from a large volume of air by passing the mixture through a spiral cooled with liquid air to a temperature of about − 185° C. At that temperature these gases and nitrogen peroxide are non-volatile solids, and therefore by exhausting the spiral with a Töpler pump all the nitrogen and oxygen could be removed. At this temperature nitric oxide is also a solid, but it has a slight vapour pressure, so that its separation from nitrogen by this means is not quite complete. But if the vapour pressure of nitric oxide at that temperature is known, the amount lost can be calculated, since its partial pressure in the escaping gas is equal to its vapour pressure. Exact measurements of this vapour pressure have not as yet been made, so that to this extent the research is incomplete. When the nitrogen oxides, carbon dioxide, and sulphur dioxide, sulphuric acid, &c., have been obtained free from nitrogen and oxygen, the further separation is not difficult. It was found that by repeated fractionation at suitable temperatures the substances could be divided into the fractions:—(1) Nitrogen and nitric oxide; (2) Nitrous oxide and carbon dioxide; (3) Sulphur dioxide; (4) Nitrogen peroxide and sulphuric acid. Fractions 1, 2, 3, were measured and then analysed in the ordinary way. The fourth fraction, which remained in the spiral, was washed out with distilled water and titrated with baryta, using phenolphthalein as indicator. The precipitate of barium sulphate was boiled with dilute nitric acid, filtered off and weighed; and then, knowing the total barium hydroxide used and the barium sulphate formed, the amount of nitrogen peroxide could be calculated.

When this method of analysis had been worked out, Dr. Messel very kindly gave me permission to carry out a series of analyses at Messrs. Chapman and Messel's works in Silvertown. I am glad to take this opportunity of thanking him for the facilities and for the advice which he was always ready to give me.

A calculation of the total loss of nitre (3 per cent. of the sulphur burnt) showed that if the total loss occurred as nitric oxide the amount in the flue gases would amount to 0·1 per cent. Hence it was evident that at least 10 or 20 litres of the flue gases must be used for each analysis. As it was obviously impossible to carry samples of 10—20 litres away from the works, the first part of the fractionation was carried out while the sample was being taken. A large aspirator drew the flue gases at the rate of 5 litres per hour through a spiral which was immersed in liquid air. At each end of the spiral there was a stop-cock, and a side tube led from the spiral through a third stop-cock to a large bulb holding about 130 c.c. Before taking a sample, this bulb was evacuated and the stop-cock turned off: the gases were then led through the spiral, and when sufficient quantity of gas had been taken, the spiral was evacuated by means of a small mercury pump. The first two stop-cocks were then closed and, the third one being opened, the condensed gases were allowed to evaporate into the vacuum. For subsequent analysis, by cooling the spiral again with liquid air the whole of the gas was condensed into the spiral, and the fractionation could then be proceeded with. In the earlier experiments the gases from the flue were led through a wash-bottle containing C.O.V. before passing through the spiral; but in the later experiments this washing was omitted as the small quantity of nitrous gases absorbed by the C.O.V. could not be accurately determined.

The total volume of the flue gases analysed amounted to 284 litres, and the results obtained were fairly constant. In every case a small quantity of nitrous oxide was obtained, amounting to about 0·002 per cent. This quantity is so extremely small that it shows that the "chemical loss" of nitre is negligible in so far as nitrous oxide is concerned. The percentage of sulphur dioxide found was quite appreciable when the gases were washed with C.O.V. (0·02 per cent.), but when the gases were taken directly into the spiral no sulphur dioxide was found. The analyses showed that about 0·02 per cent. of the flue gases was separated as nitric oxide; but it must be remembered that a certain amount of nitric oxide is always lost, owing to its vapour pressure at − 185°. This loss may easily amount to 0·02 per cent., but no exact figure can as yet be given. The total amount of nitric oxide is, therefore, about 0·04 per cent. The carbon dioxide found was about 0·05 per cent., this being the amount usually present in the atmosphere. The sulphuric acid found was always constant in parallel experiments, but seemed subject to fluctuations. It seemed to be about 0·008 grm. per 10 litres. The estimation of the nitrogen peroxide was in some ways the most difficult of all. As this gas acts on mercury it was necessary to estimate it by titration, and since it is then determined by difference, the result is not very exact. In addition, traces of nitrogen peroxide usually came over with the sulphur dioxide and got lost through combining with the mercury. The amount of nitrogen peroxide found was about 0·03 per cent. of the flue gases. Adding to this the probable amount of nitric oxide (0·04 per cent.), we find as the total nitre in the flue gases 0·07 per cent.; whereas the total loss of nitre would be accounted for by 0·1 per cent. Hence, we find that 70 per cent. of the nitre lost is lost partly as nitric oxide, partly as peroxide. The loss of nitre in the process is therefore mainly determined by the efficiency of the Gay-Lussac tower, and is thus mechanical and not chemical loss.

This is the chief result so far obtained in this research, but I hope at a later date to give a further account of my work on this subject.

I have great pleasure in expressing my gratitude to Sir W. Ramsay both for suggesting this research and for the advice and help he has so often given me. I should also like to thank Mr. E. C. Thompson for the help he so willingly rendered me at the works in Silvertown.

Discussion.

Dr. **Messel** considered that Mr. Inglis's interesting experiments had finally proved that the loss of nitric acid in the chamber process was purely mechanical and not chemical, unless its reduction to nitrogen was assumed, for which, however, there was no warranty.

Dr. **Divers** said that he had intended to try to show the great improbability of any production in the lead chambers of either the unknown dihydroxylamine-sulphonic acid, as suggested by Raschig, or even of the well-established hydroxylaminedisulphonic acid, or, again, of peroxylaminesulphonic acid (nitrosodisulphonic acid), as quite recently suggested by Trautz, to account for the loss of nitre. But such a demonstration had now become unnecessary, for Mr. Inglis's experiments had clearly settled, as Dr. Messel had just said, that the loss was after all mechanical and not chemical. They disproved the formation of any nitrous oxide, and, by showing the escape of so much of the lost nitre under the form of nitric oxide and peroxide, indirectly proved also the non-formation of nitrogen. From these experiments, therefore, it was to be concluded that hydroxylamine derivatives were not produced in a normally working lead chamber.

Mr. **Hogben** said that Mr. Inglis had not attempted to deal with the loss in the other departments of the process, the mechanical loss from the running of the acids in the different towers, and the other sources of loss there might be. He had had the privilege of working with the first Lunge tower erected in this country, and by taking special precautions he had been able to reduce the loss down to nearly one-third of the loss here stated to occur. Any one accustomed to work according to Dr. Lunge would say that it would be almost impossible to bring the consumption of nitre down below 4 parts on the 100 of sulphur; but by working on different lines he diminished that loss down to below 1·3 parts on the 100 of sulphur. He did not think that had been attained elsewhere in this country, and it was a practical proof of the conclusion Mr. Inglis had arrived at, that the loss was entirely mechanical.

Mr. Guttmann congratulated Mr. Inglis on the results obtained by examining these gases. Last week he had listened to a paper by Dr. Raschig, who had taken up again his old theory of the chamber process, and he was very gratified to hear the references made to the work of Prof. Divers and Mr. Haga. Dr. Raschig, in the presence of Prof. Lunge and others, had demonstrated the correctness of his theory by analyses on the large scale. But apart from that he could confirm what Mr. Inglis had found, *viz.*, that the loss in the Gay-Lussac tower was mechanical. He showed, in a paper read in Manchester some time ago, that it was the practice abroad, and occasionally in this country, to erect central or "catch" Gay-Lussac towers, which took up the loss out of three or four ordinary towers; but even then it was found that, owing to differences in temperature and pressure, there was a mechanical loss which could never be avoided in the manufacture of sulphuric acid.

The Chairman said they must all congratulate the author on such an interesting industrial application of a new scientific fact. It evidently was of the utmost importance to one of our greatest chemical industries that the source of loss had been identified. No doubt when the paper was published, ways might be suggested of getting out of the difficulty; for, although the loss did not appear great in itself, yet when dealing with hundreds of thousands of tons it meant a great deal to the chemical manufacturer.

Mr. Inglis, in reply, said with regard to the estimation of the loss of nitric oxide that seemed rather doubtful to many members present, but aided by the other two towers it amounted to at least 50 per cent. If nitric oxide were condensed at the temperature of liquid air with a mercury pump, a figure would be obtained which undoubtedly pointed to some loss, and the conclusion he drew at present was that something over 50 or 60 per cent. of the loss was due to nitric oxide or peroxide, which, it was not possible to say, because the nitric peroxide might be formed again by taking up the oxygen from the sulphur dioxide or trioxide. He tried to guard against any reaction in the bulb, but it seemed as if some action did take place, and that chamber crystals did form in the bulb.

ACETONE: ITS MANUFACTURE AND PURIFICATION.

BY ARTHUR MARSHALL.

Acetone, as is well known, is manufactured by the dry distillation of acetate of lime, which is one of the principal by-products obtained in the carbonisation of wood. The consumption of acetone is considerable as it is used largely in the manufacture of smokeless powders, of celluloid articles, and for the preparation of many chemicals. In this country especially there is a large demand for acetone for the manufacture of cordite. The other products that are formed together with acetic acid in the distillation of wood—charcoal, tar, creosote, wood spirit, and, in the case of resinous woods, turpentine—are all valuable and find a ready market. It is therefore evident that charcoal burning when carried out in a rational scientific manner is a remunerative ndustry, especially where there is a large supply of cheap wood, or where there is an active demand for the charcoal, which is, after all, the principal product, and the one which bears transport least well.

In the conversion of acetate of lime into acetone there are but few by-products. The material remaining in the retorts onsists of impure calcium carbonate mixed with some tar, nd is of no value. From the purification of the crude istillate some tar is obtained which may be used as fuel, nd from the fractional distillation there results a certain roportion of high boiling fractions consisting largely of thyl methyl ketone, and other higher homologues of cetone. For these there is not a very active demand, but here can be little doubt that suitable outlets will be found for them when attention has been sufficiently drawn to them. Ethyl methyl ketone is obtained directly in a state of considerable purity, mixed with about 12 per cent. of water, and only very small quantities of other impurities. There appears to be no good reason why this should not be used for denaturing alcohol for some technical purposes, as the boiling points of ethyl methyl ketone and alcohol, 79·7° and 79·3° respectively, are very close together, and they form a mixture having a constant boiling point at about 74° C.

As usually carried out the production of crude acetone from acetate of lime consists in heating charges of 300 to 600 lbs. of grey acetate of lime in retorts heated by direct fire, the last portion of distillate being driven over with the aid of steam. The distillate separates into two layers, the lower of which contains the greater part of the acetone together with water, whilst the upper layer consists largely of tarry matter. The upper layer is separated from the lower and is washed several times with water, the washings being mixed with the lower layer. The mixture thus obtained, consisting principally of acetone and water, is now neutralised with caustic soda and submitted to fractional distillation. The plant employed for this purpose is of the same type as is now used almost universally for the fractionation of organic liquids. The vapour is made to ascend a high copper tower provided with a number of plateaux, each of which is covered with liquid that is running down the tower. From the top of the tower the vapour is conducted into a tubular condenser, where a portion of it is condensed and returned to the top of the tower. The remainder is led down to another condenser where it is entirely condensed. This primary distillate is not of such a quality as to satisfy the requirements of the manufacturers of smokeless powders, for although there is no difficulty in obtaining the acetone free from water, and containing only a trace of higher ketones, there are other impurities, the last traces of which are very difficult to remove. The acetone is therefore again mixed with several times its bulk of water, with or without the addition of other substances, and is again submitted to fractional distillation. The distillate is tested from time to time by the "permanganate test," and when the colour remains for the specified time, the acetone is turned into a separate receptacle. This test has been somewhat fully discussed by Conroy (this J., 1900, 206), and it will suffice here merely to state that it consists in mixing 100 c.c. of the acetone with 1 c.c. of 0·1 per cent. of potassium permanganate solution, and observing the time required at a temperature of 15° C. for the characteristic colour of the permanganate to disappear. The present requirements of the War Department are that the acetone shall endure the test for 30 minutes. Two other clauses of the most recent official specification for acetone lay down that—

"The liquid is to be genuine acetone, and must contain no other ingredients except small quantities of substances which are normal by-products of the manufacture of acetone. It must be colourless and absolutely transparent, and when mixed with distilled water in any proportions it must show no turbidity. It must leave no residue when evaporated upon a boiling water-bath.

"The specific gravity must not be greater than 0·800 at 15·5 C. with water at the same temperature."

These clauses, combined with that which relates to the permanganate test, ensure that only the middle fractions from the distillation are supplied, and that the acetone is not contaminated with foreign matter, and contains no more than traces of any substances except ethyl methyl ketone, and only a small quantity of that. But, although all the acetone supplied to the Royal Gunpowder Factory for years past has on delivery complied with this specification in all respects, it was found that after keeping it for a year or two much of it had deteriorated very seriously, the permanganate test falling in many cases to only a few minutes, and the acetone assuming a dark yellowish brown tint. The material therefore had to be redistilled before being used. This was a serious matter as it is considered expedient to keep a large reserve stock of acetone in hand. The Superintendent of the Royal Gunpowder Factory therefore gave me instructions to inquire into this matter, to ascertain if possible why it was that some consignments of acetone rapidly deteriorated, whereas others remained unaffected after many years, and to devise means to prevent this deterioration.

Up to that time acetone had been tested for acid substances by titration with standard caustic alkali using phenolphthalein as an indicator, but no attempt had been made to detect or estimate weak bases. Upon testing various samples of commercial acetone with such indicators as methyl orange or nitrophenol it was found that many of them contained perceptible amounts of basic bodies, whilst most of the others were neutral to these indicators, a very few of the samples being slightly acid. Moreover, the interesting observation was made that the drums of acetone which had deteriorated all contained comparatively large amounts of basic substances or else were acid, whereas the drums that had kept well were almost or quite neutral. From these facts the conclusion was drawn that the presence of these basic bodies was directly connected with the deterioration of the acetone. This was confirmed by a number of laboratory tests and then comparative experiments were carried out on the manufacturing scale.

Several tons of acetone were made as described above from each of three different consignments of acetate of lime, and rectified in the presence of caustic soda. Each of the acetones thus obtained was then divided into three portions: one of these was not treated any further, the second was re-rectified over caustic soda and the third was re-rectified in the presence of a small excess of sulphuric acid, which combined with the basic bodies and enabled a distillate to be obtained which was perfectly neutral to para-nitrophenol. Some crude acetone was also purified by distilling with sulphuric acid and redistilling one-half with caustic soda and the other half with sulphuric acid. The permanganate test of the eleven portions thus obtained were taken a month after distillation and again at intervals. In the table below are given tho original results and those obtained on May 9th, 1904, when the acetones were seven months old.

——		Alkalinity, c.c. N/10 per 100 c.c.	Permanganate Test. Minutes.		Fall.
			One Month.	Seven Months.	
					Per Cent.
Acetones redistilled once with caustic soda	I.	0·12	34	33	3
	II.	0·55	90	54	40
	III.	0·57	95	58	39
The same redistilled again with caustic soda	I.	0·12	over 300	225	about 30
	II.	0·22	37	30	22
	III.	0·42	180	65	36
Ditto redistilled with sulphuric acid	I.	0	over 300	over 300	..
	II.	0	over 300	over 300	..
	III.	0	over 300	225	about 30
Crude acetone distilled with sulphuric acid and redistilled with caustic soda		0·0	80	48	40
Crude acetone distilled with sulphuric acid and redistilled with sulphuric acid		0	180	260	rise 44

All these acetones when freshly prepared stood the permanganate test for at least 100 minutes.

It will be seen that not only have the acetones that were distilled with acid maintained their very high original purity, but that they were even at first attacked by permanganate very much more slowly than the samples that had been distilled with alkali only. This is no doubt due in part to chemical actions taking place with comparative rapidity in the freshly distilled basic acetones between the alkaline bodies and other substances, producing compounds which cause the reduction of the permanganate. The basic acetones have not deteriorated so much as many that have been obtained from other manufacturers, although some of them are now giving decidedly lower figures by the permanganate test. The important fact, is, however, clearly brought out by rectifying in the presence of sulphuric acid instead of caustic soda, acetone is obtained at no additional cost, which possesses a considerably higher degree of purity as shown by the permanganate test and which does not deteriorate on keeping. The full reasons for this and the exact nature of the chemical changes involved are matters which are still being investigated.

It is not very easy to ascertain exactly what are the basic bodies that occur in commercial acetone, as they are present even in the worst samples only to the extent of about 0·01 per cent. Up to the present I have made a thorough examination only of the alkaline substances obtainable from the early fractions. In the sample that I collected they consisted of monomethylamine mixed with about 25 per cent. of ammonia. But that there are other amines as well as methylamine present is shown by the examination of various fractions obtained on distillation. The early portions show strong alkalinity due principally to the bodies already mentioned. The middle fractions are less strongly alkaline, but towards the end of the distillation the alkalinity again rises indicating the presence of bases having boiling points above that of acetone, or forming mixtures with it which boil at a higher temperature than acetone itself.

All these bodies, as well as any acid substances, it is desired to exclude from acetone supplied. A clause has, therefore, been inserted in the specification which reads:

> "The acetone is not to contain more than 0·002 per cent. of carbon dioxide and is otherwise to be quite neutral."

The acid and basic substances may of course be detected and estimated by any method the analyst finds suitable. At the Royal Gunpowder Factory the basic bodies and strong acids are usually estimated by diluting the acetone with an equal volume of boiled distilled water, adding two to four drops of a saturated solution of para-nitrophenol in water, and titrating with standard acid or alkali solution. Weak acids may be detected and estimated by mixing with water as before, boiling for five or ten minutes, adding phenolphthalein and titrating with standard caustic alkali. Carbon dioxide is readily determined by adding water and phenolphthalein and titrating at once without boiling.

By far the greater portion of the acetone used in this country is imported from abroad; yet there seems to be no good reason for this. It may be objected that there is no cheap timber available as in America or Austria. But this objection will not hold, for a large portion of our acetone is manufactured at Hamburg and other places in Germany from acetate of lime imported from America, and if this can be done at a profit in Germany, why not in England? The destructive distillation of wood might also be carried on to a far greater extent than is done at present, for although wood is more expensive here than in many other parts of the world, on the other hand the price obtainable for charcoal is also high here, and very large quantities are required for metallurgical and various other technical purposes. Every year timber is imported into the United Kingdom to the value of about 25,000,000*l.* From this there must be immense quantities of waste wood and after it has been used for structural or other purposes a large proportion of the timber might still be very economically employed for the manufacture of charcoal wood naphtha, and acetone.

Discussion.

Mr. Guttmann said that Mr. Marshall's paper showe that Waltham Abbey was moving very much with the times and also letting the public know what they were doing. The improvement shown by the author depended on th change of treatment of the crude acetone by sulphuric aci instead of caustic soda. He had not told them whether th acetone manufactured at Waltham Abbey in former time had deteriorated so rapidly as the foreign acetone to whic he alluded. He (Mr. Guttmann) had reason to think th the Waltham Abbey acetone did not deteriorate in th rapid way. The reason was obvious, for in Germany t neutralisation of the crude acetone was generally done wi lime, which economically might be preferable, but wou probably form more unstable compounds than would occ from treatment with caustic soda. He did not think t figures given in the paper were very bad, so far as t manufacture at Waltham Abbey was concerned, because if after a month it only varied to the extent of 3 per cent. in one case and 14 per cent. in another—still leaving 35 minutes—it was not so bad, and if Mr. Marshall treated them with lime he would probably find they were much worse. The question whether the crude acetone should be treated with sulphuric acid would no doubt engage the attention of all manufacturers concerned, and would be solved in a way which would confirm Mr. Marshall's results. The only objection to it could be that the acetone might become acid. A good deal of discussion was at one time carried on as to whether acetone when kept a year or two would become acid, and so have to be rejected. He saw no reason why slight traces of acidity should not be left, just the same as slight traces of alkalinity were left now. Mr. Marshall put the question why acetone should not be made cheaply in this country, and why it should be imported, and adduced, not exactly reasons, but arguments, in favour of the manufacture here. Probably he would modify his views if he were to consult the merchants who imported acetone, and the manufacturers abroad. He gave an example of a place in Germany which he said had no woods to speak of, which nevertheless produced acetone from American acetate of lime. He was not conversant with the status of the factory referred to, but he was under the impression that it was not making much profit, and that there were some difficulties about making the cost of production balance the selling price. At any rate the present price of acetone, as delivered to Waltham Abbey, was such that it would not pay anybody to produce it either here or abroad if it were made from American acetate of lime. The Americans, being prudent people, kept the price of acetone low, and that of acetate of lime high, thus preventing people making it at a profit. With regard to the factories in Germany and Austria that did produce acetone, and sent a good deal over here, that was quite intelligible when it was remembered that there were large factories for the distillation of wood which could dispose of every item they manufactured, and who manufactured probably all the prime materials they required. Last year he inspected one of the largest factories in Hungary which supplied large quantities of acetone to this country, and when he saw the way in which they undertook the manufacture of products of all kinds, and the enormous character of the works, he could quite understand that there was a profit to be made on acetone; but if he were asked whether it would be worth while to erect acetone works for the sole purpose of supplying the demand for British explosives, he would certainly say no.

Dr. Lewkowitsch said it was not to be wondered at that basic substances were produced. He pointed to the the fact brought out by the author's experiments that, after the bases had been removed, the acetone so obtained again yielded basic substances on treatment with caustic soda. This did not occur in the case of tar, shale, and lignite oils. Would the inference be correct that the basic substances, or some of them at least, were formed from some nitrogenous substance by the action of caustic alkalis?

Mr. Watson Smith, as a former wood distiller, asked Mr. Marshall first if it were not possible to produce acetone by the treatment of commercial wood spirit itself, which contained a considerable amount, by means of the bisulphite reaction and the after-treatment of the precipitate which it produced with caustic soda. He had reason to believe that owards the end of the wood-distilling process the acetone ncreased in the wood spirit, so that the latter fractions contained considerably more than the earlier stages. In the distillation of wood two fractions were obtained, an acid aqueous one and a tarry one. The acid aqueous fraction ontained the spirit, together with acetone and other bodies uch as acetic acid. This aqueous mixture had to be treated with lime to produce acetate of lime, from which by the sual process acetone was obtained. Now acetone was ot only produced by the dry distillation of calcium cetate, but might be produced to a lesser extent by passing cetic acid through hot tubes. No doubt some of it as thus formed in the wood retorts, especially as they got hotter, towards the end of the process. He thought it xceedingly probable, moreover, that a larger proportion of acetone would be found in the spirit produced towards the end than earlier in the process. The acetic acid would be, he thought, more largely decomposed as the retorts got hotter, and thus produce more of this acetone. There was another matter of considerable interest which he discovered in 1870, and which was recorded in a paper contained in the J. Chem. Soc. (1871, 1101—1108), and this contributed to make this speculation of his more probable. He found that in the distillation of wood the acetic acid increased to a maximum which was reached near the end of the process, when of course the retorts were hottest, after which some diminution took place. This being so, the acetone might hence be expected *pro rata* to be also at a maximum at that later stage. Had Mr. Marshall tested the distillate at various stages, and had he found such variations in the proportion of acetone?

Mr. B. Biggs said that it was generally believed that acetone had been a commercial product only within the last 10 or 15 years, but it was made in South Wales 50 years ago in considerable quantities. At that time methylated spirit was introduced, and Government required contracts for a large quantity of wood spirit. One of his friends had found that a spirit could be prepared from acetate of lime, and he made a considerable quantity, which was supplied and accepted as wood spirit. If he remembered rightly, brown acetate of lime was then worth about 4*l*. 10*s*. per ton, and the contract he made with Government for the spirit was at 8*s*. 6*d*. per gallon of about 8 lb. 1 cwt. of the lime produced $3\frac{1}{2}$ or 4 galls. of acetone of about 60—62 over proof, which was the standard required, so that raw material costing 4*s*. 6*d*. gave a product which fetched some 32*s*., or about 1*s*. a lb., or 112*s*. a cwt. The introduction of methylated spirit brought down the price of other spirit solvents, and the manufacture of acetone was then abandoned. Within the last 10 years acetone, brought up to the standard shown by Mr. Marshall, had been utilised in the production of smokeless explosives, and was now a manufacture of importance, although he was obliged to admit that the bulk of the supply came from abroad, a late contract for 200 tons having been all taken by foreign producers.

Dr. P. Schidrowitz said he had frequently found that in rectifying organic liquids, more especially of a spirituous nature, it was more satisfactory to use a strong organic acid, such as tartaric acid, than a mineral acid. Of course sulphuric acid was much cheaper than tartaric acid, but the quantity required for the final rectification would be very small, and it might be worth trying. Some 10 years ago he strongly advised a firm of manufacturers in the North of England to make acetone, because at that time he knew there was a very fair profit to be made.

The Chairman said this was a very interesting paper to those who used acetone, and it threw light on many things which one had noticed without being able to explain why they happened. Thus, acetone kept in glass bottles deteriorated in the test; and acetone which was apparently quite pure at first, after a time would fail to pass the test. He was inclined to think it was almost a case like one Mr. Watson Smith had pointed out some time ago, of the bottle itself taking the part of a reagent, and that the alkalinity of the glass acted on the acetone, and probably caused it to deteriorate. After this communication they would have to look on the acidity of acetone with a little less suspicion, especially if it were of an organic nature. He thought the suggestion Mr. Marshall had thrown out was a very good one, that waste wood and other sustances capable of producing acetone should be used for that purpose. There was one source of acetone which might very well be used which was, to a great extent, wood originally, namely, the enormous quantity of waste paper and cardboard. In London there was more than 100 tons a week of waste paper and cardboard, and the greater part of it was burnt to get rid of it. It seemed that this might become a source of profit to those who would take it up. There was any amount of material to be had, and a good demand for the product, and to utilise it would certainly be rendering the public a service, and getting rid of an article which was at present a nuisance. There was another opening for the production of acetone which was a very hopeful one, and that was its synthetical production. The cellulose molecule could be treated in a number of different ways; the decomposition of the molecule could be conducted under such conditions as to destroy it, and only obtain a small quantity of acetone, or in such a way as to obtain a large percentage of that particular article which was most valuable. In that direction there was considerable hope. Acetone was a liquid which could be used on a much larger scale if it could be obtained at a cheaper price. With regard to ethyl methyl ketone, there were better uses for this than for denaturing alcohol, and it could be used for purposes for which alcohol could not—such as a solvent in the celluloid and similar industries—with great advantage. If a large quantity of it could be produced, a market could easily be found for it. With regard to denaturing alcohol, he was inclined to think it was not sufficiently unpleasant, because something was required which would combine easily with the alcohol and which was extremely repulsive to the taste. He had also noticed that the test for acetone went down very rapidly if it came in contact with lead; it did not keep well in lead-lined vessels. Perhaps that had some connection with the research of Mr. Marshall. There might be some alkalinity produced.

Mr. **Marshall**, in reply, said Mr. Guttmann had suggested that foreign acetone was worse than that made at Waltham Abbey with regard to alkalinity, owing to the use of lime, and this seemed a possible explanation. He thought that as a matter of fact the price of acetone was lower in Germany than in England. If the German manufacturer could make and sell it at the lower price, he could not understand why manufacturers could not make it at a profit in England, where the price is higher. Dr. Lewkowitsch had referred to the formation of basic bodies, but there was only one experiment bearing upon the point, and it was not advisable to draw too many conclusions from it, the more so as the quantity of alkaline substance in the sample in question was extremely minute. Mr. Watson Smith pointed out that acetone might be obtained by the treatment of commercial wood spirit with bisulphite. There was certainly no chemical reason why this should not be done, but as it was not carried out anywhere, so far as he was aware, it was to be concluded that the manufacturers found a better opening in other directions for wood spirit containing acetone. Dr. Schidrowitz suggested the use of tartaric acid or other organic acid instead of sulphuric; he had the same idea himself, but had not yet been able to apply it. Mr. Reid had made a number of valuable suggestions, and he did not think that he could add anything to them. Acetone was not kept in lead vessels, so that the trouble referred to on that score had not arisen. He did not want it to be inferred that acidity was not harmful. Practically all the acetone made was distilled over caustic soda or lime, and consequently did not contain any acid, but if it did he had little doubt that it would deteriorate just as rapidly as if it contained alkaline bodies, if not more so. In one or two cases where acetone in drums had been found to be slightly acid it invariably deteriorated rapidly.

Mr. **Guttmann** asked if the acetone would be acid if it were distilled over sulphuric acid.

Mr. **Marshall** said it was not found to be so. If the distillation were carelessly carried out it might be possible for some acetic acid to distil over, but he did not see how sulphuric acid could pass over, as the vapour tension of sulphuric acid was very small compared with that of acetone.

A NEW METHOD FOR THE ANALYSIS OF TANNIN AND TANNING MATERIALS AND THE IDENTIFICATION OF ADMIXTURES IN TANNING EXTRACTS AND LIQUORS.

BY DR. J. GORDON PARKER AND E. E. MUNRO PAYNE.

Contribution from the London Leather Industries
Laboratories, Herold's Institute, Bermondsey.

In the analysis of tanning materials by the standard method prescribed by the International Association of Leather Trades Chemists certain figures are obtained which are supposed to nearly represent the results which would accrue in the ordinary course of extraction of materials and use of liquors in tanning. The figures obtained by this method give the amount of tanning matters absorbed by the hide-powder and the amount of other soluble matters which are not absorbed by the hide-powder; these are returned as being non-tannins. The process which is now about to be described will show conclusively some of the many errors caused by the hide-powder, and the extent of such, and will also show the reason why the analytical results as obtained by the hide-powder process are not borne out in practical manufacture.

It has been shown by Procter (this J., 1903, 482, and Collegium, 1903, 114) and others, and is a well-known fact that by the hide-powder process the hide-powder absorbs acids other than tannic acid, and even retains inert matters, such as dextrin and other non-tanning substances which are present in many tan-yard liquors. It has also been shown by Boegh and Paessler (this J., 1899, 927) that the hide-powder method is extremely inaccurate for the analysis of liquors surcharged with natural acids The difficulties of getting concordant results with gambier, myrobalans, and sumach are too well known to require further consideration; and although we acknowledge that the hide-powder process of tanning analysis is in many ways a great advance over the old Loewenthal process, yet the difficulties of obtaining results accurate within half a per cent. have only been surmounted by the most stringent regulations as to exactitude in every manipulative detail.

From time to time the I.A.L.T.C. have modified the process of hide-powder analysis, based on research work carried out in the various leather trades' laboratories of Europe, but one of the main difficulties, which has ever been and probably ever will be as far as the hide-powder process is concerned, is the obtaining of a standard hide-powder free from soluble matter, with an absorptive power sufficient to absorb all matters capable of uniting with hide substances. The authors have made many samples of hide-powder, under varying conditions, with and without the use of aldehydes and chrome salts, but have absolutely failed to produce a hide-powder of unvarying quality and certain standard. They have found that very little variation in the coarseness of the powder, the part of the hide from which the powder is made, the time of the preliminary liming, and the alkalinity or acidity cause the results obtained to vary 1 to 2 per cent; a hide-powder prepared from cow hide is different from a similar powder made under identical conditions from an ox or bull hide; and, again, a powder prepared from the butt varies from one prepared from the belly even of the same beast. It is a matter for congratulation that the differences obtained under present conditions by two chemists analysing the same material are not more divergent than they are.

In the first instance, it is necessary to define the general principals of tanning. Commencing on the limed skin o hide stage, the same having received the required amount of preparatory treatment, generally the process of tannin may be described as—

(1) Reduction or neutralisation of the alkalinity, wit more or less removal of the bases and salts produced.

(2) Fixation or tannage, with the necessary direc combination of the collogen or skin fibres with the acid o acids, or compounds of them.

(3) Loading or filling, which is purely a deposition o and between the fibres of difficultly soluble substance phlobaphenes, bloom and gums, which gives specifi physical characteristics to the skin or hide as leather.

Our method of analysis directly affects the substance which are present in the extracts or liquids whic accomplish the first two parts of this process of tanning and it is well known that materials, extracts, and liquo which give like results by the present method of hid powder analysis do not produce like results in practic The method about to be described shows why this is th case. Tanning materials contain generally, but n always, in addition to the true tannin and non-ac constituents, a variable amount of acid, acids, or acid sal and it is these latter which, although, strictly speakin non-tannins, are necessary and indispensable tanni adjuncts; in fact, strange though the statement may be, pure true tannin, which we term anhydrous digallic acid, does not make leather without the aid of an adjunct, and pure tannic acid does not precipitate collin without the addition of a tanning adjunct, *i.e.*, it requires the addition of a small quantity of organic acid. The ratio of pure tannin to tanning adjuncts can be determined; and the proportions or ratios vary in undoubtedly pure and authentic samples of materials and extracts, or liquors of them prepared under precisely identical conditions.

In the first place, we must consider substances in their behaviour and relations in the pure state, and afterwards draw the inferences resulting from the varying differences, relying always upon corroborative evidence of subsequent analysis, &c. The basis of tanning in almost every instance is the combination of the so-called gallotannic acid, or rather, anhydrous digallic acid, or a compound of it, with collogen, and we base our calculations upon results obtained from the combination of these two substances in their purest known form, taking the substance collin as representative of collogen, which substance it actually is, but deprived almost entirely of its calcium basis.

Having proved that the majority of tanning materials depend upon the anhydrous digallic acid content for their activity as tannin agents, it was considered expedient to devise some convenient, quick and accurate method whereby it could be estimated, and after a considerable amount of investigation and numberless experiments, it has been found that the method about to be described is quickly used, and that a number of other important onclusions can be drawn from the results obtained.

The all-important reaction upon which the method of analysis depends is the formation by anhydrous digallic cid with calcium hydroxide of a basic, insoluble compound. his we have found to proceed fairly rapidly, almost to ompletion within the hour, to be quite completed within our hours, the extra three hours making a difference of —$1\frac{1}{2}$ per cent. only. The method is as follows:—

Take 300 c.c. of an N/5 calcium hydroxide solution and dd to it 200 c.c. of the clear liquor to be examined. This quor should be of the same strength as laid down by ie I.A.L.T.C. for the hide-powder process. Shake several mes in a stoppered cylinder, allow to stand for the quired time, shaking at intervals, filter off 100 c.c., and rate the amount of N/5 calcium hydroxide remaining in e filtrate in the presence of phenolphthalein. This nount multiplied by five and deducted from 300 c.c. mount originally present) gives the quantity of N/5 lcium hydroxide solution which has been absorbed by the 0 c.c. of the original liquor. This figure may be termed e total absorption figure or total absorption value, and y be expressed either in per cent., or in terms of c.c.'s N/5 calcium hydroxide per 100 c.c. absorbed.

We have found in the case of absolutely pure anhydrous gallic acid, prepared and purified by the most careful l accurate methods by means of ether separation, that rm. will exactly absorb 125 c.c. of N/5 calcium hydroxide, ich amount exactly corresponds with the theoretical ount according to the following equation:—

$$C_{14}H_{10}O_9 + 4Ca(OH)_2 = C_{14}H_{10}O_9Ca_4(OH)_8$$
$$322 + 40 \text{ litres } N/5\ Ca(OH)_2.$$

1 molecule of anhydrous digallic acid forming with four molecules of calcium hydroxide an insoluble basic salt. This, however, only takes place if the lime water is in sufficient excess: if a large excess is not used, other salts are formed of various constitution which prevent correct estimation. Barium hydroxide may be substituted for calcium hydroxide, but we prefer the calcium. Sodium or potassium hydroxide cannot be used, as they do not form insoluble precipitates.

When tannin is impure, as in the case of all tanning materials, and contains acids or colouring matters, free or combined with it, it is necessary to make a second determination to ascertain their nature, weight, and acidity, and for this means we take another 200 c.c. of the original liquor and detannise it. This was the most difficult problem to overcome, as the precipitation by means of any of the metallic salts, such as lead nitrate, barium acetate, alumina, &c., or of a solution of gelatin and salt, removed both the tannic and gallic acids, and after numberless experiments we decided to use a neutral solution of collin which was originally devised by one of us for a specific purpose in connection with pharmaceutical preparations. A solution of collin is prepared as follows:—

Take 60 grms. of a good commercial gelatin, soak in about 500 c.c. of distilled water, and warm until dissolved; to this add 120 c.c. normal caustic soda solution, and heat on a water-bath for 20 minutes at 90° C. Filter through linen; the calcium and other salts are thus removed. When cold, fill a 500 c.c. flask exactly to the mark, and titrate 100 c.c. of the remainder with N/1 hydrochloric acid, which will give the amount of normal acetic acid necessary to exactly neutralise the 500 c.c. This amount of acetic acid is added, and the collin is neutral to phenolphthalein; 1 c.c. of pure chloroform is added as a preservative, and the whole made up to exactly a litre, making approximately a 5 per cent. solution of neutral collin. This material *plus* dilute organic acid, is found to be a more delicate precipitant for tannic acid than any we have found. It is possible to detect by means of acidified collin 1 part in 10,000.

To detannise our solution for analysis 200 c.c. of the original liquor is taken, to this is added 100 c.c. of the collin solution in the presence of an added quantity of 100 c.c. N/5 acetic acid, or in cases where old acid tanyard liquors are under analysis, which usually contain only traces of tannin, 50 c.c. of collin and 50 c.c of acetic acid suffice. The tannin is by this means completely precipitated. The precipitate, which is amorphous leather, is filtered off, 200 c.c. of the clear, bright filtrate from the collin precipitate is now placed in a stoppered cylinder, and 200 c.c. of N/5 calcium hydroxide added; this is well shaken and allowed to stand for an hour, and the absorption figure, after filtration, is taken out. This gives, after deducting the amount of added acetic acid, the absorption *minus* the tannin. From these figures, therefore, we obtain the following results:—Total absorption, A c.c.; Acid absorption, B c.c.; True tannin by difference, A − B c.c. per litre.

The following table shows a few results on some tanning materials in common use in this country, and also shows how the total absorption value corresponds with the figures returned by the hide-powder method as tanning matters absorbed by hide, thus showing that the hide-powder absorbs many organic acids other than tannic acid.

—	Percentage of Tanning Matters by Hide-Powder.	Percentage by Parker and Payne's Total Absorption.	Total Absorption, c.c. $Ca(OH)_2$ for 100 c.c. Liquor.	Acid Absorption, c.c. $Ca(OH)_2$ for 100 c.c. Liquor.	True Tannin by Difference.

n the case of samples Nos. 3, 4, and 5, columns 4, 5, and 6 are the results stated to show the relative differences of acid to tannin, and no r comparison with columns of percentages obtained.

We have found that the collin precipitate, which we refer to above as being amorphous leather, is easily removed from the linen or from the filter paper upon which it is. If this is well washed with distilled water, completely removed to a tared porcelain dish, dried at 100° C., and then carefully weighed, a portion of the same may also be submitted to Kjeldahl analysis for the determination of nitrogen; we obtain from these figures the weight-giving or leather-forming capacity of the tanning material under examination. This method will, we have no doubt, be of great value to chemists engaged in the leather trade, as by its aid one can state exactly how many pounds of leather a given extract of tanning material is capable of forming.

The following is one example taken from a number, and reveals a very interesting and important fact, *viz.*, that collin, besides precipitating true tannin, also enters into physical combination with the colouring matter of the material. Whether this be only colouring matter, or whether it be colouring matter in chemical combination with other substances, we are not prepared to state, but in the case of the following sample of chestnut extract we have been able to prove the case both by the Kjeldahl and by the exact weight. If we take the weight of the collin precipitate we know from analysis the percentage of true tannin contained in the solution. With that as our basis, and subtracting that quantity from the total weight, we get the amount of collin combined. In this case the collin is got by difference. If we further submit this precipitate to Kjeldahl analysis we get the amount of nitrogen, and from the amount of nitrogen the amount of collin in the sample, and in this case the tannin by difference, but the two figures do not agree. Now, pure anhydrous digallic acid combines with collin in the proportion of 12 to 13 approximately. Having that as our basis the following example will be clear, and if our theory is correct, it is possible by this means to estimate the amount of colour weight* in any material.

Analysis of a Chestnut Extract.

By hide-powder	29·70.
By lime precipitation	29·71.
" "	17·37 per cent. true tannin.
True tannin ratio	58·46 tannin true.
Acid ratio	41·54 acid.
By weight of precipitate found	56·38 collin.
" " "	*a43·62 tannin true (from true tannin calculation).
By Kjeldahl	*b46·80 collin.
"	53·2 tannin.

Now 12 true tannin combines with 13 pure collin (approximately); therefore *a*43·62 true tannin would combine with 47·25 collin, but by weight 56·38 were found; therefore, by difference, $56{\cdot}38 - 47{\cdot}25 = 9{\cdot}13$, colour weight.

Again, if 12 true tannin combines with 13 collin (approximately), how much tannin would *b*46·8 pure collin combine with 43·2? But the weight found was 53·2. By difference, $53{\cdot}2 - 43{\cdot}2 = 10{\cdot}0$, colour weight.

In the present method of analysis by the hide-powder process the volatile acids are largely driven off by drying the residues in the air-bath, and are only partly estimated in the analysis, but by the method above described they can be accurately determined. For this purpose the total absorption value of a liquor is taken out, and a further sample slowly evaporated to dryness on the water-bath, re-dissolved in water, and a second absorption taken out; the difference gives the amount of volatile acids contained in the sample. We have determined the following absorption factors on the purest materials obtainable:—Pure gallotannic acid (anhydrous digallic acid), 1 grm. absorbs 125 c.c. N/5 calcium hydroxide. Acid gallic, 1 grm. absorbs 177·75 c.c. N/5 calcium hydroxide. Acid ellagic, 1 grm. absorbs 125·92 c.c. N/5 calcium hydroxide. The usefulness of the method may be further applied in the detection of materials in admixtures. These may in part be obtained from the ratio of the true tans to the acid, from whic fairly accurate quantitative results are easy to calculate But the qualitative detection of admixtures is extremel easy, owing to the colour reaction given, on the one han when the tannin solution is added to the lime solution, bu still more marked when the detannised solution is adde to the lime water, the colours for each of the commercia tanning materials being very characteristic, ranging fro mangrove, which is a deep red, mimosa, which is lavender colour, to chestnut, which is a mahogany shade myrobalans, a brown yellow, and finally sumach, which if pure, is of a canary yellow colour, rapidly changing t a brilliant green, but if the sumach be adulterated wit any quantity of either pistacia or tamarix, the colour produced is a deep brown, with no trace of green colour o standing.

The authors intend this paper to be in part only preliminary note, and intend to follow the same up, as sou as time will permit, with a complete comparative list o figures showing the working of the method as compare with the hide-powder figures, and also establishing th leather-forming qualities of all the commercial materia used in the leather industry of this country.

Discussion.

Mr. R. L. **Jenks** said by the kindness of the authors h had examined this method and had had an opportunity o seeing it carried out. He was not quite sure whether D Parker had made clear the relation of this titration metho to those methods already existing. Anyone familiar wit the charming but illusory permanganate method, and th more trustworthy but tedious hide-powder one, would b curious to know what was the relation. Several hundre assays had shown that the first figure, *i.e.*, the "tot absorption" was practically the same as the ordinary hid powder result, and as this could be obtained a few minut it was a very useful check on what was at present th official method, which took a number of hours. Ther were a great many points to be found in the paper. Th interest lay not merely in determining the percentage tannic acid in a few minutes, but in the amount of lig thrown on a number of extremely difficult and compl questions. It was the only method at present which ev promised to throw light on the different tannic acids a to give a ready means of diagnosing them.

Dr. **Lewkowitsch** asked whether the precipitation tannic acid and "colline" also took place in a solution a mineral acid, or only in the presence of an organic ac He quite agreed with Dr. Parker as to the correctness proceeding in the same manner as is done in oil analys *viz.*, to determine numerical values first, obtain constan and then try to explain them.

Mr. **Duff Miller** thought it would be a very gr thing for those interested in tanning if they could get more simple method than they had at present of det mining the valuable properties of tanning materials, a he believed Dr. Parker was on the right road to sup this great want. His experience of the tanning trade been considerable, and he looked upon this as a m valuable research.

Dr. **Dvorkovitz** said about 15 years ago he working on the same lines, but for quite a differ purpose, namely, to ascertain the fermentation of tea the amount of tannin it contained. After experiment with all the existing methods, he found a reliable proc which consisted in depositing the tannin by means of bar hydroxide, and then titrating by potassium permanga the products of fermentation left in the solution. found that to use tannin as a standard was very reliable, as it had to be purified every time before it c be used; in preference, he used oxalic acid as a stand By careful comparison with pure tannin he found grms. of oxalic acid to be equal to 31·3 grms. of tannin. With regard to the colouring matters, he m say that he had at first the greatest difficulty in mating them. Most of the various kinds of tea analysed gave a tannin figure practically the same, alth he knew from the leaves he received, some being y

---

* We use the term "colour weight" in a broad sense, as the exact nature of this material is still under investigation, and we hope to obtain a term which will more correctly express our meaning.

and others old, that the tannin matters must be different; only after he separated the tannins by means of barium hydroxide was he able to get the exact percentage. By further titration of the solution he estimated the percentage of colouring matter, which represented the "product of fermentation." He thought Dr. Parker would find this method very useful, namely, after depositing the tannin matter by means of barium hydroxide to titrate the colouring matters left in solution by means of potassium permanganate.

The CHAIRMAN said everybody seemed to want a good method for estimating tannin, and there did not seem to be one. The mere fact that it took an annual conference,—and already a great number had been held,—to regulate the hide-powder process, showed that it could not be an altogether satisfactory one. He was not an expert himself, but he was told that the hide-powder had to be of a special nature, and even the sex of the animal had to be specified, so that the analysts were rather in the hands of the manufacturer of the hide-powder. They wanted some reagent like lime, which could be procured everywhere. One great advantage of the method appeared to be the differentiation of the various substances which went to make up the weight of leather, which seemed very important, but on the other hand he was not quite disposed to agree that the experiments with collin were conclusive. He thought collin was not quite the same as hide powder, and that a more definite connection between he collin and hide substance should be shown before the act could be accepted that collin was similar to the hide ubstance. Although it might give a precipitate with tannin t did not follow that the reaction would be the same as with ide.

Dr. PARKER, in reply, said Mr. Jenks had pointed out an mportant factor which was noticed before when he communicated this method privately to several of his colleagues. he view had been taken that they were going to upset the ade because they were accustomed to figures based on the ide powder, and if others were substituted they would not e understood. If they wanted those figures they had the tal absorption value, and that figure in all extracts of aterials, not spoiled in the manufacture or heated to too gh a temperature, agreed within one-tenth per cent. of a operly carried out hide-powder analysis. It was only in tracts which had been fermented or chemically treated with bisulphite or some decolorising matter which altered them completely that any difficulty would arise.

Collin was made by heating a solution of hide powder or gelatin with caustic soda, and afterwards neutralising with acetic acid. The sodium acetate present would check any antagonistic action of the mineral acids. He was glad to have heard the remarks of Mr. Duff Miller, one of the pioneers in the extract manufacture, first in Canada, then in this country, and in Slavonia. He knew he had suffered severely from the faults of chemists or of hide powder. Chemists always blamed the hide powder, but Mr. Miller sometimes said it was the chemist. He was glad to hear he was pleased with the advances they were trying to make. He had tried barium hydroxide and found it acted very satisfactorily, but lime was cheaper and was easily obtained. With regard to the colour, the colour they estimated was colour combined, not uncombined. The uncombined value could no doubt be estimated in the way suggested by Dr. Dvorkovitch. The combined colour, which was combined with materials which did not form a compound with collin, could not be estimated by that method. The Chairman had touched upon one or two difficulties with regard to the use of hide powder. It was quite true that hide powder made from a cow-hide was not so satisfactory as that made from an ox-hide, and from a bull-hide it was worse still. Then there was another fact, that hide powder made from a portion of hide from the back or butt would be quite different from that made from the animal's belly, and gave different results. Thus the tannin chemist had been in the hands of the manufacturers of hide powder very largely. They had carefully analysed the collin and found the nitrogen factor was 17·8, exactly the same as in hide powder. Collin could be made either from gelatin or from hide powder. They claimed that collin acted in the same manner as collogen. It was in fact hide substance, or hide powder, from which the lime base had been removed. It was absolutely pure gelatin. From a commercial view they were quite satisfied with the similarity. By the old method they were satisfied when they got results to agree within 1 per cent., and they were specially pleased now they found that a difference of titration of 1 c.c. would make less than one-tenth per cent. difference in the analysis, and as they worked now with 300 c.c., where they formerly used 50, the error was not multiplied as it used to be by the complexity of the hide-powder method.

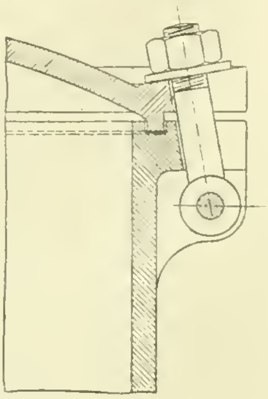
I.—PLANT, APPARATUS AND MACHINERY.

Screw Fastening; Safety —— for the Lids of Vessels [Stills, Autoclaves, &c.]. Landshoff and Meyer. Z. angew. Chem., 1904, **17**, 717.

The nature of the invention is clear from the accompanying figure:—



The flange of the cover, thicker at its outer than at its inner limit, forms everywhere an inclined plane rising outwards, and prevents the fastening-screws, when the nuts are tightened, from slipping off, as they are liable to do when the flange-surface is horizontal.—J. T. D.

English Patents.

Centrifugal Machines. J. W. Macfarlane, Glasgow. Eng. Pat. 15,015, July 7, 1903.

In machines of the "Weston" type, with bottom-discharge valve, described in Laidlaw's Eng. Pat. 16,794 of 1888, a catch is formed on the upper inner edge of the outer stationary casing, to engage with the bottom of the discharge valve when the katter is lifted and tilted, so as to allow the basket to be emptied.—W. H. C.

Separating or Grading Ground or Pulverised Materials; Improved Apparatus for ——. H. Branget, Pont de Pauy. Eng. Pat. 16,815, July 31, 1903.

The material to be separated is fed into a fixed tube, slightly inclined in the direction of its length, and is stirred up and moved forward therein by a shaft carrying stirring-blades and a spiral conveyor. A fan drives a current of air in the contrary direction, which removes the dust.—W. H. C.

Regenerator Furnaces; Construction of ——. J. West, Southport. Eng. Pat. 6718, March 19, 1904.

The division wall between the waste gas flue and the secondary air passages is constructed with special fireclay blocks instead of solid brickwork. The blocks are formed with substantial edges, but with thin centre parts, in order to offer less resistance to the transmission of heat.
—W. H. C.

Filtering Liquids; Improved System of and Apparatus for ——. P. M. Justice, London. From The Telluride Reduction Co., New York. Eng. Pat. 7210, "May 25, 1904" [Specification dated March 25, 1904].

A closed perforated box covered with filtering material is immersed in the liquid to be filtered. The liquid is drawn through into the box by suction, and is removed. The box is then transferred to a tank containing water, which is drawn through, to wash the residue. Finally, the box is removed to another tank, and water forced outward through the filtering material, to cleanse it.—W. H. C.

United States Patents.

Centrifugal Apparatus [Separator]. E. Séger, Stockholm. U.S. Pat. 760,261, May 17, 1904.

See Eng. Pat. 468 of 1904; this J., 1904, 363.—T. F. B.

Filter. P. Danckwardt, Deadwood. U.S. Pat. 760,429, May 24, 1904.

A series of vertical shells enclosing filtering chambers are arranged in steps, the bottom of one filter being connected by a pipe with the top of the next lower down. Suction pipes enter the filtering chambers, and "solvent-pipes" the outer shells, at the bottom.—W. H. C.

Evaporating or Distilling; Apparatus for ——. J. S. Forbes, Philadelphia. U.S. Pat. 760,440, May 24, 1904.

A vacuum evaporating chamber is connected with a condenser by means of an exhausting and compressing pump. Means for heating the evaporator and for drawing off the concentrated liquid are provided. Heat interchangers are arranged so that the heat, both from the evaporated and the condensed liquid, is transferred to the liquid to be evaporated.—W. H. C.

Roasting Furnace. L. T. Wright, Keswick. U.S. Pat. 760,510, May 24, 1904.

The furnace has a vertical central hollow shaft with hollow arms carried over a series of superposed floors, the shaft enclosing a pipe having conduits connected to it, discharging into the hollow arms. A feed-pipe leads upward to, and is connected with, the bottom of the enclosed pipe, and the shaft has a discharge pipe at its top.—E. S.

Muffle Kiln; Continuous ——. T. S. Nickerson, Newburyport. U.S. Pat. 760,551, May 24, 1904.

A series of muffle chambers are arranged in line, having a track running through the series, on which trucks containing the material to be heated travel. The chambers are heated by separate furnaces, and doors are placed at the ends and between the chambers. Means for operating the doors and for moving forward the trucks are provided. The material is warmed up in the first chamber and is then passed on to the second chamber, where it is heated to any desired temperature. When the material has been sufficiently heated, the truck is passed on to the las chamber, where it is allowed to cool. By this means it i claimed that there is no lowering of temperature in th middle chambers.—W. H. C.

Furnaces; Method of avoiding Loss of Heat in ——. A. Kurzweruhart, Zuckmantel, Austria. U.S. Pat 760,633, May 24, 1904.

See Eng. Pat. 1890 of 1904; this J., 1904, 434.—T. F. B.

Dryer. L. Gathmann, Washington. U.S. Pat. 761,011, May 24, 1904.

The drying chamber has a coil connected with a heatin or cooling device. A liquid is forced through the coil s that the temperature of the chamber can be varied. Mean are provided for isolating the drying-chamber from th "heater-condenser."—W. H. C.

Dryer. L. Gathmann, Washington. U.S. Pat. 761,042, May 24, 1904.

The drying chamber is arranged so that air, heated cooled as required, can be forced through it by a fan in upward or downward direction. Means are provided f regulating and for heating and cooling the air.—W. H. C.

French Patents.

Heat evolved from Reactions; Process and Apparatus f Utilising the —— for Heating all kinds of Liqu A. Lang. Addition, dated Dec. 18, 1903, to Fr. P 331,997, May 12, 1903.

See Eng. Pat. 11,632 of 1903; this J., 1904, 527.—T. F.

Concentrating and Evaporating Apparatus for Liqu Soc. Anon. des Forges et Chantiers de la Mediterran Fr. Pat. 338,603, Dec. 31, 1903.

Inside an evaporating chamber are arranged a right- a a left-handed spiral steam-heating coil, provided with inl for live steam and outlets for waste steam. The chamber is braced across to make it rigid, and the parts of the spirals are made interchangeable. Suitable doors are provided to make every part of the apparatus accessible for rapid cleaning and dismounting.—L. F. G.

II.—FUEL, GAS, AND LIGHT.

English Patents.

Coke; Treatment of ——. E. S. Beaven, Warminster. Eng. Pat. 13,047, June 10, 1903.

The coke is immersed in a solution of lime in water, containing about 2—5 lb. of lime in 10 galls., until saturated, the object being to fix the arsenic in the ash of the fuel on burning.—L. F. G.

Separating Coke and other Electric Conductors from Cinders and other Substances; Improved Electrical Apparatus for ——. H. Lelarge, Liège. Eng. Pat. 5799, March 9, 1904.

A revolving drum, with receptacles for cinders, coke, &c. on its surface, is fed with the material to be separated. If the body in any particular receptacle is a conductor, it makes a contact with one end of a wire connected, through battery and electro magnet, to the body of the drum. The electro-magnet brings a chute into position, directing he coke, &c. into a special receiver. If the body is not a onductor, it falls on to another shute and is directed into nother receiver.—W. H. C.

Tan and like Fuel; Furnaces for Burning ——. D. M. Myers, New York. Eng. Pat. 5045, March 1, 1904. Under Internat. Conv., March 2, 1903.

Long narrow feed chute, enlarged at its upper end so as o form a hopper, supplies the tan bark to inclined grate evices, the uniform movement of the tan being effected y a rotating shaft provided with teeth. Auxiliary deflectng teeth, controlled by a lever, regulate the rate of admison of the tan to the rotating stoker. The grate device onsists of horizontal bars provided with feet, resting one n the other, so as to form horizontal air inlets and an clined front down which the fuel slides. Before reaching e grate bars, the fuel passes over a "dead" plate, where is dried. The grate bars are arranged on opposite sides of e furnace, so that the horizontal draughts produced, meet the centre, causing intense heat, whilst reverberating fficient heat to heat the dead plate. The furnace is itably connected to a boiler, and the ashes are removed rough a shaking grate.—L. F. G.

ases; Purification of ——. J. Y. Johnson. From Bad. Anilin u. Soda Fabr. Eng. Pat. 11,549, May 20, 1903. VII., page 659.

s and Air; Apparatus for Producing Mixtures of —— [*for Illuminating Purposes*]. H. H. Lake, London. From Selas Ges. m. b. H., Berlin. Eng. Pat. 11,827, May 23, 1903.

e Fr. Pat. 333,033 of 1903; this J., 1903, 1287.—T. F. B.

s Producers for Poor Gas Free from Tarry Matters. Boutillier, Paris. Eng. Pat. 7979, April 6, 1904. Under Internat. Conv., April 7, 1903.

vertical retort, closed by a cap at its upper end, passes trally down through the main body of fuel in the proer, and its lower end opens into chambers situated eath the fire-bars. "Poor caking (bituminous) coal" is into the retort at its upper end; the tarry vapours which il off pass out at its lower end, and are thence carried the usual currents of steam and air up through the ndescent fuel in the producer. The coke thus produced he retort collects in the chamber below the firebars, nce it is taken as required to replenish the fuel bed in roducer.—H. B.

United States Patents.

Coke-Oven. J. B. Beam, Bigrun, Assignor to the Beam Coke Oven Steam Boiler Power Co., Punxsutawney. U.S. Pat. 760,372, May 17, 1904.

The claim is for a combination of a series of ovens connected to a main flue running below the bottom level of the ovens, but close enough to impart heat to them, the ovens being connected to the main flue by passages provided with valves, the passages entering the ovens above the coke-level close to the filling orifice. The main flue is divided into sections by means of valves, and furnaces are connected with the main flue by passages fitted with valves passing underneath and between two ovens, heating these. —L. F. G.

Gas Furnace; Regenerative ——. F. Siemens, Dresden. U.S. Pat. 760,263, May 17, 1904.

See Eng. Pat. 25,057 of 1902; this J., 1903, 1197.—T. F. B.

Gas Generator. W. F. Mattes, Scranton. U.S. Pat. 760,638, May 24, 1904.

The fuel is fed from a hopper into a series of vertical tubes, and falls into a combustion chamber containing a water-sealed ash-pit at the bottom. The tubes are surrounded by other tubes in which the hot gases from the combustion chamber circulate, and means are provided for regulating the supply of fuel and of air for combustion. —L. F. G.

Gas Purifier. P. Winand, Charkow. U.S. Pat. 760,674, May 24, 1904.

See Fr. Pat. 319,668 of 1902; this J., 1902, 1523.—T. F. B.

Electrically Smelting Materials; Process of —— [*Calcium Carbide, &c.*]. A. H. Cowles. U.S. Pat. 760,057, May 17, 1904. XI. A., page 666.

Calcium Carbide; Process of Making ——. A. H. Cowles. U.S. Pat. 760,312, May 17, 1904. XI. A., page 666.

Incandescent Mantle, and Art of Manufacturing same. W. K. L. Dickson, London. U.S. Pat. 760,317, May 17, 1904.

See Eng. Pat. 4707 of 1901; this J., 1902, 461.—T. F. B.

French Patents.

Briquettes of Coal and Peat; New ——. G. Adrot. Fr. Pat. 338,674, April 8, 1903.

See U.S. Pat. 729,711 of 1903; this J., 1903, 790.—T. F. B.

Moulding and Briquetting; Process and Apparatus for Preparing Pulverulent Substances for ——. The Zwoyer Fuel Co. Fr. Pat. 339,419, Jan. 9, 1904.

See Eng. Pat. 541 of 1904; this J., 1904, 316.—T. F. B.

Furnaces; Regenerative Gas ——. F. Siemens. Fr. Pat. 339,323, Jan. 2, 1904.

See Eng. Pat. 5866 of 1903; this J., 1904, 317.—T. F. B.

Gas Retort; Horizontal or Vertical ——. H. Gielis. Fr. Pat. 338,684, Nov. 5, 1903.

The retort, viewed in cross-section, is roughly rectangular, consisting of four walls, each of which is curved inwards slightly, the curvature serving to strengthen the retort against the outward pressure of the charge and of the gases. When used horizontally the retort is provided externally with transverse rectangular ribs, and when a number of such retorts are superposed in the furnace, the ribs form the supporting pillars for the whole, the bottom edge of each rib resting on the top edge of the one below. —H. B.

Water-Gas, &c.; Process and Apparatus for Production of ——. P. Schmidt and Desgraz. Fr. Pat. 338,626, Nov. 26, 1903.

In this apparatus the gas and tarry vapours which distil from the fresh fuel are drawn off by means of a steam injector and forced into the incandescent part of the fuel, for the purpose of producing non-condensable gases. The producer is provided with a series of apertures at various levels, communicating with the draw-off pipe, at the foot of which is situated the injector, directed into the incandescent zone. To prevent condensation within this pipe, a portion of the hot gas from the incandescent zone is led into it, or it may be provided with a jacket through which the hot gases are led. The main off-take for the gases is situated just above the incandescent zone. Air enters the producer through an inclined grate, the perforations in the lower part of which are larger than those in the upper part.—H. B.

Gas Generator worked by Aspiration. A. E. Kiderlen. Fr. Pat. 338,522, Dec. 30, 1903.

See Eng. Pat. 23,751 of 1903 ; this J., 1904, 54.—T. F. B.

Gas ; Process of Making Poor ——. W. A. Köneman. Fr. Pat. 338,587, Dec. 31, 1903.

See U.S. Pat. 749,302 of 1904 ; this J., 1904, 247.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Coal-Tar Bases. F. B. Ahrens and R. Gorkow. Ber., 1904, **37**, 2062—2066.

α-β-Dimethylpyridine has been isolated from the fraction of tar bases boiling at 160°—165° C., by treating in hydrochloric acid solution with mercuric chloride and distilling with potash. It boils at 159°—160° C., and has an odour of lutidine. On oxidising the base with potassium permanganate α-β-pyridinedicarboxylic (isocinchomeronic) acid is produced. α-β-Dimethylpiperidine is obtained by reducing the foregoing base in boiling alcoholic solution with sodium. It boils at 138°—140° C., and has an odour of piperidine.

β-β-Dimethylpyridine has been isolated from the fraction of bases boiling at 165°—170° C. by fractional precipitation with mercuric chloride and crystallisation at different temperatures. It boils at 171° C. Oxidation with potassium permanganate converts it into β-β-pyridinedicarboxylic acid. This base is identical with the lutidine obtained by Dürkopf and Göttsch from dimethylpyridinecarboxylic acid (this J., 1890, 820).—D. B.

Aniline Homologues; Direct Hydrogenation of ——. P. Sabatier and J. B. Senderens. Comptes rend., 1904, **138**, 1257—1259.

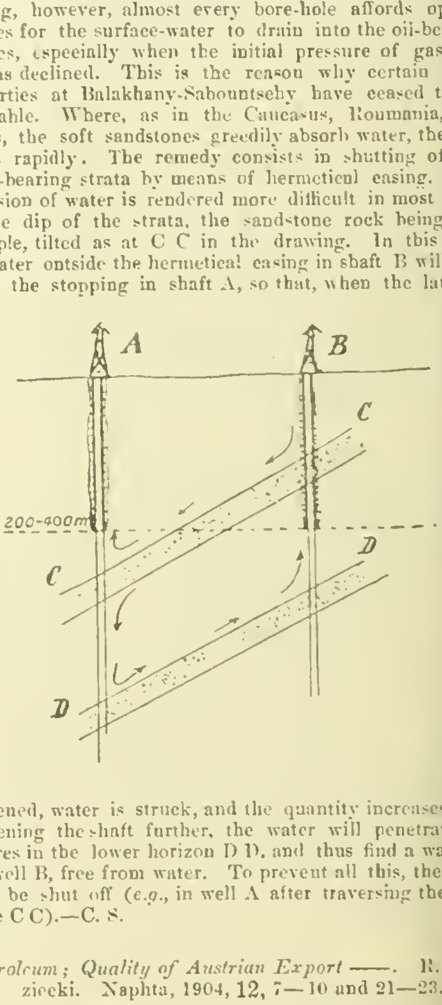
Mono- and dialkylanilines are reduced by hydrogen in presence of finely divided nickel, at 160°—180° C., to the corresponding hexahydro compounds. A secondary reaction takes place to a very small extent, viz., the formation of cyclohexane and alkylamine. Methylaniline is reduced with some difficulty; the resulting cyclohexylmethylamine possesses a powerful odour resembling that of methylamine, and boils at about 145° C. Ethylaniline similarly gives cyclohexylethylamine, of b. pt. 164° C., density 0°/0° = 0·868. Cyclohexyldimethylamine and cyclohexyldiethylamine have boiling points 165° and 193° C., and densities each of 0°/0°, 0·876 and 0·872 respectively. All these compounds are colourless powerful bases, alkaline to litmus, and form easily soluble salts. Aniline substituted in the benzene ring, by an alkyl group, is reduced in a manner similar to aniline (this J., 1904, 341) ; thus, in the case of the toluidines, hexahydrotoluidine, dimethyldicyclohexylamine and methylcyclohexytolylamine are formed. The reduction of the toluidines and xylidines, however, proceeds very slowly, and only to a limited extent.—T. F. B.

Aniline-Toluidine Oil from Russian Naphtha. W. N. Ogloblin. Z. Farben- u. Textil-Chem., 1904, **3**, 179—183 and 199—202.

The author has investigated two aniline-toluidine oils obtained from Russian naphtha by Nikiforoff's process (Eng. Pat. 10,957 of 1886 ; this J., 1887, 540). Oil No. I., of which 60 per cent. distilled below 182° C., consisted of about 60 per cent. of aniline and 32 per cent. of *o*-toluidine. Oil No. II. contained aniline and the three toluidines, the chief constituent being *o*-toluidine.—A. B. S.

Petroleum ; Wasteful Methods of Winning ——. K. Angerman. Naphta, 1904, **12**, 3—6.

Oil deposits are usually separated from surface water-bearing strata by impervious, plastic, sedimentary rocks, and if care were taken to maintain this separation in drilling oil wells a flow of oil quite free from water could be secured for many years. Under the usual conditions of drilling, however, almost every bore-hole affords opportunities for the surface-water to drain into the oil-bearing fissures, especially when the initial pressure of gas and oil has declined. This is the reason why certain large properties at Balakhany-Sabountschy have ceased to be profitable. Where, as in the Caucasus, Roumania, and Texas, the soft sandstones greedily absorb water, the evil grows rapidly. The remedy consists in shutting off the water-bearing strata by means of hermetical casing. The exclusion of water is rendered more difficult in most cases by the dip of the strata, the sandstone rock being, for example, tilted as at C C in the drawing. In this case the water outside the hermetical casing in shaft B will flow under the stopping in shaft A, so that, when the latter is deepened, water is struck, and the quantity increases. O deepening the shaft further, the water will penetrate th fissures in the lower horizon D D, and thus find a way int the well B, free from water. To prevent all this, the wate must be shut off (*e.g.*, in well A after traversing the sandstone C C).—C. S.



Petroleum ; Quality of Austrian Export ——. R. Zaloziecki. Naphta, 1904, **12**, 7—10 and 21—23.

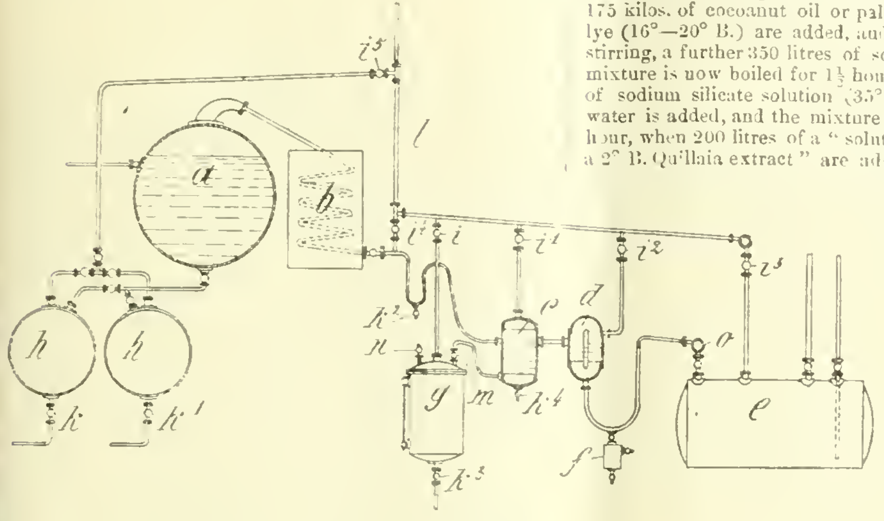
The proposal made to mix light, medium, and heav Galician oils, in order to compete with American oil, impracticable owing to the low capillarity of the heavi fractions. This has been shown by photometric tests w a 10''' Cosmos burner, an American oil, with 30·7 per cen of fractions boiling above 300° C., giving a light of 11 standard candles, whilst a Roumanian oil, with 17·4 p cent. of heavy fractions, gave a light of only 6·76 candl An examination of the fractions of Urycz crude oil sho that, to furnish a mixed oil of sp. gr. 0·800 and flashi point 21° C. (Abel), the yield would have to be reduced about 25 per cent. The essential point for increasing t consumption is the provision of a suitable lamp, the gre success of American oil being attributable to this factor. —C. S

Viscosity of Pitch-like Substances. F. T. Trouton an E. S. Andrews. XXIII., page 680.

English Patents.

Distillation of Fats, Oils, Tars, and the like; Continuous Vacuum ——. G. Bokelberg and J. Sachse, Hanover. Eng. Pat. 7204, March 25, 1904.

The still a is connected with a condenser b, and with a tar or residue outlet tube, which passes to the residue tanks h h; these are connected with a vacuum pump, and are



provided with cocks so that they can be used alternately; the gaseous products coming from the condenser are drawn up the pipe l as produced, and the distillate passes to the receiver c, which is connected with the pump; the temperature and vacuum are so regulated that the distillation products condense without the water. The receiver c is connected on the one hand with a reservoir g, in which any condensed water collects, and on the other hand with a vessel d, which enables a portion of the distillate to be inspected: both these vessels are connected with the vacuum pump. A second reservoir similar to g is provided so that these can be used alternately without stopping the distillation. The vessel d is connected with a cock f, by which a sample of the distillate can be removed as required; the distillate finally passes to the storage tanks e (of which there are two), which are also connected with the pump; the cocks shown at i, i^1, &c., serve to regulate the vacuum in the various parts of the apparatus; drain cocks k, k^1, k^2, &c., are also provided.—T. F. B.

Ammonium Sulphate from Ammonia Gases; Saturator for the Recovery of ——. K. Zimpell. Eng. Pat. 6891, March 22, 1904. VII., page 660.

Lubricating Substances for use in the Manufacture of Bricks, Tiles, Pottery, and the like. W. H. Sandwith and H. T. Rayner. Eng. Pat. 16,125, July 21, 1903. IX., page 662.

United States Patents.

Retort [for Producing Oil from Shale]. S. L. Hague, Salt Lake City. U.S. Pat. 759,988, May 17, 1904.

A horizontal retort is heated at one end by a furnace, with which are connected flues which warm the rest of the retort; it is also furnished with a revolving screw conveyor (which draws the shale from the cooler end towards the hotter end of the retort) and with a steam jet at the hotter end of the retort to drive the oil vapours towards the cooler end, where they are removed.—T. F. B.

Bituminous Pavements; Process of Preparing Compositions for, and of Heating and Laying ——. J. H. Amies, Assignor to Amies Asphalt Co. U.S. Pat. 760,051, May 17, 1904. IX., page 662.

French Patents.

Petroleum and its Homologues; Process for "Saponifying" ——. F. J. Lothammer and C. Trocquenet. Fr. Pat. 338,636, Oct. 19, 1903. Under Internat. Conv., Oct. 16, 1903.

300 litres of petroleum are added gradually to 1 litre of "Quillaia saponaria," 6° B., the mixture being stirred after each addition until it begins to thicken. The mixture is distilled, and the product of the distillation warmed with 175 kilos. of cocoanut oil or palm oil. 350 kilos. of soda lye (16°—20° B.) are added, and then, gradually, and with stirring, a further 350 litres of soda lye (20°—25° B.); the mixture is now boiled for $1\frac{1}{2}$ hours, a solution of 110 kilos. of sodium silicate solution (35° B.) in 25 litres of boiling water is added, and the mixture is again boiled for half an hour, when 200 litres of a "solution of sodium carbonate in a 2° B. Quillaia extract" are added, the boiling being continued until a sample of the product solidifies rapidly on cooling. 12 litres of ammonia solution (65° B.) are then added, and the soap is stirred until the requisite consistency is attained.—T. F. B.

Petroleum and its Homologues; Process for Saponifying ——. F. J. Lothammer and C. Trocquenet. First Addition, dated Oct. 29, 1903, to Fr. Pat. 338,636, Oct. 19, 1903 (see preceding abstract).

The petroleum, solidified as described above, is spread on plates of incombustible, badly-conducting material, provided with perforations or channels, and inclined to the horizontal. The mass is ignited and the oil which separates is collected and treated as described.—T. F. B.

Vaseline Soluble in, or easily Miscible with Water; Process for Making ——. Ges. z. Verwerthung der Boleg'schen Wasserlöslichen Mineralole und Kohlenwasserstoffe G. m. b. H. Fr. Pat. 338,640, Oct. 26, 1903.

Mineral oils soluble in water (*viz.*, crude mineral oils which have been oxidised, in presence of alkali, by means of compressed air or ozone, and subsequently heated under pressure) are added, in the proportion of about 10 or 15 per cent., to vaseline, melted at as low a temperature as possible (40°—50° C.); the mixture is allowed to cool, with continual agitation. In place of the mineral oils, crude rosin oils which have been subjected to a similar treatment may be employed. The resulting greases are easily miscible with water. (Compare Fr. Pat. 332,324 of 1903; this J., 1903, 1289.)—T. F. B.

Hydrocarbons Soluble in Water [Disinfectants, &c.], i.e., capable of Easily Forming Stable Emulsions; Process of Making Derivatives of ——. Ges. z. Verwerthung der Boleg'schen Wasserlöslichen Mineralöle und Kohlenwasserstoffe G. m. b. H. Fr. Pat. 338,738, Oct. 26, 1903.

"Derivatives of hydrocarbons" soluble in water are produced by heating the compound to be rendered soluble (*e.g.*, nitrobenzene, phenols, &c.) with soluble mineral oils (see preceding patent) under pressure, and in presence of alkali. For instance, 20 parts of nitrobenzene are treated with compressed air, at 50° C., in presence of alkali for 15—20 minutes, 70—80 parts of soluble mineral oil or rosin oil are added, and the mixture is heated to about 70° C. These "derivatives" are intended for use in the manufacture of soaps and disinfectants.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

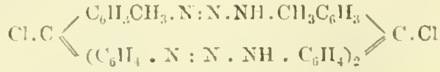
Diazobenzene and Phenol; Limit of Coupling of ——. L. Vignon. Comptes rend., 1904, **138**, 1278—[illegible].

The author obtains p-hydroxyazobenzene in satisfactory yields by the action of diazobenzene chloride on a solution

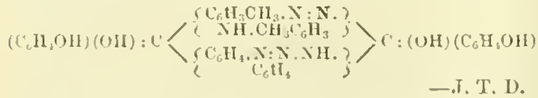
of phenol in excess of caustic alkali. On treating this substance with diazobenzene chloride in alkaline solutions phenolbisdiazobenzene, $C_6H_3(OH)(N:N.C_6H_5)_2[1.2.4]$, is formed. The same substance is more satisfactorily prepared by the action of 2 mols. of diazobenzene chloride on phenol in alkaline solution. It is very soluble in alkaline solutions. It is also formed by the action of diazobenzene chloride on *p*-hydroxybenzoic acid, and is identical with the substance obtained by Griess by acting on diazobenzene chloride with potassium carbonate. The author attempted in vain to prepare phenoltridiazobenzene.
—E. F.

Diazo-amino-fuchsine and Diazo-amino-rosaniline. L. Pelet and W. Redard. Bull. Soc. Chim., 1904, **31**, 644—646.

Graebe and Caro, and later E. and O. Fischer, showed that by the action of nitrous acid on Fuchsine it was converted into Rosolic Acid, and that an unstable chloride of diazofuchsine was formed as an intermediate product. The authors find that by careful addition of a solution of Fuchsine of known strength to an acidified solution of potassium nitrite, there is formed diazo-amino-fuchsine chloride—



The speed of reaction increases with the strength (degree of ionisation) of the acid employed, and for the same acid, with its concentration. Sodium carbonate produces in the solution of diazo-amino-fuchsine a brown flocculent precipitate, unstable, having the composition of di-diazo-amino-rosaniline—

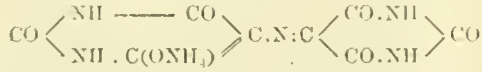


—J. T. D.

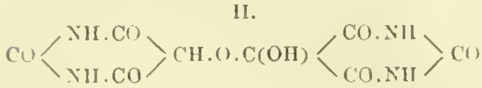
Purpuric Acid and Murexide; Constitution of ——. M. Slimmer and J. Stieglitz. Amer. Chem. J., 1904, **31**, 661—679.

From the results of a study of the derivatives of purpuric acid, the authors conclude that the constitution of murexide (the ammonium salt of purpuric acid) and of alloxantin may be best expressed by the formulæ I. and II. respectively—

I.



II.

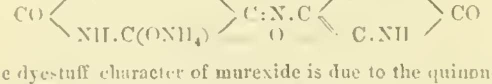


Purpuric acid in the free state probably exists in the pseudo form—

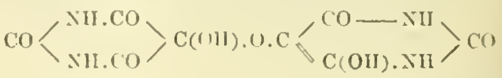
—A. S.

Murexide; Constitution of —— and of some Uric Acid Derivatives related to it. O. Piloty and K. Finckh. Annalen, 1904, **333**, 22—71.

From the results of their investigation, the authors conclude that murexide is the ammonium salt of diureide-oxazone—



The dyestuff character of murexide is due to the quinonoid character of the alloxan nucleus it contains, and its stability to the oxazone ring. No derivatives of murexide substituted at the nitrogen atom connecting the two ureide rings could be obtained, and this fact is in accordance with the formula given. The existence of two isomeric sodium salts of murexide is due to the unsymmetrical structure of the two ureide rings. For alloxantin the most probable formula is—



—A. S.

Indigo Plant; Fermentation of the ——. C. Bergtheil. Chem. Soc. Proc., 1904, **20**, 139.

The fermentation of the indigo plant has been ascribed to a bacterium and also to enzymes, but has hitherto never been satisfactorily investigated. The author shows that, although there are many bacteria capable of producing the fermentation, it is in the main due to a specific enzyme occurring in the plant cells. A very active solution of this enzyme has been obtained, and the course of the fermentation produced by adding this to an extract of the indigo plant made in boiling water, has been studied. It is found that the fermentation proceeds in a similar manner to that observed by Adrian Brown for invertase (Chem. Soc. Trans., 1902, **81**, 373) and by Horace Brown and Glendinning for diastase (Chem. Soc. Trans., 1902, **81**, 388), namely, that equal quantities of substance are transformed in equal intervals of time in the early stages, but not in the later ones. The point at which the course of the change can no longer be represented by a straight line is when 17 to 20 per cent. of the total action has taken place. The curve representing the reaction ceases to be linear at about the same point when the time factor is kept constant, but the quantity of acting enzyme varied. The optimum temperature for the action is almost exactly 50° C., and the temperature at whicht he enzyme is destroyed is 71° C. The rate of action is decreased by the presence of both acids and alkalis. Sodium acetate up to 1 per cent. does not affect the rate of action. Various antiseptics all produced inhibition, formalin to the greatest, and boric acid to the least extent. Emulsin can produce the indigo fermentation, but has a very weak action. It is doubtful whether the indigo enzyme can decompose amygdalin. Myrosin cannot ferment an extract of the indigo plant, and the indigo enzyme cannot ferment sinigrin. No evidence of the existence of an oxydase in the indigo plant was obtained.

Polyhydric Phenols and their Derivatives; Action of Molybdates on —— [Distinguishing between m- and p-Phenylenediamine]. C. Frabot. XXIII., page 685.

"Flocculation" Phenomena [Aniline Dyestuffs, &c.]. M. Neisser and U. Friedemann. XXIV., page 688.

United States Patents.

Indigo; Chlorinated ——, and Process of Making same. P. E. Oberreit, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on-Rhine. U.S. Pat. 761,007, May 24, 1904.

Cyanmethylanthranilic acid is chlorinated and treated with caustic alkali, chlorinated phenylglycocoll-o-carboxylic acid being formed; this is then treated with acetic anhydride, and the resulting acetylchloro-indoxyl is oxidised by air in alkaline solution to a chlorinated indigo. Tetrachloro-indigo obtained thus from dichloro-indoxyl, is claimed, and also the "indigo colouring matter from acetylated monochlorindoxyl," which dyes cotton blue shades.—T. F. B.

Azo Dyestuff; Red ——. H. Witter, Elberfeld, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 761,123, May 31, 1904.

See Eng. Pat. 7353 of 1903; this J., 1904, 319.—T. F. B.

Anthraquinone-α-Sulphonic Acids; Process for Preparing —— [*Anthracene Dyestuffs*]. Soc. Anon. Prod. F. Bayer et Cie. Addition, dated Dec. 11, 1903, to Fr. Pat. 333,144, June 17, 1903.

See Eng. Pat. 13,808 of 1903; this J., 1904, 438.—T. F. B.

Mono-azo Dyestuffs; Process for Making Mordant ——. Act.-Ges. f. Anilinfabr. First Addition, dated Dec. 30, 1903, to Fr. Pat. 331,121, April 11, 1903.

Dyestuffs similar to those described in the principal patent (this J., 1903, 1126) are obtained from 1-hydroxy-2-diazo-4-mono-arylaminobenzene, or its sulphonic or carboxylic acids, or nitro or halogen derivatives. They may be prepared by coupling diazotised *p*-aryl-acetamino-*o*-aminophenol [1-hydroxy-2-diazo-4-arylacetaminobenzene] or its derivatives with an amine, phenol, &c., and subsequently eliminating the acetyl group, or by coupling 1-hydroxy-2-diazo-4-mono- or diarylamino benzene or its derivatives with phenols, &c.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

New Azo Bistre [*from Chrysoïdine*], *produced upon the Fibre; and Discharge for Same.* La. Soc. de la Manuf. E. Zundel. Bull. Soc. Ind. Mulhouse, 1904, **74**, 54.

A bistre, which, it is stated, is very fast and of great brightness of shade, is produced by padding cotton tissues in a solution containing 20 grms. of "Chrysoïdine" per litre, drying, and passing at full width through a bath containing 27 grms. of diazotised paranitraniline per litre. The tissues are afterwards washed, soaped for 10 minutes at a temperature of 50° C., dried, printed with a discharge-mixture containing formaldehyde-hydrosulphite, steamed for 2—4 minutes, soaped for 2 minutes at 50° C., washed, dried, and, finally, cleared with bleaching powder solution.
—E. B.

Hydrosulphites; Application of —— *in Tissue Printing.* J. Frossard, C. Sünder, and G. Thesmar (of La Soc. de la Manuf. E. Zundel). Bull. Soc. Ind. Mulhouse, 1904, **74**, 36—46.

A. Sodium Hydrosulphite in Solution.—The strength of the preparation employed by the authors was such that 8—9 c.c. of it decolorised 20 c.c. of a solution of ammoniacal copper, containing 25 grms. of copper per litre, or 4—4·5 c.c. of it decolorised an amount of indigotin-disulphonic acid corresponding with 0·5 grm. of indigotin.

(*a*) *Slop-padding with "Modern Violet."*—The dyestuff in the form of powder is mixed first with its own weight of the sodium hydrosulphite solution and then with water, acetic acid, glycerin, gum tragacanth paste, and chromium acetate. Other dyestuffs, *e.g.*, "Alizarin Blue," may also be added to the mixture for shading purposes. The tissues, padded with the mixture and dried, are, in the case of dark and medium shades, passed through the Mather-Platt ager, printed with chlorate ferricyanide discharge-mixtures, again passed through the ager to render the shades even), and are then steamed without pressure for an hour, and soaped in an open-soaping range. In the case of pale shades, the tissues are preferably steamed for an hour before, and for a few minutes after, printing the discharges upon them, as the action of the latter can be made much more rapid than is possible with darker shades.

(*b*) *Slop-padding with Indigo.*—The apparatus employed for this purpose consists of a small trough into which an alkaline solution of "Indigo White," prepared by means of sodium hydrosulphite, is continuously fed through a perforated tube fixed near the bottom of the trough. The tissue to be padded passes vertically downwards into the trough between two upright boards, to prevent it from coming into contact with the froth on the surface of the solution, and, on leaving the trough, passes over an expander, between two squeezing rollers and then over a series of rollers to oxidise the reduced indigo. The vat must be maintained at a constant level. The solution employed must not contain more "Indigo White" than corresponds with 10 grms. of indigotin per litre. Sixteen pieces, each 100 metres in length, can be padded per hour with this apparatus. The method is, however, successful only with mercerised tissues. With these, in the medium and pale shades of blue produced, the evenness and regularity of dyeing obtained are excellent and greater than are commonly found in the dyeings done in vats in the ordinary manner, but the fastness to soaping is inferior, as the deposition of dyestuff takes place too superficially.

(*c*) *Slop-padding with Mixtures of Basic Dyestuffs, Tannic Acid, and Sodium Hydrosulphite.*—In presence of acetic acid, the leuco-bases of basic dyestuffs are not precipitated by tannic acid. The padding liquor employed contains besides a basic dyestuff, *e.g.*, Methylene Blue, and sodium hydrosulphite (30 parts of the solution of the strength given above to 1 part of Methylene Blue), acetic acid, water, tannic acid, gum-senegal solution, and zinc acetate. The colour-lakes fixed on cotton tissues by means of such mixtures, are faster to soap and are more evenly distributed than those obtained by padding first with basic dyestuffs and tartar emetic and then, after drying, with tannic acid. They are, however, less fast to light than the latter.

B. Solid Zinc Hydrosulphite.—This was prepared in a crystalline state by acting, at a temperature not exceeding 42° C., with zinc and sulphuric acid, diluted with ice, upon sodium bisulphite diluted with ice. Two hours after the whole of the acid had been added, the crude zinc salt which had separated out, was collected, pressed, well ground, mixed with thick gum-senegal solution and made up to a standard strength. This was called paste A. It was employed for the following purposes:—

(*a*) *Discharging Dyed Silk Tissues.*—A mixture of paste A, sodium carbonate, zinc oxide made into a paste with glycerin, and gum-senegal thickening, was printed, the printed tissue being steamed for 4 minutes, washed, soured, washed, and dried.

(*b*) *Discharging Paranitraniline Red.*—To this end, the paste A was mixed with stannous hydroxide paste, sodium acetate, and common salt. The discharge was produced by steaming for 4½ minutes, souring, washing, drying, and clearing with bleaching powder.

(*c*) *Printing Indigo.*—A mixture is made of paste A, "Indigo pure" ground with glycerin, sodium carbonate, and gum-senegal solution. The tissues printed with this are steamed, and are then passed through a 5 per cent. solution of sodium carbonate. They are then squeezed and left piled up and exposed to the air for about an hour, to oxidise the Indigo White, afterwards being soured, washed, soaped, washed, and dried. This process is highly successful. Shades of any intensity can be produced with regularity and certainty. They are very smooth, full, and even, and the colours are rather faster to soaping than those produced on the fibre from Kalle's "Indigo salt." Moreover, the process is economical, and has the advantage of allowing colours which require for their development or fixation a steaming of short duration, *e.g.*, "Aniline Black," to be printed along with the "Indigo" colour mixtures.—E. B.

Hydrosulphurous Acid Derivatives [*Formaldehyde-Hydrosulphite Compounds*] *and their Application in Tissue Printing.* La Soc. de la Manuf. E. Zundel. Bull. Soc. Ind. Mulhouse, 1904, **74**, 48—53.

The grinding operation necessary to reduce zinc hydrosulphite to a sufficiently fine state to be suitable for use in tissue printing is a serious drawback to the use of this salt. No such objection attends the use of the double compounds of hydrosulphites and formaldehyde. Sodium hydrosulphite-formaldehyde is readily prepared by adding formaldehyde (40 per cent.) to solid sodium hydrosulphite. Solution takes place very rapidly and much heat is evolved. On fractionally crystallising, the compound is obtained, separating out last, in the form of small, colourless needles very soluble in water. The zinc compound may be similarly prepared. It is less soluble than the sodium compound. For the preparation of zinc hydrosulphite in quantity the following method was adopted:—Zinc powder, dilute sulphuric acid, and ice are added simultaneously to a well-stirred mixture of sodium bisulphite and ice, enough of the last-named being used to keep the temperature below 10° C. The stirring is continued for 10 minutes. Then the mixture is allowed to rest for 10 minutes, and the clear solution is withdrawn from the greyish black sediment of zinc, lead, metallic sulphides, sulphites, &c. After standing for about an hour, the zinc hydrosulphite begins to crystallise out. Its separation may be assisted by heating to 30°—40° C., or, better, by adding common salt. The product thus obtained is quite colourless. On admixture with formaldehyde and a little acid it dissolves with evolution of heat, and, on cooling, the formaldehyde compound partly separates out in small, colourless plates. The latter compound may also be prepared by boiling together for a few minutes a mixture of formaldehyde, sodium bisulphite, acetic acid, water, and zinc powder. This method, judging from the reducing power of the solution obtained, would appear to give a good yield, but it has the disadvantage of requiring the evaporation of a relatively large quantity of water in order to obtain the compound in a sufficiently concentrated state for use in tissue printing. This is the case also with the solution obtained by adding formaldehyde to the product of the reaction of zinc powder on sodium bisulphite solution. On adding sodium carbonate to an aqueous solution of the zinc compound, the sodium compound is formed with precipitation of zinc carbonate. The formaldehyde hydrosulphite compounds possess the remarkable property of not exhibiting their reducing action and of behaving as indifferent substances under ordinary conditions; thus, they do not reduce "Indigo Carmine" or ammoniacal copper solution. They are perfectly stable in the cold, and may be boiled in the presence of a small quantity of acid, with little decomposition. Under reduced pressure, their solutions may be concentrated without loss. The concentrated solutions, when thickened and printed, &c., discharge "Paranitraniline Red" exceedingly well. Hence it would seem that scission of the compounds into their components occurs during the operation of steaming, and that the hydrosulphite then liberated, exerts to the full its reducing power. The two, *i.e.*, the zinc and the sodium, compounds are not equally decomposable by steam, for, while the sodium compound completely discharges Paranitraniline Red after four minutes, 15 minutes' steaming is required with the zinc compound. The time may be shortened by adding to the printing mixture a sodium salt, *e.g.*, sodium chloride, which is capable of converting the zinc compound into the more easily decomposable sodium compound. The hydrosulphite-formaldehyde compounds can replace with advantage almost all the reducing-agent reserves and discharges employed in tissue printing. They give, for example, with suitable additions, an excellent white reserve under "Aniline Black" on silk. They resist "Nitroso Blue," and discharge most of the direct azo dyestuffs, even in very dark shades, both on silk and on cotton. The white produced upon tissues dyed with "Paranitraniline Red" is perfect and unalterable; and does not suffer when the red ground is converted into a brown by treatment with a copper salt. This "Paranitraniline Brown" may be first produced on the tissue, it may then be discharged in the same way as the "Red." "Naphthylamine Bordeaux" may also be discharged. Mixed with sodium acetate, the hydrosulphite-formaldehyde compounds furnish excellent discharge-reserves for tissues dyed "Paranitraniline Red" and overprinted with "Aniline or Diphenyl Black." Similarly, when printed upon tissues dyed "Paranitraniline Red" and padded with "Aniline Black," the mixture gives excellent whites upon a bronze ground. Moreover, coloured discharges may readily be produced with the aid of the new compounds; thus, for example, a "Prussian Blue" discharge of great brilliancy, may be obtained upon tissues dyed "Paranitraniline Red" by means of a mixture containing, besides one of the hydrosulphite-formaldehyde compounds, ferrous ferrocyanide and albumin.—E. B.

Hydrosulphite-Formaldehyde Compounds; Application of —— in Tissue Printing. Reports upon the preceding communications from La Soc. de la Manuf. E. Zundel and C. Kurz. H. Schmid. Bull. Soc. Ind. Mulhouse, 1904, **74**, 55—66.

Frossard (see abstract above) has observed that sodium hydrosulphite may be employed with advantage in effecting and maintaining the reduction of certain dyestuffs of the "Gallocyanine" group, such as "Modern Violet." The latter dyestuff comes into commerce in the form of a leuco-compound which has the property of readily becoming oxidised and, in consequence, insoluble. By the addition of hydrosulphite to it this action is prevented, and perfectly even and regular dyeings are obtained in slop-padding with it. A second application consists in reducing basic dyestuffs. The leuco compounds of these are not precipitated by tannic acid, the slop-padding bath containing them remaining clear even in the presence of a precipitant of tannic acid, such as zinc acetate, provided that sufficient acetic acid is added to keep the zinc tannate in solution. The method devised in the year 1902 (see above abstract) has since been modified. The padding bath, free from zinc salt, is now applied to oil-prepared tissues, which are steamed and then passed through a tartar emetic fixing bath. The application of zinc hydrosulphite and of sodium hydrosulphite-formaldehyde in effecting the fixing of "Indigo" in calico printing is of the highest technical importance. This method is likely to supersede all other methods of printing with "Indigo." As a discharging agent for "Naphthylamine Bordeaux" zinc hydrosulphite is superior to sodium hydrosulphite-formaldehyde. Unfortunately the printing mixtures containing zinc hydrosulphite suffer from the drawbacks attending the use in printing of insoluble matters of high density. They are unsuitable for printing mercerised and "raised" (flannelette, etc.) tissues. For these it is preferable to employ sodium hydrosulphite-formaldehyde. C. Kurz deposited (Dec. 1, 1902) a sealed note (this J., 1904, 58) concerning the preparation of a discharge-mixture, containing sodium hydrosulphite and formaldehyde, for "Paranitraniline Red" and "Diamine," &c., dyestuffs. The principle of the reaction had been previously indicated by Pellizza and Zuber (this J., 1900, 438). Kurz's mixture gives satisfactory results shortly after it has been made, but, as it contains too little formaldehyde, it soon decomposes and becomes unfit for printing.

The hydrosulphite-formaldehyde compounds described in the note deposited by La Soc. de la Manuf. E. Zundel are well defined, highly stable, crystallisable compounds in which the reducing power of the hydrosulphites is latent. They are more stable than the difficultly soluble zinc hydrosulphite and have the advantage of being soluble and therefore applicable to all kinds of tissues. The most important of them is sodium hydrosulphite-formaldehyde, $Na_2S_2O_4 + 2CH_2O$, which is manufactured under the name of "Hydrosulphite N F" (this J., 1904, 369). This compound discharges "Paranitraniline Red" perfectly, without the least injury to the fibre. A good white is also obtained with this compound upon the author's (H. Schmid's) puce, which is produced by padding tissues dyed "Paranitraniline Red" with "Aniline Black" and developing the "Black." The compound is printed before the "Black" is developed, and thus acts as a discharge-reserve. By printing along with it an ordinary white reserve for "Aniline Black," two-colour, red-and-white, effects are obtained on the puce ground. The puce from "Chrysoidine" and diazotised *p*-nitraniline (see abstract above) was discovered by Binder and Vernier in 1899. The impossibility of reserving it and, prior to the discovery of the hydrosulphite-formaldehyde discharge, of discharging it, has prevented it from hitherto coming into use.—E. B.

English Patents.

Wool; Apparatus for Treating [Degreasing] ——. N. Rousselle, Verviers. Eng. Pat. 10,234, May 5, 1903.

See addition of Dec. 2, 1902, to Fr. Pat. 300,492 of 1900; this J., 1903, 905.—T. F. B.

Mercerising, Scouring, Bleaching, Dyeing, &c. of Yarn in Hank form; Machine for ——. W. H. Crompton and W. Horrocks, Radcliffe, Lancaster. Eng. Pat. 10,255, May 6, 1903.

The yarn is hung on pairs of reels, one above the other, the lower of which revolves in a trough. The dye-liquor or mercerising solution to be applied is sprayed over the hanks from perforated pipes and caught in the lower trough, from which it is raised by suitable means so as to cause a continuous circulation of the liquid. The reels are easily removable for filling, &c.—A. B. S.

Drying, Bleaching, or other purposes; Apparatus for Treating Materials with Air or other Gases or Vapours for ——. H. Haas, Manchester. Eng. Pat. July 8, 1903.

The apparatus consists of chambers for holding the material to be treated and heating compartments containing steam coils or similar arrangements for heating the air. These chambers are arranged alternately, and the hot air from one heating chamber passes over the material to be dried, and then into another heating chamber, and so on. By a suitable arrangement of valves and pipes, the compartments can be heated in any order or only a part of them used.—A. B. S.

Dyeing of Cotton Cloth. W. Grime, Manchester. Eng. Pat. 15,358, July 11, 1903.

The warp or weft of a cotton material is mordanted with tannin before weaving; the tannin is fixed with antimony before or after weaving. The piece is then first dyed with basic dyestuffs, and finally, the unmordanted cotton in it is dyed with direct cotton dyestuffs.—A. B. S.

Waterproofing of Materials, such as Tissues, Fabrics, Paper, Leather, and Cords. S. Serkowski, Lodz, Poland. Eng. Pat. 8433, April 12, 1904.

The material is soaked in a solution of lanoline in benzene or other suitable solvent, and the solvent removed by drying.—A. B. S.

United States Patents.

Treating [Bleaching] Fabrics; Apparatus for ——. M. Muntadas y Rovira, Barcelona. U.S. Pat. 761,107, May 31, 1904.

See Fr. Pat. 327,931 of 1902, and addition thereto; this J., 1903, 948, and 1904, 251.—T. F. B.

Discharging Halogen Indigos; Process of ——. A. J. Stiegelmann and K. Reinking, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. U.S. Pat. 760,817, May 24, 1904.

Halogenated indigo dyestuffs are discharged by printing on the dyed material a mixture of an oxidising agent (*e.g.*, an alkali bichromate), a substance which acts as an oxygen carrier (*e.g.*, the double salt of antimony sulphate and fluoride), and a thickening agent, then drying, and treating the material with dilute acid.—T. F. B.

Oiling and Finishing Textile Materials; Process of ——. R. S., J., and F. R. Carmichael, Paris. U.S. Pat. 761,203, May 31, 1904.

See Eng. Pat. 5998 of 1902; this J., 1903, 211.—T. F. B.

French Patents.

Skins and other Materials; Degreasing of —— by Carbon Tetrachloride or other Volatile Solvent. C. Liliemaud. Fr. Pat. 338,495, March 28, 1903. XIV., page 671.

New Tissue; Manufacture of a ——. J. Clémencin. Fr. Pat. 338,731, April 14, 1903.

A material such as muslin is passed through a gum solution and hair or other animal or vegetable fibre shaken over it, through a sieve, whilst it is drying. The resulting material can be made to resemble plush or fur.—A. B. S.

Dyeing Machine. T. Robatel, J. Buffaud and Co. First addition, of Nov. 17, 1903, to Fr. Pat. 326,597 of Nov. 22, 1902. (See this J., 1903, 794.)

The lower roller for the yarn is fixed to a lever and the yarn is kept stretched by means of a counterpoise attached to the other end of the lever. The up and down movement of the whole frame supporting the yarn reels is also assisted by counterpoise weights.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Iodates; Formation of —— in Alkaline Solutions of Iodine. E. L. C. Foster. J. of Phys. Chem., **7**, 640—651. Chem. Centr., 1904, **1**, 1392.

The influence of the concentration of potassium hydroxide, iodine, and potassium iodide on the rate of formation of potassium iodate was investigated. With a large excess of alkali (colourless solutions) the velocity is approximately proportional to the concentration of hypoiodous and iodine ions and of iodic acid. With excess of iodide the relations are complicated; the velocity increases with the concentration of potassium hydroxide and iodine, but decreases on addition of potassium iodide. If potassium hydroxide be added continuously to the solution, so that the latter changes from brown to colourless, the rate of formation of iodate rises to a maximum and then again decreases.—A. S.

Sodium Picrate; Action of —— on Sodium Carbonate Solutions [Detection of Sodium Carbonate]. C. Reichard. XXIII., page 682.

Sodium Nitrite; Analysis of ——. G. Lunge. XXIII., page 683.

Nickel Salts; Action of Alkali Nitrites on ——. C. Reichard. XXIII., page 683.

Gases; Purification of [for Manufacture of Sulphuric Acid] ——. J. Y. Johnson, London. From Bad. Anilin und Soda Fab., of Ludwigshafen-on-Rhine. Eng. Pat. 11,549, May 20, 1903.

Sulphurous or other gases containing arsenic are passed at an elevated temperature, but below a red heat, into contact with granular or porous material, such as that described in Eng. Pat. 6,828 of 1901 (this J., 1902, 344); or with lumps of iron oxide, copper oxide, or chromic oxide or the like, separately, or mingled with porous material. Sulphurous gases, for use in the manufacture of sulphuric acid by the contact process, may, it is stated, be thus purified without formation of an appreciable quantity of sulphuric anhydride. But the process is claimed for the purification as well of burner and other gases generally.—E.S.

Potassium Chromate; Treatment of Chrome Iron Stone for the Production of ——. G. W. Johnson, London. From Chem. Fabr. Griesheim - Elektron, Frankfurt-a-Main. Eng. Pat. 17,589, Aug. 13, 1903.

See Fr. Pat. 334,712 of 1903; this J., 1904, 116.—T. F. B.

Sulphate of Ammonia from Ammonia Gases; Saturator for the Recovery of ——. K. Zimpell, Stettin. Eng. Pat. 6891, March 22, 1904.

The apparatus comprises a large closed saturator, in an opening in the top of which is fixed a bottomless cylindrical vessel, whose lower rim reaches to just above the level of the acid in the first saturator. In this cylindrical vessel is placed the second saturator, which is of somewhat smaller diameter than the cylindrical vessel, and which is closed by a lid provided with a funnel for introducing acid and an outlet pipe for the waste gases. This second saturator is also provided with an acid-overflow, to keep the acid at a constant level, and also with a curved gas-inlet pipe, the bottom of which reaches below the acid level. The ammonia gases are introduced into the acid in the first saturator through a tube which passes through the second saturator; the gases pass thence up the cylindrical vessel, and into the second saturator; the object of this arrangement is to prevent the condensation of the steam in the second saturator.—T. F. B.

Iron Pyrites; Process of Preparing ——, *for Desulphurisation.* U. Wedge, Montgomery. Eng. Pat. 8994, April, 19, 1904.

VIII.—GLASS, POTTERY, ENAMELS.

Porcelain; Molybdenum Yellow for ——. T. Hertwig. Sprechsaal, 1904, **37**, 791—792.

"Molybdenum and Tungsten Yellows" can be produced in a reducing fire on porcelain, provided certain bodies and glazes are used, together with metallic compounds that will cede oxygen to the pigmentary substances. Up to the present the only materials found suitable for this purpose are a felspar and quartz of the following composition:—felspar: silica, 72·98 per cent.; alumina, 15·32; ferric oxide, 0·52; lime, 0·28; potash, 6·85; soda, 3·59; loss on calcination, 0·43 per cent. Quartz: silica, 97·52 per cent; alumina, 1·40; ferric oxide, 0·36; lime, 0·12; magnesia, trace; alkalis, 0·68 per cent. The body from these ingredients had the composition: K_2O, 4·332 Al_2O_3, 20·906 SiO_2, with 0·08 per cent. of calcined sodium carbonate for casting. A moderate degree of fineness was found essential to prevent the glaze (fired at No. 12 Seger cone) from crazing. The glaze, 0·22, K_2O; 0·78, CaO; 0·70, Al_2O_3; 6·35, SiO_2; was compounded of: the above felspar, 290 parts, Wunsiedel calcspar 150, Zettlitz kaolin 220, and the above quartz, 140 parts. The pigment consisted of 10 grms. of crystallised ammonium molybdate and 100 c.c. of boiling water, the cooled solution being treated with 12 grms. of hydrochloric acid (15·5° B.), to dissolve the precipitate first formed. By the gradual addition of 1 grm. of granulated zinc, a deep indigo colour was obtained, the solution being immediately filtered, and the residue dissolved without washing. After firing the applied colour at 500° C., it was coated over with manganese nitrate (66·6 parts per 100 of water), dried and re-fired, then glazed and fired at No. 12 Seger cone. The yellow does not appear suitable for covering large surfaces. The omission of the manganese coating furnishes a delicate pale yellowish-green, while the manganese alone gives an ivory yellow. Reversing the order of applying the pigments also gives a yellow, but not so bright and sulphur-like. From the behaviour of the ware in the kiln it would seem as though the presence of air contributes to the development of the colour; but even if the action of manganese depends less on its oxidising properties than on pigmentary power, the use of molybdenum determines the production of the sulphur tint.—C. S.

English Patents.

Sheet Glass; Apparatus for the Manufacture of ——. E. Rowart, Anvelais, and L. Francq, Obourg. Eng. Pat. 9033, April 19, 1904. Under Internat. Conv., April 23, 1903.

Melted glass is poured into a hopper and is then caused by atmospheric pressure to pass through a narrow space formed between two rollers into a chamber exhausted of air and cooled by a refrigerating liquid circulating through compartments at the sides of the chamber, so that the glass in passing down between the rollers becomes solidified in the form of a thin sheet. The descent of the sheet of glass into the cooling chamber is controlled by means of a supporting bar carried by vertical rods supported by plungers, which work in hydraulic cylinders, by the discharge of water from which the plungers and consequently the supporting bar are allowed to descend at a regulated speed. Gripping tongs, supported by the hydraulic plungers, are also provided; these tongs descend into the hopper as the sheet is formed, seize the glass in the hopper to which the sheet is connected, and in rising again, lift the sheet out of the chamber, after which it is removed from the tongs and conveyed to the annealing chamber.—A. G. L.

Ceramic Articles; Manufacture of ——. J. Dausette, Paris. Eng. Pat. 13,046, June 10, 1903.

A piece of wire gauze cut to the size of the article to be manufactured is placed in a fusible paste consisting of kaolin, silica, boric acid, and alkali salts, ground so as to pass through a sieve having 3,600 meshes per sq. in. The plates or slabs obtained are allowed to dry at 40° C. in a vertical position, and are then heated for 4 or 5 minutes to about 900 C. in an enamelling furnace. A slightly less fusible paste ground so as to pass through a sieve having 14,400 meshes per sq. in., is then applied to one or both surfaces of the plate, which is then dried at 40 C. and heated for 5 minutes to 1,000° C. The surfaces are then coated with enamels consisting of various silicates with fusing points below 1,000° C. and possessing the same coefficient of expansion as the original paste, after which the plates are baked in the enamelling furnace for about 5 minutes and allowed to cool. Should any flaws appear, they are remedied by applying more enamel and repeating the operation. Suitable compositions are:—For the paste, kaolin, 120 parts; silica, 750; flint glass, 500; potassium nitrate, 75; soda glass, 300; boric acid, 600; and for the enamel, silica, 60 parts; minium, 80; boric acid, 15; potassium nitrate, 10.—A. G. L.

[*Pottery*] *Gas Kilns.* C. Celulla, Liberty City. Eng. Pat. 15,148, July 8, 1903.

Pottery kilns of the "Escherich" type are arranged so that the combustible gas can enter the kiln chamber

through apertures in the floor, through vertical pipes rising from the gas passage beneath the floor and having lateral perforations for distributing the gas, and through apertures provided over the whole area of the walls and leading from passages therein. By means of suitable valves the flow of gas to the various flues and outlets can be regulated.
—H. B.

Soda Glass and Pitch-like Substances; Viscosity of ——. F. T. Trouton and E. S. Andrews. XXIII., page 680.

FRENCH PATENT.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Normal [Standard] Lime. H. Seger and E. Cramer. Thonind.-Zeit., 1904, **28**, 587.

THE trials made on various kinds of limestone at the testing station Gross-Lichterfeld, in order to discover a normal lime suitable for testing the purity of trass, other puzzolane materials, cement-mortars, &c., have resulted in the selection of lime from the Christinenklippe (Harz) limestone quarries. The stone loses 43·89 per cent. on calcination, and furnishes a lime containing 97·79 per cent. of calcium oxide, 0·71 per cent. of silica and insoluble matter, 0·43 per cent. of ferric oxide, alumina, &c., 0.32 per cent. of magnesia, 0·12 per cent. of sulphur trioxide and 0·62 per cent. of alkalis and other residual substances. The lime is burned in ring kilns, and is carefully hand-picked before slaking. In this latter operation, the water is left to stand over the lime for some time, and only the upper three-fourths of the milk of lime is run off for settling in another tank. After storage for some months in a closed tank, the lime is packed in airtight tins, each of which bears an official leaden seal.—C. S.

Clay; Artificially Increasing the Cohesive Power of ——. H. Seger and E. Cramer. Thonind.-Zeit., 1904, **28**, 641—642.

SAMPLES of clay were stored for six months, in admixture with water either alone or in conjunction with 2 per cent. of starch, dextrin or tannic acid, the tensile strength and shrinkage being determined after three weeks and at the end of the experiment. Taking the tensile strength of fresh clay as unity, that of the stored wet clay at the end of three weeks was found to be 1·35 (kilos. per sq. cm.), and 1·39 after six months. No appreciable increase was found in the case of starch; and though dextrin gave an increase to 3·0 in three weeks, a decline to 2·63 was obtained in the final test, probably due to the putrefactive decomposition of the reagent. On the other hand, tannic acid gave higher results, the tensile strength being raised to 1·75 in three weeks and to 3·22 at the end of the experiment, thus confirming Acheson's results, though after a longer storage than he employed. The shrinkage was greater in all the treated samples than in the case of the stored wet clay (5·12 per cent. in six months), the figure for the one treated with tannic acid being 7·18 and rather less in the case of starch and dextrin. In this connection it is pointed out that Bischof in 1880 found the shrinkage of Westerwald clay was diminished from 10·2 per cent. to 6·9 per cent. by an admixture of 4 per cent. of gum arabic.
—C. S.

Clays; Relation between the Fusibility and Chemical Composition of ——. Ludwig. Thonind.-Zeit. 1904, **28**, 773—783.

THE law enunciated by Richter, on the action of various fluxes is now found to constitute a special application of a general natural law governing all dilute solutions. It must, however, be restricted to very dilute solutions, or mixtures containing relatively small quantities of flux, and does not apply when the flux attains considerable proportions as in the case of brick-earth and glazes. Unless the components are intimately mixed, the influence of the flux is not fully manifested, in laboratory tests, but will become more apparent under the prolonged heating usual in practice. The action of iron differs according to its condition of oxidation, one molecule of ferric oxide corresponding to two of ferrous oxide, and since the tendency is for the latter to form in the fusing process, the protoxide should be taken as the basis of calculation. The author rejects the assumption that double silicates are formed in the process of fusion, there being no endothermic silicates known, and the fusion products having a lower fusing point than the original constituents.—C. S.

Lime-Sand Brick and Ordinary Brick; Relative Drying Properties of ——. H. Seger and E. Cramer. Thonind.-Zeit. 1904, **28**, 788—789.

OBJECTIONS having been urged that lime-sand bricks take longer to become dry than ordinary bricks, the authors made comparative tests with the two kinds, by saturating a certain number of each with water, and taking the weights at intervals until constant. Curves plotted from the results show that the amount of water retained by the lime-sand bricks is considerably the smaller of the two during the early stage of drying. at the end of 30 days the amounts are equal in the lime-sand and ordinary brick, whilst towards the last the ordinary brick is slightly the better. Since the total amount of water absorbed by lime-sand brick is considerably smaller than that taken up by ordinary brick, it was considered advisable to make a second calculation, based on the percentage of water absorbed. In this case the original figures were 8·94 per cent. for lime-sand brick, and 13·07 per cent. for ordinary brick, and both parted with 5·3 per cent. in 15 days, the curves then running almost parallel until the percentage had fallen to from 3 to 4 per cent., and then drawing together until they coincided at the 75th day. The differences were attributed to the circumstance that the lime-brick examined was relatively close-grained, while the ordinary bricks were more porous.
—C. S.

(Portland Cement) Drying Chambers; Light Dust in ——. H. Seger and E. Cramer. Thonind.-Zeit., 1904, **28**, 531.

CLOUDS of fine dust deposited in the drying chamber of a Portland cement works where the waste furnace gases were utilised for drying, were found to consist of 43·65 per cent. of insoluble and 56·35 per cent. of soluble matters. The insoluble portion gave: loss on calcination, 10·9 per cent.: silica, 31·4; alumina, 14·7; ferric oxide, 4·9; lime, 36·8; and magnesia, 1·3 per cent. The proportion of silica is too high for the dust to have been formed from the cement. The soluble portion consisted of potassium sulphate, 61·1 per cent. and potassium carbonate, 38·9 per cent.—C. S.

Portland Cement and Blast-Furnace Slag. H. Passow. Thonind.-Zeit. 1904, **28**, 586—587.

FOR the production of "iron" Portland cement it is necessary to use vitreous slag, obtained by granulation: subsequent heating causes crystallisation. Mixed with cold water, these vitreous slags harden very slowly, but more quickly with hot water, and still more so with alkaline solutions. The useful proportion of the latter increases with the vitreous character of the slag, since the devitrified portions have an alkaline reaction. Microscopic examination shows that devitrification is accompanied by the separation of lime compounds. When ground vitreous slag is made up into tubular blocks and exposed in a current of carbon dioxide, no increase of temperature is recorded by an inserted thermometer, whereas in the case of calcined devitrified slag the temperature rises considerably. This behaviour shows that the latter slag contains active lime compounds, which form, with water, an alkaline solution capable of reacting on vitreous slag: a circumstance explaining the great hydraulic value of mixtures of two substances individually weak in this respect. The author ascribes greater influence to the preparation of the slag than to its composition, which may vary within considerable limits. By granulation in air, blast-furnace slag can be made to acquire hardening properties rendering it inde pendent of admixture with Portland cement. The product is termed by the author "Hansa" Portland cement, and can be modified by controlling the action of the air, a purely vitreous slag being obtained by energetic atmospheric action, whilst more gradual cooling results in crystallisation, which, however, does not extend to physical disintegration. If this latter product be ground to powder it will furnish cement said to exhibit the properties of good Portland. Since the vitreous portion of the slag reacts more slowly than the rest, it requires to be ground very fine. The addition of Portland cement to the mass is solely for the production of certain special effects, and plays a part analogous to that of gypsum in ordinary Portland cement making.—C. S.

Portland Cement; Washed ——. H. Seger and E. Cramer. Thonind.-Zeit., 1904, **28**, 625.

To ascertain the efficacy of washing the ground cement as a means of eliminating the soluble salts and free caustic lime, which produce efflorescence on cement tiles, 500 grms. of slow-setting Portland cement were mixed with 1,500 grms. of normal sand and stirred in 10 litres of water. The operation was twice repeated, the cement and sand settling down sufficiently in 10 minutes to enable the water to be poured off. The pasty residue was spread out on gypsum plates and dried with filter paper until it would ball in the hand without sticking. In the Böhme hammering tester the blocks withstood 110 blows. Other blocks, with 8·8 per cent. of moisture gave the following average results:—After seven days' hardening the tensile strength of those from unwashed cement was 16·04 kilos. per sq. cm. and the crushing strength 143·4 kilos., the corresponding figures for the washed cement being 8·95 and 78·0. After hardening for 90 days the results were (in the same order) 28·41 kilos., 234·7 kilos., 17·99 kilos., and 191·2 kilos. respectively, so that the method does not seem to afford any advantage.—C. S.

Concrete; Influence of Clay on the Tensile Strength of ——. H. Seger and E. Cramer. Thonind.-Zeit., 1904, **28**, 726—727.

The authors having found that no improvement is effected in sand by washing, made a series of tests in which pure sand was intentionally mixed with brick clay or kaolin. The bulk of the sand consisted of granules from 0·2 to 0·4 mm. in diameter. The tests were made with blocks, prepared in the Böhme apparatus and composed of 3 parts of sand to 1 of Portland cement (with $10\frac{1}{2}$ per cent. of water), 0·3 part of the sand being replaced by brick earth or kaolin in a certain number of the samples. In these latter cases, the clay was first stirred up with 11·4—11·5 per cent. of water, then mixed with the sand, and the whole incorporated with the cement, so as to produce the most unfavourable conditions. The blocks were stored for a month, part of them in the air, the rest under water. The tests gave the following results:—

——	Storage	
	In Air.	In Water.
	Kilos. per sq. cm.	Kilos. per sq. cm.
Cement-sand:—		
Tensile strength	20·91	17·85
Crushing „	175·3	142·9
Cement-sand-kaolin:—		
Tensile strength	27·84	21·12
Crushing „	163·4	140·5
Cement-sand-clay:—		
Tensile strength	26·21	16·43
Crushing „	157·8	125·4

Both clay and kaolin considerably increase the tensile strength, while the loss of crushing strength is small, especially in the case of the kaolin mixture when stored under water. The results are regarded as confirming those of Sherman (Engineering News, 1903, [21]).—C. S.

Portland Cement and Blast-Furnace Slag; Action of Acetic Acid on ——. F. Hart. XXIII., page 683.

English Patents.

Lubricating Substances for Use in the Manufacture of Bricks, Tiles, Pottery, and the like. W. H. Sandwith, Bracknell, and H. T. Rayner, Rettendon. Eng. Pat. 16,125. July 21, 1903.

Sodium stearate, oleate, or palmitate, and potassium oleate or stearate, are dissolved in water or other suitable menstruum, with or without the addition of suitable colouring matters. Petroleum, shale oil, or creosote oil is then added, and the whole mixed to form an emulsion. Suitable proportions of the ingredients are:—(1) 20 lb. of potassium oleate, 30 galls. of water, 10 to 20 galls. of shale or other oil; (2) 15 lb. of potassium oleate, 5 lb. of sodium oleate and stearate, 30 galls. of water, 10 to 20 galls. of shale or other oil. These mixtures should be diluted with two or three times their volume of water before use.—A. G. L.

Bricks; Coating ——, *and Apparatus therefor.* M. Perkiewicz, Ludwigsberg, Germany. Eng. Pat. 3760, Feb. 15, 1904.

To a liquid coating material composed of a mixture of gelatin and flour (see Eng. Pat. 12,095, this J., 1903, 1088), substances which prevent putrefaction are added, *e.g.*, carbolic acid (phenol), lysol (obtained by dissolving tar cresols in neutral soaps), sublimate (mercuric chloride), nitric acid, aluminium sulphate, tannic acid, or salts of chromium. To apply the coating, the bricks are laid upon an inclined conveyor and passed under a distributing box, from which the liquid drops on to the upper surfaces of the bricks through fine perforations or slits. The superfluous material runs along a trough into a well, from which it is pumped back to the distributing box, after passing through a sieve, if necessary.—A. G. L.

Portland Cement; Manufacture of ——. F. C. W. Timm, Hamburg. Eng. Pat. 11,324, May 18, 1903.

See Fr. Pat. 332,243 of 1903; this J., 1903, 1196.—T. F. B.

Portland Cement; Manufacture of ——. C. Hocke, Hamburg. Eng. Pat. 21,947, Oct. 12, 1903.

Low-grade fuel is utilised by mixing slack or powdered coal with the raw cement materials, pressing the mixture into bricks, and then burning it. The cement clinker produced is very porous, owing to the distillation of the fuel. —A. G. L.

White Cement; Manufacture of ——. H. Earle, Hull. Eng. Pat. 24,911, Nov. 16, 1903.

White chalk, kaolin, and felspar are mixed, either dry or wet, and burnt as a Portland cement; the resulting cement should contain 28 to 30 per cent. of silica, 61 to 63 of lime, 4 to 6 of alumina, and 2 to 3 of alkalis. Sodium or potassium carbonate may be used instead of felspar. Granite or gneiss may also be employed. All the materials used should be free from iron.—A. G. L.

United States Patents.

Bituminous Pavements; Process of Preparing Compositions for and of Heating and Laying ——. J. H. Amies, Germantown, Assignor to Amies Asphalt Co., Philadelphia. U.S. Pat. 760,051, May 17, 1904.

Granulated or powdered asphalt is mixed with cold, sharp, fine sand, which has been previously wetted with crude petroleum oil, and the composition is subjected to a suitable degree of heat to secure cementation and hardening. The heating may be effected by adding naphtha or gasolene to the petroleum oil, and afterwards sprinkling the composition with gasolene, the vapours given off being then ignited and the mass agitated in the flame, after which it is rolled with hot rollers.—A. G. L.

Sandstones [Artificial]; [Electrical] Process of Producing Refractory Calcareous ——. W. Schwarz, Zurich, Assignor to Schwarz System Brick Co., New York. U.S. Pat. 760,571, May 24, 1904.

Granulated quartz is heated nearly to its fusing point by means of a current of electricity. Lime is then added, and the plastic mass obtained moulded under pressure to the desired shape.—A. G. L.

Stone, Artificial; Apparatus for the Manufacture of ——. W. Schwarz, Zurich, Assignor to Schwarz System Brick Co., New York. U.S. Pat. 760,651, May 24, 1904.

See Eng. Pat. 18,163 of 1901; this J., 1902, 479.—T. F. B.

French Patents.

Bricks, Refractory, and other Ceramic Articles; Drying of —— before Burning. D. F. Henry, jun. Fr. Pat. 338,561, Dec. 31, 1903.

The drying kiln is divided by means of vertical partitions into a number of compartments connected by a zigzag passage. In each compartment a vertical endless conveyor s placed, which moves the materials to be dried, a current of air being forced through the compartments in a direction opposed to that in which the materials travel.—A. G. L.

Cement from Blast-Furnace Slag; Manufacture of ——. C. v. Forell. Fr. Pat. 339,316, Jan. 2, 1904.

The slag is granulated by pouring it into water, or ground nd pressed into bricks. In either form it is heated in an xidising flame to a temperature just below its fusing point, nd is then cooled as rapidly as possible and finally ground. ither just before, or at the commencement of, the cooling, he slag is treated with small quantities of water, which, ithout cooling the slag sensibly, exercise a considerable hemical action on it. The water used to granulate the ag may contain lime, alkali, &c.—A. G. L.

Blast-Furnace Slag; Process permitting the Transformation of —— into a Powder resembling Cement. W. Mathesius. Fr. Pat. 339,378, Jan. 6, 1904.

HE slag, which should be preferably in the granulated contion obtained by pouring it into water whilst still liquid, exposed to the action of steam under pressure until oroughly disintegrated. A dry powder resembling cement obtained, from which foreign bodies are removed by fting.—A. G. L.

ement; Process of Making White ——. E. Gogler and H. Seinfeld. Fr. Pat. 339,499, Jan. 11, 1904.

EE Eng. Pat. 388 of 1904; this J., 1904, 443.—T. F. B.

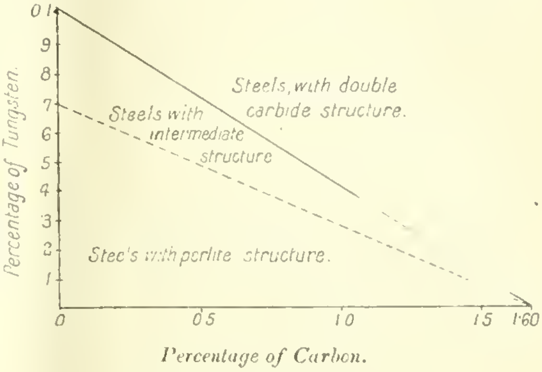
X.—METALLURGY.

Tungsten Steels. L. Guillet. Bull. Soc. d'Encourag., 1904, **106**, 263—283.

IE author examined two series of tungsten steels conining (1) from 0·110 to 0·276 per cent. of carbon, and) from 0·328 to 0·867 per cent. of carbon. The amount of ugsten present varied from 0·397 to 36·967 per cent. ie results show that tungsten steels may be divided oadly into two classes :—

ass.	Steels containing up to about 0·2 per cent. of Carbon.	Steels containing up to about 0·8 per cent. of Carbon.
.	From 0 to 7 per cent. of tungsten.	From 0 to 5 per cent. of tungsten.
I.	Above 7 per cent. of tungsten	Above 5 per cent. of tungsten.

The steels belonging to Class I. have a perlite structure l possess properties analogous to those of ordinary carbon els. Compared with carbon steels containing the same portion of carbon, they show higher breaking strength, stic limit, and hardness, but lower elongation, contraction, resistance to shock, as the percentage of tungsten reases. Quenching affects these steels in the same way carbon steels, but to a much greater degree. Annealing ens them distinctly. The steels belonging to Class II. e a double carbide (of iron and tungsten) structure; r properties vary with the percentage of carbon present. y are extremely brittle, and have a considerably lower aking strength and elastic limit than steels of Class I. containing the same amount of carbon. By quenching at 850° C., an extremely fine martensite structure is produced, but some of the double carbide is left undissolved, at least, when the percentage of tungsten is high. After quenching, the breaking strength, elastic limit, and hardness of the steels are much higher than before. By subjecting tungsten steels with a perlite structure to cementation, or steels with a double carbide structure to decarburisation, products having an intermediate structure can be obtained. By aid of the diagram (see figure) analogous to that previously given for nickel steels (this J., 1903, 999), the properties of a tungsten steel may be deduced from its composition.
—A. S.



Gold and Silver; Concentration of —— in "Iron Bottoms." M. N. Bolles. Trans. Amer. Inst. of Mining Engineers, Sept. 1904.

The absorption of gold in "iron bottoms" is generally satisfactory, and corresponds to, but is somewhat less than the absorption of silver in "copper bottoms." Silver is not well absorbed by "iron bottoms," the quantity obtained very seldom exceeding 5 per cent. of the total silver present. The precious metals tend to collect in the crust formed in liquation of the matte. Aluminium has no marked influence on the absorptive power of "iron bottoms," but the addition of potassium ferrocyanide gives a greater gold absorption. The addition of metallic iron to the mattes (corresponding to an increase in the reducing power and temperature of the furnace) raises their avidity, and the absorptive power for gold of a matte containing only iron and sulphur is largely dependent on the excess of iron present over the amount required for the formation of ferrous sulphate.
—T. F. B.

Slimes [Gold] Treatment; The Decantation Process of —— : Its Possibilities and Limitations. E. J. Laschinger. J. Chem., Metall. and Min. Soc., S. Africa, 1904, **4**, 348—364.

The author considers that the Rand treatment of low-grade slime gives very satisfactory results. It consists in washing the slimes into settling vats with a stream of water, allowing them to settle, and decanting off the water, about 45 per cent. of moisture being left in the slimes. The latter are then washed twice with cyanide solution; the first wash extracts about 92 per cent. of the gold which is precipitated by zinc, the resulting liquid being used for the second wash, which is not precipitated, but is used to make up the first wash, fresh cyanide being added to bring it up to strength. Thus, over 90 per cent. of the gold is recovered, even with slimes containing only 2 dwts. of soluble gold per ton, the working costs being less than 2s. per ton for a large plant, whilst the other expenses amount to less than 1s. per ton, taking interest at 4 per cent., and depreciation at 9 per cent. per annum. The best results are obtained when the ratio of cyanide solution to dry slime in each wash is as 3½ to 1. For slimes containing 2 dwts. of gold per ton, it is most economical to give only two washes; with 4 dwts., or more, of gold, however, three washes give better results, only the first being precipitated. When as much as 20 dwts. of gold are present, 98·3 per cent. can be recovered by giving three washes, and precipitating the first two, but this treatment should not be used unless the slimes contain at least 12 dwts. of gold. It is found that in all cases the best results are obtained when the slimes are allowed to settle thoroughly before each decantation, and when as much as possible of the gold is dissolved in the first extraction. It follows from the above that it should prove advantageous to grind finely the coarse and pyritic particles rich in gold and treat them together with the ordinary slimes. The author believes that by the Rand treatment a small profit may be made, after paying all expenses, on slimes even containing but 1 dwt. of gold.—A. G. L.

Zinc Oxide; Reduction Temperature of ——. W. McA. Johnson. Electrochem. Ind., 1904, **2**, 185—187. Paper read before Amer. Electrochem. Soc.

The determinations were made by enclosing the oxide mixed with charcoal or other reducing agent in a crucible constructed of Acheson graphite and provided with a screwed-on cover of the same material. An outlet tube through which the zinc vapour and gases could escape, as also a cavity drilled for the pyrometer, were provided in the crucible walls. The heating was effected in a gas reverberatory furnace, the temperature being regulated by varying the flow of gas. Pure zinc oxide was reduced by charcoal at 1,022° C., by soft coke at 1,029° C. The temperature of calcination of the ore or oxide influences the reduction. Zinc oxide, for example, calcined at 1,100° C., was only reduced by soft coke at 1,048°, and calcination at 1,300° brought the reduction temperature up to 1,061° C.
—R. S. H.

Blast-furnace Gases: Determination of Calorific Value of ——, *by the Mahler Bomb.* G. Arth. Bull Soc. Chim., 1904, **31**, 576—578.

The small weight of the quantity of gas which it is possible to burn in the Mahler bomb makes the experimental errors, and even the errors in the thermometer reading alone, of great relative magnitude, more than 5 per cent. of the quantity to be measured. Moreover, where there is not an unlimited quantity of the gas under test to draw upon, the filling of the bomb, the ascertaining of the quantity of gas employed, and the regulation of the oxygen so as not to overstep the limits of explosiveness, present very great difficulties. As these gases are mixtures of well known substances, the calorific values of which have been determined, and do not, like coals and similar fuels, contain complex compounds of unknown constitution, an accurate calculation of their calorific value is obtainable from the results of their analysis; and this calculated value is to be preferred to the direct result of combustion in the bomb.—J. T. D.

Tin-Coating Machinery [Electrical]; Temperatur Regulating Apparatus for ——. A. M. Goodwin, Ea Toledo. Eng. Pat. 5009, Feb. 29, 1904.

The space in the tank, above the bath of molten metal divided by a transverse depressed bridge, extending a litt way below the level of the metal bath, into two com partments, in which separate bodies of oil rest upon t surface of the molten metal. The sheets of metal to b tioned enter the bath through the compartment containi the greater depth of oil. This compartment communicat by a valved horizontal pipe with a supplementary ta containing cold oil, in which a pump operated by mach nery is placed, whereby the cold oil can be forced throug an elevated tube on to the surface of the oil in the coat tank, whilst the heated oil flows into the supplementa tank through a horizontal connecting pipe. One end of vertical pyrometer bar is immersed in the oil, the oth end being connected to an indicator communicating w an electrical system including solenoid magnets, so th when a certain temperature is reached in the bath, the pump is actuated so as to supply cold oil to the san whilst another branch of the system is arranged to cont the fluid fuel burners whereby the bath is heated. Th the main circuit being established or broken by variatio in the temperature of the bath, the latter may be ma tained at a substantially steady temperature.—E. S.

United States Patents.

Blast Furnace. G. K. Hamfeldt, Munhall. U.S. Pat 759,991, May 17, 1904.

The claim is for "a blast furnace having an annu metal shell with its lower portion within the upper par the masonry stack, the shell being extended above the stack, and having its upper portion, where the dropping charge strikes it, of smaller diameter than the internal diameter of the top of the stack proper."—T. F. B.

Furnace for Melting Metals. J. Southern, Belleville. J. J. Connell, administrator of said J. Southern, deceased, assignor to W. H. Steinbrecher, New York. U.S. Pat. 760,195, May 24, 1904.

The thick wall in front of the hearth or melting chamber has a combination of combustion chambers leading through it, comprising passages adapted at their outer ends to receive burners, such passages being enlarged at their middle portions, through which they communicate with one another and with auxiliary passages which open into he melting chamber.—E. S.

luminium Sulphide and Aluminium Alloys; Manufacture of ——. Miyagoro Onda, Nagoya. U.S. Pat. 760,554, May 24, 1904.

Alumina or an aluminous ore is mixed with carbonaceous naterials and a metal sulphide, and the mixture is heated o a high temperature in a suitable furnace to obtain luminium sulphide and aluminium alloys.—E. S.

luminium; Flux for Soldering ——. C. Ellis, Boston, Assignor to N. L. Foster, Brooklyn. U.S. Pat. 760,783, May 24, 1904.

he flux consists of a salt of a heavy metal of which the eat of formation is less, and a saline body of which the heat f formation is greater, than that of the corresponding luminium salt, together with an organic body.—E. S.

Ore-Treating Furnace. C. C. Wilson, Denver.
U.S. Pat. 760,941, May 24, 1904.

horizontal ore-roasting cylinder is secured within a otating flue cylinder, and projects through a combustion hamber at one end and a smoke-stack at the other end, as to form a flue for fire-gases between them. For eding and rabbling the ore, a number of shelves project ngentially inwards from the inner periphery of the enosed cylinder, arranged to form a clear space at the axial atre, and on one side of each shelf a number of partition ades are fitted to stand at a transverse angular pitch to ich shelves and to the longitudinal cylinder axis, there ing a dam or apron at the end of each shelf. The rangement of the shelves is spiral, so that the ore verses the cylinder from the feeding to the discharge d. The closed feeding end of the inner cylinder moke-stack end) has a number of curved spouts to oop up ore delivered from a fixed hopper. An air steam pipe extends into and through the combustion amber a certain distance into the cylinder, and provision made for introducing hot air or superheated steam into e discharge end of the same. The flue cylinder has an larged diverging conical end to receive the products of mbustion from the combustion chamber, which is at one d of the furnace, opposite to the smoke-stack end. The claims include numerous details of the invention.
—E. S.

Ore-roasting Furnace. W. H. Smyth, Berkeley.
U.S. Pat. 761,049, May 24, 1904.

e furnace has superimposed chambers, the roof to the per and the hearth of the lower, being slotted longiinally and substantially centrally to the width of the nace. The slotted hearth is supported on arches and usverse beams, to which latter, apparatus is attached to intain the alignment of the slot, which is closed by ible overlapping plates, so arranged as to give way to passing arm and then automatically resume their sing position. The supports to the furnace are such as ermit free circulation of air beneath the hearth floor. netal skeleton or frame is suitably arranged to form the port and attachment for the rabble tracks and slot ependently of the brick structure. Rabbles are adapted ravel above the hearths, and devices for actuating the bles project downwards through the slot in the furnace roof, which is closed by laterally-swinging plates or gates, the ends of which swing transversely across the slot. Means are provided for transferring the devices which actuate the rabbles from one slot to another. In furnaces having more than two hearths, the superposed roasting chambers are provided alternately with a slotted roof and with a slotted hearth. An arm extending through each slot connects a carrier outside the furnace to the rabbling mechanism.—E. S.

Ore-roasting Furnace. W. H. Smyth, Berkeley.
U.S. Pat. 761,050, May 24, 1904.

The hearths are placed longitudinally adjacent on the same level, and each is divided longitudinally into two sections, slightly separated so as to form a slot. A metal framework bears members adapted to support the hearth sections. The slots are closed by flexible overlapping plates. The ore is stirred by travelling rabbles, which are worked by transferable devices projecting through the slots and supported on tracks. Compare the preceding abstract.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

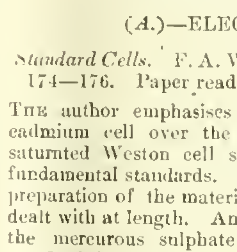
(*A.*)—ELECTRO-CHEMISTRY.

Standard Cells. F. A. Wolff. Electrochem. Ind., 1904, **2**, 174—176. Paper read before Amer. Electrochem. Soc.

The author emphasises the superiority of the Weston cadmium cell over the Clark cell, and urges that the saturated Weston cell should be adopted as one of the fundamental standards. The importance of the methods of preparation of the materials employed in standard cells is dealt with at length. An electrolytic method for preparing the mercurous sulphate is described. As a working standard the portable cell of the Weston Electrical Instrument Co. is stated to have given excellent results at the American National Bureau of Standards. In this cell a solution of cadmium sulphate is employed saturated at 4° C., and containing no excess of crystals.—R. S. H.

Standard Cells; Preparation of Materials for —— and their Construction. H. S. Carhart and G. A. Hulett. Electrochem. Ind., 1904, **2**, 176—177. Paper read before Amer. Electrochem. Soc.

Methods are described for preparing pure mercury, cadmium sulphate, cadmium amalgam, and mercurous sulphate. The purity of the latter substance is very important, since it greatly influences the E.M.F. of the cell; it is prepared by an electrolytic method similar to that independently developed by F. A. Wolff (see preceding abstract). Mercury is employed as anode in dilute (1 : 6) sulphuric acid, using a low-current density and stirring so as to keep the surface of the mercury exposed. In this way, and with 0·3 ampère, about 2·8 grms. of the salt can be prepared in an hour; the product is free from mercuric sulphate and, provided pure mercury and sulphuric acid are used, from other metallic salts. As to the construction of the cell, the modified H form shown in the figure is preferred. The necks of the two limbs are each contracted at *a*, so that the cell can be hermetically sealed after the materials have been introduced.
—R. S. H.



Weston Cell; The ——. H. T. Barnes and S. B. Lucas. J. Phys. Chem., 1904, **8**, 196—207. Chem. Centr., 1904, **1**, 1511.

The authors have made comparative tests with Weston cells of different construction. They find that cells containing solutions saturated at 0° C. have practically no temperature-coefficient; those with damp crystals and a 13 per cent. amalgam have the coefficient 0·0055 per cent. per degree; those with a 14·7 per cent. amalgam, 0·008 per cent. per degree centigrade. The ratio of the E.M.F. of the Clark cell at 15° C. and of the Weston cell at 20° C. is 1·40666; and as this value has been determined very accurately, it is immaterial whether the Clark cell or the Weston cell be used as a standard.—A. S.

Primary Cell; Experiments with a New ——. E. G. P. Bousfield. Electrochem. and Metall., 1904, **3**, 730—733.

A carbon pole is immersed in 31 per cent. nitric acid in a porous pot, the outer liquid being a 12—15 per cent. solution of caustic soda, with a zinc pole. Initial voltage, 2·6. Great "efficiency for laboratory purposes" is claimed.
W. A. C.

Copper and Aluminium Anodes; Behaviour of ——. F. Fischer. Z. physik. Chem., 1904, **48**, 177—219.

In dilute sulphuric acid a film of cupric sulphate gathers on copper anodes, whilst oxygen is evolved. When the current raises the temperature of the anode, cuprous sulphate is also formed, and the evolution of oxygen ceases. On still further heating, finely-powdered copper separates from the anode; in solutions of neutral sulphates, however, the powder separated, consists of cuprous hydroxide. The presence or absence of the film of sulphate, and consequently the resistance, depends on the comparative rates of formation and solution of the salt. Aluminium anodes, if kept cool, develop a film of considerable mechanical strength, having a thickness proportional to the voltage applied. In the absence of special cooling, the film is exceedingly thin, and is thrust away by hydrogen bubbles on reversing the current; hence the familiar action of aluminium in converting alternating into direct currents.—W. A. C.

Rotating Electrodes; Electrolytic Analysis with Application of ——. R. Amberg. XXIII., page 684.

English Patents.

Electric Furnaces or Ovens. A. Eimer, New York. Eng. Pat. 28,780, Dec. 31, 1903. Under Internat. Conv., May 22, 1903.

The electric oven described is one intended for use as a dentist's muffle or small laboratory crucible furnace. The plate which supports the articles to be heated, is formed in one piece with the door closing the furnace, so that the removal of both is operated at the same time. On the bottom of the oven is another movable plate, having depressions containing a resistance conductor, such as a platinum wire, the heating being effected by passing a current through this conductor. For purposes of observation the furnace is also provided with a transparent plug of fused quartz.—R. S. H.

Electric Sectional Furnaces. A. Eimer, New York. Eng. Pat. 28,782, Dec. 31, 1903. Under Internat. Conv., May 28, 1903.

The furnace is composed of a number of heating sections arranged end to end in trough-like conformation, and disposed in an approximately horizontal plane, each heating section comprising a separate base member and opposite side members of refractory material. Each member is provided with a resistance conductor embedded or disposed in suitable grooves in the material. The furnace is supported in a frame about its base, sides, and opposite ends by means of an intermediate packing of non-conducting material, and the top of each section is closed with a removable plate of refractory material, each plate being provided with an observation aperture having a transparent covering of mica, quartz, &c. Screws at the corners of the frame provide for the vertical adjustment of the furnace. Suitable ports at the ends serve for the introduction of the articles to be heated, the latter being centralised in the furnace by the upper concave surfaces of the refractory base members. Each terminal of the resistance conductors is bound by means of a binding screw to a slotted binding post, strips of metal being fastened in the slots, or connectors jointed pivotally may be used, for connecting the various heating sections in series or in multiple, or for throwing one or more sections out of the circuit.—B. N.

[*Electric Heating.*] *Apparatus for Regulating the Intensity and Heating Effect of Electric Currents.* Soc. Anon. l'Ind. Verrière et ses Dérivés, Brussels. Eng. Pat. 3912, Feb. 16, 1904. Under Internat. Conv., Feb. 18, 1903.

A layer of carbon or other solid resistance material, in the form of powder or small pieces, is interposed in the circuit of an electric current. By lengthening or shortening this resistance the regulation is effected. Apparatus is described for industrial and domestic heating, with fixed or movable electrodes, to pairs of which the current is directed by the [illegible] of suitable switches. (See Eng. Pat. 5921, March 10, 1904; this J., 1904, 550.)—R. S. H.

Electrodes for Electrolytic Purposes; Manufacture of ——. G. W. Johnson, London. From Chem. Fabr Griesheim-Elektron, Frankfurt. Eng. Pat. 17,587, Aug 13, 1903.

See Fr. Pat. 334,684 of 1903; this J., 1904, 119.—T. F. B

Bichromates and Alkali; [Electrolytic] Treatment o Alkali Chromates for the Production of —— there from. G. W. Johnson, London. From Chem. Fabr Griesheim-Elektron, Frankfurt. Eng. Pat. 17,588, Aug 13, 1903.

See Fr. Pat. 334,685 of 1903; this J., 1904, 119.—T. F. B

Electrically Smelting Materials; Process of —— [*Ca cium Carbide, &c.*] A. H. Cowles, Cleveland. U. Pat. 760,057, May 17, 1904.

For smelting reducible materials which are normally po conducters of electricity, but whose conductivity increas with the temperature, a charge of the materials and reducing agent is supported in an electric furnace havi a conducting casing. An electric current, the density which increases along its path, is passed through the sol charge, which thus becomes heated to the temperatu required for its treatment. Those portions of the char adjacent to the inner face of the furnace-casing are cool to a sufficient extent to prevent any shunting of t current through the casing. (See also U.S. Pats. 750,093— and 750,170—1; this J., 1901, 192—3).—R. S. H.

Calcium Carbide; Process of Making ——. A. Cowles, Cleveland. U.S. Pat. 760,312, May 17, 1904.

A resistance conductor either of molten carbide or some independent material, is heated by the passage of electric current through it, to a temperature sufficient cause the surrounding carbide mixture to react, and bring the carbide into a molten condition suitable tapping. (See also U.S. Pats. 750,093—6 and 750,170— this J., 1904, 192—3, also preceding abstract.)—R. S. H

(*B.*)—ELECTRO-METALLURGY.

lectrolytic Iron. C. F. Burgess and C. Hambuechen. Electrochem. Ind., 1904, **2**, 183—185. Paper read before Amer. Electrochem. Soc.

HE authors show how it is possible to obtain electrolytic on in large quantities and at reasonable cost. As ectrolyte a solution of ferrous sulphate with a certain rcentage of ammonium sulphate, was employed. The rrent density was 6 to 10 ampères per square foot of thode surface, and at the anode slightly less. The P.D. r each cell was a little under 1 volt, and the temperature the electrolyte 30 C. The anodes were of ordinary ades of wrought iron and steel, the starting sheets for e cathodes of sheet iron. The current efficiency was arly 100 per cent. The electrolytic iron absorbs large antities of hydrogen during deposition, which accounts : its extreme hardness.—R. S. H.

rro-Nickel from Pyrrhotite; Manufacture of ——. [*Electric Smelting*]. E. A. Sjöstedt. Electrochem. Ind., 1904, **2**, 188. Paper read before Amer. Electrochem. Soc.

E author has investigated the electric furnace treatment nickeliferous pyrrhotite of the Sudbury district. The rtially roasted ore, mixed with lime and coke, was uced, yielding a ferro-nickel pig, containing 3 per cent. nickel. About 200 h.p. produce a ton of ferro-nickel per hours. The total cost of production at Saulte Ste. rie (Canada), is estimated at about 5*l.* 5*s.* per ton.
—R. S. H.

ctrolytic Copper Refining; The Economic Balance in ——. L. Addicks. Electrochem. Ind., 1904, **2**, 180—81. Paper read before Amer. Electrochem. Soc.

economic balance is understood the interdependence of t conditions of working, and their bearing on the cost manufacture. The three chief factors are tank stance, age of electrodes, and current density; but all hese factors are of a somewhat complex nature. The k resistance is made up of metallic conductors, contacts, de slimes, counter E.M.F., electrolyte and a negative ntity due to imperfect efficiency. The author enters in ail into the relative importance of the several varying ditions, and shows how these conditions may differ in ortance from one refinery to another, according to local ditions. The only way to solve the problem of cheap luction is to consider the multiplicity of relations a pair time, and finally decide on those most favourable for particular works concerned. (Compare this J., 1903, 5.)—R. S. H.

Nickel; Passivity of ——. M. Le Blanc and M. G. Levi. Boltzmann Festschrift, 1904, 183—195. Chem. Centr., 1904, **1**, 1396—1397.

At the ordinary temperature and with a current of 0·5 ampére per sq. dcm., nickel goes quantitatively into solution in electrolytes containing haloid salts or cyanides, and in sulphuric acid, but in solutions of other salts, it is "passive"; in sodium acetate solution the behaviour of the nickel depends upon the treatment to which it has been previously subjected, but it exhibits a distinct tendency to become passive. Increase of temperature favours, as in the case of other metals, the change to the active condition. In potassium hydroxide solution, nickel is passive even at 80° C., and partially so, also in ammonium oxalate and sodium acetate solutions. Increase of current density renders the metal more passive; the concentration of the electrolyte is without influence. In sodium carbonate and potassium hydroxide solutions, the passivity of the nickel may be due to the production of an insoluble coating on the metal, but in the other solutions it appears to be a phenomenon depending on the reaction-velocity. The ions are formed too slowly, hence evolution of oxygen must take place. A small addition of sodium chloride to a solution in which the nickel becomes passive, suffices to bring the rate of formation of ions to the degree requisite for the quantitative solution of the metal; addition of sulphuric acid is less effective. The addition of sugar or acetone is without effect.—A. S.

Palladium; Electro-deposition of ——. R. Amberg. Z. Elektrochem., 1904, **10**, 386—387.

For the electrolytic precipitation of palladium, and for the determination of the atomic weight of this element, the author makes use of a solution of palladious-ammonium chloride ($PdCl_2.2NH_4Cl$) such as was used by S. Cowper-Coles (this J. 1899, 589). Under ordinary conditions the current density must be very low (0·013 ampère per 100 sq. cm.); but with a rapid rotation of 600—650 revolutions per minute, currents up to 0·3 ampére can be employed, and about 1 grm. of the metal deposited in 3 hours. It is advisable to work at 60°—65° C., and, above all, it is important not to exceed the critical P.D. of 1·25 volts, above which point peroxide appears on the anode, and the metal is no longer deposited in an adherent form.
—R. S. H.

Furnace; Electric ——. P. R. J. Willis, Kingston. From E. A. Sjostedt, Sault Ste. Marie. Eng. Pat. 14,963, July 6, 1903.

See U.S. Pat. 726,364 of 1903; this J., 1903, 637.—T. F. B.

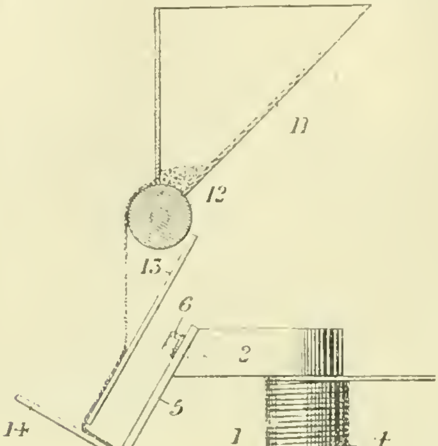
Furnaces; Electric. [*Induction Furnace.*] O. Frick, Stockholm. Eng. Pat. 4866, Feb. 27, 1904.

In order to avoid too great self-induction a transformer furnace is constructed with the annular crucible, which forms the secondary circuit, surrounding one leg of a magnetic iron core, the primary coil being wound around this leg, but above the melting crucible. In this manner the distance between the primary and secondary circuits is made very small; which can only be accomplished otherwise by making the inside wall of the annular crucible inconveniently thin.—R. S. H.

Electro-Magnetic Separators. The Edison Ore-Milling Syndicate, Ltd., London. From T. A. Edison, Llewellyn Park. Eng. Pat. 14,295, June 27, 1903.

In the drawing below, showing a portion of the magnetic separator in transverse section, the pole pieces 5 and 7 are of considerably greater length than the width of the magnet, corresponding in length to the inclined chute 13, on to which the ore falls from the hopper 11, and is deflected on to the inclined board 14, so as to descend to the pole pieces 5 near its edge, whence the non-magnetic portions pass by gravity to the front of the partition 10, whilst the magnetic portions are attracted to the opposite pole piece 7, and fall inside the partition.

The upper pole piece is of flat plate, and inclined in a direction transverse to its length, and its lower edge is on a vertical plane different from that of the edge of the lower pole piece. Both pole pieces are formed independently of, and are secured by screws to, the magnet body.



The pole pieces are "of such cross-sectional area in relation to their length and to the width of the air-gap between them, that with a given amount of electrical energy applied, a magnetic field of uniform strength throughout the length of the pole pieces is formed."—E. S.

Copper and Nickel from Mattes and Ores; Electrolytic Separation of ——. P. R. J. Willis, Kingston. From C. S. Shields, Sault Ste. Marie. Eng. Pat. 14,731, July 2, 1903.

Electrolytic Refining of Metals; Apparatus for ——. A. Schwartz, Assignor to General Metals Refining Co., New York. U.S. Pat. 760,023, May 17, 1904.

A cathode of large surface is employed, consisting of a number of parallel plates. The cathode plates are spaced apart and arranged at an angle to the face of the anode, so that there will be a free circulation of the solution.

—R. S. H.

[Precious] Metals; Recovering —— *from Ores or Sands.* W. J. and J. H. Jory, San Francisco. U.S. Pat. 760,539, May 24, 1904.

Ores containing precious metals are simultaneously powdered and treated "with reagents adapted to form by combination with less valuable constituents of the ores, solvents which will combine with the noble metals to form salts which, under electrolytic action, will be decomposed with the regeneration of the solvent." Thus, an alkaline sulphide solution, together with the "hydrate of the metal forming the base of the sulphide" may be used, the precious metals being recovered from the solution electrolytically. Ammonium sulphide solution is also claimed as a suitable solvent.—E. S.

French Patent.

Steel; Deoxidising ——. Aluminium Industrie Act.-G Fr. Pat. 338,702, Dec. 31, 1903

Molten steel, refined by the Bessemer, Thomas, or oth process, is freed from scoria, and is transferred, preferab to an electric furnace, where it is allowed to cool to ne its solidification point (in order that oxides may separate and is then covered with chalk, sand, or the like, or with slag, such as that formed in the manufacture of the ste The mass is then reheated for ordinary treatment. Inste of conducting the process in separate phases, as describ it may be carried out in a single furnace.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Fats; Auto-Hydrolysis of Crude Animal ——. P. Pastr vich. Monatsh. f. Chem. 1904, **25**, 355—361.

Crude animal fats are hydrolysed spontaneously on kee ing, owing to the presence of decomposition products of t glutinous substance of the membranes; the products a free fatty acids and glycerin. The membranes were isolat from crude beef tallow, scraped free from fat, cleansed fro adhering particles by means of damp filter-paper, dried, ar powdered; the powder when digested in the dark at 35° with cotton-seed oil in presence of a little water caused steady increase in the acid value of the oil. Crude be tallow obtained from various organs of the body w reduced to a pulp and digested in the dark at 35° C., t increase in the free acidity being determined from ti to time. The tallow from the different organs differ considerably as regards the rate of hydrolysis. The tallo rich in oleïn were hydrolysed more rapidly than tho containing less oleïn. The addition of 12—18 per cent. water considerably increased the rate of hydrolysis. (S Dieterich, Chem. Rev. ü. Fett- und Harzind., 1899, **6**, 16 181, 201.) The addition of ammonia or caustic alkalis very small quantities favoured the hydrolysis, but larg quantities restricted it. The hydrolysis was also co siderably restricted by the addition of dilute mineral aci and of a 2 per cent. solution of chloral hydrate, whi the presence of mercuric chloride nearly prevented hyd lysis altogether. The odour of the decomposing mas was not unpleasant, but sour, somewhat resembling t of fresh cheese. The presence of ammonia or of fix alkalis caused in some cases a reddish-yellow colorati of the fat; in other cases the colour was unchang The products always contained small quantities of amn nium soaps, and in most cases formic acid was detect after acidification. The hydrolysis is probably due to an enzyme but to the decomposition of the al minoids by aërobic micro-organisms. It may be attribu to the saponifying influence of the ammonia derived fr the decomposing albuminoids; but since the saponifyi power of such minute quantities of ammonia under above conditions is very slight, it must be assumed that ammonium soaps produced are constantly dissociated, that the saponification is carried on under the catal influence either of the bacteria or of the albuminoid matt

—J. F. B

Therm-oleometer: Apparatus stated to permit of Detection of Adulteration of Olive Oil and ot Vegetable and Animal Oils. M. Tortelli. Boll. Ch Farm., **43**, 193—203. Chem. Centr., 1904, **1**, 142 1426.

The author's apparatus, by means of which the Maum test can always be carried out under the same conditi comprises a vacuum vessel and a thermometer provide the bottom with stirring blades. 20 c.c. of the oil introduced into the vacuum vessel, stirred well for abou minute with the thermometer, and the temperature no 5 c.c. of sulphuric acid are then cautiously added in course of about 30 seconds, with continuous stirring, the highest temperature attained in about two minute observed. The difference between the two readings g "degree of heat evolution" of the oil. Acid of gr. 1·8413 is used. From experiments under the ve conditions the author obtained the following results the "degree of heat evolution" of different oils:— ve oil, 44; cotton seed oil, 78; sesamé oil, 71·3; za oil, 61·2; rape oil, 60·8; arachis oil, 50·6; grape- l oil, 73·6; maize oil, 82; poppy-seed oil, 88·4; icline oil, 103·2; almond oil, 50·7; apricot kernel oil, 5; peach oil, 70·1; hazelnut oil, 48; peach-kernel oil, 7; mustard oil, 58·6; castor oil, 67·8; hemp-seed oil, niger-seed oil, 91·5; candle-nut oil, 96; "native nut" 104; linseed oil, 124·4; stillingia oil, 136·2. The hor is not able to confirm the statement of Thomson Ballantyne (this J., 1891, 234) that the formula

$$\frac{\text{rise of temperature with oil}}{\text{rise of temperature with water}} \times 100$$

ls to constant values; he finds that even with this nula the values obtained decrease as the strength of acid is reduced.—A. S.

ulmoogra Seeds; Constituents of ——. F. B. Power nd F. H. Gornall. Chem. Soc. Proc., 1904, **20**, 135.

seeds which afford the chaulmoogra oil of commerce derived from *Taraktogenos Kurzii* (King), a native of mah, and not, as has until quite recently been assumed, *Gynocardia odorata* (R.Br.). The oil has previously examined by Moss (Year-book of Pharmacy, 1879, –533), Petit (J. Pharm. Chim., 1892, **26**, 445), and recently by Schindelmeiser (Ber. deutsch. pharm. Ges., , **14**, 164), but their results differ in many respects those obtained by the present authors, which are as ws:—The seeds of *Taraktogenos Kurzii* (King) con- a hydrolytic enzyme, and also an unstable cyanogen ound, which reacts with the enzyme when the seeds crushed, giving rise to hydrogen cyanide. On expres- the seeds yielded 30·9 per cent. of a fatty oil, which the following constants:—m. pt., 22°—23° C.; sp. gr., 1 at 25° and 0·940 at 45° C.; $[\alpha]_D^{15°} = +52°$; acid value, ; saponification value, 213; iodine value, 103·2. On olysis, the fatty oil yielded glycerol, a very small int of phytosterol, $C_{26}H_{43}.OH$ (m. pt. 132° C.), and a ure of fatty acids (m. pt. 44°—45°; $[\alpha]_D = +52·6°$ in oform; acid value, 215; iodine value, 103·2), which sted chiefly of several homologous acids belonging to ries $C_nH_{2n-4}O_2$ containing a closed ring and one enic linking, no member of which has hitherto been ed from a fatty oil. The highest of these homologues nt, which was isolated in a pure condition, separates most of the usual organic solvents in glistening leaflets t. 68° C.; b. pt. 247°—248°/20 mm., $[\alpha]_D = +56°$), he formula $C_{18}H_{32}O_2$, and is designated *chaulmoogric* It combines with only two atomic proportions of ne or iodine. Palmitic acid also was identified, and is reason for assuming the presence of a near logue or homologues of chaulmoogric acid, but ging to the series having the general formula $_4O_2$ with two ethylenic linkings. Undecylic acid ydroxy acids were proved to be absent, and an indi- acid corresponding to hypogæic acid, could not be d. The "gynocardic acid" of all previous investiga- believed to be a mixture of several substances. The scake" yielded, besides formic and acetic acids and small amount of volatile esters having the character- lour of the seeds, an appreciable amount of a neutral *ubstance*, $C_{18}H_{32}O_2$ (b. pt. 214°—215°/18 mm.; sp. ·9066 at 16°/16° C., $[\alpha]_D = +42·4°$), which is ic with chaulmoogric acid.

moogric Acid; Constitution of ——. *Part I.* . Power and F. H. Gornall. Chem. Soc. Proc., 1904, 126—137.

he object of ultimately determining the constitution *ulmoogric acid*, $C_{18}H_{32}O_2$ (see preceding abstract), a r of its derivatives have been prepared and studied. *chaulmoograte*, $C_{17}H_{31}.CO_2CH_3$ (m. pt. 22°, b. pt. rr./20 mm., sp. gr. 0·9119 at 25°/25°, $[\alpha]_D^{15°} + 50$ roform), was prepared by the interaction of the nethyl alcohol, and hydrogen chloride. *Ethyl chaulmoograte*, $C_{17}H_{31}.CO_2C_2H_5$, a colourless oil (b. pt. 230 corr./20 mm., sp. gr. 0·9079 at 15°/16°, $[\alpha]_D^{20°} + 50·7°$), was prepared in like manner. *Chaulmoogramide*, $C_{17}H_{31}.CO.NH_2$ (m. pt. 106°, $[\alpha]_D^{27°} + 57·3°$ in chloroform), was obtained according to Aschan's method (*Ber.*, 1898, **31**, 2341). *Bromodihydrochaulmoogric acid*, $C_{17}H_{32}Br.CO_2H$ (m. pt. 36—38°; optically inactive), is formed when chaulmoogric acid is treated with hydrogen bromide in glacial acetic acid. Ethyl chaulmoograte absorbs two atomic proportions of bromine in the cold, forming *ethyl dibromodihydrochaulmoograte*, $C_{17}H_{31}Br_2.CO_2C_2H_5$, which is an oil. When chaulmoogric acid is treated with sodium in boiling amyl alcohol, the ethylenic linking is not resolved, but there were obtained, after fractional distillation of the product, *chaulmoogryl alcohol*, $C_{18}H_{33}.OH$ (m. pt. 36°, $[\alpha]_D + 58·4°$) and *chaulmoogryl chaulmoograte*, $C_{17}H_{31}.CO_2.C_{18}H_{33}$ (m. pt. 42°), together with unchanged chaulmoogric acid. The saturated acid, *dihydrochaulmoogric acid* $C_{17}H_{33}.CO_2H$ (m. pt. 71—72°, b. pt. 248°/20 mm.; optically inactive), is formed, however, on reducing bromodihydrochaulmoogric acid with zinc dust and alcohol, or chaulmoogric acid with hydriodic acid and phosphorus. By the latter process a hydrocarbon, *chaulmoogrene*, $C_{18}H_{34}$ (b. pt. 193—194°/20 mm.) is also formed. *Methyl dihydrochaulmoograte*, $C_{17}H_{33}.CO_2CH_3$ (m. pt. 26—27°, b. pt. 222—223°/20 mm.), was prepared from the corresponding acid. Chaulmoogric acid is not attacked by fused caustic alkalis even at 300° C. When chaulmoogric acid was oxidised with cold permanganate (1 atom of oxygen), *dihydroxydihydrochaulmoogric acid*, $C_{17}H_{31}(OH)_2.CO_2H$ (m. pt. 102°), was produced, but when the amount of permanganate was equivalent to 4—5 atomic proportions of oxygen, formic acid and *two dibasic acids* were obtained, the latter having the formulæ $C_{15}H_{28}(CO_2H)_2$ and $C_{15}H_{28}O(CO_2H)_2$ (m. pt. 128°). The *ethyl esters* of these acids were described. The molecular magnetic rotation of ethyl chaulmoograte very closely approximates to the calculated value for an unsaturated ester of the formula $C_{20}H_{36}O_2$, having a closed ring and one ethylenic linking, the latter being contained in an allyl group. This conclusion, based on the magnetic rotation, is in harmony with the results obtained by the oxidation of the acid.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

English Patent.

Colouring Matter Lakes [*from Azo Dyestuffs*]; *Manufacture of* ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. Eng. Pat. 15,493, July 13, 1903.

Insoluble azo dyestuffs which have a soft, oily, or resinous consistency, or which are soft or liquid at about 100° C. (*e.g.*, those prepared from diazotised crude xylidine or toluidine and β-naphthol, &c.), are warmed and intimately mixed with a substratum of finely ground, dry barium sulphate, kaolin, alumina, &c., and the paste dried, or employed directly in the moist condition. Other substances which assist the "liquefaction" of the dyestuff may be added, such as phenols, glycerin, aniline, the alkali salts of higher fatty acids, &c. Other azo dyestuffs which are not alone adapted for use by this process (*e.g.*, "aniline-azo-betanaphthol") may be added to the dyestuffs first mentioned, and can then be used for lake-making by this process. In the place of the usual white substrata for these lakes, coloured compounds, such as minium or previously prepared lakes, may be used. As an example of the process, two parts of "aniline-azo-phenol" and three parts of sodium ricinoleate are melted by steam heat, and incorporated with 50 parts of ground barium sulphate and 10 parts of water; when dry, a yellow lake is said to result.
—T. F. B.

United States Patent.

Composition of Matter [*Varnish*]. C. Ellis, Assignor to G. M. Port, both of Boston. U.S. Pat. 760,185, May 17, 1904.

The composition of matter consists of a metallic palmitate, such as zinco-aluminium palmitate, dissolved in linseed-oil, to which Chinese wood-oil, gilsonite, and turpentine, or other similar substances, are added.—A. G. L.

(*B.*)—RESINS, VARNISHES.

Varnishes; Studies on ——. A. Tixier. Monit. Scient 1904, **18**, 413—421.

A varnish consists of a solution of a substance, C, such a a gum, resin, &c., in a solvent, S. If to this solution ther be added a second liquid (an "insolvent"), I, which i miscible with S, but in which C is insoluble, a limit, *k*, will b reached beyond which any increase in the quantity of I wil cause precipitation of some portion of C. This limit, *k*, ma be represented by the formula $\frac{s}{s+i}$, where *s* is the weigh of the solvent S, and *i* that of the "insolvent" I. Th application of this law of "limit solvents" is of particula interest in the study of varnishes. Varnishes may b classified as "perfect" (consisting wholly of C + S), an "imperfect" (C + S + I), and each of these groups ma further be subdivided into "volatile" and "semi-fixed varnishes. In the "perfect" varnishes C is soluble in al proportions of S; such are those containing colophony o resinates dissolved in alcohol, oil of turpentine, &c. O the "imperfect" varnishes those made from copal ar the most important. In consequence of the insolubility o the gum-resins classed as copals in most of the liquid suitable for varnish manufacture, it has hitherto been th practice to form S by the partial depolymerisation of th copal at a high temperature. During this "preliminar fusion" a loss of weight, which may reach 20 per cent takes place. The author has, however, shown (compar Fr. Pat. 334,430, 1903; this J., 1904, 69) that terpineol i a solvent for unfused copals. The suitability of terpinec for playing the part of S in a copal varnish is, moreover increased by its high boiling point (218° C.). For if in varnish consisting of C, S, and I, S be more volatile than there is a tendency during the drying of the varnish fo the ratio $\frac{s}{s+i}$ to fall below the limit *k*, in which cas precipitation of C, and consequent turbidity of the film would occur. Solutions of copal in terpineol may therefor be mixed with alcohol, oil of turpentine, &c., in any propor tion below the solvent limit, and the resulting films retain portion of the terpineol, which confers on them gre flexibility and durability. As a general rule the gum-resi exhibit the character of acids or mixtures of acids, wit only traces of saponifiable esters. The optical rotatic ranges from − 83° 8′ to + 82° 24′.—M. J. S.

United States Patent.

Shellac; Substitute for ——. C. Ludwig, Schönber U.S. Pat. 760,541, May 24, 1904.

Fifty-six parts of "cheap resin," soluble in alcohol, a added to a boiling solution of 9 parts of potassiu hydroxide in 140 parts of water, 1 to 1·5 parts of ol acid are added, the mixture is diluted, and dilute sulphu acid added; the precipitate produced is suitable for use a substitute for shellac.—T. F. B.

(*C.*)—INDIA-RUBBER, &c.

English Patent.

India Rubber Substitutes; Manufacture of ——. T Velvril Co., Ltd., London, and J. S. Howkins, Thorn Heath. Eng. Pat. 13,306, June 13, 1903. (See a Eng. Pat. 21,995 of 1895.)

Nitrated castor or other oils are heated for, say, hours, to a temperature of 130° C., the resulting prod being a tough elastic body, which may be used a substitute for rubber.

The same effect may be produced by adding to nitrated oil, 2 per cent. of lead peroxide and heating 100° C. with constant stirring (compare this J., 1899, 9
—J. K. I

XIV.—TANNING; LEATHER, GLUE, SIZE.

Kangaroo Leather; Manufacture of ——. B. Kohnstein. Der Gerber, 1904, **30**, 97—99, 111—112, 145.

Kangaroo hides are tanned:—(1) with pure gambier, (2) as "dongola" or chrome for shoes, and (3) as "splits" for enamelling, the "flesh splits" with oak and the "grain splits" with chrome.

Preparatory Treatment.—One pack (500 kilos.) of dried skins are placed in an old "soak," handled the same day, transferred to fresh water (containing sodium sulphide, if necessary) the next day, stocked on the third, and then put in water containing salt to further soften them. Instead of the stocks a travelling millstone is often employed, as by its use alone the workmen can soften down the hard places n the hides. They are washed twice in fresh water and ass to an old lime-liquor, being lifted the following day.)n the third they enter a stronger lime-liquor, "sharpened" y the addition of lime (36 kilos.) and realgar (2 kilos.), are ilted the next day, the pit is strengthened up on the fifth ay, and on the sixth the skins are washed off in lukewarm ater, unhaired, and fleshed; again washed, smoothed on e grain with a stone sleeker, and then passed to a bran rench employed in the usual manner.

Gambier Tannage.—The skins are coloured by paddling an old gambier liquor (22° Barkometer) for about 30 inutes, and then suspended for 12 days in liquor of which e strength is gradually raised to 12°. They are then essed and sorted. Fuller skins are obtained by adding lt to the first weak liquors, chiefly to suppress fermentation and decomposition of the tan, drumming or paddling r 2 days in 12° liquor, and laying away for 16 days in sh 34° liquor. The tanned skins are well washed, set t by the machine, oiled on the grain, and dried at 70°— ° F., in a dark room if good colour is desired.

Dongola Tannage.—The lightly tanned skins may be anned with such a mixture as (for 200 middle-weight ins): alum (2 kilos.), salt ($4\frac{1}{2}$ kilos.), flour (12 kilos.), g-yolks (10 doz.), olive oil ($\frac{1}{2}$ litre), and water (24 es), made into an emulsion, after which they are finished sumac. A simpler process is to dissolve salt and alum the gambier liquor (12°—24° Bk.), and add flour and -yolk to the fat-liquor. Also the skins may be first kled in salt and sulphuric acid, or salt and aluminium phate for 24 hours, neutralised, washed in brine of 25°, l then tanned with gambier liquor containing flour, -yolk, and some neatsfoot oil.

)ther Vegetable Tannages.—Canaigre extract followed l palmetto extract has been employed successfully on root- hier in the suspenders, with quebracho extract, or q bracho with hemlock, in the stronger liquors, and final t tment in sumac.

hrome Tannage.—A basic chromium liquor gradually i eased from 4° to 40° Bk., followed by drumming in s nger liquor, is sometimes used, but the two-bath process is ore usual. Chromed skins, when carefully neutralised, n be further tanned with mangrove (R. Catechu brand) o almetto extract.

inishing Processes.—Skins tanned with gambier are d ped down and washed over with dilute lactic acid (4 litres of per cent. acid in 200 litres of water per 80 kilos. of dry le er). They are then given a sumac bath. Fuller and so r leather is obtained if the skins are treated in this or after lying for some time, than if treated with sumac im ediately after the gambier tannage. After again lying co ed up with a cloth, they are fat-liquored with soap and su onated oil, or neutral soap and best French moëllon ($\frac{1}{2}$ lo. and 5 litres respectively per 80 kilos. leather), set ou n both sides, and hung up to dry. They may be fat-liq ed a second time, washed with lactic acid, and, before dy g, treated first with warm sumac and then tartar em c. They are dyed in a drum or paddle, set out, oiled on e grain with light seal oil, dried on frames, and glazed wit soap and casein finish.

cked Skins receive a further quebracho ($\frac{1}{3}$) and he ck ($\frac{2}{3}$) bath of 35° Bk. before being fat-liquored. Th llowing fat liquors are arranged each for 80 kilos. of dry ather.

(1) Water (100 litres), sod-oil (8 litres), hard soap (500 grms.), borax (300 grms.), calcined sodium carbonate (100 grms.).

(2) Brown cod-oil (4 litres), potassium carbonate (400 grms.), water (59 litres).

(3) Olive-oil (4 litres), cod-oil (4 litres), moëllon (2 litres), hard soap ($\frac{1}{2}$ kilo.), borax (300 grms.), water (100 litres).

(4) Egg-yolks (3 doz.), olive-oil (1 litre), soap ($\frac{1}{2}$ kilo.), water (16 litres).

(5) Neatsfoot oil (6 litres), sod oil (2 litres), borax (300 grms.), water (59 litres).

(6) Egg yolk (4 litres), cod-oil (6 litres), borax (300 grms.), water (100 litres).

After fat-liquoring, the leather is piled and allowed to lie for at least 14 days, then damped down again and treated with turmeric (5 kilos.) and sumac (5 kilos.) in water (100 litres per 140 kilos. of leather). This is drummed in at 36° for 30 minutes. The skins are washed off and then blacked. A first dressing is applied, made from potassium bichromate ($1\frac{1}{4}$ kilos.), ammonium chloride ($2\frac{1}{2}$ kilos.), and borax ($2\frac{1}{2}$ kilos.) in water (100 litres), to avoid the use of urine. Then follow two coats of the following: logwood extract (60 kilos.), calcined sodium carbonate (10 kilos.), fustic extract (10 kilos.) in water (1,000 litres), and a final coat of "copperas" (ferrous sulphate) solution or copperas with "blue vitriol" (copper sulphate). The blacked skins are then washed on the grain with cold water, set out on the machine, and oiled with neatsfoot oil. Mould is liable to form on damp skins left on the horse, but may be avoided by a weak coat of phenol. When dry the skins are damped down, smoothed on the grain, and glazed, usually with a final coat of tragacanth and mineral oil.—R. L. J.

Tanning Materials; Extraction of Vegetable ——. L. Manstetten. Collegium, 1904, 130—133, 145—151.

The author discusses the principles of the various methods used by tanners for extracting barks and other solid materials, and advocates systems that involve quiet maceration at carefully regulated temperatures (rather than violent agitation at higher temperatures), such, for instance, as the slow displacement, by steam pressure from above, of the warm liquor in the leaches.—R. L. J.

Palmetto Extract; Manufacture of ——. B. Kohnstein. Der Gerber, 1904, **30**, 112—113.

The white or scarlet-red roots of the feather-palm (*Sabal serrulata*), growing freely in Georgia and Florida, are collected and crushed between rolls. Usually old sugar-cane presses are employed. The roots contain about 40 per cent. of water, and the astringent juice is caught in vessels and concentrated in a vacuum pan to about 30° B. This method is preferable to extraction with water, because only foul swamp water, containing much salt in solution, is available.—R. L. J.

Bleaching Leather; Apparatus for ——. E. C. Amidon, Corry. U.S. Pat. 759,844, May 17, 1904.

The skins are attached to an endless carrier, which automatically immerses them in the bleaching vats for any required time, and then lifts and removes them.—R. L. J.

French Patent.

Skins and other Materials; Degreasing of —— by Carbon Tetrachloride or other Volatile Solvent. C. Lallemand. Fr. Pat. 338,495, March 28, 1903.

A self-contained and hermetically closed apparatus in which all the operations of extracting grease, drying the materials extracted, and recovering the solvent, are claimed to be conducted without loss of solvent or exposure of the workmen to its fumes.—R. L. J.

XV.—MANURES, Etc.

Rothamsted Experiments. Plans and Summary Tables arranged for Reference in the Fields, 1904, pp. 22. Lawes Agricultural Trust.

The pamphlet contains, in addition to the usual summaries relating to the continuous experiments on four-course rotation (57th year), on mangels (29th year), on grass land (49th year), on wheat (61st year), and on barley (53rd year), results obtained with unmanured wheat, grown for five years after various leguminous crops, and with unmanured barley, grown for two years on the old potato plots. The institution of new experiments on the cropping and disease-resisting powers of nine varieties of potatoes, and on mangels and swedes, in which the manurial effect of calcium cyanamide will be compared with sulphate of ammonia, are also recorded. An interesting illustration of the after-effects of manures is afforded by the experiments on unmanured barley on the potato plots, which had been variously manured for 26 years. Large yields of barley were obtained the first year (1902), and in 1903 the yield, although much less on all the plots than in 1902, was about twice as high on the plots to which ammonium salts or nitrate of soda had been applied for the last time in 1901, as on the continuously unmanured plot; whilst on the plots which had been furnished with a complete mineral fertiliser as well as with nitrogen, the yield was nearly three times as high. (See also this J., 1890, 871; 1891, 938.)—N. H. J. M.

Nitrous Acid; Formation of ——, and Nitrification as a Chemical Process in Culture Soils. F. Sestini. Landw. Vers.-Stat., 1904, **60**, 103—112. Chem. Centr., 1904, **1**, 1499—1500.

According to Bonnema (Chem.-Zeit., **27**, 148) ferric hydroxide is capable of oxidising free nitrogen to nitrogen trioxide. The author finds, however, that it is not the nitrogen of the air, but the ammonia present therein, which is oxidised by ferric hydroxide and converted into nitrogen trioxide. There is thus no increase of assimilable nitrogen, but only a change of form of the latter. From further experiments the author concludes that the whole of the nitrous acid present in soils is not produced by *Bac. nitrosomonas*, but that a part is produced in a purely chemical manner.—A. S.

French Patents.

Molasses and similar Substances [Fertilisers]; Process for Drying and Preserving ——. L. L. Honoré. Fr. Pat. 338,517, Dec. 30, 1903. Next col.

XVI.—SUGAR, STARCH, GUM, Etc.

Saturation; Double and Triple ——. K. Andrlik and V. Stanek. Z. Zuckerind. Böhmen, 1904, **28**, 381—404.

Neither in the laboratory nor in the works can any marked chemical difference be detected in the purification produced by double as compared with triple saturation, although in the latter case sulphurous acid gave a greater purification than carbonic acid in organic substances, but with an increase in inorganic constituents. In practice the view prevails that triple saturation is of great value in giving the best results and yielding fine products.—L. J. de W.

Molasses Waste Lyes; Preparation of Betaïne from——. K. Andrlik. Z. Zuckerind. Böhmen, 1904, **28**, 404—406.

Molasses lye at 70·4 Bg. from the strontium desaccharification process is used. The lye is gently boiled until the temperature rises to 144° C., when syrupy phosphor acid is added in quantity sufficient to form potassiu dihydrogen phosphate with the potash present. Aft cooling, the filtrate is concentrated until it boils at 152°– 153° C., cooled to 80° C., and 96 per cent. alcohol adde The mixture separates into a syrupy portion containing th amino-acids and an alcoholic solution rich in betaïne. (adding syrupy phosphoric acid to the warm alcohol solution, betaïne phosphate separates in distinct crysta When cold, the precipitate is washed with alcohol, d composed with milk of lime, and the remaining lin removed with carbon dioxide. The filtrate is concentrat on the water-bath and the betaïne obtained recrystallis from alcohol. Betaïne phosphate is soluble in water a easily crystallises in anhydrous granular crystals whi melt at 199°—200° C. to a clear liquid. At 234° C. deco position occurs with frothing and escape of gases whi smell of amines. The yield of betaïne is about 12 per ce on the dry solids of the molasses lye.—L. J. de W.

West Indian Starches. W. R. Buttenshaw. West In Bull., 1904, **5**, 1—10.

The author gives the results of the microscopic examinat of a large number of starches prepared from West Ind plants. A large majority of the specimens examined w "root" starches. Attention is drawn to the unsatisfact nature of the artificial methods of classification that are use at the present time. Several of the starches exam would probably be suitable for laundry purposes, whilst meal from some of the starch-yielding plants, *e.g.*, from cho-cho root and yam bean, forms an easily digested fo A short bibliography is appended to the paper.—A. S.

Molasses and Similar Substances [Fertilisers]; Pro for Drying and Preserving ——. L. L. Honoré. Pat. 338,517, Dec. 30, 1903.

Molasses or other similar residues from the manufa of sugar are reduced to a state in which they contain a small proportion of water. They are then made alk by the addition of sodium carbonate and boiled for 10 minutes. A considerable deposit of nitrogenous ma then separates out, perfectly free from hygroscopic mu ginous matters. This deposit is dried and utilised fertiliser, whilst the liquid residue is mixed wi pulverulent material and the mixture dried, the re mass being also used for fertilising purposes.—J. F. B

XVII.—BREWING, WINES, SPIRITS, E

Culture Yeast; Vitality of certain Races [Frohberg, Race II. and Race XII.] of —— in the Moist St Low Temperatures, and the Influence of ca Organisms on these Yeasts. W. Henneberg. Wo Brau., 1904, **21**, 260—263, 288—290, 299—301, an —312.

The duration of vitality is shortest in the case of yeast, then follow Race II., Race XII., and Frohberg Low temperatures are especially favourable to prol vitality; at 7° C. in the case of Frohberg yeast one-f the cells were alive after 120 days, although the conc vere such that no reproduction had taken place during the eriod of storage. Some individual cells [reserve cells] xceptionally rich in fat and albumin, in the case of rohberg yeast, are endowed with a much longer life than he bulk of the yeast cells. The youngest, immature cells lways die first. The period of vitality depends also on the nanner of cultivation; prolonged contact with the fermented vort is unfavourable. In vessels containing large quantiies of yeast the cells generally die earlier than in those ontaining smaller bulks, owing to the accumulation of netabolic products. For the same reason the cells in the ottom layers die earlier than those near the surface; reservation in cotton wool is favourable. The gradual lrying of the yeast exerts at first a favourable influence, ut when the moisture falls below a certain point all the ells die. The addition of a large quantity of water is enerally very unfavourable; it intensifies the metabolism nd restricts respiration; in presence of water a growth of ew cells occurs at the surface. In closed vessels the yeast lies earlier than in open vessels, owing to the pressure of he carbon dioxide produced. In the early stages of storage he cells do not multiply, but later the products of autoligestion afford nourishment for a surface growth. The roduction of spores during storage was observed only in he case of Race II. Infection with lactic acid bacteria ppears to be without influence on the vitality of the yeast, ut *Oidium lactis* and *Penicillium glaucum* kill the yeast ells; the latter organism brings about the digestion of the ll membrane of the yeast. Infection with mould-yeasts lso reduces the period of vitality.—J. F. B.

Pressed Yeasts, with Squarrose Budding Chains.
P. Lindner. Z. Spiritusind., 1904, **27**, 225—226.

s a result of the observations recorded in a previous paper his J., 1904, 497) the author has put forward a proposal at all pressed-yeast factories should agree to use only ch yeasts as form squarrose budding chains when cultited for 24 hours in a hanging droplet (*loc. cit.*), in order facilitate the diagnosis of adulteration with bottommentation beer yeast. These observations have now en extended to several samples of pressed yeast manufacred in Vienna, with the result that the general law has en further confirmed. The introduction of a general stom such as that suggested would enable both the nufacturer and the analyst to pronounce on the purity l type of the yeast in the simplest manner. Figures are en illustrating more clearly the nature of the differences erved in the form of the budding chains.—J. F. B.

een Malt; Distribution of the Diastatic Enzyme in ——.
R. F. von Teichek. Chem. Ind., 1904, **27**, 270—275.

EEN malt corns, germinated until the length of the ospire reached three-quarters of that of the corn, were ected, and the component parts were dried over huric acid. From about 4,500 corns there were ined in the dry state, 169·5 grms. of endospermi and s, 11·02 grms. of acrospires and scutella, 10·95 grms. ootlets. Each product was finely ground with sand and ied with absolute alcohol; the enzymes were then acted by treatment with concentrated glycerin. The ed extracts were precipitated by alcohol, and the precates were washed with alcohol and ether. The dried arations were gelatinised but not really dissolved by r; they gave the characteristic enzyme reaction with acum tincture and hydrogen peroxide. Analysis having n that the three preparations (calculated ash-free) had ically the same composition, the relative yields were n as representing the relative distribution of the diastase e different organs. The yields on the dry substance :—2·83 per cent. from the endosperms, 5·57 per cent. the acrospires, and scutella, and 4·25 per cent. from ootlets. Calculated in terms of the total quantity of ise present in the whole corns, the distribution was:— 80 4 per cent. in the endosperm, 10·93 per cent. in the pire and scutellum, and 8·33 per cent. in the rootlet. numbers differ from those obtained by Brown and s, from the activity of aqueous extracts, chiefly in t of the values found for the rootlets. Those authors ed mere traces of diastase in the rootlets, owing to the fact that they based their conclusions solely on saccharifying powers. Mashing experiments showed that the components of the diastatic enzyme are unevenly distributed in the different parts. 50 c.c. of a 2 per cent. starch paste were treated at 25° C. with 0·05 grm. of the different diastatic preparations, and the temperature was continuously raised in 30 minutes to 55° C.

Diastase from the Endosperms.—Liquefaction was apparently complete after 20 minutes, and saccharification was complete after 30 minutes.

Diastase from the Acrospires and Scutella.—Liquefaction was complete after 14 minutes and saccharification after 35 minutes.

Diastase from Rootlets.—Liquefaction was complete in 5 minutes, but the iodine test showed the presence of starch after four hours. The filtered mash had absolutely no reducing action on boiling Fehling's solution. This preparation, moreover, completely liquefied a thick starch paste in a few minutes.

The above observations show conclusively that the starch-liquefying and the saccharifying powers of malt diastase are due to the presence of two distinct enzymes. The liquefying enzyme occurs in the rootlets in considerable quantities, and it is there accompanied by such small quantities of the saccharifying enzyme, that the latter is totally destroyed during the operations necessary for the isolation of the diastase.—J. F. B.

Green Malt; Starch Hydrolysing Enzymes in ——.
A. Pollak. Woch. f. Brau., 1904, **21**, 317—319.

Average samples of germinating barley were taken daily throughout the period of malting and the acidity, starch-liquefying power and saccharifying power of the samples were determined. The results are illustrated by means of curves, showing the values from day to day.

Sample 1 was a pale malt of Pilsen-type, prepared with the ordinary water-steep, prolonged cool growth and careful kilning. The acidity, saccharifying and liquefying powers increased steadily until the time of withering, at which stage the liquefying power rose, whilst the acidity and saccharifying power remained constant; towards the end of the kilning all three factors fell rapidly. The starch-liquefying power always remained below the saccharifying power.

Sample 2 was a Pilsen malt steeped with alternate aeration and immersion; it was treated on the kiln with sulphurous acid. All the factors rose more rapidly under the stimulus of aeration; the starch-liquefying power was, throughout, higher than the saccharifying power and increased all the time. This sample was grown at a higher temperature, and was allowed to "felt" earlier than Sample 1. During the "felting" the acidity remained constant, the saccharifying power decreased somewhat, and the liquefying power continued to rise. The sulphuring on the kiln, whilst the moisture was still considerable, caused a sudden rise in all three factors, followed by a considerable decrease towards the end of the kilning.

Sample 3 was a Bavarian malt, treated in the same way as Sample 2, and it showed the same tendencies but in a more exaggerated degree. The Bavarian system of kilning, accompanied by sulphuring, caused an initial increase of the saccharifying power and acidity and a steady decrease of the liquefying power, followed by considerable decreases of both kinds of diastatic power at the higher temperatures of kilning. The author concludes that the liquefying diastase is the first product of the metabolism; from the third to the sixth day the saccharifying diastase is produced with greater intensity, partly at the expense of the liquefying enzyme. During "felting" the production of saccharifying diastase slackens and enzyme formation only proceeds as far as the first of the two diastases, with perhaps even reversion from the saccharifying to the liquefying modification.
—J. F. B.

Barley and Malt; Nitrogen Content of ——. E. Prior.
Allgem. Zeits. f. Bierbrau., 1904, **32**, 231—235.

Referring to the proposals of Haase to utilise the nitrogen content of barley as a basis for estimating its malting value, the author states that, in his experience, the beers prepared from well modified malts rich in nitrogen, are better and more stable than those from imperfectly modified malts low in that constituent. He therefore concludes that a greater influence is exerted by the method of preparing the malt than by its nitrogen content. It would also appear that the character of the nitrogenous compounds affects the malting quality, since whilst Delbrück has found nitrogenous barleys exhibit a tendency to heat on the malting floor, the author has known others rich in nitrogen that gave rise to no objection on this score. The author also points out that the *circa* 10 per cent. limit of nitrogen was mentioned by Lintner in 1880, and that excellent malt is furnished by thin-skinned Austrian barleys containing more than the above percentage, from which the conclusion is drawn that the proposed standard is unsuitable for general application.—C. S.

Fermentation; Action of Phosphorescence on ——. A. Perret. La Bière, 1904, **12**, 33—34.

The influence of phosphorescence on fermentation has been investigated by Richet, the phosphorescent employed being calcium sulphide, and the organism the lactic ferment, owing to the ease with which the degree of fermentation can be determined. The calcium sulphide was contained in small flasks filled with cottonwool and immersed in the milk, forming the culture medium. Determinations of the acidity of the milk were made with nine samples, and showed that while, in comparison with similarly fermented check samples, the acidity of the milk increased more rapidly at the outset it afterwards declined (at the end of six to eight hours). The influence of phosphorescence is similar to that of any other cause threatening the vitality of an organism, the first result being to stimulate activity, which is afterwards crippled when the exposure is prolonged. The effects are intensified by an increased temperature. Richet admits that the phenomenon may be due to the action of X-rays, the actual luminosity of the calcium sulphide being too small to affect the organisms. The author considers that the fermentation industries may derive benefit from radio-active bodies by a suitable modification of methods.—C. S.

Fusel Oil formed by the Alcoholic Fermentation of Acorns; Composition of the ——. T. Rudakow and A. Alexandrow. J. russ. phys.-chem. Ges., 1904, **36**, 207—219. Chem. Centr., 1904, **1**, 1181.

The fusel oil from acorns is similar, qualitatively, to that from potatoes, rye, and maize. It contains about 2·7 per cent. of normal propyl acohol, 9·8 per cent. of isobutyl alcohol, and 87·4 per cent. of fermentation amyl alcohol; about one-quarter of the latter consists of optically active amyl alcohol. The fusel oil also contains small quantities of hexyl alcohol, acetaldehyde, esters, and furfural.—A. S.

Beer; Influence of Volume of Mashing Liquor on the Quality of ——. E. Jalowetz. Allgem. Zeits. Bierbrau., 1904, **32**, 7—10.

The author concludes that the volume of the mashing liquor has very little influence on the quantity and ratio of maltose and dextrin in the resulting wort, but that a slight increase in the dextrin content is observed as the concentration of the wort is diminished. For high-class beer it is undesirable to start with a wort of very high initial gravity, and the best relation between the main wort and the spargings is attained when the concentration of the first runnings is 1·3—1·4 times that of the final wort. With these proportions a good yield of extract can be obtained without so far washing out the grains as to bring undesirable constituents into the beer.—C. S.

Beer; Conditioning of —— by Bunging with Yeast. P. Lindner. Woch. f. Brau., 1904, **21**, 305—306.

The practice of conditioning beer by bunging it down with an addition of fresh yeast instead of "Kräusen" has met with considerable success. This treatment comes into greater prominence in view of the recent modifications introduced in the mashing process with a view of restricting the fermentability of the worts. In such worts the yeast settles out earlier than in those prepared by the old method and ceases to work as soon as the readily fermentable bodies have been consumed. The closer the approach t the final degree of attenuation which is obtained in th primary fermentation, the more difficult it becomes to bring about sufficient conditioning in the after-fermentation i cask. The addition of "Kräusen" is a ready means o surmounting this difficulty, but it has the defect of intro ducing raw wort to the beer, thereby not improving th flavour, and it sets up a violent agitation during its action By bunging with yeast instead of "Kräusen," sufficien carbon dioxide is produced by a gentle secondary fermenta tion, the head-retaining properties of the beer are increase and the liability to become turbid is reduced. The pro portion of pasty yeast added may vary from 1·5 litres p 50 hectolitres of beer to five times that amount. Th yeast should be well nourished and should be taken from primary fermentation which has not been too prolonged; should not be weakened by excessive washing. In th condition the yeast is not likely to withdraw extracti matter from the beer for its own nourishment, since n reproduction takes place at low temperatures. The carbo dioxide, which exerts such a favourable influence upon t stability and condition of the beer, is probably large produced by the fermentation of the glycogen stored up the yeast. The improvement in the permanence of t "head" is doubtless due to the separation of nitrogeno matters from the yeast which are favourable to th property. Finally the glutinous, flocculent condition fresh yeast exerts a powerful clarifying effect on the be treated with it.—J. F. B.

Beer; "Head" Retention in ——. W. Rössel. Mitt. V Stud. Lehr.- u. Versuchs-Anst. München. Allgem. Zei Bierbrau., 1904, **32**, 145—148.

Apart from the influence of the chemical constituents the beer, the retention of head depends on the method maturing and the cellar management. For example, li beers must not be over attenuated or left too long conditioning, or they will produce a frothy head wh quickly disappears, leaving the beer flat and thin flavour This is particularly the case in the warmer season of year. The defect of insufficient condition may be coun acted to some extent by the addition of fermenting wor the storage cask.—C. S.

Proteids and "Head" Retention in Beer. P. Schüle Gambrinus, 1904, **31** (Special No.), 22—23.

The peptones have but a very low "head"-forming po and being readily precipitable by hop tannin can be left of consideration. The influence of the amides in wo also small, as might be expected from the demonstr fact that the frothing power of the proteids increases the complexity of the molecule, and *vice versâ.* actual nitrogenous "head"-forming constituents are unpeptonised proteids which are precipitable by tannic a and therefore to ensure "head" retention in beer necessary to keep these proteids in solution. The suc of these attempts depends not only on the quantity of added, but also on the condition of the hops, containing modified tannic acid being calculated to an unfavourable influence on "head" retention. H gas pressure (carbon dioxide) produces cloudiness precipitating the proteids, and diminishes the "head." —C.

Beer recovered by Pressing Yeast. Thausing. Allg Zeits. Bierbrau., 1904, **32**, 17.

The beer recovered by passing barm through the press has a much smaller percentage of extract (*e.g.,* per cent., falling after 6 hours to 3·23 per cent.), that racked off into and matured in cask (5·9 per c In another case the ripe beer contained 4·16 per ce extract, but the barm beer only 2·94 per cent. Anal results are obtained in the beer from the cask "foots one case 2·9 per cent. of extract as compared with 3 cent. in the rest of the beer.—C. S.

Distillery Process; The New Somló ——. A. Mar Z. Spiritusind., 1904, **27**, 238.

The process first introduced by Somló consists in ste the green malt employed in the distillery by immersi solution of formaldehyde. The formaldehyde kills all bacteria present on the malt without impairing the diastatic power, which, in fact, is rather increased by the treatment. The formaldehyde solution is recovered for further use and the malt is washed with water. It has since been found that the formaldehyde treatment may be dispensed with and that efficient sterilisation of the malt can be obtained by steeping it for some time in water at a temperature of about 55° C. and then washing with cold water. Most of he bacteria are thus loosened from the green malt corns and washed away, whilst the adherent spores which remain are caused to germinate and exist in the subsequent mashing process only in the form of vegetative cells which are readily killed at the mashing temperature. The danger of subsequent infection of the malt during milling is voided by using a special centrifugal mill for kneading he green malt. This machine is sealed up and sterilised by steam under pressure before use. The fermentations btained by this process are exceptionally pure and are uperior to those in which hydrofluoric acid is employed, he yields of alcohol are such as have hitherto been btained only by the "amylo" process. Somló's process an be used either with maize or potato mashes, and the nal acidities are remarkably low (*e.g.*, 0·35).—J. F. B.

Wines; Process and Apparatus for Making Sparkling ——. E. W. Kuhn. Addition, dated Dec. 12, 1903, to Fr. Pat. 331,382, April 21, 1903. (See this J., 1903, 1144.)

The application of the apparatus, described in the main specification, is extended to the transference of the sparkling wine to casks.—T. H. P.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A.*)—FOODS.

Grain and Flour; Catalytic Properties of ——. N. Wender and D. Lewin. Oesterr. Chem.-Zeit., 1904, **7**, 173—175. Chem. Centr., 1904, **1**, 1530.

In quiescent grain several enzymes have been detected, *e.g.*, diastases, glucases, and oxydases. Germination depends upon enzymic processes, many of the most important enzymes being formed during germination and increasing as the process goes on. The authors have, however, proved by measuring the amount of oxygen set free from hydrogen peroxide, that the enzymes possessing catalytic properties do not increase during germination. By heating to a suitable temperature the diastatic properties of grain may be destroyed, whilst the catalytic properties remain unaffected. Solutions of mercuric chloride (0·1 per cent.), silver nitrate (0·1 per cent.), caustic potash (0·2 per cent.), acetic acid (1 per cent.), and hydrochloric acid (1 per cent.), destroy the catalytic properties; 96 per cent. alcohol and ether are without influence. The ground grain has a powerful action on hydrogen peroxide. Bran possesses a considerably greater catalytic power than flour from the same kind of grain, and flour from the outer portions of the grain is distinctly richer in catalases than flour from the inner portions. A flour shows less catalytic action the finer it is, and the authors have based on this fact a simple method for distinguishing between commercial flours.—A. S.

Starch in Stale Bread; State of ——. E. Roux. Comptes rend., 1904, **134**, 1356—1358.

Although wheat starch, like potato starch, is partially converted into amylocellulose on standing for some days at 10° C., the formation of amylocellulose in bread after standing could not be detected. The amylocellulose was estimated by carrying out comparative saccharifications on the sample before and after heating in a sealed tube to 150° C.—T. F. B.

Butter; Keeping Quality of ——. I. Canned Butter. L. A. Rogers. U.S. Dept. of Agric., Bureau of Animal Ind., Bull. No. 57.

From the results of a large number of experiments, chemical and bacteriological, the author concludes that the changes which first occur in canned butter, producing more or less disagreeable flavours, are due to the formation of free acid by lipolytic enzymes. The enzymes may be produced in the milk, or secreted with the milk in the udder of the cow, and carried over into the butter, or may be produced in the butter itself through the activity of certain micro-organisms. The predominating species of yeast in the samples of butter examined was a kind of torula which was capable of forming a lipolytic enzyme. In the preparation of the butter the author recommends that the milk or cream be pasteurised at a temperature sufficiently high to destroy the enzymes, and that the "starter" be prepared and maintained in such a manner that danger of contamination by yeasts will be minimised.—A. S.

English Patent.

Blood, Desiccated; Apparatus for Preparation of ——. Union de la Boucherie en gros de Paris. Aubervilliers. Eng. Pat. 10,615, May 9, 1903. Under Internat. Conv., Jan. 30, 1903.

The blood is (1) lifted by suction from a collecting tank into a large rotating steam-heated drum, (2) coagulated under pressure or *in vacuo*; the product is then (3) squeezed under a press to remove moisture, and (4) passed by a lift and hopper to a chamber where it is dried *in vacuo*.
—R. L. J.

French Patents.

Flour from Wheat and other Grain; Process and Apparatus for Producing ——. E. F. Clark. Fr. Pat. 338,680, Oct. 20, 1903.

The mill consists of two parallel cylindrical rolls provided with spiral grooves cut in the same direction. When the rolls are rotated in opposite directions, the summits of the spirals approach each other at right angles and form a series of contacts which are only points. One roll is rotated at a higher speed than the other. When the grooves are comparatively far apart, the bran and the germs are removed with the slightest possible damage, and very little flour is mixed with the grist. The grist is then ground to fine flour in a similar mill provided with very fine grooves.
—J. F. B.

Phospho-organic Compound contained in most Vegetable Foodstuffs; Process for Preparing the Assimilable ——. S. Posternak. First addition, dated Oct. 24, 1903, to Fr. Pat. 318,311, Feb. 2, 1902.

Purifying Water; [Electrical] Method of ——. V. M. George, Youngstown. U.S. Pat. 761,044, May 24, 1904.

The water or other liquid to be purified is forced, under pressure, into a receptacle and there acted on by "energised" electrodes of different metals. Then, either at once or after passing through charcoal and a separator, it is subjected to the action of ozone, which is produced by subjecting the liquid to an electric current of sufficient voltage.—W. H. C.

French Patent.

Water and Effluents; Purification of ——. E. Serpin and A. Bertrand. Fr. Pat. 338,586, Dec. 31, 1903.

Aluminium sulphate is automatically added to the water to be purified. The treated water is then passed over a bed of alumina or bauxite and finally through a sand filter.
—W. P. S.

(*C.*)—DISINFECTANTS.

Disinfectants; Testing the Action of Soluble —— on Micro-organisms. H. Zikes. Allgem. Zeits. Bierbrau., 1904, **32**, 10—13.

Vigorous cells or germs of the micro-organism unde examination are placed in a suitable nutrient medium, th culture being afterwards shaken up with a small quantit of calcined talc powder in a test tube and centrifugalised. The tubes used for this purpose are provided with a loos capsule forming the bottom of the tube, and attached to the body of the latter by rubber tubing, so that the whole o the sediment can be easily separated from the liquid. Th capsule is next attached to a second tube and the sediment shaken up with sterilised water and centrifugalised, afte which it is connected to a third tube containing the antiseptic. The duration of exposure to the latter is 5—2 minutes; and the mixture is again centrifugalised, th sediment being afterwards washed and transferred to suitable nutrient medium. In the case of direct application to wort and beer, the antiseptic is added to the inita culture, and after a single passage through the centrifuga machine the deposit is washed and placed in a nutrien solution. The powdered talc does not exert any detectabl surface attraction on reagents or antiseptics, so no loca concentration of the latter is produced. The advantage claimed for the method are that the antiseptic can b brought and left in contact with the levigated organism o culture for a given time, in a manner that is not open t any objection; nearly the whole of the germs tested ca be returned to the medium for further investigation, afte having been freed from the antiseptic by repeated washings and, with rapid working and the usual precautions against infection, the operation can be carried through without lo of sterility.—C. S.

French Patent.

XIX.—PAPER, PASTEBOARD, Etc.

Writing Papers; Penetration of the Ink through ——. P. Klemm. Woch. f. Papierfab. 1904, **35**, 1620—1621.

Referring to the article on the transparency of German 'normal" writing papers (this J., 1904, 500), the author emarks that the appearance of the ink on the back of the aper does not depend only on the transparency. It epends to a great extent on the resistance of the paper to he action of the ink, and consequently on the hardness of be sizing and on the composition of the ink. The deternination of the opacity of a paper does not, therefore, by tself afford any guide as to its behaviour when written pon. The same remarks apply equally to printing papers, hich are frequently valued according to their opacity. Vith a bad printing ink an excess of oil may penetrate the aper beneath the impression, thereby destroying all its riginal opacity. Writing ink penetrates all papers to a reater or less extent. In order to test this, sections are ut through the writing by means of a razor, the paper eing clamped in a split cork. When these sections are ounted in oil and examined under a microscope it will found that only in very rare cases is the ink confined to e uppermost layer of fibres, and that it generally penetates to the second and frequently to the third or fourth yers. This examination, besides showing the extent of e impregnation of the fibres with the colouring matter due capillary penetration, affords a measure of the secondary emical reactions between the ink and the paper, as shown changes in the coloration of the ink in the deeper layers fibres.—J. F. B.

gnified Fibres [Mechanical Wood Pulp] in Paper; Colorimetric Determination of ——. E. Valenta. XXIII., page 686.

English Patents.

per Pulp; Apparatus for Straining ——. F. G. Busbridge, West Malling. Eng. Pat. 25,075, Nov. 17, 1903.

E strainer, the walls of which are provided with a series suitable slits, is situated in a vat containing the crude p. A vertical reciprocating motion is imparted to the ainer, so that the liquid enters it in the upward stroke l tends to be expelled in the downward stroke, thereby shing off any knots which may clog the slits. The ined pulp is withdrawn from inside the strainer by ans of a pipe situated below the level of the liquid, ich pipe partakes of the reciprocating motion of the ainer and communicates with the outflow by means of oint of flexible material. The draw-off pipe is surnded by a wider pipe which extends above the surface the liquid and prevents any floating impurities from ching the mouth of the draw-off pipe.—J. F. B.

terproofing of Materials such as Tissues, Fabrics, Paper, Leather, and Cords. S. Serkowski. Eng. Pat. ,433, April 12, 1904. V., page 659.

uid Refuse Discharged from Distilleries, Breweries, aper Works, and other Places; Purification or Filtraon of ——. T. T. Street and H. Street. Eng. Pat. 461, April 13, 1904. XVIII. B., page 676.

United States Patents.

Paper Machine. R. S. Case, Unionville. U.S. Pat. 759,862, May 17, 1904.

I a paper machine of the multiple-cylindrical type each n ing-cylinder, immersed in a separate vat, is composed o a number of independent, separate, annular, pulpg ering sections. The width of these sections increases p gressively from the first making-cylinder to the last, a they are so registered that the webs from each s essive cylinder-section are couched together on a felt, and form a series of independent, bevel-edged strips, in which condition they are finished in the usual way. —J. F. B.

French Patent.

Paper Pulp; Manufacture of —— *from Fibrous Tubers and Bulbs.* A. Badoil and J. E. Valadon. Fr. Pat. 338,177, Nov. 28, 1903.

It is proposed to utilise the bulbs of the daffodil, which grow to a large size in Corsica and Algeria, for the manufacture of paper pulp. The bulbs are harvested in the third year, when the sap has descended, the sugars are first extracted by cold water and converted into alcohol, the resin is separated in a second operation at a higher temperature, and the residue is converted into paper pulp. —J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Cerium Metals; New Method of Fractionation of Compounds of the ——. H. Lacombe. Bull. Soc. Chim., 1904, **31**, 570—573.

Welsbach's method of fractionating the double earth-ammonium nitrates fails when little or no lanthanum is present, as the salts do not crystallise, and Demarçay's method (this J., 1900, 462) of fractionating the double earth-magnesium nitrates from strong nitric acid solution, whilst it affords an excellent separation of the cerium earths proper from those of the yttrium earths lying between yttrium and samarium, does not afford a good separation of the constituents of didymium. The author finds that the earth-manganese nitrates of the type $2Di(NO_3)_3.3Mn(NO_3)_2.24H_2O$, afford an excellent means of separation, especially with earths rich either in neodymium or in praseodymium. The solvent is nitric acid of sp. gr. 1·3, and the mother liquors at each operation should be much less in quantity than the crystals. If any manganese peroxide should form, a few drops of fuming nitric acid will destroy it. To prevent supersaturation, seed with a crystal of the isomorphous bismuth manganese nitrate (this J., 1903, 1365).

Earths Rich in Neodymium.—Three fractions were obtained in two days; the last mother liquors were almost pure samarium, containing a mere trace of neodymium. After eliminating the samarium, eight successive fractions were obtained; the first six showed plainly the presence of praseodymium, but the seventh contained only a trace, and the eighth was spectroscopically pure neodymium.

Earths Rich in Praseodymium.—Ten fractions were obtained, the earlier being praseodymium without neodymium, the later neodymium without praseodymium. By successive working up of these fractions, almost the whole of the praseodymium and neodymium were separated, the ultimate intermediate portion being very small in amount. The small amount of lanthanum present accumulated in the early fractions.—J. T. D.

Basic Zirconium Sulphate. O. Hauser. Ber., 1904, **37**, 2021—2026.

The descriptions in chemical literature of basic zirconium sulphates are conflicting. The author attributes this to the varying (and unrecorded) physical conditions under which different authors have worked. He finds that water at 10° C. gradually dissolves anhydrous normal zirconium sulphate, converting it into $Zr(SO_4)_2.4H_2O$; and 100 parts of the saturated solution contain 59·3 parts of this salt. If this solution be diluted with water it remains clear up to a certain point, but beyond this undergoes hydrolytic dissociation with formation of $4ZrO_2.3SO_3.14H_2O$. This salt begins to separate after 4—5 hours, and its separation is complete when about 75 per cent. of the zirconium present is deposited, after about 30 hours. At 70° C. practically no such separation occurs, and at the ordinary temperature it takes place exceedingly slowly. The precipitated salt is crystalline (microscopic needles) and is of absolutely constant composition.—J. T. D.

Menthol; Products of the Reaction of Formaldehyde on ——. E. Wedekind and K. Greimer. Z. angew. Chem., 1904, **17**, 705—711.

Four products have been described as resulting from the reaction of menthol with formaldehyde :—(1) Methylene-dimenthyl ether, $C_{10}H_{19}.O.CH_2.O.C_{10}H_{19}$; (2) Chloromethyl-menthyl ether, $C_{10}H_{19}.O.CH_2Cl$; (3) Compounds produced by dissolving formaldehyde or trioxymethylene in liquefied menthol; (4) The compound $C_{10}H_{19}.O.CH_2OH$, said to be formed by heating menthol and aqueous formaldehyde solution with hydrochloric acid. The first is a well-defined and very stable substance, crystalline, melting at 56°—57° C.; and the second equally well defined though less stable, a liquid which boils at 160°—162° C. under 16 mm. pressure, and is readily decomposed by water, yielding menthol, formaldehyde, and hydrochloric acid. The authors find that the compounds mentioned under (3) are mere mixtures, and they have failed by any process to prepare the substance (4).—J. T. D.

Artemisia herba alba; Essential Oil of ——. E. Grimal. Bull. Soc. Chim., 1904, **31**, 694—697.

The fresh non-flowering herb of *Artemisia herba alba*, which is very common in Algeria, yielded 0·3 per cent. of a yellowish-green essential oil, having a pleasant aromatic odour and a powerful, slightly bitter, camphoraceous taste. It had the following characters :—Solubility, in 60 per cent. alcohol, 1:25; in 70 per cent. alcohol, 1:2—1:2·5, more alcohol causing a slight turbidity; very soluble in 80 per cent. alcohol. Sp. gr. 0·9456; $a_D = -15°\ 30'$; n_D 1·47274; acid value, 6·46; ester value, 89·23. It contained 31·15 per cent. of esters calculated as $CH_3.COOC_{10}H_{17}$; 12·65 of free alcohols, as $C_{10}H_{18}O$; *l* camphene, *d*-camphene, cineol, with esters of caprylic and capric acids.—J. O. B.

Apopin [Essential] Oil, Shu-yu; Further Notes on ——. Keimazu. J. Pharm. Soc. Jap., 1903 [250]; through Schimmel's Report, May 1904, 10—12.

Apopin oil is found to contain formaldehyde, pinene, and a new sesquiterpene alcohol, $C_{10}H_{18}O$, apopinol, in addition to the constituents previously recorded (this J., 1903, 1306). The presence of formaldehyde, which occurs in apopin oil in considerable quantity, and is not met with in true camphor oil, which contains only acetic aldehyde, will serve as a ready means of distinguishing the two oils.

—J. O. B.

Oil of Camphor; Presence of Borneol in Essential ——. Schimmel's Report, May 1904, 17.

Borneol has been isolated from the fraction of camphor oil boiling between 210° and 222° C.—J. O. B.

Cananga Flowers; Essential Oil of ——, *from Bangkok.* Schimmel's Report, May 1904, 18.

The oil distilled from the fresh and dried flowers of Cananga cultivated at Bangkok had the following characters:—Sp. gr. at 15° C., 0·920; $a_D = -51°\ 40'$; acid value, 1·82; ester value, 34·17. The oil was insoluble in 10 volumes of 90 per cent. alcohol, but dissolved in half a volume of 95 per cent. alcohol, separating, however, on the addition of more of the solvent.—J. O. B.

Acacia Farnesiana; Essential Oil of the Flowers of —— [*Oil of Cassie Flowers*]. Schimmel's Report, May 1904, 23—25.

Para-cresol has been recognised as a constituent of essential oil of cassie flowers, and the presence of anisic aldehyde has been confirmed.—J. O. B.

Cinnamon [Bark]; Essential Oil of ——. Schimmel's Report, May 1904, 25—26.

Stress is laid on the fact that cinnamic aldehyde is not the most important constituent of cinnamon bark oil; the characteristic aroma being due to the non-aldehydic constituents of the oil. Specimens of so-called cinnamon oil have lately occurred in commerce which contained from 80—85 per cent. of aldehyde and were obviously adulterated with cassia oil or cinnamic aldehyde. The average percen age of aldehyde in genuine cinnamon bark oil of know origin lies between 70 and 75 per cent., rarely fluctuatin from 65—77 per cent. In the genuine bark oil the amou of eugenol does not exceed 4—8 per cent.; any great proportion indicates admixture with the cheaper cinnamo leaf oil. The limit of specific gravity required by the Britis Pharmacopœia, 1·025—1·035, is found to be too high. O several occasions pure oils have been distilled, of whic the specific gravity fell below these figures. Low specit gravity coupled with freedom from excess of eugenol and cinnamic aldehyde indicate purity rather than sophisticatio

—J. O. B.

Cypress; Essential Oil of ——. Schimmel's Repor May 1904, 36—42.

In addition to *d*-pinene and cypress camphor, which ha been previously recorded, the following constituents a found in cypress oil. Furfural; *d*-camphene; *d*-sylvestren cymene; two ketones, as yet unidentified; an alcoh probably sabinol; a terpene alcohol; terpineol esters acetic and valeric acids, but no free terpineol. The are present in approximately the following proportions :- Terpenes, chiefly camphene and sylvestrene, 65 per cent cymene, 1—2 per cent.; alcohols, about 8 per cent esters, chiefly of terpineol, about 8 per cent; ketones, le than 1 per cent.; cypress camphor, 15 per cent.—J. O. B.

Eucalyptus Globulus; New Sesquiterpene Alcohol in t Essential Oil of ——. Schimmel's Report, May 1904, 5

In the last runnings of a distillation of the oil of *Eucalypt globulus* a crystalline body was separated in the for of almost odourless needles, m. pt. 88·5; b. pt. 283° C. $a_D = -35°\ 29'$. It is a sesquiterpene alcohol, $C_{15}H_{25}O$ By dehydration it yielded two isomeric sesquiterpene $C_{15}H_{24}$, one lævo-rotatory, $a_D = -55°\ 48'$, the other dextr rotatory, $a_D = +58°\ 10'$. The former boils at 247°—248° C the latter at 265·5°—266° C.—J. O. B.

Geranium; Essential Oil of Réunion ——. Schimme Report, May 1904, 55—56.

Amyl alcohol, pinene, phellandrene, and linalool have bee recognised as constituents of geranium oil.—J. O. B.

Ginger-grass; Essential Oil of ——. Schimmel's Repor May 1904, 56.

The examination of ginger-grass oil showed the presen of a large proportion of alcohols accompanied by a sma amount of esters. A little phellandrene was detected. T alcohols consisted of geraniol and another unidentifi alcohol having a linalool-like odour, and forming an acet with the odour of spearmint.—J. O. B.

Laurel [Laurus nobilis] Leaves; Essential Oil of —— B. Molle. Schimmel's Report, May 1904, 59.

From the essential oil of the leaves of *Laurus nobi* dissolved in ether, 2 per cent. sodium hydroxide solut removed free acetic, iso-valeric, and iso-butyric aci Eugenol was present to the extent of 1·7 per cent. in free state and 0·4 per cent. as esters. No aldehydes ketones were found. After removing the free acids a phenols, the esters present were saponified with alcoho potash, and the acids liberated from the resulting salts w identified as acetic and probably valeric and caproic aci as well as a trace of a monobasic solid acid, $C_{10}H_{14}$ m. pt. 146°—147° C. This is probably not present in oil, but may be formed from pinene by the action alcoholic potash. Cineol was present to the extent of ab 50 per cent. No methyl-chavicol could be isolated. T higher boiling fraction, 212°—230° C., contained gera and terpinene was obtained by dehydration, also terp hydrate by the action of dilute sulphuric acid. The high boiling fractions probably contain sesquiterpenes and ses terpene alcohols.—J. O. B.

Patchouli Leaves; Constituents of Essential Oil of — Schimmel's Report, May 1904, 68—71.

The oil examined, distilled at Miltitz, had the follow characters:—Sp. gr. at 15° C., 0·9769; $a_D = -55$ 4 acid value, 2·2; saponification value, 4·2; saponification value after acetylating, 15·4; one volume and over, of 90 per cent. alcohol gave a clear solution with the oil.

About 97 per cent. of normal patchouli oil consists of bodies of little or no odour value. Of this 40—45 per cent. distilled between 260°—270° C., and consisted mainly of one or more sesquiterpenes. The first fraction, b. pt. 228°—240° C., had an extremely unpleasant odour, not resembling that of patchouli. By extracting the odorous bodies with 70 per cent. alcohol, and distilling off the solvent, the following constituents were identified:—Benzaldehyde, eugenol, cinnamic aldehyde, a terpene alcohol, a ketone with a caraway-like odour, which formed a semi-carbazone, m. pt. 134°—135° C. Another compound is also formed with a higher m. pt., 246°—247° C., which may be Thiele's hydrazodicarbonamide, $NH_2CONH.NH.CONH_2$. A basic body is present in all the fractions of the oil, removed by shaking out with sulphuric acid; this body has a peculiar and characteristic odour. It is also found in the water of distillation. From the results of fractionation *in vacuo*, it appears that this base may be separated into two distinct bodies, one boiling between 80° and 130° C., the other from 135° to 140° C. under 3 to 4 mm. pressure. Patchouli lcohol, which is probably the major constituent of the oil, ccurs in the fraction boiling above 140° C. under 8 mm. ressure. It melts at 56° C. when repeatedly recrystallised rom light pretroleum spirit. Patchoulene obtained by he dehydration of this alcohol is a colourless liquid with a edar-like odour; b. pt., 255°—256° C.; $\alpha_D = -36° 52'$. It ave no solid derivatives; when distilled over sodium it had he sp. gr. 0·9334.—J. O. B.

Pimento; Constituents of Essential Oil of ——. Schimmel's Report, May 1904, 75—77.

HE following constituents have been identified in pimento il:—Cineol, phellandrene, caryophyllene, methyl-eugenol, ugenol, palmitic acid, with, probably, small amounts of erpene alcohols.—J. O. B.

bies Pectinata; Occurrence of Lauric Aldehyde in Essential Oil of ——. Schimmel's Report, May 1904, 77—79.

AURIC aldehyde has been isolated as the bisulphite ompound from the fractions of the oil of *Abies pectinata* oiling above 82° C. under 5 mm. pressure. The amount esent was only 0·3 per cent., but it has an important aring on the odour of the oil. A second aldehyde is also esent, probably decylic aldehyde.—J. O. B.

alyptranthes paniculata; Essential Oil of —— ("*May Oil*"). Schimmel's Report, May 1904, 95.

HE oil, derived from Porto Rico, resembles lemongrass oil character; sp. gr. 0·9509; $\alpha_D = -1° 52'$; readily soluble 80 per cent., but sparingly in 70 per cent. alcohol. contains 62·5 per cent. of citral.—J. O. B.

Mentha Citrata; Essential Oil of ——. Schimmel's Report, May 1904, 95.

entha citrata, known in Florida as "bergamot mint," lds about 0·2 per cent. of oil from the young, not flower-; but fresh plants. The oil had a pleasant odour, more embling lavender than bergamot. It had the following racters:—sp. gr. at 15° C., 0·8826; $\alpha_D = -5° 35'$; ester ue, 31·28, equivalent to 10·95 per cent. of linalyl acetate. e frozen leaves of the same plant gave about the same ld of oil, but this was much richer in esters, having the r value of 111·28, equivalent to 38·95 per cent. of lyl acetate.—J. O. B.

Ambrosia artemisiæfolia; Essential Oil of ——. Schimmel's Report, May 1904, 96.

NG plants, not in flower, yielded 0·15 per cent. of a en, aromatic oil; sp. gr. at 15° C., 0·876; $\alpha_D = -1°$; ester ue, 7·94. It gives a clear solution, with an equal volume 0 per cent. alcohol, which becomes cloudy with more ent.—J. O. B.

Hyptis spicata; Essential Oil of ——. Schimmel's Report, May 1904, 96.

Hyptis spicata, a labiate, common in Florida, yields 0·005 per cent. of a bright yellow oil with a faint mint-like odour. Sp. gr. at 15° C., 0·915; $\alpha_D = -27° 25'$; acid value, 2·17; ester value, 4·35. It is insoluble in 10 volumes of 80 per cent. alcohol. The oil probably contains small quantities of menthone or pulegone.—J. O. B.

Erythroxylon Monogynum; Essential Oil of the Wood of ——. Schimmel's Report, May 1904, 97.

THE wood of *Erythraxylon monogynum* gave 2·56 per cent. of a viscous crystalline essential oil with a pleasant odour resembling that of guaiacum-wood oil. It was lighter than water; m. pt. 42°—45° C.; acid value, 6·77; ester value, 1·56; ester value after acetylation, 131. Soluble with slight turbidity in an equal volume of 90 per cent. alcohol, and completely soluble in a larger volume. The crystalline alcohol, $C_{20}H_{32}O$, was isolated from the fraction boiling at 212°—216° C. under 8 mm. pressure by freezing out of solution in light petroleum spirit. It occurs in brilliant needles; m. pt. 117°—118° C. The acetic ester, recrystallised from alcohol, had the m. pt. 72°—73° C.

French Patents.

Cream of Tartar, Tartaric and Citric Acids, and Secondary Products; Manufacture of ——. L. Faucheux and A. J. Boissière. Fr. Pat. 338,735, April 14, 1903.

Wine lees, crude tartar, &c., are subjected to a preliminary slight degree of external roasting or scorching ("torréfaction") by means of hot gases, to decompose organic matter other than tartrates, and to render the iron and aluminium salts and phosphates insoluble; the product is converted into potassium bitartrate and washed with hydrochloric or sulphuric acid, and the solution filtered, decolorised, and treated with sodium carbonate; the mother liquors are precipitated with lime and the sodium chloride or sulphate recovered by evaporation. Tartaric acid is made from the roasted raw material by treatment with hydrochloric acid; calcium tartrate is precipitated from the solution, and is decomposed by means of sulphuric acid. Citric acid is produced in a similar manner by treating lemon juice with lime or calcium carbonate. In each case the crude tartrate or citrate as prepared may be purified by scorching or slight roasting, preferably with addition of small amounts of lime.—T. F. B.

Borneol, Isoborneol, and Camphor; Process for Preparing ——. Chem. Fabr. von Heyden, Act.-Ges. Fr. Pat. 339,504, Jan. 11, 1904.

See Eng. Pat. 26,785 of 1903; this J., 1904, 204.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographs in Colours; New Method of Obtaining ——. A. and L. Lumière. Comptes rend., 1904, **138**, 1337—1338.

Three equal quantities of particles of potato starch of 0·015 to 0·020 mm. diameter are coloured orange-red, green, and violet, and are then thoroughly mixed together, and spread in a thin layer by means of a brush on a glass plate coated with wax; the interstices between the particles are filled with a fine black powder, such as pulverised wood charcoal. The whole is now coated with a varnish having approximately the same refractive index as that of the starch, and finally a panchromatic silver bromide emulsion is applied. The plate thus prepared is exposed, with the film side away from the light, in the usual way, and developed; by reversing the image (dissolving out the reduced silver) and re-developing the plate, transparencies the correct colours are obtained.—T. F. B.

English Patent.

Intaglio Printing Forms on Cylindrical Surfaces; Art of Producing ——. H. H. Lake, London. From G. F. & J. W. McIndoe, Boston. Eng. Pat. 4206, Feb. 19, 1904.

The textile or other flexible material, a representation of which is required, is coated with size or other glutinous material and dried by being subjected to heat and pressure; a thin coating of some pasty material which is impervious to light (*e.g.*, printers' ink) is applied to the fabric, and transferred to the prepared cylinder, which is then exposed to light: the light-resisting coating is washed off by means of a suitable solvent, and the soluble portion of the sensitive coating is removed by washing; the cylinder is now heated "to a sufficient degree to render the remaining portions of the sensitised material acid-resisting," and etched, and the remainder of the sensitive material removed by some solvent. Compare Eng. Pat. 4207 of 1904; this J., 1904, 487.
—T. F. B.

United States Patent.

Stripping-film for Photographs; Positive ——. J. E. Thornton and C. F. S. Rothwell, Manchester. U.S. Pat. 760,585, May 24, 1904.

See Eng. Pat. 17,165 of 1899; this J., 1900, 68.—T. F. B.

French Patents.

Photographic Plates, &c.; Sensitive ——. E. F. Beckwith and T. A. Carten. Fr. Pat. 338,499, Dec. 15, 1903.

See Eng. Pat. 27,059 of 1903; this J., 1904, 268.—T. F. B.

[Photographic] Developer; Acid ——. G. Balagny. Fr. Pat. 338,650, Dec. 2, 1903.

The exclusive use of acid solutions of developers of the aromatic series is claimed. The following solution is an example of such an acid developer:—Diaminophenol, 1 grm.; bisulphite solution, 10—15 cc.; potassium bromide (10 per cent. solution), 5 c.c.; water, 150 c.c. The bisulphite solution consists of anhydrous sodium sulphite, 25 grms.; sodium bisulphite ("commercial, 35°"), 100 c.c.; water, 100 c.c. The image generally appears in four or five minutes, development being complete in 20 to 25 minutes. The use of this solution dispenses with the necessity for a ruby light after the plate is immersed, and softer results are said to be obtained than when alkaline solutions are employed.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives; New ——. A. Mikolajczak. Glückauf, 1904, **40**, 630. Chem.-Zeit., 1904, **28**, Rep., 174—175.

The freezing of explosives prepared with nitroglycerin forms a great disadvantage. The author states that he has prepared mono- and dinitroglycerin, and believes that the latter compound will form a valuable basis for explosives, free from this disadvantage. Dinitroglycerin is stated to be an odourless and unfreezable oil, less sensitive to percussion, friction, and increase of temperature, and possessing a greater solvent power for collodion cotton than ordinary nitroglycerin. It can thus be used for the preparation of explosives of high stability, which will maintain their plastic nature even in winter. The explosives can be mixed with those prepared from ordinary nitroglycerin, and are not inferior in power to the latter.—A. S.

English Patents.

Explosive Mixture. A. Fischer, London. Eng. Pat. 10,789, May 12, 1903.

Equal parts of di- or trinitrobenzene, or their chlorine derivatives, and an alkali salt of trinitrophenol (picric acid) are made into a paste with a solution of paraffin, and the resulting mass incorporated in the proportion of 5 to 20 per cent. with a mixture consisting of an alkali nitrate (preferably 80 parts), sulphur (preferably 4 parts), and a suitable form of carbon (preferably 16 parts).—C. A. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Viscosity of Pitch-like Substances. F. T. Trouton and E. S. Andrews. Phil. Mag., 1904, **7**, 347—355.

The authors use a torsion method for determining the viscosity of pitch-like substances. A constant torque is applied to a cylindrical bar of the material, and the relative motions of the ends are observed, from which and from the dimensions of the cylinder the viscosity is calculated. A shaft turning freely on anti-friction wheels has a pulley attached, from which is hung a weight for the purpose of applying the constant torque. The ends of the cylindrical bar of the material to be tested, are made square and tapering, and somewhat thicker than the cylinder itself. One end is fitted tightly into a square socket carried by the shaft, and the other into a similar but fixed socket. The cylinder can be surrounded by a jacket, and determinations made at different temperatures. The rate of rotation is observed by means of a divided circular disc carried on the shaft. It was assumed that any two planes in the body, lying at right angles to the axis of the cylinder, move over each other about the common axis, remaining plane all the while. The following formula was deduced for the coefficient of viscosity: $\mu = \frac{2T}{\pi U R^4}$, where T is the torque applied, U the relative angular velocity per cm. of length of the cylinder, and R the radius of the cylinder.

Pitch.—Tests with a material sold as "British pitch" showed that whilst the assumption that the rate of rotation is proportional to the torque applied, is sufficient for practical purposes, the phenomena are, in reality, more complicated. For small torques the rate of rotation is relatively less than for larger ones, but above a certain value the curve develops into a straight line. On first applying the torque there is a rapid flow or movement, which gradually diminishes and finally reaches a "steady" stage. If a white line be painted along the specimen before twisting, a spiral line of many twists is ultimately obtained. It was found that the coefficient of viscosity of bodies, such as pitch, is a function of the time, the velocity of flow for a given stress diminishing from its initial value down to a constant quantity. On removing the stress there is a flow back in the opposite direction, which gradually diminishes to zero with time. The strain energy thus shown to exist in a viscous substance when the latter is flowing, will disappear in course of time without there being any movement of the substance as a whole. The rate of dissipation of this strain energy can be determined by gradually diminishing the torque until a weight is obtained which will just suffice to hold the cylinder at rest; this weight must be continually diminished, and finally reaches zero. The fact that the strain energy can disappear without any deformation of the viscous body occurring, enables a distinction to be drawn between a viscous and a plastic substance, since when the latter is held under constant deformation beyond its elastic limit, the strain energy it then contains does not sensibly decrease with time.

Soda Glass.—The tests were made with a tube in which as inserted a thermo-electric junction. The tube was rrounded by a thick-walled iron pipe heated by a row of nall gas-jets. In this case R^4 in the formula for calculating the coefficient of viscosity must be replaced by $R_1^4 - R_2^4$), where R_1 and R_2 are the external and internal dii respectively, of the glass tube.

Shoemakers' wax was tested both by the authors' method d by Stokes' method (rate of sinking of a spherical body the material). A steel bicycle ball was used as the nere, and its position was observed from time to time by ans of X-rays. The value obtained for the coefficient of cosity by Stokes' method varied from 6 × 10^6 to 23 × 10^6, mean value being about 10 × 10^6, *i.e.*, of the same ler of magnitude as the value obtained by the authors' thod (see table below). The authors' result is probably low, because the sagging of the rod was so great that the que could not be applied long enough for the "steady" ge to be attained.

Modelling clay, when examined by the torsion method, aved quite differently to the other substances tested. ien subjected to a given torque, it moved slowly up to a en position and stopped there. On removing the stress, nade an immediate partial recovery to a point where it nanently remained.

he results obtained are given in the following table:—

Substance.	Temperature.	Coefficient of Viscosity.
	° C.	
P h	0	5·1 × 10
	8	9·9 × 10
	15	1·3 × 10
S glass	575	1·1 × 10
"	660	2·3 × 10
"	710	4.5 × 10^{10}
S im stearate	8	5·0 × 10
S nakers' wax	8	4·7 × 10

—A. S.

Pyrometer; New Form of ——. C. Féry. Bull. Soc. Chim., 1904, **31**, 701—702.

A TELESCOPE, the field of view of which is subdivided by means of two very fine wires (the "reticule"), one of iron, the other of "*constantan*," an alloy of copper and nickel, receives the radiations of the source of heat towards which it is directed. The point of intersection of the threads of the reticule, which constitutes one of the junctions of the thermo-electric couple thus formed, becomes heated, and the current which is set up deflects the needle of a dial galvanometer, which may be made registering. The known laws of radiation show that if the objective be composed of slightly absorbent material, such as rocksalt or a fluoride, the deviation obtained is proportional to the absolute temperature (ordinary temperature + 273 C.) of the heated body.

In the case of industrial pyrometers, the objectives of which are of glass, graduations are made by comparison with a standard pyrometer provided with a fluoride objective. The indications obtained are independent of the distance of the heated body and of its dimensions.—J. O. B.

Dephlegmator; New ——, *for Fractional Distillation and as a Reflux Condenser.* J. Houben. Chem.-Zeit., 1904, **28**, 525–527.

THE apparatus is a modification of that proposed by Winssinger (Ber., 1883, **16**, 2640). The distillation flask (see Fig. 1) has two necks, the shorter of which is fitted with a thermometer and carries a side tube for the condenser. Through a stopper in the longer neck of the flask passes the aluminium mantle-tube A, which is widened just above the stopper, and inside the widened portion is provided with spring clips which hold in position the brass cooler B. The latter consists of a tube open at the bottom, enclosed in an outer tube closed at the bottom, and provided with a side outlet-tube for the cooling water. When it is desired to distil under reduced pressure, the flask has a small tubulus through which passes the capillary tube. On starting the apparatus, the cooler B is pushed down to the bottom of the mantle-tube A, and the liquid in the flask is heated to vigorous boiling. The cooler is then gradually

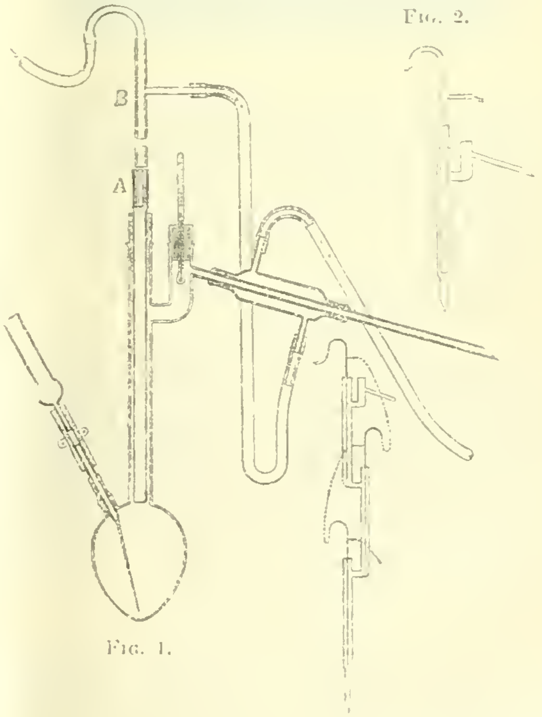

FIG. 1.

FIG. 2.

FIG. 3.

raised until the distillate passes over at the desired rate. The dephlegmator can also be fitted into a suitable glass still-head, as shown in Fig. 2, and can then be used with an ordinary short-necked flask. In Fig. 3 a combination of three dephlegmators is shown. The author has found the still-head shown in Fig. 4 especially suitable for distillation under reduced pressure. It consists of a bayonet-shaped tube with two side tubes, the upper one for the thermometer, and the lower one for the capillary tube. In order to prevent, as far as possible, contact of the vapour with the rubber stopper, the neck of the distillation flask, close to the bulb, is constricted, and the tube of the still-head is pushed down to the constricted part. The results of test experiments are given, showing the efficiency of the dephlegmator.—A. S.

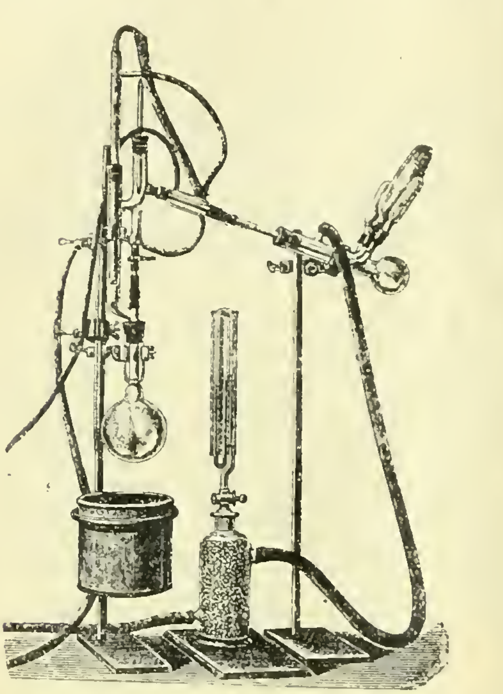

Fig. 4.

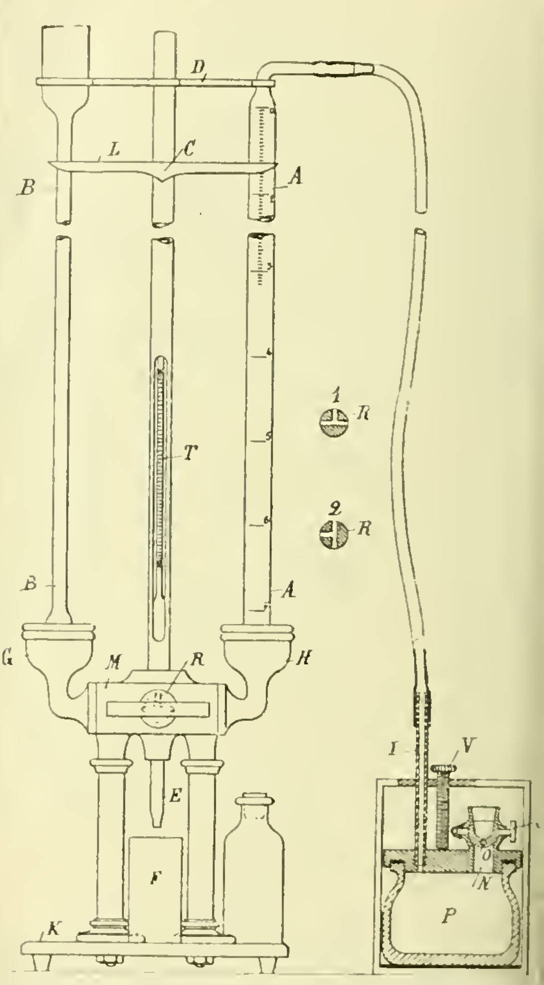
Paranitrophenol as Indicator. L. Spiegel. Z. angew. Chem., 1904, **17**, 715–716.

The author maintains, against the criticims of Lunge, his former statements (this J., 1900, 1040) as to the superiority of paranitrophenol to methyl orange as an indicator in alkalimetry, quoting experiments to show that it is equally insensitive to carbon dioxide, and as delicate in indicating excess of acid or alkali, in whichever direction the titration is effected. He attributes the difference between Lunge's results and his own to the fact that he uses a 2—3 per cent. solution of the indicator, whilst Lunge used one containing only 0·1—0·2 per cent., two or three drops in each case being added to 70 c.c. of the liquid to be titrated.—J. T. D.

French Patent.

Acidimeter; Universal ——. Soc. L. Legrand et Lafaverge. Fr. Pat. 338,634, Dec. 5, 1903.

The two-limbed tube, of which one limb, B, has a funnel-shaped top, and the other is graduated, and connected by a flexible tube to the reservoir P, has at the bottom of the bend, a 3-way cock R, which is so turned that both arms communicate, whilst mercury is poured into the arm B, until it rises in both arms to the height of the zero point in arm A. A measured quantity, such as 10 c.c., of the oil, vinegar, wine, or other acid liquid of which the acidity is to be determined, is then placed in the reservoir P, and the cover is screwed down air-tight. An excess of sodium-hydrogen carbonate is put into the cup, and, on turning the spherical tap J, falls into the cistern. The tap is then closed, and the reservoir is shaken. The carbon dioxide generated depresses the mercury in the limb, A, the mercury rising in the opposite limb. The tap R is then turned to allow mercury to escape through the tube E into the



receptacle F until equilibrium is established, the tap bein then closed for that outlet. This process is repeated a often as necessary until equilibrium is permanent, the leve of the mercury in the two limbs being shown by means o the sliding pointer C, carried by the centrally-placed meta tube enclosing the thermometer T. The temperature bein read, as well as the height of the mercury in the limb A the usual corrections and calculations are made by the a of tables annexed to the apparatus.—E. S.

INORGANIC—QUALITATIVE.

Sodium Picrate; Action of —— on Sodium Carbona Solutions. [Detection of Sodium Carbonate.] (Reichard. Z. anal. Chem., 1904, **43**, 269—275.

Normal sodium carbonate is the only sodium sa possessing the property of precipitating sodium picrate fro its solutions. Even quite dilute solutions (1 per cen of sodium picrate are rendered turbid by sodium carbona and a 10 per cent. solution solidifies to a jelly. The pr cipitation is always gradual and occurs also in solutio containing other salts. Sodium carbonate may, in this wa be detected in solutions in which other sodium salts a also present; the reaction may farther be used to indica the presence of sodium picrate in a liquid.—T. H. P.

Nickel Salts; Action of Alkali-metal Nitrites on ——. C. Reichard. Chem.-Zeit. 1904, **28**, 479—480.

It is well known that the separation of cobalt from nickel by precipitation with potassium nitrite in acetic acid solution cannot be accurately carried out in presence of alkaline earth compounds, as triple nitrites of nickel, potassium, and barium, strontium or calcium are precipitated with the cobalt compound. The addition, to a mixture of nickel salt and potassium nitrite, of the oxide, hydroxide, or peroxide of the alkaline earth metal, does not cause the formation of this compound, but precipitates nickel hydroxide (with evolution of oxygen when the peroxide is used). If the nitrite be substituted for the oxide, however, the triple salt precipitates after a short time. If the acetic acid be added before the nitrite no precipitation occurs. The precipitate dissolves in hot water to a bright green solution, and on cooling is deposited as a green powder, which slowly turns yellow. The calcium compound is more soluble than those of barium and strontium, and comes down much more slowly. No similar precipitates were formed by salts of magnesium, zinc, or cadmium, but beryllium salts formed a precipitate not yet investigated, perhaps a nickel beryllium potassium nitrite. If sodium nitrite be used instead of the potassium salt, in no case is a precipitate formed; even a mixture of sodium nitrite with another potassium salt is ineffectual. Potassium nitrate and a reducing agent can be used, but the reduction is apt to go too far. Like the double cobalt salt, these triple nitrites are all much less soluble in potassium nitrite solution than in water.—J. T. D.

Portland Cement and Blast-Furnace Slag; Action of Acetic Acid on ——. F. Hart. Thonind.-Zeit., 1904, **28**, 809.

To distinguish between Portland cement and blast-furnace slag, the following test is proposed: One grm. of the finely-powdered sample is well shaken up for 10 minutes in a corked flask with 100 c.c. of a 10 per cent. solution of acetic acid in alcohol. On allowing the undissolved residue to subside, the light-coloured, vitreous granules of blast-furnace slag will be readily distinguishable from the flocculent deposit of silica and the dark granules of undissolved particles of Portland cement. With a little experience, 5 per cent. of the former can be detected in mixtures.—C. S.

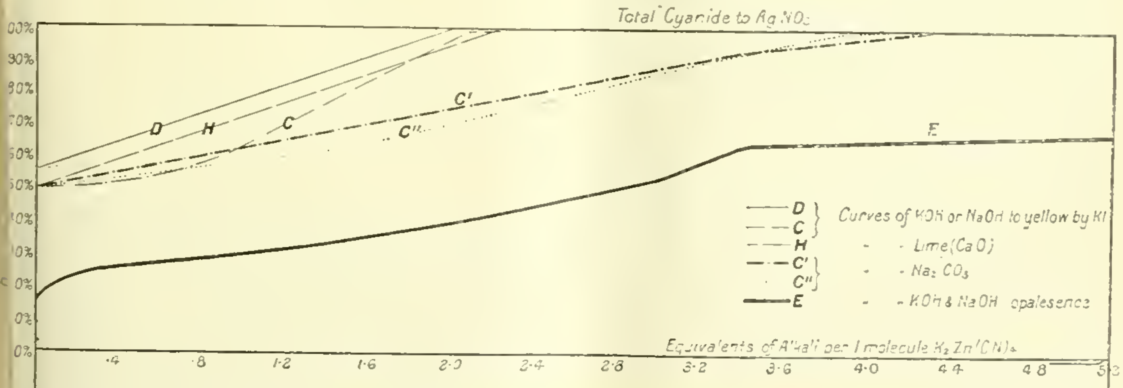
INORGANIC—QUANTITATIVE.

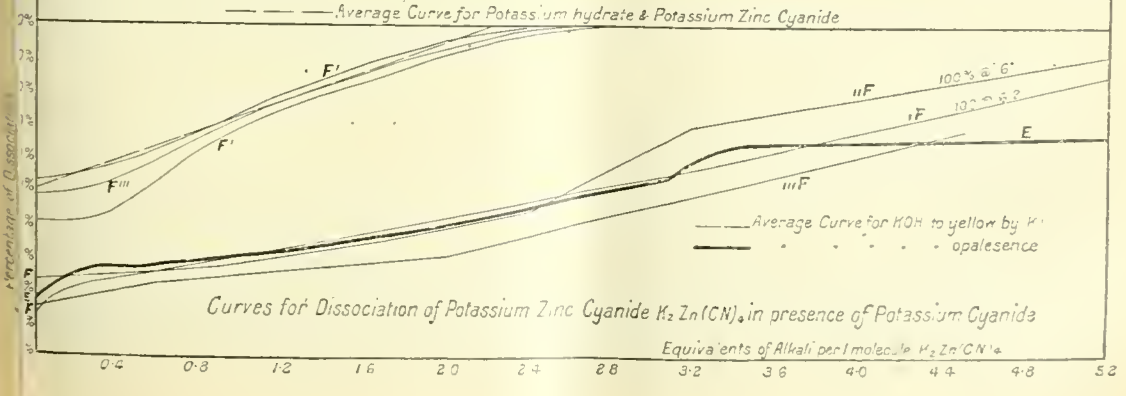
Sodium Nitrite; Analysis of ——. G. Lunge. Chem.-Zeit., 1904, **28**, 501—502.

The "diazo" method with the use of sulphanilic acid can be made to yield results equivalent in accuracy to those obtained by the permanganate method, but in most cases the latter method will be found to be more convenient. For the titration, 45 c.c. of N/2 permanganate solution are acidified with sulphuric acid and diluted to 400 c.c. with water at 40° C., then titrated with a solution of sodium nitrite containing 23 grms. per litre. In order to obtain accurate results with sulphanilic acid, this substance must be purified by recrystallisation, and the crystals must be dried for two days in the desiccator over sulphuric acid. The starch solution should be freshly prepared each day, and the end point should correspond with an immediate coloration of the iodide-starch paper permanent for some minutes.—J. F. B.

Cyanide Solutions; Determination of Constants in Working ——. G. W. Williams. J. Chem., Metall., and Min. Soc., S. Africa, 1904, **4**, 288—298.

The author has endeavoured to determine the degree of dissociation, and hence the gold-dissolving power of the double potassium-zinc-cyanide under various conditions. The method used was to titrate the solutions with silver nitrate, using as an indicator the permanent yellow developed by potassium iodide. It was found that under these circumstances the reaction cannot be represented as a simple interchange between the silver nitrate and the potassium cyanide of the dissociated double salt, for some of the zinc cyanide also reacted, and zinc nitrate remained in solution. Accordingly, the results were always too high





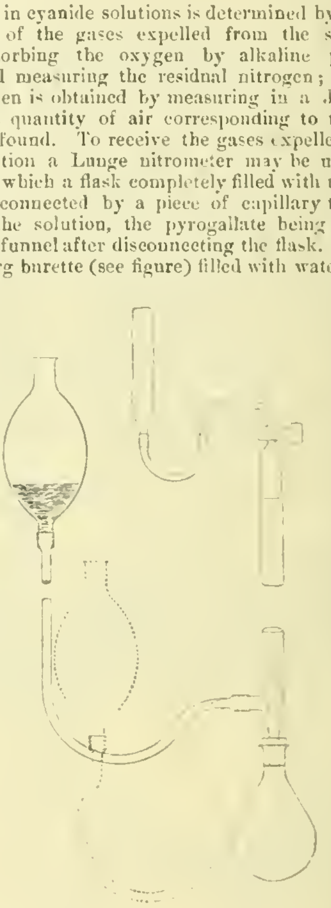
Curves for Dissociation of Potassium Zinc Cyanide $K_2Zn(CN)_4$ in presence of Potassium Cyanide (though comparable among themselves), and better results were obtained when the potassium iodide was omitted, and the appearance of opalescence, owing to precipitation of zinc cyanide, was taken as the end of the reaction. Dilution of the solution from 1/500 to 1/6000 produced gradually increasing dissociation from about 50 to 77 per cent. of the total double cyanide; further dilution produced no effect. In the later experiments the effect of dilution was eliminated. Addition of potassium cyanide not only reduced, as was to be expected, the degree of dissociation of the double cyanide, but the latter appeared to act in some way upon the added cyanide, for the amount of silver nitrate required was less than that calculated for the added cyanide alone. The addition of alkali was then investigated, and the results are plotted in the accompanying curves. The first set of curves show the effect of addition to the double cyanide solution of potassium or sodium hydroxide, lime or sodium carbonate, using potassium iodide as indicator (curves D, C, H, C′, and C″), and also the effect of alkali hydroxide when opalescence is taken as the indication (curve E). The general parallelism of E with the other curves is noticeable, and also the sudden lowering of slope at about 64 per cent. The second set of curves show the effect (by both methods of indication) of adding alkali hydroxide to mixtures of the double cyanide with potassium cyanide (molecules of $K_2Zn(CN)_4$: molecules of KCN = (I) 10 : 3·3, (II) 1 : 1, (III) 1 : 3·1 approximately; the average curve in each series is also drawn). The general similarity of the one average curve to D, C, or H, and of the other to F is obvious. The author's conclusions (in part to be seen from careful inspection of the curves) are as follows:—*In titrations with potassium iodide:* (I.) The silver nitrate enters into reaction with the zinc cyanide in part, forming zinc nitrate. (II.) The "free" cyanide (gold-dissolving cyanide) is proportional to the amount of alkali present. (III.) The effects of equivalent quantities of sodium, potassium, and calcium hydroxides are alike, save that zinc oxide is insoluble in lime, and that no soluble zincate is formed as with alkali hydroxide. (IV.) Alkali carbonates have only half the efficiency of the hydroxides. *In titrations to opalescence without potassium iodide:*—(I.) The free cyanide shown is, within limits, proportional to the amount of alkali, and the amount of dissociation indicated is about half of that shown with iodide. (II.) The limiting value of 64·4 per cent. indicated on the curve coincides with an amount of alkali hydroxide sufficient to form with the zinc oxide produced, the zincate $K_2ZnO_2 . 8 KOH$, shown by W. J. Sharwood (this J., 1903, 907) to exist. In general, the "free" cyanide present is a function of the ratio between zinc and alkali, and is not affected by the addition of potassium cyanide to the solution. Although the free cyanide increases with the addition of alkali, in practice the secondary effects of this free alkali on the solutions quickly impose a limit to the amount that can be added, and the bulk of the double cyanide present is inert and useless for the purpose of dissolving gold. Finally, the author emphasises the fact that the figures given are not to be regarded as accurately representing the degrees of dissociation, but merely as being proportional, and probably nearly approximate to them.—J. T. D.

Vanadium; Separation of —— *from Aluminium and Iron.* B. Glasmann. J. russ. phys.-chem. Ges., 1904, 36, 314—317. Chem. Centr., 1904, 1, 1537.

For the determination of vanadium in presence of aluminium and iron salts, the solution is treated with potassium iodide and sulphuric acid, the iodine set free removed by treatment with sulphur dioxide, the solution neutralised with potassium hydroxide, and the aluminium and iron precipitated by a mixture of potassium iodide and iodate. The reactions which occur are expressed by the equations:—$V_2O_5 + 4HI = V_2O_3 + 2H_2O + 2I_2$; $Fe_2(SO_4)_3$ or $Al_2(SO_4)_3 + 5KI + KIO_3 + 3H_2O = Fe_2(OH)_6$ or $Al_2(OH)_6 + 3K_2SO_4 + 3I_2$. The free iodine is removed by sodium thiosulphate, and the precipitated hydroxides are filtered off, washed and ignited. The filtrate is evaporated repeatedly with sulphuric acid, then with nitric acid to oxidise the vanadium trioxide, and then again with sulphuric acid. For the determination of the vanadium, it is reduced by sulphur dioxide, the excess of the latter removed and the solutio
titrated with potassium permanganate at 70° C.—A. S.

Oxygen in Working Cyanide Solutions; Industri
Method for the Determination of the ——. A. Priste
J. Chem. Metall. and Min. Soc., S. Africa, 1904, 4
364—369.

The oxygen in cyanide solutions is determined by measurin
the volume of the gases expelled from the solution o
boiling, absorbing the oxygen by alkaline pyrogallat
solution, and measuring the residual nitrogen; the weigh
of the oxygen is obtained by measuring in a Japp grav
volumeter a quantity of air corresponding to the volum
of oxygen found. To receive the gases expelled from t
boiling solution a Lunge nitrometer may be used, to th
side tube of which a flask completely filled with the cyanid
solution is connected by a piece of capillary tubing als
filled with the solution, the pyrogallate being introduce
through the funnel after disconnecting the flask. Or else,
Rammelsberg burette (see figure) filled with water free fro



air may be used to receive the gases, the side tube
the burette being connected to a vessel containing wat
whilst the upper end is joined, after the gases have be
expelled from the cyanide solution, to a U-shaped tu
containing the pyrogallate solution; the mixed gases a
forced to enter this tube repeatedly by raising and lowerin
the water reservoir. The boiling of the cyanide solutio
must in this case be continued until the water in th
burette becomes warm, when it may be assumed that
gases dissolved by it have been again expelled. Not les
than 300 c.c. of the solution should be taken for eac
test. Either modification of the method is said to gi
good results.—A. G. L.

Rotating Electrodes; Electrolytic Analysis with applic
tion of ——. R. Amberg. Z. Elektrochem., 1904, 1
385—386.

The author seeks for an explanation of the very favourab
effect of rapid rotation on the deposition of metals. T
current density cannot have such an important bearin
on the condition of the metal as is ascribed to it
ordinary cases of deposition, for with rapid rotation
can exceed 10 times that allowable in such cases, witho
any ill effects on the nature of the deposit. The auth
considers that the important factor is the relation of th
current strength to the "virtual" volume of the elec
trolyte; this apparent volume being proportional to t
velocity of rotation.—R. S. H.

Platinum; Determination and Separation of —— from various other Metals by means of Hydrazine in Ammoniacal Solution. P. Jannasch and C. Stephan. Ber. 1904, **37**, 1980—1992. (See also this J., 1898, 1157.)

From Potassium.—To the solution (containing about 0·15 grm. of platinum in a bulk of 30 c.c.) is added 0·5—1·0 grm. of hydrazine hydrochloride, and the whole is boiled for about 5 mins. Concentrated ammonia is now added till the yellow colour of the liquid just disappears, and the solution is vigorously stirred with a glass rod. If properly done, the platinum separates in a powdery condition, and does not adhere to the glass. About 5 c.c. of ammonia are now added, the liquid is boiled for 5—10 mins., and is then filtered through a double filter consisting of a small filter inside a larger one; care must be taken not to fill up over the edge of the small filter. Wash once or twice with hot water, then with warm nitric acid (1—5 per cent., free from chlorine); if water alone be used, some of the platinum invariably washes through towards the end. Place filter and precipitate in a porcelain crucible, burn off, ignite, and weigh. Evaporate the filtrate, expel ammonium salts, dissolve the residue, filter, evaporate and weigh as potassium chloride. *From Sodium.*—The process is worked exactly as in the case of potassium. *From Calcium, Strontium, and Barium.*—Proceed exactly as with potassium. In the filtrate, calcium is determined by precipitation as oxalate, strontium or barium as sulphate. *From Magnesium.*—Exactly as with potassium. The magnesium in the filtrate is determined as pyrophosphate. *From Manganese.*—The platinum is precipitated as above; as small amounts of manganese peroxide are formed by atmospheric oxidation, however, and adhere to the sides of the beaker and to the platinum precipitate, these must be washed with hot dilute nitric acid containing hydrogen peroxide, which reduces and dissolves the manganese compound, and does not affect the platinum. The manganese in the filtrate is determined by any usual method, the authors preferring precipitation by hydrogen peroxide. *From Tungsten.*—The platinum is precipitated as usual, but must be washed with dilute ammonia, not with nitric acid. The filtrate is evaporated to dryness with nitric acid, and the residue taken up with hot 10 per cent. nitric acid and well washed on a filter with the same. The tungstic acid in the filtrate is precipitated, according to Kehrmann's method, by means of quinoline acetate; the main quantity of tungstic acid is ignited gently, evaporated with hydrofluoric and sulphuric acids to remove silica, ignited, the quinoline precipitate added, and the whole ignited again and weighed. *From Copper.*—The whole of the copper, as well as the platinum, is precipitated if the quantity of hydrazine be sufficient; but the copper can be nearly all dissolved out from the washed precipitate by washing with hot dilute nitric acid, and treatment of the ignited platinum for a very short time with hot concentrated nitric acid removes the remaining traces without dissolving any of the platinum. *From Nickel.*—Some nickel goes down with the platinum, but can be completely removed by washing on the filter with hot 10 per cent. nitric acid. The filtrate is evaporated, ammonium salts removed, the residue dissolved n hydrochloric acid, filtered, and the nickel precipitated by sodium hydroxide. *From Cobalt.*—This metal behaved exactly like copper, save that not quite the whole of it was precipitated with the platinum. The separation of the cobalt from the precipitate was effected exactly as described under copper. If the platinum compounds, in these separations, contain any of the associated metals, some of these are not precipitated with the platinum, but go through into the filtrates.—J. T. D.

Hydrogen Peroxide; Analysis of Commercial ——. P. Sisley. Rev. Gen. Mat. Col., 1904, **8**, 164—165.

N a previous article (this J., 1901, 1028) the author pro-osed to detect oxalic acid in hydrogen peroxide by eutralising with ammonia, and adding acetic acid and alcium chloride. Recently, however, hydrogen peroxide ontaining fluorides has been put upon the market, and ich a product would give by the test a precipitate of alcium fluoride. The precipitate obtained with calcium chloride should therefore be examined as to whether it consists of fluoride or oxalate. The presence of a fluoride has no influence on the determination of oxalic acid in the precipitate by dissolving in dilute hydrochloric acid and titrating with permanganate.—A. S.

ORGANIC—QUALITATIVE.

Polyhydric Phenols and their Derivatives; Action of Molybdates on ——. [Distinguishing between m- and p-Phenylenediamine.] C. Frabot. Ann. Chim. anal. appl., 1904, **9**, 123—124. Chem. Centr. 1904, **1**, 1397—1398.

Pozzi-Escot has recently described a new reaction for molybdates with tannic, gallic and similar acids. The author finds that a solution of a molybdate acidified with sulphuric acid gives a blue coloration with a number of polyhydric phenols and derivatives of the same, substituted in the *p*-position. The molybdate solution (10 grms. of ammonium molybdate in 100 c.c. of water and 10 c.c. of concentrated sulphuric acid) may be used, for example, for rapidly distinguishing between *m*- and *p*-phenylenediamine. —A. S.

Fatty Acids; Process for Characterising ——. R. Locquin. Comptes rend. 1904, **138**, 1274—1276.

The hydroxyacetone esters of fatty acids R.CO.OCH$_2$.CO.CH$_3$, obtained by the action of the acid on hydroxyacetone or monochloro-acetone, give, with semicarbazide, very well defined semicarbazones, which are suitable for the characterisation of the fatty acids. One mol. of the acid under examination, dissolved in ether, is converted into its sodium salt by the addition of the calculated quantity of sodium; 1 mol. of monochloro-acetone is added, the ether is removed by heating on the water-bath, and the mixture is heated to 120°—130° C. for about 4 hours; the product is extracted with water and then with ether, and the ethereal solution is washed with sodium carbonate solution and water, and fractionated. The yield of ester is 70 to 75 per cent. of theory. The esters have boiling points several degrees higher than those of the parent acids. The semicarbazones of these esters are obtained in quantitative yield, are easily purified, and have sharply defined melting points.—T. F. B.

Sugars; Microchemical Detection of —— by Phenylhydrazine Acetate. E. Senft. Monatsh. f. Chem., 1904, **25**, 397—420.

In order to avoid the extractive action of aqueous reagents on the sugars, the author employs separate 10 per cent. solutions of phenylhydrazine hydrochloride and sodium acetate in glycerin. Two preparations of the tissue to be studied are made, by mixing one drop of each of the reagents on a glass slide, laying the object therein and covering with a glass slip. One of these preparations is maintained at the ordinary temperature and examined from time to time. The production of osazone generally occurs after one or two days, but earlier in the case of fructose than with glucose; in some cases, however, the period of examination may have to be prolonged to 14 days. The second preparation is heated on a boiling water-bath for half-an-hour, and is then examined after cooling. Saccharose is differentiated from glucose and fructose by the fact that the latter sugars form osazones at the ordinary temperatures if sufficient time be allowed, whereas saccharose yields an osazone only after heating. The test at the ordinary temperatures enables the localisation of the sugars in the tissues to be studied, whereas the hot test causes more or less diffusion. The crystalline form of the osazone, however, is not so striking in the cold tests as in the hot tests. In doubtful cases the osazone, after its formation, can be caused to crystallise more definitely by treatment with alcohol and evaporation of the solvent. The turbid preparations can be cleared by concentrated caustic potash or chloral solutions without injury to the osazone formations; the preparation may be mounted in glycerin jelly. In objects containing a certain amount of moisture, the sugars being in solution, the production of osazone in needle-shaped crystals is very rapid by the hot test. In dry objects containing the sugars in the solid state, the osazone forms slowly, and takes the form of granules, spheroids, or indefinite tufts. The author describes the application of the above tests to a large number of vegetable tissues, the description being accompanied by coloured illustrations.—J. F. B.

Citronella Oil; Modified Schimmel's Test for, and Nature of Adulterant of ——. Schimmel's Report, May, 1904, 27—33.

Nature of Adulterant.—Examination of large quantities of sophisticated citronella oil has failed to show any adulterated with resin spirit as stated by Parry and Bennett (this J., 1903, 163). In none of the lighter fractions obtained was metacymene found, which Kelbe has shown to be a normal constituent of resin spirit. All the specimens examined were adulterated with petroleum.

Modification of Schimmel's Test.—In view of the fact that certain more soluble kinds of Russian petroleum may be added to citronella oil to the extent of 5 or 10 per cent., without affecting its solubility in 80 per cent. alcohol, it is proposed to modify "Schimmel's test" as follows:—Two tests are made, one with the normal oil, the other with the oil to which 5 per cent. of Russian petroleum has been added; both should be soluble, neither should separate oily drops. [Schimmel's test is as follows:—The oil should yield a clear solution with one to two volumes of 80 per cent. alcohol. On increasing the volume of alcohol to 10, a slight turbidity may occur, but on standing in a closed vessel no oily drops should separate.]—J. O. B.

Oil of Cassia; Detection of Rosin in Essential ——. Schimmel's Report, May 1904, 19.

If added rosin be present in cassia oil a precipitate will be formed when a 25 per cent. solution in alcohol is treated with a freshly prepared saturated solution of lead acetate in the same solvent. Adulteration with colophony appears to be again prevalent, many specimens being met with which yield an unduly high residue on distillation.

—J. O. B.

ORGANIC—QUANTITATIVE.

Sugar Determination; Volumetric ——. L. Rosenthaler. Z. anal. Chem., 1904, **43**, 282—285.

The method devised by the author for determining dextrose and levulose, either separate or mixed, depends upon the fact that these reducing sugars, when oxidised with alkaline copper solutions, are transformed into acids which partially neutralise the alkalinity of the liquid. Experiment shows that 1 mol. of sugar yields eight equivalents of acid, and that each c.c. of the difference in volume between the normal acid required for neutralising the alkalinity before and after the reduction of the sugar, is equivalent to 0·0225 grm. of anhydrous dextrose or levulose. The alkaline copper solution employed, contains in every litre: crystallised copper sulphate, 17·5 grms.; glycerin, 75 grms.; sodium citrate, 125·0 grms.; 15 per cent. sodium hydroxide solution, 100 grms. This solution deposits a little cuprous oxide, which should be filtered off through asbestos after three or four days standing, or a few hours heating on a steam-bath. The alkalinity of the solution is measured by filtering 30 or 40 c.c. through a Gooch crucible, which is well washed through; to the filtrate and washings are added phenolphthalein and a slight excess of N/1 hydrochloric or sulphuric acid. The liquid is then boiled for 10 minutes over a naked flame, after which N/1 alkali is added until the solution becomes red, and then a drop of N/1 acid to produce decolorisation. In estimating dextrose or levulose, 5 c.c. of an approximately 1 per cent. solution are mixed with 20 c.c. of water and excess (30 c.c.) of the alkaline copper liquid, and the mixture heated to boiling, which is maintained for five minutes. The separated cuprous oxide is filtered off through a Gooch crucible, and washed with 150 c.c. of water. An excess of acid is then added to the liquid which is treated as in the alkalinity estimation described above. Many estimations can be made without renewing the asbestos of the Gooch crucible.—T. H. P.

Lignified Fibres [Mechanical Wood Pulp] in Paper; Colorimetric Determination of ——. E. Valenta. Chem.-Zeit., 1904, **28**, 502—503.

An ordinary colorimeter with two graduated tubes of 100 c.c. capacity, provided with stopcocks, and a horizontal reflector is required. A suitable reagent for lignified fibres having been selected, a mixture of coal tar dyestuffs having approximately the same spectroscopic value as the wood colour-reaction is prepared. This solution is standardised by means of sheets of thin paper, one containing 100 per cent. of mechanical wood, and the other a known lower percentage, *e.g.*, 50 per cent. Pieces of these papers are steeped for about ten minutes in the wood-pulp reagent in thin, flat-bottomed glass dishes, which fit between the tubes of the colorimeter and the reflector. One tube is filled with water and placed above the dish containing the stained paper with 100 per cent. of wood. Under the other tube is placed a dish containing the same paper soaked in water. The colour solution is then run into the second tube until the colour intensity is practically identical in the two tubes; the shade is then adjusted by the addition of very dilute solutions of other suitable dyestuffs, drop by drop. When the exact shade and intensity of colour have been established, the colour solution is diluted with water to the 100 c.c. mark. One c.c. of this solution should then correspond to one per cent. of wood, and the accuracy of the shade is tested, and adjusted if necessary, by comparison with the paper containing a known lower percentage of wood. For papers containing less than 10 per cent. of lignified fibres, the colour solution may be diluted with nine times its volume of water. A 10 per cent. solution of aniline sulphate is a convenient reagent for staining the paper, and the coloration so obtained, can be matched with "Naphthol Yellow S" or "Mikado Yellow," the shade being adjusted with dilute solutions of red and blue acid dyestuffs.—J. F. B.

Formaldehyde and its Polymers; Determination of ——. A. Seyewetz and Gibello. Bull. Soc. Chim., 1904, **31**, 691—694.

The method is based on the reaction—

$$6Na_2SO_3 + 2(H.COH)_3 + 3H_2SO_4 =$$
$$2[(NaHSO_3)_3 + (H.CHO)_3] + 3Na_2SO_4.$$

Although no reaction appears to occur between sodium sulphite and formaldehyde, on the addition of sulphuric acid and the consequent formation of sodium bisulphite, the aldehydic bisulphite compound is instantly formed, in the cold. The bisulphite compound being neutral to phenolphthalein, the sulphuric acid does not exercise its action on the indicator until sufficient bisulphite has been formed to combine with the whole of the aldehyde. The solution of sodium sulphite employed contains about 20 per cent. of the anhydrous salt. Its alkalinity towards phenolphthalein is first determined by titration with standard acid. A known weight of formaldehyde solution, or from 0·5 to 0·7 grm. of trioxymethylene is dissolved in 20 c.c. of the sulphite solution, after the addition of phenolphthalein, and the titration performed in the usual manner with standard acid. Although trioxymethylene is insoluble in water, it is readily dissolved by sodium sulphite solution. The method gives very exact results, and is available for very dilute solutions of formaldehyde. It compares favourably th methods of Legler, modified by Loesekann, and that of Craig.—J. O. B.

Roses, Essential Oil of [Otto of Roses]; Iodine Absorptio Test as a Factor in the Examination of ——. F Hudson Cox and W. H. Simmons. Analyst, 1904, **29** 175—178.

From 0·1 to 0·2 grm. of the sample to be examined dissolved in 10 c.c. of 90 per cent. alcohol is mixed wit 25 c.c. of Huebl's iodine solution and allowed to stand fo three hours at normal temperatures. The uncombine iodine is then titrated in the usual manner. Samples o genuine otto of rose are found, under these conditions, t show an iodine absorption value ranging from 187 to 194

Artificial otto, with stearoptene, has the values 224 to 254; without stearoptene, 261 to 279; palma-rosa oil, 296 to 307; African geranium oil, 213 to 225; Bourbon geranium oil, 213 to 215; Spanish geranium oil, 211; geraniol (apparently natural), 239; geraniol (apparently artificial), 307; Citronella oil, 217; citronellol, 187; linalol, 280; citral, 175; guaiacum wood oil, 298; stearoptene, none. All these bodies, which may be met with in adulterated rose oil, have iodine values well over 200, except citronellol and citral; geranium oils which have a relatively low iodine value have also a comparatively high ester content, so that heir presence would be at once detected by an abnormally igh ester value. A series of eight samples of doubtful purity had iodine values ranging from 133 to 234. Two, n which the addition of geraniol was suspected gave the odine values 219 and 212. The sample with the lowest odine value (133), contained ethyl alcohol. A mixture of wo parts of artificial otto and one part of genuine rose oil ad the value 215. It has been stated that temperature arkedly modifies the rate of iodine absorption in oils. In e case of rose oil this is not found to be so. Between 4° C. nd 27° C. no appreciable difference was observed. The ge of the reagent has a great modifying influence, older olutions being less active. In these experiments the ercuric chloride and iodine solutions were kept separate, ing mixed immediately before use. Titration was performed as rapidly as possible, since otherwise the colour found to be redeveloped. In the discussion following e above communication, A. C. Chapman suggested the bstitution for Huebl's reagent of a well cooled solution of omine in a suitable solvent, to be run into the cooled lution of essential oil under examination. This would nd to minimise intramolecular change, and to produce npler addition compounds. In that case, any difference the condition of saturation between various bodies would obably be more accentuated, and therefore more pronouncedly evident.—J. O. B.

XIV.—SCIENTIFIC & TECHNICAL NOTES.

dium in Uranium Compounds. B. B. Boltwood. Eng. and Mining J., 1904, **77**, 756.

om the results of the determination of the amount of io-active emanation from a number of minerals conning uranium, the author concludes that the amount of ium in a mineral varies directly with the percentage of nium present.—A. S.

con; Solubility of —— in Silver. A Variety of Crystalne Silicon Soluble in Hydrofluoric Acid. H. Moissan nd F. Siemens. Comptes rend., 1904, **138**, 1299—1303.

icon is much more soluble in silver than in lead or z (see this J., 1904, 374); moreover, the silicon which c tallises from the silver on cooling contains varying a unts of an allotropic modification soluble in hydrofl ric acid. In the subjoined table column I. shows the p entage of silicon dissolved in silver at various tempera s, and column II. the percentage of this dissolved silicon w h is soluble in hydrofluoric acid:—

Temperature.	I.	II.
° C.	Per Cent.	Per Cent.
970	9·22	58·02
1150	14·89	27·66
1250	19·26	19·00
1470	41·48	16·00

dissolving 2 to 4 per cent. of silicon in silver, and re ving the silver by means of nitric acid, specimens of th soluble variety of silicon were obtained; it remains un anged when heated in hydrogen or nitrogen to 1200° C., au onsists entirely of silicon; the density at 20° C. of a sample of which 99 per cent. is soluble in hydrofluoric acid was found to be, in water 2·3 to 2·38; in benzene, 2·42. —T. F. B.

Ferric Phosphate and other Phosphates; Soluble Colloidal Form of ——. W. J. Sell. Proc. Cambr. Phil. Soc., 1904, **12**, 388—390.

On treating 100 c.c. of a solution containing 50 grms. of anhydrous ferric chloride per litre, with 400 c.c. of a solution of diammonium hydrogen phosphate (100 grms. of the crystallised salt per litre), and, after shaking, making the mixture faintly ammoniacal, the white phosphate precipitate gradually became brown, and finally dissolved to a clear brown liquid. The solution was dialysed through parchment paper. The dissolved colloidal substance was found to consist of ferric phosphate ($FePO_4$), together with a little ferric hydroxide. When the dialysed solution was evaporated on the water-bath, the residue consisted mainly of the compound $2FePO_4.H_2O$, together with some hydroxide. This colloidal solution of ferric phosphate is tasteless, without action on litmus, and is gelatinised by various salts. Silver nitrate and potassium ferrocyanide merely coagulate the solution; potassium thiocyanate does not give a red coloration. The electric conductivity of the solution is very low. Colloidal phosphates of aluminium and chromium having analogous properties were also prepared.—A. S.

Formaldehyde in the Atmosphere; Determination of ——. H. Henriet. Comptes rend., 1904, **138**, 1272—1274.

Air was filtered through glass-wool and passed through a U-tube containing mercuric oxide, heated to about 250° C., to oxidise the formaldehyde to carbon dioxide; the air was then passed through potash bulbs. The difference between the amounts of carbon dioxide obtained by this method, and by the usual method, omitting the mercuric oxide tube, corresponds to the amount of formaldehyde in the atmosphere, which is found to be 2—6 grms. per 100 cubic metres.—T. F. B.

Enzymes; Connection between Instability and Activity in ——. O. Loew. Pflüger's Arch., 1904, **102**, 95—110. Chem. Centr., 1904, **1**, 1435—1436.

In the author's opinion the free chemical energy of enzymes depends upon the fact that they contain labile groups of atoms. In studying the nature of these labile groups the two labile forms and the stable form of the enzyme must be distinguished. The one labile form, the *zymogen*, is much more stable than the other, the peculiar *enzyme*, produced from it. The conversion of the zymogen into the enzyme is probably due to a chemical alteration within the molecule, possibly a breaking of a lactam linking. The mother substances of the zymogens, the *prozymogens*, are insoluble; they are probably compounds of the zymogens with nucleoproteids. From a consideration of the effect of various agents on the enzymes, the author concludes that the instability of the latter depends upon the presence of keto- and amino-groups.—A. S.

Castor-Seeds [Ricinus communis]; Hydrolysing Properties of ——. E. Urbain and L. Saugon. Comptes rend., 1904, **138**, 1291—1292.

Castor-seeds were heated with ten times the weight of starch and a small quantity of acetic acid. After 24 hours it was found that 10·9 per cent. of the starch was saccharified. Saccharose (about half the weight of castor-seed used) was then substituted for starch, with the result that 33 per cent. of the saccharose was inverted in 24 hours. Fatty oils are also hydrolysed by castor-seeds; in one case 90·8 per cent. of fatty acid was formed. It was found that cytoplasma could be substituted for the castor-seeds with success in all these experiments.—T. F. B.

Hydrolytic Properties of the Cytoplasma of Castor-Seeds are not due to a Soluble Ferment. M. Nicloux. Comptes rend., 1904, **138**, 1352—1354.

Cytoplasma, prepared from castor-seeds, was freed from oil, dried, and extracted with water, and also with dilute acetic acid. In neither case had the extract or the residue the hydrolytic power possessed by the cytoplasma in the first place (see this J., 1904, 614; and preceding abstract), showing that the hydrolytic action is not due to a soluble ferment, and that water destroys the hydrolysing power of the substance in the absence of oil.—T. F. B.

"*Flocculation*" ["*Ausflockung*"] *Phenomena.* M. Neisser and U. Friedemann. Münch. Med. Wchschr., **51**, [11]; Chem. Centr., 1904, **1**, 1387—1388.

An emulsion of mastic was prepared by pouring an alcoholic solution of the latter into distilled water. In such an emulsion, the particles of mastic have an electro-negative charge, as is shown by the fact that if the emulsion be brought between the platinum electrodes of a battery of high E.M.F., the particles travel to and are deposited at the anode. The addition of small quantities of salts or acids to the emulsion causes, as is known, the separation of the particles in flocks. Experiments with aluminium sulphate, ferric chloride, ferric nitrate, colloidal ferric hydroxide, arsenic trisulphide, and ordinary ferric hydroxide, showed that when colloids and suspensions carrying opposite electric charges, are brought together in certain proportions, they are simultaneously separated in the form of flocks. Aniline dyestuffs behave like colloids, the acid dyestuffs bearing electro-negative and the basic, electro-positive charges. The basic dyestuff causes the "flocculation" of a mastic emulsion. With an excess of the negatively-charged mastic, arsenic trisulphide, Benzopurpurin, and Eosin, or of the positively-charged colloidal ferric hydroxide, Bismarck Brown, Neutral Red, and Methylene Blue, a so-called "checking" occurs, *i.e.*, flocculation no longer takes place; even the colloid present in smaller proportion is not separated. This "checking" is due, in the authors' opinion, to the envelopment of the one colloid (or suspension) by the other. Albuminoid colloids, such as gelatin, serum, and bacteria, also protect negatively-charged suspensions and colloids from the action of those precipitants, by which they are not themselves precipitated. These latter colloids, which by themselves are not capable of causing flocculation of suspensions and colloidal solutions, acquire that property when a quantity of a salt insufficient in itself to cause flocculation is added to them. The albuminoid colloids may be regarded as mixtures of colloids, or as colloids which, unlike the metallic colloids, possess both electro-positive and electro-negative properties. A small addition of a salt is sufficient to change the amphoteric colloid into one carrying only either an electro positive or electro-negative charge; the colloid then behaves like the metallic colloids, *i.e.*, in small quantities it causes the flocculation of oppositely-charged colloids or suspensions, whilst in large quantities it prevents flocculation.—A. S.

Crystals; Formation and Transformation of Fluid Mixed ——. A. C. de Kock. Z. physik. Chem., 1904, **48**, 129—176.

It is known that *p*-azoxyanisol and *p*-methoxycinnamic acid melt to the fluid-crystalline state, and at higher temperatures become isotropic liquids. Mixtures of the two fluid crystals exist in all proportions, and pass into or from isotropic liquids like a single body; an eutectic mixture was observed. Quinol (hydroquinone) or benzophenone, mixed with either of these bodies, forms a fluid crystal, but only up to a certain concentration, and equivalent quantities depress the solidifying point to the same extent. The behaviour of these mixtures supports the view that fluid crystals consist of a homogeneous phase and not of an emulsion.—W. A. C.

Alcoholates. J. W. Brühl. Ber., 1904, **37**, 2066—2068.

The method of Biltz and the author (this J., 1891, 568) for obtaining alcoholates free from alcohol of crystallisation, by boiling a solution of the alcohol in toluene or xylene with metallic sodium is exceedingly slow, for the metal is melted and exposes only a limited surface, and the alcohol is in large excess till towards the end of the operation, so that the crystallised alcoholate is first formed, and has to be gradually decomposed. The author's new process is as
follows:—The sodium is pulverised under boiling xyle
(Brühl, Ber., **35**, 3516) in a roomy flask, and more xyle
added so as to make about 250 c.c. to 23 grms. of sodiu
The flask is fitted with a cork carrying a Brühl's stir
and a reflux condenser with a soda-lime guard tube and
dropping funnel, and is placed in cold water. T
calculated quantity of the alcohol is now very slow
dropped in, and the reaction, if not complete when t
addition is finished, is readily completed by warming for
short time. The alcoholate formed can be used either
suspension in the xylene, or the latter can be filtered off
the pump, leaving a paste of alcoholate and xylene.
desired, benzene, petroleum spirit, or ether can be us
instead of xylene, after pouring off the xylene that was u
to pulverise the sodium.—J. T. D.

New Books.

Die Galvanoplastik. Von Dr. W. Pfanhauser.
Wilhelm Knapp's Verlag, Halle a/S. 1904. Price M.

8vo volume, containing preface, 137 pages of subje
matter, and alphabetical index of authors. The table
contents at the beginning, given in detail, serves as ind
of subjects. The text is illustrated with 35 engravi
The leading subjects are the following:—I. Historic

The Extra Pharmacopœia of Martindale and W
cott. Revised by W. Harrison Martindale, P
and W. Wynn Westcott, M.B., D.Ph. 11th Ed
H. K. Lewis, 136, Gower Street, London, W.C.
Price 9*s*. 6*d*. nett.

This, the 11th edition, contains 645 pages of subject-m
and an alphabetical index and Posological Table, foll
by a Therapeutic Index of Diseases and Symptoms. Wh

mitting many of the other drugs, chemicals, and prepara- ons, &c., of past editions, in the present edition more than 00 new remedies, drugs, &c., have been added. The ubject of Radium, and the notes on Röntgen Rays, High- equency Current, Finsen Lamp and Radiant Heat, are in his edition introduced with considerable detail under Radiology." The section also termed "Analytical Memo- anda" has been made more complete by enlarging the aragraphs devoted to Tests for Various Substances in, or f significance for, Urine, as also those for Glucose and for Vater Analysis. The sections on Antitoxins have also een almost entirely rewritten.

ahrbuch der Elektrochemie. Begründet und bis 1901 herausgegeben von Profs. Dr. W. Nernst und W. Borchers. Berichte über die Fortschritte des Jahres 1902. Unter Mitwirkung der Herren Dr. P. Askenasy, W. Borchers, K. Elbs, F. Harms, M. Mugdan und O. Saekur. Herausgegeben von Dr. H. Danneel. IX. Jahrg. W. Knapp's Verlag, Halle a/S. 1904. Price M. 24.

arge 8vo volume, containing 678 pages of subject-matter, ith 137 illustrations, and followed by alphabetical indexes authors and subject-matters. The subjects dealt with e the following:—I. Scientific Part. (i) General; i) Conductivity and State of the Solutions; (iii) Chemical nergy and Electrical Energy; (iv) Polarisation and lectrolysis. (v) Electrical Phenomena in Gases. II. pplied Electrochemistry. (i) Current-production;) Inorganic Electrochemical Processes and Products; i) Organic Compounds. (iv) Electrolysis of Alkalis d Bleaching Agents. (v) Apparatus for Electrochemical echnology. Bibliography and Journals.

Compendium of Chemistry, including General, Inorganic, and Organic Chemistry. By Dr. Carl Arnold, Prof. of Chemistry in the Royal Veterinary College of Hanover. Translated by John A. Mandel, D.Sc. First Edition. John Wiley and Sons, New York. 1904. Price 3.5 dols. Chapman and Hall, Ltd., London.

volume, containing 572 pages of subject-matter, with habetical index, and divided into the following branches: General Chemistry; II. Inorganic Chemistry; and III. ganic Chemistry.

nual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions, 1903. Volume II. [Cd. 2081.] Price 5*s.* Eyre and Spottiswoode.

s is the second volume of the Annual Statement of de, the first volume having been noticed on page 285 of *Board of Trade Journal* for May 12. This volume tains statements of the trade of the United Kingdom each foreign country and British Possession during years 1899–1903, and of the imports and exports at British port during the same period, as well as ounts of transhipment, warehousing, and goods passing ansit.

es and Quarries: General Report and Statistics r 1902. Part IV. Colonial and Foreign Statistics. Cd. 2084.] Price 1*s.* 8*d.* Eyre and Spottiswoode.

T return, which is compiled annually in the Home e, contains statistics of the number of persons em- ed, of accidents, and of the output of minerals at mines quarries in British Colonies and foreign countries. It ars from the statistics contained in the report that the amount of coal produced in the world in 1902 unted to 800 million tons, the value of which is ated at more than 270 million pounds sterling. The ving figures show the main sources from which the supply of the world is obtained:—

Country.	Met. Tons.	Value.
		£
United States	273,600,000	75,373,000
Great Britain	230,739,000	93,521,000
Germany	150,600,000	52,654,000
Austria-Hungary	39,479,000	10,528,000
France	29,997,000	17,459,000
Belgium	22,877,000	12,081,000

Trade Report.

I.—GENERAL.

Trinidad; [Chemical] Trade of ——.

U.S. Cons. Reps., Nos. 1967 *and* 1968, *June* 1 *and* 2, 1904.

Petroleum of good quality is found in Trinidad, but up to the present it has not been produced in any quantity; attempts are being made to establish the industry on a commercial basis. Kerosene is obtained entirely from the United States, and imports are increasing. Asphalt was exported to the value of 162,000*l.* in 1903. The quantities of the various kinds were—"crude," 145,000 tons; "epuree," 11,000 tons; liquid, 20,000 galls. Manjak has recently been found in considerable quantity.

About 10,000,000 cocoanuts are exported annually, 6,000,000 going to England last year, and the remainder to the United States. 25,000 galls. of cocoanut oil, and 1,325,000 lb. of copra (containing 65 to 75 per cent. of oil) were also exported last year. Soap is manufactured locally to a small extent, and about 2,000 tons (mostly blue mottled soap) were imported in 1903.

48,000 barrels of cement were imported in 1902–3, about 36,000 barrels coming from England.

68,000*l.* worth of balata was exported from Trinidad in the year 1902–3; of this quantity, nearly 52,000*l* worth was received from Venezuela and re-exported; the greater part goes to Holland.

The exports of sugar amounted, in 1903, to 47,000 tons. The value of the product is rapidly decreasing, being 394,000*l.* in 1903, as against 594,000*l.* in 1900, and 768,000*l.* in 1880. 310,000 galls. of molasses and 213,000 galls. of rum were exported last year.

Italy; Chemical Industry of ——.

Foreign Office Miscellaneous Series, No. 610

A notable increase in the importation of the following raw materials has taken place:—Coal, roots for dyeing or dressing, phosphates, manures, and india-rubber. There has also been an increase, but to a less degree, in the importation of gums, resins, and oleaginous seeds.

Among partly manufactured materials there has been a more or less marked increase in the case of the following articles:—Heavy mineral oils, potash, caustic soda, alkaloids, carbonates, oxides, chlorides, nitrates, sulphates, paraffin, wood-pulp, pig iron, copper, lead, zinc, and tin, and iron and zinc in sheets. The importation of acids, dressed hides, palm and cocoanut oil has remained stationary, whilst there has been a decline in cements and hydraulic lime.

There has been a marked decline in the importation of terra-cotta, majolica, and plate-glass. A diminution, though to a less degree, has also taken place in the importation of wrought iron, forged iron, wrought copper, earthenware, and glasswork; whereas the importation of petroleum, soap, and paper has remained stationary. On the other hand, there has been an increase in the importation of varnishes, bricks, porcelain, starch, and india-rubber.

The importation of foodstuffs has increased in the case of olive oil, cotton oil, and lard, and decreased in the case of beer and sugar.

With regard to exports :—

Of raw materials the exportation of raw hides, mineral ores, marble, cement, hydraulic lime, and sulphur is increasing; whereas the exportation of tartar and roots remains stationary.

Partly manufactured materials showing a general increase in their exportation are the following:—Essential oil of orange, unpurified gallic and tannic acid, tartaric acid, liquorice juice, tanned hides, and lead in ingots. The exportation of boric acid has remained stationary.

Among manufactured goods an increased exportation has taken place in matches, writing and wrapping paper, tiles, bricks, and worked india-rubber. The exportation of soap and wrought lead remains stationary.

In foodstuffs there is an increased exportation of wine in bottles, oranges and lemons. The exportation of wine and olive oil fluctuates considerably, depending on the yearly home crops. During the last few years the exportation of wine has been declining owing to a decreasing demand from the Austro-Hungarian market. The increased importation of potash, caustic soda, alkaloids, carbonates, chloride of lime, copper sulphate, and oxides of zinc and lead, points to the fact that home production is still inadequate to meet the growing demands of Italian industry for these products. The increased importation of nitrate of soda and chloride of potash may be accounted for by the fact that these chemicals are being increasingly used in Italy for agricultural purposes. The increase in the importation of solid paraffin, gums and resins, points to an increased consumption of these articles for the manufacture of candles, soap, and paper respectively. There has been a considerable increase in the importation of scrap and pig iron. The production of the latter in Italy does not yet reach 25,000 tons annually, whereas its consumption is computed at between 180,000 and 190,000 tons. Two new blast furnaces, however, one of which has already commenced operations at Portoferraio, are capable of yielding about 100,000 tons of forged pig iron annually. The amount of iron and steel produced annually is now estimated at about 190,000 and 115,000 tons respectively. The importation of copper, lead, tin and zinc in ingots and in sheets has increased, whilst that of copper manufactures has diminished. The exportation of lead in ingots has increased; that of lead manufactures, however, has remained stationary.

The native production of lead has steadily increased since the year 1890. The importation of the mineral has, however, undergone no material change, whilst its exportation has been gradually declining. There has thus been an increasing quantity of this mineral at the disposal of the home market, and the native production of lead in ingots has consequently made an important advance.

The increased importation of tin in ingots may be ascribed to the development of the tin plate industry in Italy.

Very little zinc is produced in Italy, although large quantities of the ore are mined and exported. There is a growing demand for foreign zinc in ingots. For zinc in sheets Italy is entirely dependent on foreign production.

The advance made in the paper industry accounts for the increasing importation of wood-pulp. The export of both writing and wrapping paper is rapidly increasing.

Both the importation and exportation of raw hides and skins have increased to a like degree, but those of dressed hides have not varied. The export of articles manufactured from skins is brisker than their import, and the importation of articles required for tanning and dressing hides is increasing. Italian trade in hides and skins is making substantial progress.

Marble quarries have been more productive of late years, and there has been an increased export both of the raw and worked material.

The abolition of the export duty on sulphur and the formation of the Anglo-Italian Sulphur Company, have favoured the sulphur industry, and since the year 1896 a great increase has taken place in the exportation of this substance in all its forms.

The increased exportation of bricks from Italy corresponds to the increase in home production. Between 1890 and 1902 the total output of bricks increased from 3,605,509 to 4,643,569 tons. The cement industry is also sharing in the general progress. From the year 1890 onwards importation has decreased and exportation has greatly augmented. In the pottery industry since the year 1890 the national production of terra-cotta has advanced from 63,996 to 78,184 tons; majolica and earthenware from 24,458 to 37,242 tons; porcelain from 1,378 to 4,026 tons. The importation of pottery has considerably diminished of late years, whilst its exportation is steadily increasing.

In 1890 the home production of glass and crystal in sheets, &c., was computed at 9,854 tons; that of articles made of glass and crystal at 31,546 tons. In 1902 the figures were 17,050 and 45,220 tons respectively. The importation of glass and glassware is diminishing.

The quantity of soap imported is still three times i excess of the amount exported; but the increasing importa tion of soda, fats, and other materials used in the manufacture of soap is a sign that the industry is beginning to develop, though it will doubtless be many years befor it can be in a position to supply the demands of the hom market. Greater activity is likewise being displayed i the manufacture of candles, as the quantity imported i decreasing, whilst a small export trade is commencing The progress achieved in this branch is confirmed by th increase in the importation of candle ingredients, such a stearic acid and paraffin.

The manufacture of matches in Italy is progressing bot in quantity and quality. The amount exported increase annually.

The starch industry, although progressing, has hither been unable to compete with the imported article, especiall that of fine quality.

The increasing demand for guttapercha and india-rubbe as insulating materials has helped to foster the industry i Italy. There has been a great increase in the importatio of the raw material, but at the same time there are a numb of gutta and rubber articles which are not yet produce in Italy.

During the last few years there has been a marke increase in the importation of linseed, rape seed, and colz

The manufacture of beet sugar has progressed ve rapidly. The production is now about sufficient to supp the requirements of the home market. 1,000,000 tons raw sugar were produced in Italy in the year 1902, a before long it is probable that there will be a surpl for export.

Native beer is being brewed in larger quantities, a foreign importation has declined proportionately.

The following table shows the values of some of the abov mentioned products in Italy in 1903 :—

	£		£
Sulphur	1,720,000	Sulphuric acid	357,30
Iron	140,000	Copper sulphate	351,50
Zinc	480,000	Calcium carbide	115,20
Bricks	1,635,360	Lead carbonate	102,60
Lime	800,000	Ballistite	89,04
Cement	218,000	Dynamite	72,64
Glass	680,000	Other explosives	68,2
Porcelain	143,680	Nitric acid	38,84
Plaster of Paris	113,800	Potassium nitrate	32,00
Superphosphates and other manures	1,030,800	Hydrochloric acid	18,44

UNITED KINGDOM; TRADE OF —— WITH SOME FOREIGN COUNTRIES.

Pharm. J., June 11, 1904.

The following table shows the value of certain classes articles (of interest to British chemical manufactur imported into Great Britain from certain foreign countr and exported from the United Kingdom to certain fore countries during the years 1902 and 1903.

Country.	Imports from Various Countries to Great Britain.			Exports from the United Kingdom to Various Countries.		
	Article.	1902.	1903.	Article.	1902.	1903.

II.—FUEL, GAS, AND LIGHT.

GAS TESTING; REPORT OF COMMITTEE ON ——.

Times, June 8, 1904.

The departmental committee appointed by the Board of ade to inquire as to gas testing in the metropolis, recom- nd that the standard burner to be used for testing the minating power of all qualities of gas should remain, as present, the Sugg's London (No. 1) Argand burner, and t the chimney to be used therewith should be of uniform —namely, 6 ins. long and $1\frac{7}{8}$ ins. internal diameter; that the purpose of determining the nominal illuminating ver of gas of any quality, the gas should be burnt in the ndard burner at the rate of five cubic feet an hour; t t provision should be made for official testing of i minating power in a flat flame burner of a kind to be scribed by the gas referees, and that the result of such t s be recorded and notified to the various authorities a companies concerned and to the Board of Trade; that c ial tests of the calorific power of the gas supplied by e company should also be made, recorded, and notified a above; that the existing statutory provision which r ires the gas to be wholly free from sulphuretted h rogen (which is, in fact, impracticable) should be n ified, and that for the future the test which the gas s ld be required to pass should not be more severe than t specified in the schedule to the Gasworks Clauses Act, l ; that the obligation placed upon the companies with r rd to the removal of sulphur compounds (other than s huretted hydrogen) should be abolished, but that test- ir for information only should continue to be made in su manner and to such extent as may be prescribed by tl gas referees; that the gas to be tested should be brought di t from the main to the testing-room by a single service p , without tap, branch, or connection; that in case of di rence between the gas companies and the gas referees as the reasonableness of any requirements of the referees th lecision of the chief gas examiner should be conclusive; that, except as may be involved in the foregoing recommendations, the powers and duties of the gas referees should remain as at present; that it should not be obligatory upon the controlling authority to test on Sundays; and that the duties of the chief gas examiner should include the hearing of all applications by the controlling authority for the recovery of forfeitures in respect of illuminating power, purity, or pressure, and the assessment of the forfeitures to be paid by the company in all cases except those in which he is unable to certify that the default is not substantial, or that it is not due to careless conduct of the works.

TAR FOR MANUFACTURE OF BRIQUETTES IN RUSSIA; DUTY-FREE ADMISSION OF ——.

Bd. of Trade J., June 2, 1904.

With reference to the notice which appeared at page 278 of this Journal for the 15th March last, relative to the probable reduction or abolition of the Russian import duty on coal tar, the Russian Government has authorised the duty-free importation of that article for the purpose of manufacturing briquettes for a period of 10 years, under regulations to be framed by the Minister of Finance in consultation with the Minister of Agriculture.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PETROLEUM INDUSTRY; THE CAUCASIAN ——.

S. Bartoszewicz. Naphta, 1904, **12**, 119—121.

The number of producing wells at Balakhany is diminishing, the figures in 1901 being 817, in 1902, 729, and 673 in 1903. The average output per well has declined, being 16·1, 14·3, and 13·5 thousand poods in the respective years. The number of new borings continues to decrease, being only 76 in 1903, as compared with 97 in the preceding year and 187 in 1901; and there is an increase in the number of pumping wells, 475 in 1903 against 262 in 1901. The total monthly output has fallen away to a corresponding extent, from an average of 9,815,000 poods in 1901, to 8,458,000 in 1902, and 7,784,000 in 1903. The estimate for the present year is 8 million poods per month.

The Sabountchy district is also considered to show signs of exhaustion, though the output is now estimated at 22 million poods per month, against 20—21½ million in the last few years.

The small Romany field is expected to yield an increased output, estimated at 9 million poods per month. At Bibi-Eibat there has been an increase in the number of producing wells and new borings, the former numbering 143 in 1902 and 164 in 1903, whilst the latter amounted to 72 and 98 respectively. The average output for the current year is taxed at 13 million poods a month, which, with the other fields already mentioned, gives a total of 54 million poods per month, or 640 to 650 million for the whole year. To these figures must be added the oil furnished by spouters; and as the yield on this head for the past eight years has never been less than 67·8 million poods, an estimate of 60 million poods is considered reasonable. This raises the total to over 700 million poods, which, with 40 million from the Grosny field, makes a grand total of nearly 760 million poods for the current year.

The capacity of the Baku refineries is set down as half as much again as the estimated output. Of the crude oil produced in the district, 610 million poods are refined on the spot, yielding about 175 million poods of refined oil. The total consumption, for the home and export trades, is 150 million poods.—C. S.

X.—*METALLURGY.*

TRANSVAAL MINERAL PRODUCTION IN 1903.

Bd. of Trade J., June 2, 1904.

The following table showing the value of the mineral output of the Transvaal during the six months and year ended 31st December last, is compiled from the half-yearly report of the Transvaal Government Mining Engineer :—

—	Jan. to June, 1903.	July to Dec., 1903.
	£	£
Gold	5,587,510	7,040,547
Silver	15,974	20,771
Coal	412,474	465,502
Diamonds	43,956	195,796
Chemicals	10,962	13,608
Stone, lime, bricks, &c.	103,816	155,480
Total	6,174,692	7,891,704

The total value of the minerals produced in the year 1903 was, therefore, 14,066,396*l*.

The total output of gold from all sources in the Transvaal for the half-year ending 31st December, 1903, amounted to 1,657,485 oz. fine, an increase over the preceding half-year of 342,072 oz.

The figures of the gold output since the resumption of mining operations subsequent to the war are as follows :—May to December, 1901, 1,097,219*l*.; January to December, 1902, 7,301,501*l*.; January to December, 1903, 12,628,057*l*.

The value of gold produced during the past year is therefore at the rate of 1,052,338*l*. per month.

The estimated quantity of silver contained in the gold bullion declared for the half-year under review, amounted to 194,788 fine oz., as against 155,282 fine oz. for the previous half-year.

STEEL-HARDENING METALS IN THE UNITED STATES.

Bd. of Trade J., June 2, 1904.

The following is given by the *Iron Age* (New York) of 12th May from the preliminary report of the United States Twelfth Census :—Under the head of steel-hardening metals are included metals used or experimented with in the hardening of steel, although some of them are used more generally for other purposes. The metals included in this class are nickel, chromium, tungsten, molybdenum, titanium, uranium, and vanadium. There is still another metal that naturally comes under this head, namely, manganese; but on account of its comparatively large production it is treated separately. The statistics for these metals during 1902 state the number of mines at 12, with a product of 4,444 tons (of 2,000 lb.), valued at 83,717 dols.

Of the 12 mines, four were producing tungsten ores; three, uranium and vanadium ores; one each, chrome ore, molybdenum ore, and rutile; and two, nickel and cobalt ores. Nickel and cobalt ores were concentrated into a matte. Tungsten ores were concentrated more or less. The value of the other ores is the value as mined. One chrome ore mine in California, four tungsten mines in Arizona, Colorado, Nevada, and Wisconsin, and two uranium and vanadium mines in Colorado were reported idle during 1902.

Manganese Ore.—The statistics include those ores carrying over 44·3 per cent. of metallic manganese. At the eleventh census the number of mines was not stated, but the product was given as 24,197 long tons, valued at 240,559 dols. The production reported was in Arkansas, California, Georgia, Nevada, North Carolina, South Carolina, Tennessee, Vermont, and Virginia. The statistics for the year 1902 make the number of mines 19, and the product 16,477 long tons, valued at 177,911 dols. The preparation usually given the ore at the mine is crushing, washing, and screening. There were 68 mines—in Arkansas, California, Georgia, Indian Territory, Maine, Montana, North Carolina, South Carolina, Tennessee, Virginia, West Virginia, and Wisconsin—reported idle during 1902, and three in Colorado, Utah, and Virginia, at which development work was reported.

XV.—*MANURES, Etc.*

CHEMICAL MANURES IN THE CANARY ISLES.

Bd. of Trade J., June 2, 1904.

The French Consul at Las Palmas reports that the development of the agricultural resources of the Canary Isles is causing a large demand for chemical fertilisers Liverpool, London, and Hamburg are the principal sources of supply.

The kinds most in request are: ammonium sulphate sodium and potassium nitrate, superphosphates, potassium sulphate, and vitriol.

CHEMICAL MANURES IN ITALY.

Bd. of Trade J., June 2, 1904.

The "Bollettino Ufficiale del Ministero d'Agricoltura, &c.," publishes a report on the consumption of chemical manures in Italy, which contains the following particulars :—

Superphosphates.—The most widely used chemica manures are superphosphates. The annual consumptio of these is about 4,000,000 quintals (quintal = 220·4 lb avoirdupois), mostly manufactured in Italy. The importa tion from the United Kingdom, France, and Belgium i very slight.

Thomas Slag.—About 700,000 quintals of Thomas sla were consumed in 1903, a figure which shows a larg advance on previous years. Most of it was imported fro Luxemburg, Germany, and Belgium: a small quantity cam from the United Kingdom.

Nitrate of Soda.—For various reasons, scientifi agriculturists have not availed themselves of this fertilise so much in Italy as in other countries; its use is, however becoming more general. In 1903, 200,000 quintals wer consumed, the whole of which came from Chile.

Sulphate of Ammonia.—About 125,000 quintals o sulphate of ammonia are used annually, the major portio coming from the United Kingdom. Only one-third of th amount consumed is produced in the country.

Potassic Manures.—Up to the present, the use o potassic manures has been somewhat restricted, as com pared with other manures. The demand for them i however, certain to increase greatly, more particularly fo the cultivation of beetroot, in which salts of potash ar largely used. About 30,000 quintals were imported in 19 from Stassfurt.

The following table gives a rough estimate of the uantity and value of chemical manures annually consumed u Italy :—

——	Quantity.	Value.
	Quintals.	Lire.
Mineral superphosphates	3 700,000	26,400,000
Bone superphosphates	300,000	3,000,000
Thomas slag	700,000	3,600,000
Nitrate of soda	200,000	4,600,000
Ammonium sulphate	125,000	4,100,000
Potassium salts	50,000	1,250,000
Total	5,075,000	42,950,000

XX.—*FINE CHEMICALS, Etc.*

CAMPHOR AND CAMPHOR OIL.

Schimmel's Report, April—May 1904.

The new Japanese Act regulating the monopolisation of ie camphor and camphor oil production in Formosa and apan has now been published in the "Deutsches Handels-rchiv," 1904. It reads as follows :—

Crude Camphor and Camphor Oil Monopoly.

(Japanese Gazette, 17th June 1903.)

Par. 1. The Government has the right of monopoly of ude camphor and camphor oil.

Par. 2. Whoever produces camphor and camphor oil, ust deliver the crude camphor and camphor oil to the overnment.

The time and place of delivery are fixed by the vernment.

Par. 3. The Government pays an indemnity for the crude mphor and camphor oil delivered. The amount of the lemnity is fixed by the Government, and must be blished beforehand.

Par. 4. In so far as it is not a question of crude camphor camphor oil sold by the Government, no one is allowed have these articles in his possession, or to hold, transfer, othecate, or use them; nor to ship them abroad, or from l Japan to Formosa, or *vice versa*. This does not apply, wever, to the possession of holding prior to the date of ivery to the Government, or if this delivery has been ayed for legitimate reasons.

ar. 5. Camphor and camphor oil may only be exported, shipped from Old Japan to Formosa, or *vice versa*, from ports indicated by the Government.

ar. 6. Whoever desires to produce crude camphor or c phor oil, or to purify crude camphor, must fix the place o production, the number of furnaces, the weight and q ntity of the estimated annual production, and also the d of the commencement of the manufacture, and must a ly to the Government for permission therefor.

f it is desired to make a change on any of the points for w ch under the foregoing paragraph permission has been g nted, or to discontinue the manufacture, permission must fi be obtained from the Government.

r 7. When a person has taken over the manufacture of ca phor or camphor oil by right of succession, he must gi notice of the fact to the Government.

hen a person otherwise than by way of succession de es to take over the manufacture, he must apply to the G ernment for permission.

r. 8. No person carrying on the manufacture of crude ca hor and camphor oil, is allowed to carry on at the sa time the purification of crude camphor.

ar. 9. The Government has the power of limiting the pr uction of crude camphor and camphor oil, in accordance wi the relation between supply and demand of camphor an amphor oil.

r. 10. When a person to whom permission for the ma facture of camphor and camphor oil has been granted act ontrary to the provisions of the present Act, or of the reg ations issued in accordance with this Act, or when he do not fulfil the conditions which have been determined in advance, the Government has the right to withdraw the permission granted.

When in view of the situation in the district of the Savages it is considered necessary for the purpose of maintaining public order, the Government may temporarily suspend the manufacture of crude camphor or camphor oil, or withdraw the permission to manufacture.

Par. 11. The producers of camphor and camphor oil must, in accordance with the regulations, enter in their business-books all facts concerning the manufacture.

Par. 12. The competent officials have the right to examine all business books relating to the production of camphor and camphor oil, and to make an inspection of all places where camphor or camphor oil are, or are suspected to be, produced or stored, and further to take all other steps required for the exercise of control.

Par. 13. Camphor and camphor oil are as a rule sold at a fixed price, but where necessary the sale takes place by auction instead.

Par. 14. Crude camphor or camphor oil which have not been sold by the Government are subject to seizure by the Government when found in possession of any person who holds them without conscious infringement of the present Act. In such case indemnity is paid in accordance with par 3, unless it is a question of crude camphor or camphor oil which have been mixed with other substances.

Pars. 15 to 23. (Articles dealing with penalties.)

Par. 24. With regard to the regulations required for carrying this Act into effect, the Governor General of Formosa decides in Formosa all questions which (in Old Japan) appertain to the department of the competent Minister.

Supplementary Regulations.

Par. 25. This Act comes into operation on the 1st of October, 1903.

The Regulations concerning the camphor and camphor oil monopoly in Formosa,* and also the Regulation concerning the manufacture of camphor and camphor oil in Formosa† are abrogated.

Par. 26. Crude camphor and camphor oil which in Old Japan, at the time this Act comes into operation, are the property of producers of or dealers in camphor and camphor oil, must, in accordance with the present Act, be delivered to the Government in accordance with the regulations which shall be published hereafter.

Par. 27. The provisions of this Act do not apply to crude camphor and camphor oil, which in Old Japan, at the time this Act comes into operation, are the property of other persons than producers of or dealers in camphor and camphor oil.

Par. 28. Whoever, at the time this Act comes into operation, produces in Old Japan camphor or camphor oil, must obtain before the 1st November 1903 permission (for continuing his trade). Up to that date he may continue the production as hitherto.

Par. 29. Whoever, in accordance with the regulations concerning the production of camphor and camphor oil in Formosa, has obtained permission, will be considered, until the expiration of the said permission, as having obtained it in accordance with the present Act.

ROSE OIL [OTTO OF ROSES]; COMMERCIAL POSITION OF ESSENTIAL ——.

Schimmel's Report, May 1904, 79—80.

The otto market has been very dull this year. The abundant rose harvest of 1903 stopped any manipulation of prices, and trade has also been upset by the troubles in the Balkans. Although otto has been plentiful, parcels of high quality have been rare. Exports in 1903 amounted to 6,210 kilos. as compared with :—1902, 3,676 kilos.; 1901, 3,028 kilos.; 1900, 5,346 kilos.; 1899, 3,534 kilos. Of last year's exports, 1,054 kilos. went to the United Kingdom, 1,027 kilos. to Germany, 1,456 kilos. to the United States, and 1,870 kilos. to France.—J. O. B.

---

* D. Hand.-Arch., 1899, I., p. 840. † *Ibidem*, p. 841.

CITRONELLA OIL; COMMERCIAL POSITION OF ——.

Schimmel's Report, May 1904, 27.

Conditions limiting the production have caused a marked rise in the price of citronella oil, the advance being from 9*d*. to 1*s*. 1½*d*. per lb. Last year's export showsa considerable decrease, being the lowest recorded since 1896. The figures for the last three years are :—1901, 1,430,168 lb.; 1902, 1,294,750 lb.; 1903, 1,062,594 lb.—J. O. B.

PEPPERMINT OIL; JAPANESE ——.

Schimmel's Report, May 1904, 72.

The harvest of peppermint last year was good, the crop being estimated in October at 200,000 catties, or about 120,000 kilos. From official data, the total exports of dementholised oil for the year 1903 amounted to 31,021 catties, of which 12,735 catties came to London, 9,900 to Hamburg, and 1,790 to New York. The export of peppermint crystals for the same period amounted to 46,410 catties, London taking 14,895 and San Francisco 900 catties. The total export amounted to 77,341 catties, or 103,340 lb. Probably the stock on hand in Japan is not more than 50,000 catties.—J. O. B.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

„ 17,585 (1903). Schwab. Saturators for sulphat of ammonia. June 15.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 12,270. Lake (Oehler). Sulphur dyes.* May 30

„ 12,512. Newton (Bayer and Co.). Manufactur of new colour lakes. June [illegible]

„ 13,227. Lennox. *See under* [illegible]

[C.S.] 15,700 (1903). Imray (Meist[illegible] und Brüning). *See under* XI.

„ 16,581 (1903). Newton (Bayer and Co.). Manufacture of new azo colouring matters and of ne intermediate products therefor. June 8.

„ 16,684 (1903). Imray (Ritsert). Manufacture o alkyl esters of 3.4-diamidobenzoic acid. June

„ 17,347 (1903). Johnson (Badische Anilin un Soda Fabrik). Manufacture of oxybenzalde hydes and oxybenzoic acids and intermediat products. June 15.

„ 17,565 (1903). Newton (Bayer and Co.). Manufacture of new anthraquinone derivatives. June

„ 17,768 (1903). Johnson (Badische Anilin un Soda Fabrik). Manufacture of colouring matters of the acridine series. June 15.

„ 17,805 (1903). Meyenberg and Clayton Aniline Co Ltd. Manufacture of sulphur dyestuffs. June 1

[C.S.] 17,965 (1903). Newton (F. Bayer and Co.). Manufacture of new derivatives of the anthracene series. June 15.

„ 18,131 (1903). Imray (Meister, Lucius and Brüning). Manufacture of indoxyl and its homologues. June 15.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 12,397. Textile Fibres, Ltd., and Tickel. Treating rhea, ramie, or China grass, flax, and other similar vegetable fibres. June 1.

„ 12,630. [illegible]. Detergent for degumming fibres. June [illegible]

„ 12,631. Wo[illegible]. Method of refining and separating vegetable fibres and a mixture therefor. June 3.

„ 12,632. Wohle. Detergent for scouring wool. June 3.

„ 13,090. Haddan (Elosegui). Fulling of woollen fabrics and other fibres or compositions adapted to be felted.* June 9.

„ 13,110. Girdwood. Preparing flax and similar fibres and means therefor. June 10.

C.S.] 12,342 (1903). Lumb, Walshaw, and White. Machines for milling or fulling and washing and scouring textile piece goods. June 8.

„ 14,840 (1903). Imray (Peterhauser and Rechberg). Process for improving the fastness of indigo-dyed woollen goods to wear. June 8.

„ 2680 (1904). Johnson (Goldman). Manufacture of felted or matted goods or fabrics from fibres or fibrous material. June 8.

„ 2681 (1904). Johnson (Goldman). Manufacture of felted or matted goods or fabrics from fibres or fibrous material. June 8.

„ 2682 (1904). Johnson (Goldman). Manufacture of felted or matted goods or fabrics from fibres or fibrous material. June 8.

„ 2683 (1904). Johnson (Goldman). Treatment of fibres or fibrous materials to form felted or matted goods or fabrics. June 8.

„ 2684 (1904). Johnson (Goldman). Production of felted or matted goods and fabrics from fibres or fibrous materials. June 8.

„ 8107 (1904). Ostersetzer. Process for finishing woven and other textile fabrics printed with patterns in metal powder. June 15.

VII.—ACIDS, ALKALIS, AND SALTS.

A.] 12,358. Soc. [illegible]'Air Liquide and Lévy. Method of separat[illegible] air and gaseous mixtures into their el[illegible]nd apparatus therefor. [Fr. Appl., [illegible]3.]* May 31.

, 12,[illegible] [illegible]m (Tcherniac). Treatment of ferrocyanides to obtain hydrocyanic acid. June 3.

, 12,639. Robson. Apparatus for vaporising ammonia and re-absorbing ammoniacal and other gases soluble in water. June 3.

, 12,694. Wheelwright. Manufacture and application of a new form of amorphous phosphorus. June 4.

13,140. Von Grätzel. Process and apparatus for the manufacture of sulphuric acid. June 10.

[S.] 8117 (1903). Tee. Manufacture of salt. June 15.

12,391 (1903). Monin. Treatment and utilisation of artificial sulphates and carbonates of lime. June 8.

17,449 (1903). Tcherniac. Manufacture of cyanides. June 8.

17,585 (1903). Schwab. *See under* III.

[C.S.] 17,981 (1903). Johnson (Badische Anilin und Soda Fabrik). Manufacture of a sulphate of a higher oxide of manganese. June 15.

„ 1066 (1904). Niedenführ. Process and arrangement for manufacturing sulphuric acid. June 8.

„ 9619 (1904). Parker. Production of Glauber salts and ferrous sulphate from nitre cake or acid sodium sulphate. June 8.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 12,201. Fidler. Continuous kilns for burning blue and salt-glazed and vitrified bricks, tiles, pipes, and terra cotta and like goods. May 30.

[C.S.] 12,861 (1903). Diaz. Drying- and baking-kilns for ceramic ware and the like. June 8.

„ 9295 (1904). Rowart and Francq. Apparatus for the manufacture of sheet glass. June 8.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 12,570. Winstanley. Machines and process for making bricks. June 3.

„ 12,707. Akerman. Kilns for burning cement and other substances. June 4.

„ 12,708. Thompson (Chem. Elekt. Fabr. "Prometheus"). *See under* XI.

„ 12,940. Vokes. Artificial granite, and process for the manufacture of the same. June 8.

[C.S.] 7068 (1904). Mahieux. Non-inflammable composition for use as a protective coating. June 8.

„ 9444 (1904). Jacobs. Coating bricks, plastering, &c. June 8.

„ 9765 (1904). Denaeyer. Cements and limes. June 8.

„ 9963 (1904). Imray (Carborundum Co.). Manufacture of carborundum articles. June 8

X.—METALLURGY.

[A.] 12,269. Eskuchen und Georgs-Marien-Bergwerks und Hütten verein Act.-Ges. Process of and apparatus for the production of pig iron by reduction and smelting. May 30.

„ 12,347. Steuart. Apparatus for the extraction of metals from their ores. May 31.

„ 12,507. Thorpe. Process of etching and apparatus therefor. [U.S. Appl., June 4, 1903.]* June 2.

„ 12,603. Evans. Treatment of minerals. June 3.

„ 12,621. Bailey. Sea-gold recovery. June 3.

„ 12,785. Fleischer. Process for the manufacture of iron. June 6.

„ 12,797. Leduc and Griffiths. Process for the enriching of calcareous ores.* June 6.

„ 12,816. Brayshaw. Melt or bath for hardening steel. June 7.

„ 12,817. Brayshaw. Process of hardening high-speed steel. June 7.

„ 12,976. Cutler. Furnace for calcining quicksilver ores. [U.S. Appl., June 10, 1903.]* June 8.

„ 13,121. Nicholas. Treatment of zinc ores. June 10.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 12,433. Brit. Thomson-Houston Co. (Allgem. Elektricitäts Ges.). Process for the production of insulating materials. June 1.

„ 12,541. Montlaur. *See under* I.

„ 12,633. Alton and Ramsay. Separating zinc by electrolysis. June 3.

[A.] 12,707. Thompson (Chem. Elekt. Fabr. "Prometheus"). Production of electrical resistance bodies from amorphous or crystalline carbide of silicon or boron or of silicon, &c. June 4.

„ 12,844. Franklin and Furnival. Bunsen semi-dry battery. June 7.

[C.S.] 13,182 (1903). Croucher. Electro-deposition of metals upon aluminium, alloys of aluminium and other metals. June 15.

„ 15,700 (1903). Imray (Meister, Lucius und Brüning). Process for reducing organic substances in electrolytic bath. June 8.

„ 9523 (1904). Duntley. Galvanic battery cells. June 8.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[C.S.] 8233 (1904). Nicloux. Material for saponifying fats and oils and method for obtaining it. June 8.

„ 9018 (1904). Van Meerdervoort. Process and apparatus for the continuous manufacture of sterilised fish oil and fish guano. June 8.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—Pigments, Paints.

[A.] 12,512. Newton (Bayer and Co.). *See under* IV.

[C.S.] 17,120 (1903). Kollinger. Binding media for oil colours. June 8.

(*B.*)—Resins, Varnishes.

[A.] 12,663. Melville, Rees, and Rees. Substitute for oilcloth or linoleum.* June 4.

(*C.*)—India-Rubber.

[A.] 12,273. Richter. Manufacture of artificial india-rubber. May 30.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

[A.] 12,388. Tullis. The tanning of hides into leather. June 1.

[C.S.] 21,379 (1903). Weiss. Detanning mineral-tanned leather or leather waste or the like for the manufacture of gelatin and glue. June 15.

XV.—MANURES, Etc.

[A.] 12,573. Beater and Toppin. Fertiliser. June 3.

[C.S.] 9018 (1904). Van Meerdervoort. *See under* XII.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 12,385. Weiss. Saccharometers. June 1.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 12,417. Storrier. Method of producing non-deposit beers and stouts for bottling. June 1.

[A.] 12,718. McKenny. The maturing of whiskey an other spirituous liquors. June 6.

„ 12,917. Hemming. Aerated beverages.* June 7.

„ 12,962. Vignier. Materials for the production o whiskey and beer. June 8.

„ 13,227. Lennox. *See under* I.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—Foods.

[A.] 12,754. Oetker. Manufacture of substitutes fo honey. June 6.

„ 13,159. Spurge. *See under* XX.

„ 13,266. Craveri. Process of preserving meat.* June 11.

(*B.*)—Sanitation; Water Purification.

[A.] 12,232. McLean and Paterson. Treatment of sewage.* May 30.

„ 13,227. Lennox. *See under* I.

[C.S.] 13,560 (1903). Hewes. Method and means fo treating sewage. June 8.

„ 14,536 (1903). Cameron. Treatment of distillers refuse, sewage, and the like. June 8.

„ 21,668 (1903). Boudry. Process for the simultaneous production of purified and sterilise water as well as of distilled water. June 8.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 12,576. Dobson. Method of and means for removing sand and like foreign matter from pape pulp, &c. June 3.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 12,440. Newton (Bayer and Co.). Manufacture o a pharmaceutical compound. June 1.

„ 13,159. Spurge. Treatment of fruits and the production of scents or flavours therefrom. June 1

„ 13,171. Hunter. Machine for extracting oil fro the rind of limes and other citrous fruits. June 10.

„ 13,285. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new derivatives of lecithins. June 1

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 13,179. Gem Dry Plate Co., Ltd., and Bake Method of photographing coloured objects i monochrome. June 10.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 12,627. Hough. Nitrated carbohydrates. [U. Appl., June 13, 1903.]* June 3.

„ 12,637. Weiller and Weiller. Explosives. June

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who propose to attend the meeting are requested to inform the General Secretary, as soon as possible, by what steamer they will travel. The principal boats will be met on arrival at New York by a representative of the Reception Committee, who will escort the guests to the Hotel Seville, Madison Avenue and 29th Street, which will be the Society's Headquarters in New York. A similar system will be observed at all the other cities visited by the special train. A revised programme appeared in the March 31st issue.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Wm. H. Nichols has been nominated to the office of President under Rule 8; Dr. Edw. Divers, Prof. W. R. Eaton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. Parker have been nominated Vice-Presidents under Rule 8; and Sir Wm. Ramsay has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18 :—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the Annual General Meeting at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

CORRECTION.

THE LOSS OF NITRE IN THE CHAMBER PROCESS.

BY J. H. K. INGLIS.

(This J., June 30th, 1904, 643—645.)

In the remarks of Mr. Oscar Guttmann, in discussion 645, col. 1), the following sentence occurs:—"Dr. schig, in the presence of Prof. Lunge and others, had monstrated the correctness of his theory by analyses on e large scale."

Prof. G. Lunge writes, under date July 5th, that it might em from the above that he had, by his silence, conceded e correctness of Raschig's views, but that this was not so. the annual meetings of the Society of German Chemists, pers were only exceptionally followed by discussions, and this particular case, the lateness of the hour precluded y discussion whatever.

DR. V. COBLENTZ IN THE CHAIR.

METHODS FOR THE RAPID ESTIMATION OF BORIC ACID.

BY DR. MILTON F. SCHAAK.

The estimation of boric acid has, until recent years, been nded by many difficulties. This has been chiefly owing he fact that none of its compounds appear to possess properties necessary for a satisfactory separation or vimetric estimation.

o mineral analyses it was customary to determine the on indirectly, or to estimate all the constituents of the eral, and calculate the difference as boric acid.

Methods for the titration of boric acid were also lacking l it was observed by Thomson (this J., 1893, 433) that addition of glycerol to solutions increased the acidic ure of boric acid to such a degree that accurate titrations d be made by using phenolphthalein as the indicator.

he method most in favour at the present time for the vimetric estimation appears to be that of Gooch (Amer. r. of Science, 1899, 34; see also this J., 1887, 385). this method the boric acid is liberated from its compounds by acetic acid, and heated with methyl alcohol, forming the volatile ester trimethyl borate, which is completely removed by distillation. The distillate is collected over a weighed amount of calcium oxide or sodium tungstate, by which the ester is decomposed; the boric acid becomes fixed, and, after ignition, is calculated from the increase in weight. This method, while appearing simple, yet requires great skill and patience for the attainment of accurate results.

he method of Berzelius, by which the potassium borofluoride is separated and weighed, was selected by Thaddeeff (this J., 1898, 953) after an extended investigation of other methods. He recommends the isolation of the boric acid by distillation with sulphuric acid and methyl alcohol, collecting the distillate in aqueous solution of potassium hydrate, treating with hydrofluoric acid, potassium acetate, and alcohol for the separation of the potassium borofluoride, which is then weighed. Since the borofluoride is not entirely insoluble in the mixture used, very accurate results cannot be expected; besides which, the operations are tedious.

Partheil and Rose (Ber., 1901, 3611) have suggested extracting the boric acid from its aqueous solutions by means of ether in a perforator, and weighing. The extraction requires 18 hours, and easily becomes complicated by the presence of other substances.

The most recent attempt to effect a gravimetric determination is that of Mylius and Meusser (Ber., 1904, 397; this J., 1904, 269), who sought to utilise the fact that boric acid possesses basic properties, and will react with acids. They selected a compound with phosphoric acid, boryl phosphate (BPO_4) and proceed as follows:—An aqueous alcoholic solution of boric acid is treated with ammonia and phosphoric acid, evaporated to dryness, and finally heated in an atmosphere of steam to assist in removing the excess of phosphoric acid before weighing as BPO_4. The method has not yet been perfected, their results being only approximately accurate.

It is evident from the foregoing that the gravimetric methods available at the present time are not suited to the rapid estimation of boric acid, and recourse must therefore be had to volumetric methods.

As is well known, aqueous solutions of boric acid are but slightly dissociated, and alkalis have an uncertain action in the presence of phenolphthalein as indicator, while methyl orange is practically not affected, and solutions containing free boric acid will react neutral with it.

The observation of Thomson, already mentioned, led to the use of glycerol to increase the acidic properties sufficiently for the titration in the presence of phenolphthalein.

Since that time the action of glycerol upon boric acid has been investigated at various times, and it has been shown that substances having hydroxyl groups all acted upon boric acid to a greater or less degree, and that it is probable that alkyl compounds are formed which are highly dissociated in the solvent, and which, according to the law of mass-action, are stable only in concentrated solution of the reacting substance; it is therefore necessary to employ a large excess of the alkyl base in proportion to the water present.

Glycerol and mannitol are the polyatomic alcohols most available for the purpose of the titration mentioned.

It has been shown by Jones (Amer. J. of Science, 1899, 127) that the alkyl compound with mannitol acts quite as energetically upon a mixture of potassium iodide and iodate as a mineral acid in liberating iodine according to the equation—

$$5KI + KIO_3 + 6HBO_2 = 3I_2 + 6KBO_2 + 3H_2O.$$

He has made this fact the basis of a method for the iodometric determination of boric acid (this J., 1899, 947).

Jones has also used a mixture of potassium iodide and iodate in conjunction with sodium hyposulphite to neutralise the free mineral acid in a borate solution previous to the titration with mannitol and phenolphthalein. The method has no advantage over the use of methyl orange to indicate the neutral point, and it is more complicated, and this is especially the case with his iodometric method.

A solution of boric acid in methyl alcohol acts almost like an aqueous solution, and can be titrated only after the addition of a polyatomic alcohol. Gladding (J. Amer. Chem. Soc., 1898, 288) has used this method for titrating the distillate obtained by distilling a borate with syrupy phosphoric acid and methyl alcohol.

The application of this method is rather limited, as no provision is made for operating in the presence of carbonates or volatile mineral acids.

The general application of the methods for the volumetric determination of boric acid in minerals and in presence of other substances is very desirable, and it is my purpose to point out several sources of possible error, and to present methods by which the interfering substances may be eliminated and correct results attained.

Of the methods thus far proposed for the volumetric determination of boric acid, it appears to me that the employment of methyl orange to indicate the point at which all the boric acid in a borate solution has been liberated, and the subsequent addition of glycerol for the titration of the acid in the presence of phenolphthalein, can be relied upon to give results with rapidity and accuracy in all cases where the solution to be titrated is free from interfering substances. A type of this class of titration may be illustrated by the method now in general use.

I. To about 50 c.c. = 1—2 grms. borax, 1—2 drops solution methyl orange are added and standard acid until all the boric acid has been liberated, when the solution will react acid with the indicator. In the presence of a carbonate the acid solution is heated a short time with a reflux condenser until the carbon dioxide is removed. The solution is cooled and made exactly neutral to methyl orange, and an amount of neutral glycerol, equivalent to fully one third the volume of the solution at the finish, is added together with about ½ c.c. solution phenolphthalein. The titration is then finished with standard alkali, which must be free from carbonate. The calculation is based upon the following equation :—

$$B_2O_3 + 2NaOH = 2NaBO_2 + H_2O.$$

Borates insoluble in water are dissolved in dilute hydrochloric acid, in the cold or with a reflux condenser, and treated as in the foregoing.

This method will not give accurate results when aluminium salts are present, as the solution when neutral to methyl orange will contain free alumina, which will combine with the alkali when titrating with phenolphthalein and glycerol, and thus be calculated as boric acid. Iron salts, when present in considerable proportion, also interfere by obscuring the colour reactions of the indicators. There appears to be no combination of indicators known which will serve to prevent this error, and it therefore becomes necessary to separate the iron and aluminium from the solution before titrating.

Most of the minerals containing aluminium also contain small amounts of silica, and when an attempt is made to remove the aluminium by means of alkali carbonates, insoluble borates are formed, and therefore this method is unsatisfactory for the removal of the disturbing elements.

I have found that when barium carbonate in excess is added to a solution containing free boric acid with aluminium and iron salts, all the latter will be precipitated and can be removed by filtration, while only a slight portion of the free boric acid will react with the barium carbonate and pass into solution as borate, and this can again be decomposed by the addition of acid. Upon this observation I have based the following method (II.) :—

A convenient amount of the substance is placed into a flask with an excess of dilute hydrochloric acid, and heated with a reflux condenser for solution. After cooling, the solution is brought to a definite volume and filtered. 100 c.c. of the filtrate, which may represent 2—4 grms. substance, are brought almost to the neutral point of methyl orange with alkali, 2—3 grms. barium carbonate are then added, and the solution warmed on the steam-bath ½ hour, cooled, brought to 200 c.c., and filtered. The solution will then be free from the interfering substances, and may be titrated as in I.

This method has been found to be well suited for the rapid assay of the various natural compounds of borate of lime, such as colemanite and pandermite, which usually contain small amounts of alumina and silica, iron, magnesia, and gypsum.

In cases where it is desirable to have the boric acid free from other substances before titration, I have found, after investigation, that distillation with methyl alcohol and titration of the distillate can be accomplished with rapidity and accuracy, and that the interference of volatile mineral acids or carbon dioxide can be eliminated.

A study of the properties of methyl borate shows that it is immediately decomposed into its components upon contact with water. This fact led to the introduction of water into the receiver, which at once leads to the formation of free boric acid, and the chances for loss at this point are thus minimised. It also suggests that the use of concentrated sulphuric acid and the exclusion of water during the distillation will secure freedom from hydrolytic action an thus lead to the greatest rapidity of distillation.

As already mentioned, solutions of boric acid in methy alcohol may be titrated like aqueous solutions. Whe however, mineral acids or carbon dioxide are present, the cannot be eliminated as in water solutions.

I find that mineral acids in the methyl alcohol distillat may be neutralised with alkali, previous to the titration c the boric acid in presence of glycerol, by the use of methy orange or Congo red test-papers. By spotting upon Cong red test-paper, 0·1 c.c. N/5 acid to 100 c.c. methyl alcoh may be detected. Organic acids which would interfere ca readily be excluded from the substance. The carbo dioxide can be removed by heating the substance wit sulphuric acid before the distillation.

III. The apparatus for distillation may conveniently b arranged as follows :—A long wide-necked 200 c.c. Kjeldal flask may serve as the decomposing flask. This flask fitted with a stopper carrying three tubes, one of whic serves to connect it with a condenser in such a manner to avoid any of the acid liquid being carried over durin the distillation. Another tube is to be connected with flask for supplying a current of methyl alcohol vapou which is to be conducted to the bottom of the decomposin flask, thus serving to keep the mixture agitated and avo bumping during the distillation. The third tube serves t introduce the methyl alcohol needed to form the mixtu with the sulphuric acid and the substance, and may also b fitted with a clamp and valve for equalising the pressur when needed. The receiver which is to be connected wit the condenser is trapped with a Mohr's bulb.

For the estimation a portion of the dry, finely pulveris substance is placed into a long narrow tube and weighe The contents are then emptied into the decomposing flas without allowing any of the substance to remain in the nec of the flask. The tube is now weighed again, the differen being the amount of substance used for the estimation.

A sufficient amount of concentrated sulphuric acid added to form a thin paste with the substance, and th flask heated gently to expel carbon dioxide or other volat acids, and cooled.

About 60 c.c. of water are placed in the receiver, th terminal tube of the condenser being made to dip into th water. The Mohr's bulb is also filled with water an attached as a trap to the receiver. The decomposing flas containing the cold mixture of the substance and sulphur acid, is now connected with the flask for the generation methyl alcohol vapour, and with the condenser, all th connections being air-tight.

The distillation is then started by adding to the decomposing flask, in one portion, sufficient cold methyl alcoh to equal about 20 times the amount of free sulphuric aci present. Methyl alcohol vapours are then passed from th generating flask until the boric acid has all passed into th receiver.

During the distillation the decomposing flask is heated a temperature sufficient to prevent any marked change volume of the methyl alcohol which was originally added.

The distillation will usually be complete in abo 30 minutes, when the receiver can be changed, and, ensure complete removal of the boric acid from the su stance, a further distillate collected and tested.

The water from the Mohr's bulb is added to the distillat which is then neutralised with alkali, when necessary, the aid of Congo-red or methyl orange test-paper. Th titration is then completed after the addition of neutr glycerol and phenolphthalein as in I.

When pure methyl alcohol is used and care is taken n to allow the mixture with sulphuric acid in the decomposi flask to become concentrated, accurate results can attained, even in the presence of large amounts of chlorid and carbonates. Fluorine, when present in large amou must be removed from the substance before distillatio Borates which are not decomposed by concentrated su phuric acid are treated by suitable methods of fusion befo distillation.

The following results of the assay of several samples commercial borate of lime will serve to illustrate the val of the three methods. The results by Method I. s erroneous, except with the crystal colemanite, which is free from the impurities mentioned:—

MR. J. T. WOOD IN THE CHAIR.

NOTES ON PETROLEUM SPIRIT OR BENZINE.

BY H. STANLEY GARRY AND H. J. WATSON.

The distillation fractions of crude petroleum which are collected between certain arbitrary ranges of temperature yield a variety of products which are sold in commerce under the trade names of petroleum ether, gasoline, benzine, ligroin, or light petroleum. These are colourless mobile liquids used as solvents for gums and resins, for removing grease from textile fabrics, wool washing, paint mixing, and in preparation of varnishes, manufacture of oil-cloth, preparation of alkaloids, extraction of oils and fats in the leather and rubber industries, and in dry cleaning. The requirements of these trades vary considerably as to the character of spirit required, but it is more especially with regard to the range of boiling points of the spirit than the specific gravity of it that this variance exists, and to this particular phase of industrial requirements we would direct attention in this discussion.

Speaking generally, those qualities of naphtha which have come into the most common use are the naphthas of medium gravities and in which the range of boiling points is limited to about 40° C. In dealing with petroleum spirit for extractive purposes there is very considerable difficulty in arriving at any satisfactory basis of examination of samples. Specific gravity is of little assistance, as the effect of the spirit depends principally on the range of boiling points. The success of the operation in bulk depends on the restriction of the boiling points to the possible temperatures at which the operation can be conducted in the first place, and secondly to the recovery of the spirit from the extract.

It is practically impossible to obtain a petroleum spirit possessing the special range of boiling points suitable to any particular material to be treated unless the spirit has been prepared by a special distillation beforehand and the extremes eliminated. It is possible, however, to obtain a petroleum spirit which will either commence fractionating

at the minimum of the range required, in which case the heavier portion of the spirit may be rejected by stopping the distillation at the maximum temperature; or, alternatively, a spirit may be obtained finishing at the maximum temperature, in which case the distillate up to the minimum of the range is rejected.

Tables A and B give comparative analyses by fractional distillation of samples of petroleum spirit from different sources, showing the variations in range of boiling points of the principal grades of petroleum spirit now on the market.

Table B gives typical analyses of a number of benzines of different specific gravities, and is a fair experience of the variations in boiling point to be met with in commercial spirit.

Taking the limit of the range of boiling points at 40° C., it will be seen that none of these samples in Table A will satisfy this requirement, there being an excess under and over this range. In many cases the only solution of the matter is for the purchaser to distil the spirit to his own requirements. The effect of different designs of apparatus for conducting the fractional distillation, both in samples and in bulk operations, is very marked, as is shown by Tables C and D.

The following table shows shows the difference resulting in the employment of three different vessels for distilling the same spirit in simultaneous distillations:—

TABLE C.

Specific gravity, 0·700.

" " "	90° C.	85·0	84·4	84·7
" " "	100° C.	93·0	92·6	92·1

A. Ordinary flask 2¾ inches from side tube to swell of sphere.

B. Wurtz flask, 3 bulbs, 6 inches in length from side tube to swell.

C. Plain tube, 24 cms. from side tube to swell, and having a distance of 8·5 cm. of glass beads in tube.

The rate of distillation in each case was 1½ to 2 c.c. per minute.

It was found in practice that the effect of the glass beads was analogous to the return tubes, but that the retention of the heavier volumes was considerably facilitated by the obstruction of the beads. Care, however, is required in manipulation or there is a rush of spirit when nearing the end of the distillation.

T.—Glinsky's dephlegmator, as above. Liquid readings.

The rate of distillation in each case, 2½ c.c. per minute condensation commenced, taken from appearance of first drop of distillate.

There are also marked variations in the distillations of the same spirit taken at different fractions and at one continuous distillation due to the carrying over of the heavier spirit at the earlier stages. Of this Table E gives a striking illustration.

The distillates from eight separate distillations of the same spirit were collected between the following ranges of temperature:—Below 70° C., between 70° C. and 80° C., between 80° C. and 90° C., above 90° C. These were marked V, W, X, and Y, and subjected to distillation in the same apparatus. Below is the result of these distillations with the fractional distillation of the original spirit, and the calculation back from the distillates to the original spirit:—

TABLE E.

The fractional distillation of the spirit on small lots, owing to the effect of these variations, renders it generally desirable for the purchaser to arrange for the distillation of the spirit to his special range of boiling points beforehand in order that it may be carried out on a large scale, and so give a fairly average distillate.

There are a number of firms who undertake the distilling of spirit, but the experience of the writers is that no two firms can agree upon the range of boiling points, and there is considerable discrepancy in the results obtained.

There is urgent necessity for the adoption of a standard test for petroleum spirit similar to that adopted for benzol, which would considerably simplify the labour of further researches into the characteristics of the spirit.

The carrying out of experiments or tests of the range of boiling points should in all cases contain the particulars of the volume of the distillate as compared with the original sample and should be possible of comparison as set out in Table E.

There are very considerable differences in the working characteristics of petroleum spirit, which are not measurable either by specific gravity or range of boiling points and which are due both to blending and to inefficient distillation of the original spirit. The principal variations in petroleum spirit occur up to 100° C., as appear from the foregoing tables, as also from Sidney Young's results given in his book on "Fractional Distillation." An apparatus constructed for laboratory tests, should as far as possible approximate to the apparatus for bulk operations, and the adoption of the form of still should provide for such construction and obstruction as will retard the passing of the heavier portions with the more volatile vapours. In large scale operations this is to a large extent provided by the material operated upon.

In the selection of a spirit for the special requirement of an extractive process the conditions of the bulk operating should as far as possible be reproduced in the laboratory, the moisture in the material, density and obstructions to vaporisation in bulk plant should be taken into consideration.

DISCUSSION.

The CHAIRMAN said that he had had some experience in the use of petroleum spirit for taking out grease from skins and leather. The advance made in degreasing skins was due in the main to the experiments carried out by Mr. F. N. Turney, which resulted in the erection of the plant at Whitemoor. The work that had been done in England had not been fully recognised. The main point of the paper so far as the use of petroleum spirit was concerned, was to be found in the sentence "there are very considerable differences in the working characteristics of petroleum spirit, which are not measurable, either by specific gravity or range of boiling points, but which are due both to blending and to inefficient distillation of the original spirit." This was a very abstruse question which had been partly discussed by Professor Young in his book on Fractional distillation, but he (the Chairman) could confirm what the authors of the paper said on the point. He had collected some figures from analyses made eight or ten years ago. The vapour tension of the spirit was more important than any other of the physical properties. He had made a great number of tests in the vapour-tension of spirits of varying gravities, and in some cases the spirit with the highest vapour tension had also the highest gravity, and a spirit with low gravity might have also a low vapour-tension. In certain mixtures the vapour given off was of less tension than one would anticipate from the gravity. Had Mr. Garry any data bearing upon that part of the question? He had had no practical experience with Russian petroleum, but in the Compagnie de Degraissage de St. Denis, he believed, they used a Russian spirit coming over below 110°, and so far as he knew they had no difficulty with it. The point he mentioned about the vapour-tension or vapour pressure, was important in the recovery of the spirit. In the apparatus in question there was a large tank in which skins were suspended, they were washed with spirit, and then dried in a current of warm air. When they were thoroughly dried the valve between the tank and the spirit was shut off preparatory to opening the tank and getting the skins out. Enclosed in the tank was a certain amount of vapour, which it was impossible to condense. The amount of this vapour depended of course upon the vapour pressure of the spirit used. The tank must be opened to the air to get the skins out. There were perhaps several hundred cubic feet of air charged with the vapour of petroleum, that was all lost. The smaller the vapour-tension in the spirit, the less they lost in that way, and if they were opening seven or eight tanks a day, they lost a great deal of spirit, although the apparatus might be in perfect working order. In working with chloroform, the solvent had been recovered by passing the vapour through a tower in which oil was falling. The oil absorbed the vapour which was afterwards recovered by distillation.

Dr. KIPPING and Messrs. ARCHBUTT and TROTMAN agreed that the adoption of a standard method for the distillation test was desirable. There should be no difficulty about this, as Mr. Archbutt pointed out that years ago the most minute directions were laid down for the distillation test of coal-tar benzenes.

Mr. H. S. GARRY, in reply, said, so far as he knew, most of the research work done in England had been done at Whitemoor. All he knew about the matter from a commercial standpoint had been gained by experience and not from college study. He had not seen any literature on the subject up to the time Professor Young published his book. There was a good deal about petroleum spirit which nobody seemed to understand. The notes were put forward in order to urge the necessity in having a reliable method for estimation for boiling points. The petroleum trade had, so far, adopted no specific method.

Scottish Section.

Meeting held at Glasgow, on Tuesday, Dec. 1st, 1903.

MR. H. BUMBY IN THE CHAIR.

A COMPARISON OF DIFFERENT TYPES OF CALORIMETER.

BY THOMAS GRAY, PH.D., D.Sc., AND JOSEPH G. ROBERTSON, PH.D.

The experiments here recorded were instituted with the object of ascertaining the degree of accuracy of the calorific values of coal obtained by the Lewis Thompson and Wm. Thomson calorimeters by comparison with those determined by combustion in compressed oxygen. Some of the results of the work were communicated to the Scottish Section on Dec. 1, 1903, but publication was delayed in order to complete the series. Whilst the experiments were in progress, a paper dealing with the same subject appeared in this Journal (Brame and Cowan, 1903, 1230); but although our conclusions were largely anticipated by these authors, we decided to complete the work, as the experience gained with a larger number of coals of a different character would probably prove of general interest. As the previous publications referring to the comparative values obtained with different calorimeters have already been reviewed by Brame and Cowan (*loc. cit.*), we may proceed at once to give the results of our experiments.

The designations and sources of the coals used are given below (page 707). Numbers are attached for purposes of reference.

The samples were passed through a hand mill, thoroughly mixed, and air-dried to prevent, as far as possible, any change of composition on exposure to air in the subsequent operations.

The Lewis Thompson Calorimeter.—A standard thermometer graduated in 1/10° C. was used with this instrument and the temperature was read to 0·01° C. The coals were very finely ground to facilitate complete combustion, and at least four experiments were made in each case with 11 parts of the oxidising mixture to 1 part of coal. Coals 1 to 8 burned quietly and regularly, with 9, 10, and 11 the combustion was very rapid, but attempts to burn the anthracite were all unsuccessful. In some experiments the coal failed to ignite, and when ignition did take place the combustion stopped before the mixture was completely burned. The combustion was finally effected by using a mixture of equal parts of the anthracite and a bituminous coal, the calorific value of the latter as determined with the Lewis Thompson calorimeter being used in calculating the value for the anthracite. As the object of the experiments was to ascertain the degree of accuracy of the method as it is usually carried out, the amount of unburnt carbon was generally not determined. This determination complicates the method and removes the only advantage which can be claimed for the Lewis Thompson apparatus, viz., simplicity of manipulation. Except in the case of the anthracite the amount of unburnt carbon was small. Further reference to this point will be made under the discussion of the results.

The proportion of oxidising mixture was increased in the case of the quicker burning coals, but the calorific value was not raised thereby. Seven experiments with Kilsyth coking coal, using 11 to 13 parts of the mixture per 1 part of coal, gave results varying to the extent of 88 calories = 1·2 per cent., whilst the mean was 7 per cent. below that obtained by the bomb. This difference between the extreme results is not greater than that observed using a fixed pr portion of the oxidising mixture. In the case of the samp of anthracite, on the other hand, a higher value was obtaine by increasing the proportion of the oxidising mixture. Th figure in the table (page 707) is the mean obtained usin the ratio 13:1. As the combustion of the Kilsyth cokin coal proceeded very rapidly there was a possibility of lo of heat through imperfect cooling of the products. Fou estimations were accordingly made with the addition to th mixture of 1 to 2 grms. of ignited kaolin; the rate o combustion was reduced thereby, but the mean result wa slightly lower than that previously obtained.

The differences between the extreme values in each serie varied in the case of the bituminous coals from 0·5 t nearly 3 per cent. These differences are smaller than thos observed by Brame and Cowan, and this result is probabl due to the difference in the character of the coals exper mented on, and partly also to the finer state of division i which they were used. With the sample of anthracite th difference between the extreme results reached 4·5 pe cent., which agrees more closely with the observations o the authors referred to.

The William Thomson Calorimeter.—The water valu was calculated from the weights and specific heats of th various materials. For the estimation of the weight of th glass beaker in contact with the water the method used b Thomson (this J., 1886, 584) was followed, the level o the water in the calorimeter-beaker having been marke with the combustion chamber and stand immersed.

The coal was burned in the form of compressed pellet in order to prevent the irregular combustion which was observed when the coal was used in the powdered form the danger of loss through particles of coal being blown ou of the crucible by the rapid current of oxygen was als avoided in this way. The coals all readily cohered on pressing, with the exception of the anthracite, which was compressed with admixture of an equal weight of Kilsyth coking coal.

The ignition of the coal was effected electrically. Fo this purpose two insulated copper wires were passed through the bottom of the metal stand into the glass combustion chamber, with the ends about half-an inch apart and level with the top of the platinum crucible. The ends of the wire were connected by means of a piece of fine platinum wire to which a piece of cotton yarn was fixed, the other end of the cotton being tied round the coal pellet. The combustion chamber was allowed to stand in the water for 10 minutes, after which the coal was ignited by the passage of an electric current sufficiently strong to fuse the platinum wire instantaneously. By this arrangement errors due to handling the apparatus before immersion in the water were avoided, and the ignition of the coal was effected with greater certainty. A correction was made in each case for the heat of combustion of the fuse.

In one series of experiments a standardised Beckmann thermometer graduated in 1/100° C. was used. A thermometer of this type is, however, not always available, and is rather delicate for technical work. For the sake of comparison a series of experiments was therefore carried out, using the thermometer reading directly to tenths, already referred to under the description of the Lewis Thompson method.

The Cooling Correction.—This is determined by Thomson (*loc. cit.*) by allowing the apparatus to stand at the end of the experiment for a period equal to the duration of the combustion; the fall of temperature which takes place is added to the observed rise. This correction assumes the temperature to have its maximum value during the whole period of the combustion, and is therefore obviously too high. With an imperfectly insulated vessel, such as that under discussion, an exact estimation of the loss of heat in the course of an experiment extending over 8 to 10 minutes is scarcely practicable. As the temperature rises uniformly during the combustion, the method of compensation first proposed by Rumford is applicable, and by starting with water having a temperature as much lower than that of the room as it will be above that of the surroundings at the end of the experiment, the necessity of applying a correction for loss of heat is obviated. The rise in temperature is usually known approximately, and in any case can be determined by a preliminary experiment. This method of operating is sufficiently accurate for all practical purposes if an ordinary thermometer with a small mercury reservoir is used, as the maximum temperature is quickly attained; but with a Beckmann thermometer a slight modification is advisable on account of the lag caused by the large volume of mercury. In the latter case the rise in temperature at the end of the combustion was noted before the water was admitted to the combustion chamber, and from this the initial temperature of the water to be chosen in future determinations was fixed; the time which elapsed before the thermometer indicated the maximum temperature, after admission of the water to the chamber, was observed; and the fall of temperature which took place when the apparatus was allowed to stand for the same period after the maximum had been reached, was added to the observed rise. Thus correction was usually 0·010° to 0·015° C.

The oxygen used for the combustion was saturated with water vapour by passage through a wash-bottle, followed by a tower containing pumice soaked in water. As the oxygen entered the calorimeter at the mean temperature prevailing during the experiment, it may be assumed without appreciable error that it gave up to the calorimeter during he first half of the combustion as much water vapour as he products of combustion carried away during the second half while the temperature of the water was in excess of hat of the surrounding air. Even when water of the air emperature is used at the beginning of the experiment, no considerable error is committed by neglecting this orrection. If we suppose that oxygen saturated with water apour at 15° enters water at the same temperature and that he temperature at the end of the operation is 19° C., we nay assume that the oxygen leaves the water with an verage temperature of 17°, and on this basis calculate pproximately the loss of heat due to evaporation. One ubic metre of oxygen saturated with water vapour at 15° nd at 17° C. contains respectively 12·74 and 14·38 grms. f water, and the amount of heat necessary to convert the ifference between these two weights of water into vapour t ordinary temperature is 1·64 × 600 = 984 calories. he amount of oxygen used for the combustion may be taken to be about 10 litres, and the heat loss due to evaporation under these conditions will therefore be approximately 10 calories. The amount of heat necessary to raise the temperature of the excess oxygen and the products of combustion through 2° C., calculated from the specific heats O_2 0·217, CO_2 0·202, and water vapour 0·480, does not exceed 10 calories, so that the total correction to be applied for these two losses will be less than 20 calories. As has been already explained, loss of heat from these two causes was obviated by the method of working.

Three determinations were made with each coal, using the fine thermometer. The difference between the extreme values obtained for the individual coals varied from 0·3 to 1·5 per cent. The average difference for the 12 samples was 1 per cent.

The differences observed with the thermometer graduated in 1/10° C. were somewhat greater, as was to be expected. The temperature in this case was estimated to 1/100° C., and assuming reading errors of this order at the beginning and end of the experiment in opposite directions, the value for the observed rise of temperature would be infected with an error of ± 0·02; there is thus a possible difference of 0·04° C. between the results of two experiments due to incorrect reading, and this is equivalent to rather more than 80 calories. Although this is an extreme case, such differences from this cause alone are possible, and this additional error necessitates a larger number of experiments. In all cases at least four determinations were made, and in some cases six to eight were necessary. The mean of all the results was taken.

The mean results obtained with the two thermometers are given below, and in the third column are tabulated the mean calorific values calculated from the water equivalent of the apparatus, based on the results of the combustion of Kilsyth coking coal in the bomb and Wm. Thomson calorimeters; six combustions were made with the latter, and the mean result was adopted. This method of determining the water equivalent of the Wm. Thomson apparatus gives a high result, as there is unmistakable evidence of incomplete combustion in every case, but the adoption of the value thus obtained approximately corrects for the small quantity of gas which escapes unburnt.

The mean values with the different thermometers show irly close agreement, and indicate that perfectly servicele results may be obtained with the help of an accurately ide thermometer reading directly to tenths, where a high gree of accuracy is not required. The results in the rd line of the table are all higher, and approach more sely those obtained by the bomb. The first series only included in the final statement of the comparative ues.

The Bomb Calorimeter.—For the determination of the orific values by combustion in oxygen under pressure, modification designed by Langbein and Hugershoff was d in conjunction with the Stohmann calorimeter; both these are fully described by Langbein (Zeits. angew. em., 1900, 1236). This bomb resembles the well-known hler form; the chief difference, apart from certain chanical alterations which facilitate the manipulation, is lining of platinum foil in place of enamel. The ignition the substance is effected by means of a short piece of ing cotton, which is fixed to a fine platinum wire necting the two pole pieces; the thread may either be l round the pellet or simply allowed to rest in contact with the coal. On making the current the platinum wire fuses and ignites the thread, which falls on to the coal and ignites the latter. The use of iron wire is inadvisable, on account of the danger of perforation of the platinum lining by fused particles of iron oxide.

A thermometer of the Beckmann type standardised by the Physikalische Reichsanstalt was used; the corrections were given to the nearest 0·001° C.

The Cooling Correction.—The accurate methods of correcting for loss of heat proposed by Berthelot, and by Regnault and Pfaundler, as modified by Stohmann, are much too complicated for technical work. Langbein (*loc. cit.*) applied the formula $\Sigma \Delta t = n v' + \frac{v + v'}{2}$, in which n is the number of minutes which elapse after ignition before the maximum temperature is indicated, and v and v' respectively the average differences of temperature per minute before ignition and after the maximum has been reached. This correction is obviously too high; if we suppose the temperature to be constant before the combustion, *i.e.*, $v = o$, the correction then becomes $n v' + \frac{v'}{2}$; and this value is greater than that of the loss of heat which the apparatus would suffer if the temperature were at the maximum for the whole duration of the combustion. In calculating the cooling correction we made use of the formula $\Sigma \Delta t' = (n - 1) v' + \frac{v + v'}{2}$, which gives a result sufficiently near the truth for all practical purposes. The figures given below may be taken to represent a typical case. A glance at these will show that, although the highest temperature was not reached till the third minute after ignition, the temperature at the end of the first minute did not fall much short of the maximum. In supposing the heat loss during the second and third minutes to be the same as that observed per minute after the combustion, and taking the correction for the first minute to be the mean of the heat changes before and after the combustion, no serious error is committed.

Corrections were also applied for the nitric and sulphuric acids formed in the combustion. In all cases 10 c.c. of water were placed in the bomb at the beginning of the experiment. The excess of heat developed by the sulphur over that obtained in practice, *viz.*, that due to the reaction $SO_2 + O + x$ aqua, is corrected for with sufficient accuracy, according to Langbein (*loc. cit.*), by deducting from the calorific value found 22·5 calories per 1 per cent. of S, if the amount of water is 10 c.c. For the estimation of the acids, the contents of the bomb were washed out, boiled to expel CO_2, and titrated with 1/10 N $Ba(OH)_2$, using phenolphthalein as an indicator. Excess of sodium carbonate solution containing 3·706 grms. per litre (1 c.c. neutralises an amount of HNO_3 in the formation of which 1 calorie is developed) was added to convert the barium nitrate into carbonate, the solution was filtered, and the excess of sodium carbonate titrated with 1/10 N HCl with addition of Methyl Orange.

The following results are given to illustrate the method:—

Weight of Coal used, 1·0058.

Temperature before Ignition.		During Combustion.		After Maximum.

Correction for S (0·79 per cent.)	19	„
Calorific value	6,453	„

The water value of the apparatus was calculated from the results of the combustion of pure naphthalene (9692), phthalic anhydride (5300), salicylic acid (5269) and cane sugar (3955), using the values given in brackets. The mean of a number of closely agreeing results was adopted. The corrections in 40 estimations had the following extreme values:—Cooling correction, 0° to 0·015° C.; mean, 0·005° C.; HNO_3 correction, 10 to 18 calories; mean, 15.

The value of the sulphur correction depends on the quantity of that element present in the coal (22·5 calories per 1 per cent. S), and in the case of coals rich in sulphur the omission of this correction may involve a considerable error. For technical purposes an average value for the nitric acid correction might be adopted, but there is no advantage in omitting the titration of the contents of the bomb, as the estimation of the sulphur, which is usually necessary, is most easily effected in this way.

The difference between the extreme values obtained for the individual coals varied from 0·06 to 0·7 per cent., the average for the 12 series being 0·35 per cent.

Discussion of Results.—The values directly obtained with the Lewis Thompson instrument neglecting the unburnt carbon are much too low. The deficit varies, with the coals investigated, from 1 to 13 per cent., and, generally speaking may be said to increase with the carbon content of the coal. As has been already shown by Thomas, the results obtained with anthracite coals are absolutely unreliable. Scheurer Kestner, in a series of determinations with twelve coals, found the 10 per cent. correction to be too small, and suggested an increase to 15 per cent. The present experiments confirm the first conclusion, but it is evident from a glance at the figures that it is not possible to arrive at accurate values by applying any constant correction. By taking account of the carbon which escapes combustion, results nearer the truth may be obtained. As a mean of two experiments with coals II., XI., and XII., the values 6521, 7755, and 7691 were obtained, assuming the substance which remained unburnt to be carbon having a calorific value 8140. These numbers agree very much better with the bomb results 6439, 7801, and 7912 in the two last cases; the value for coal II. is higher than that obtained by the bomb. The estimation of the unburnt carbon involves a considerable expenditure of time, and the results arrived at by applying this correction are still unreliable: Brame and Cowan (*loc. cit.*) find in the case of coal B a difference of 6·2 per cent. At best the method may be taken to give a very rough indication of the heating values of bituminous coals. The directly determined numbers in such a case may deviate from the absolute heating values by as much as 8 per cent.

The Wm. Thomson Calorimeter.—The chief difficulty in operating with this instrument consists in regulating the current of oxygen so as to avoid loss of heat through imperfect cooling of the products, and at the same time to ensure that the combustion shall be as complete as possible. The rate of flow of the oxygen should be adjusted so as to reduce to a minimum the formation of smoke which is always observed at the beginning of the operation; and the tube should be kept well up in the glass bell till the volatile matter has been burned, as recommended by Thomson. The figures obtained with the 12 coals examined are from 0·7 to 2·9 per cent. lower than those determined by the bomb, the mean deficit being 1·8 per cent. Our experience of the method is more favourable than that of Brame and Cowan, who found differences with 5 coals of 1·8 per cent. (coal E) to 6·9 per cent. (coal B), mean 3·6 per cent. The use of the coal in the form of compressed pellets, which ensures more uniform combustion, probably explains this result to some extent, and this mode of operating is certainly to be recommended. In using the method we suggest that the constants of the apparatus should be determined from the combustion of a sample of coal of average composition and of known calorific value. In the present series of experiments one of the coals was chosen at random for this purpose. The results agree very well with those obtained by the bomb; only in one case—coal 10—is there any considerable difference, and here also the error has been reduced by the use of this water value in place of that calculated from the weights and specific heats of the materials. From the results of our experiments we conclude that numbers sufficiently accurate for most practical purposes may be obtained from the Wm. Thomson calorimeter by careful attention to the regulation of the oxygen supply. The determination of the water value of the apparatus by the combustion of a sample of coal in the calorimeter may be objected to on the ground that the amount of unburnt gases varies with different coals; but it should be recognised that the method is only an approximate one, and that absolutely reliable results can only be obtained by the use of some form of bomb calorimeter.

Wm. Thomson's Values, using Water Equivalent calculated from Results of Combustion of Coal.

Calorific values	6,065	6,432	6,739	6,742	7,053	7,224	7,314	7,380	7,512	7,394	7,800	..
Difference from bomb per cent.	− 1·1	− 0·1	+ 0·5	− 0·7	− 0·6	− 0·6	− 0·3	− 0·2	+ 0·04	− 1·8	0·0	..

Formula for calculated values $$\text{C.V.} = \frac{1}{100}\left[8{,}140\,C + 34{,}500\left(H - \frac{(O+N)-1}{8}\right) + 2{,}220\,S\right].$$

1. Splint coal, Lochgelly, Fife.
2. Boiler fuel (a mixture), Fife.
3. Ell coal, Bothwell.
4. Main coal, Bothwell.
5. Pyotshaw coal, Bothwell.
6. Dunfermline splint, Cowdenbeath, Pit 10.
7. Splint coal, Bothwell.
8. Dunfermline splint, Cowdenbeath, Pit 7.
9. Boiler fuel, Aitken Pit, Kelty.
10. Haughrigg coking coal, Kilsyth.
11. Coking coal, Kilsyth.
12. Anthracite, Kilsyth.

Calculation of Calorific Values from the Results of Ultimate Analyses.—Before referring to the figures in the bove table we will consider the possible differences in the alues calculated by means of the modified Dulong formula hich may result from errors in analysis. From the xample which follows it will be evident that differences of ± 50 calories are well within the limits of experimental rror :—

—	I.	II.
	77·20	77·00
	4·56	4·51
	0·78	0·78
O	2·41	2·31
sh	7·20	7·17
+ N by difference	7·85	8·23
lculated calorific value	7577	7530

The differences between the calculated and bomb values ary in our tests from + 65 to − 146 (+ 0·9 to − 2·0 per nt.), and are distinctly greater than the possible experiental error in three cases only. Considering that the lues for free carbon and hydrogen are used in the rmula, and that the oxygen is assumed to be present as ater—which is certainly not the case—the close agreement tween the calculated and directly determined values is rprising. A further comparison of the figures in the ble shows that the calculated values approach more osely to the bomb results than those obtained by the illiam Thomson calorimeter, but that they are, taken as a hole, rather less accurate than the William Thomson values sed on the water equivalent determined by the combustion coal.

Brame and Cowan find differences in five coals of − 0·7 − 4·8 per cent. To the summary of previous work en by these authors may be added the results of the periments of Bunte (Schilling's J., 1901, 34, 21), which show differences of − 3·7 to + 2·0 per cent. A full discussion of this subject lies outside the scope of the present paper; but it is evident that the method of calculation from analytical results only gives approximate values, and that it should only be employed in cases where a direct determination is not possible.

Obituary.

CAPT. H. C. ASPINWALL.

Capt. HENRY CHAPPELL ASPINWALL was born on Nov. 19, 1855, at Epsom, Surrey, and died June 28, 1904, at the Post-Graduate Hospital, New York City. He was general superintendent of the smokeless powder department of the Dupont Powder Co., residing at Haskell, N.J., and was unmarried. He was educated partly in England and partly in America. In 1879 he entered the Twenty-Second Regiment of New York State, and subsequently joined the Twelfth Regiment, leaving the service in 1893 with the rank of captain. During his career he devoted his studies to the improvement of explosives for military purposes, and was well known as a smokeless powder expert. He was a member of the American Chemical Society and the Society of Chemical Industry, and at his death was Vice-President of the New York Section of the Verein Deutscher Chemiker.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e^).

I.—PLANT, APPARATUS, AND MACHINERY.

English Patents.

Filters. G. Lebedinsky, Kieff, Russia. Eng. Pat. 16,760, July 30, 1903.

A horizontal, double-walled sieve drum, with corrugated outer surface, is mounted in a casing and is filled to a certain height only with granular filtering material such as sand or porcelain beads, &c. The fluid to be filtered flows from the outside to the inside, but for washing, the water flows in the opposite direction. During the washing operation the sieve drum is rotated, so that the filtering material may be shaken about and be thoroughly cleansed. —W. H. C.

Filtering Apparatus. J. Wetter, London. From E. Boellinghaus, Hamburg. Eng. Pat. 27,287, Dec. 12, 1903.

A number of superposed filtering chambers are connected with the liquid supply-, discharge-, and rinsing-canals, situated in a tube common to all, by means of openings controlled by annular slides. Each chamber may act independently, and the filtration may take place, and the filtering medium be washed, in either an upward or downward direction, as desired.—W. H. C.

United States Patents.

Drying-kiln. F. Meyer, Assignor to E. J. Kirby and the Chicago American Fuel Briquetting Co., all of Chicago. U.S. Pat. 761,088, May 31, 1904.

The material to be dried is passed through the drying-chamber by a horizontal conveyer consisting of a number of open buckets, and is agitated by blades fixed to rotating shafts placed transversely across the conveyer. Hot air is admitted to the chamber, and suitable means are provided for rotating the shafts.—L. F. G.

Drying Powders; Apparatus for ——. H. Croizier, Paris. U.S. Pat. 761,763, June 7, 1904.

See Eng. Pat. 18,661 of 1901; this J., 1902, 1178.—T. F. B.

Still. F. B. Merrill, Jonespoint, New York, Assignor to Merrill Process Co., New York. U.S. Pat. 761,315, May 31, 1904.

The still is horizontal, and of egg-shaped cross-section, the wider part being at the bottom; and is provided with a pendent swinging agitator, fixed to a horizontal axis nea the top of the still.—L. F. G.

Calcining Apparatus. D. L. Kibler, Acme, Texas. U.S. Pat. 761,684, June 7, 1904.

A semi-cylindrical, horizontal shell or kettle, situated i a furnace, has flues traversing it. An oscillating agitato is arranged in the shell to keep both the flues and shel free from deposit.—W. H. C.

Muffle Roasting-Furnace. F. Meyers, New York. U.S. Pat. 761,691, June 7, 1904.

A series of vertical furnaces, each consisting of a meta shell with refractory lining and superposed hearths, similar to the Herreshof furnaces, are connected together. A heating furnace is common to the series, and suitable flues are provided for conveying the hot gases through the series to the stack.—W. H. C.

Extracting Apparatus. H. J. P. Hampton, Albany, New York. U.S. Pat. 761,828, June 7, 1904.

The combination is claimed, in the case of a steam-boiler, of a cylinder, pipe-connections between the steam and water space of said boiler and cylinder, a cup detachably secured to the lower end of the said cylinder, a strainer forming a bottom for the cup, and an agitator arranged within the cup. —W. H. C.

French Patents.

Vapour from a Liquefied Gas such as Ammonia or Methylamine, &c.; Production of ——. J. B. Fournier. Fr. Pat. 338,706, April 11, 1903.

A reservoir containing the ammonia or other liquid communicates with a tubular vaporiser by means of a piston, actuated by the pressure of the vapour and regulated by a spring.—W. H. C.

Crystals; Process for Obtaining Good, Chemically Pure ——. V. Schütze. Fr. Pat. 339,896, Jan. 26, 1904.

The liquid to be crystallized is made to flow slowly through a double-walled tube, whilst warm or cold water or other liquid is circulated through the annular space in an inverse direction. The liquid in the inner tube is slowly and progressively cooled, and pure regular crystals are deposited. Means are provided for watching the progress of the ɔeration, for regulating the temperature and flow of the ɔoling liquid, and for filling and emptying the apparatus. —W. H. C.

Furnace; Rotary ——. W. S. Rockwell. Fr. Pat. 339,768, Jan. 21, 1904.

:E Eng. Pat. 1503 of 1904; this J., 1904, 443.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Combustion: Mechanism of ——. H. B. Dixon. J. Gas Lighting, 1904, **86**, 715—753.

HE author discusses the chemical processes in flames, the :bject being treated under the following headings:—unsen's theory of discontinuous combustion; pressures odnced in explosions; influence of aqueous vapour on mbustions; rate of explosion in gases; photographic ıalysis of explosion flames; velocity of a sound-wave in e flame of exploded gases; initiation of the explosion-ave.—A. S.

russian Blue in Spent Oxide, &c.; Determination of —— *by Feld's Method.* R. Witzack. XXIII., page 728.

English Patents.

istillers' Refuse, Sewage, or the like; Treatment of —— [*Fuel Briquettes*]. L. Cameron. Eng. Pat. 14,536, June 30, 1903. XVIII. B., page 721.

riquettes for Fuel; Manufacture of ——. H. H. Lake, London. From A. Petit and Co., Verviers, Belgium. Eng. Pat. 16,908, Aug. 1, 1903.

:E Fr. Pat. 334,301 of 1903; this J., 1904, 54.—T. F. B.

vens for the Manufacture of Ovoid or other Shape Smokeless Briquettes. J. W. Mackenzie, London. From La Comp. des Charbons et Briquettes de Blanzy et de l'Ouest, Nantes, France. Eng. Pat. 9483, April 25, 1904.

IE ovens have a number of openings running longitudin-y entirely through the partitions between them. These enings increase in size from the central partition to the d walls, and are placed in zig-zag form to increase the aught and allow the vapours to escape easily. —W. H. C.

eating and Enriching Gas; Means and Apparatus for use in ——. A. G. Brookes, London. From M. M. Makeever, Boston, Mass. Eng. Pat. 6540, March 17, 1904.

CASING is divided by means of a horizontal partition into ɔ chambers, each of which is divided by means of vertical rtitions into several compartments which communicate th each other alternately at opposite ends, so that the ;, in flowing through the apparatus, must pursue a zig-; course first in the lower and then in the upper com-tments. The lower compartments, in which the car-etting liquid is maintained at a certain level by means a suitable reservoir, are packed with wicks in rope form, de from hemp or the like; whilst the upper compart-nts, which serve to filter the carburetted gas, are packed h ropes made of wood-fibre and asbestos.—H. B.

s Generating or Gasogen Apparatus for Producing Poor Gas free from Tarry Matters. L. Boutillier, Paris. Eng. Pat. 9942, April 30, 1904. Under Internat. Conv., Aug. 14, 1903.

SHORT "distilling retort," open at the top, extends up ɔugh the centre of the grate of the generator into the ıdescent zone of fuel. The fuel supply to the generator ed upwards through the retort, by means of a screw veyor or otherwise, at such a rate that the fuel remains the retort long enough for all the tarry matters to be en off before the residue mingles with the incandescent . The tarry matters are decomposed during their sage upwards through the hot zone. Steam and air are introduced at the base of the generator, and the gases are led off at the top as usual.—H. B.

Gas Washers; Construction of ——. O. Imray, London. From F. Burgemeister, Celle, Germany. Eng. Pat. 15,060, July 7, 1903.

SEE Fr. Pat. 333,726 of 1903; this J., 1903, 1342.—T. F. B.

Gas; Process for Making ——. W. Kent, New York. Eng. Pat. 15,645, July 15, 1903.

SEE U.S. Pat. 735,272 of 1903; this J., 1903, 990.—T. F. B.

Feeding and Distributing of Material in Gas Producers, Furnaces, and the like; Apparatus for the Continuous ——. C. W. Bildt, Stockholm. Eng. Pat. 9376, April 23, 1904.

THE invention relates to fuel-feeding devices in which a distributing disc rotates beneath the lower end of the feed hopper. To prevent the fuel (waste wood, bark, peat, &c.) from sticking or locking in the hopper, two or more upright pins of sufficient length are attached rigidly to the upper side of the disc, extending up into the lower part of the hopper.—H. B.

Incandescence Bodies for Electric Glow Lamps; Manufacture of ——. C. D. Abel, London. From Siemens and Halske, Act.-Ges., Berlin. Eng. Pat. 26,776, Dec. 7, 1903.

SEE Fr. Pat. 337,608 of 1903; this J., 1904, 484.—T. F. B.

United States Patents.

Coke-Oven. J. S. Maxwell, Cumberland, Md., U.S.A. U.S. Pat. 761,521, May 31, 1904.

AT either side of a long series of coke-ovens, are arranged a pair of coke-ovens with straight end walls, and straight front and rear walls, the roofs of the ovens being arched. Suitable tie-rods and beams brace the ovens together, a central vent is provided in each, and car-tracks are laid on the top of all the ovens.—L. F. G.

Coke-Oven. C. Schroeter, Chicago. U.S. Pat. 761,789, June 7, 1904.

THE coking chambers are surrounded by heating flues, which also pass beneath the retorts. Means are provided for introducing gaseous fuel and air under pressure, and for isolating any retort.—W. H. C.

Coal Gas; Process of Manufacturing ——. T. Settle and W. A. Padfield, Exeter, England. U.S. Pat. 762,495, June 14, 1904.

SEE Eng. Pat. 12,552 of 1902; this J., 1903, 789.—T. F. B.

French Patents.

Briquettes from Powdered Fuel; Manufacture of ——. R. Middleton. Fr. Pat. 339,370, Jan. 6, 1904.

A STARCHY paste is obtained by adding the minimum amount of boiling water to cereals, old potatoes, or the like, and the paste is mixed while hot with coal tar or Stockholm tar. The product is incorporated with pulverised fuel, and the mixture is compressed into blocks.—H. B.

Fuel; Artificial —— *and its Manufacture.* E. J. Hoffman and N. J. Clark. Fr. Pat. 339,859, Jan. 25, 1904.

SEE Eng. Pat. 1887 of 1904; this J., 1904, 483.—T. F. B.

Coal, Minerals and Similar Substances; Process and Apparatus for Drying ——. F. Baum. Fr. Pat. 339,952, Jan. 27, 1904.

SEE Eng. Pat. 2485 of 1904; this J., 1904, 539.—T. F. B.

Illuminating and Heating Gas; Manufacture of ——. Deutsche Continental Gas Ges. and J. Bueb. Fr. Pat. 339,534, Jan. 12, 1904.

VERTICAL retorts, the diameter of which increases gradually from top to bottom, are arranged within the furnace so that they may be strongly heated over their whole exterior. Having been brought to a high temperature, they are filled almost completely from above with the coal to be carbonised, the heat being well maintained. Gas is given off rapidly from the fuel contiguous to the retort walls, and a layer of compact impermeable coke is formed immediately. The gas passes up through the comparatively cool central part of the coal to the gas exit at the top of the retort, being kept from contact with the hot walls by the crust of coke. Distillation gradually proceeds towards the centre. The coal dust which is produced is retained by the column of fuel through which the gas has to ascend. It is claimed that the formation of naphthalene is thus prevented, and that the tar is obtained as a fluid brown oil, containing little coal.—H. B.

Generator for Low-grade Gas. Lerouge, Fornas and Cie. Fr. Pat. 339,817, Jan. 22, 1904.

At the base of the column of fuel in the producer, steam alone is admitted; at the upper end, at the foot of a cylindrical charging hopper, air, or a mixture of air and steam, is admitted; whilst the gas generated is drawn off from an intermediate point. By this arrangement the tarry matters distilling from the fresh fuel are caused to pass down through the incandescent zone before reaching the outlet, whilst the steam entering the lower region of the fuel prevents clinkering, utilises the heat of the cinders, and forms water-gas with any carbon remaining unburnt in the latter.—H. B.

Calcium Carbide; Agglomerating ——. L. Leinss. Fr. Pat. 339,492, Jan. 11, 1904.

For mixture with 400 kilos. of calcium carbide, 100 kilos. of molasses, containing about half its weight of sugar, is deprived of water as far as possible by heating to about 100° C., a small proportion of potassium permanganate is added with agitation, then 5 kilos. of dry sodium carbonate, 2 kilos. of zinc oxide, and 1 kilo. of finely-powdered lime. The crushed calcium carbide is then worked into the mass, whilst the temperature is kept at not below 90° C. The agglomerated mass is then moulded under pressure, and the cakes are rolled. Many advantages are claimed for this mixture over calcium carbide by itself, especially in reference to the application to the production of acetylene gas.—E. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM AND MINERAL WAXES.

Indophenine Reaction. L. Storch. XXIII., page 730.

English Patents.

Phenols of Coal Tar; Process for the Separation of the —— from the Neutral Constituents of the Latter. E. Schulze and Chem. Fabr. Ladenburg, G. m. b. H., Ladenburg, Germany. Eng. Pat. 17,266, Aug. 8, 1903.

See Fr. Pat. 334,525 of 1903; this J., 1904, 55.—T. F. B.

Protective Coating [from Tar]: Non-inflammable Composition for use as a ——. G. MaLieux, Asnières, France. Eng. Pat. 7068, March 23, 1904. Under Internat. Conv., March 26, 1903.

See Fr. Pat. 330,608 of 1903; this J., 1903, 1081.—T. F. B.

United States Patent.

Mineral and Rosin Oils; Process of Making Watery Solutions of ——. F. Boleg, Esslingen, Germany, Assignor to Ges. z. Verwertung der Bolegschen Wasserlöslichen Mineralöle und Kohlenwasserstoffe, Ges. m. beschr. H., Berlin. U.S. Pat. 761,939, June 7, 1904.

See Eng. Pat. 12,349 of 1899; this J., 1900, 526.—T. F. B.

French Patent.

Peat Wax and Analogous Products; Manufacture of —— E. Bouchaud-Praceiq. Fr. Pat. 338,736, April 14, 1903.

Peat, lignite, &c., are extracted with suitable volatil solvents, *e.g.*, alcohol or ethylic esters, and the extrac evaporated. The residual wax-like substance, which resembles beeswax, is hard and has a high melting point an a specific gravity above 1·000.—C. A. M.

IV.—COLOURING MATTERS AND DYESTUFFS.

Rosanilines; Polyacid Salts of ——. J. Schmidlin. Comptes rend., 1904, **138**, 1508—1510.

The existence of triacid derivatives of rosanilines wa asserted by Hofmann, who prepared brown substances t which he assigned that composition: but his analytica figures did not support the conclusion very strongly. Th author finds that by placing these substances *in vacu* over potassium hydroxide for a month they lose complete the excess of acid which they contain, and the brown mas becomes quite black and inodorous. The substances thu obtained are exceedingly stable, and their analysis give figures agreeing exactly with the composition of tri-hydrochloride of rosaniline, pararosaniline, and hexamethyl pararosaniline respectively. They dissolve in alcohol an in water with the same colour as the corresponding monaci salts, and the colouring properties are not lessened by th saturation of all the basic functions in the molecul In the case of pararosaniline, Rosenstiehl obtained tetrahydrochloride by saturating with hydrochloric aci gas and removing the excess by means of a current of air but the author finds that the evolution of hydrochlori acid does not cease at this point, for the tetrahydrochlorid still gives off the gas to the atmosphere. The substanc saturated with hydrochloric acid gas at the ordinary temperature and pressure is red, and contains hydrochlor acid more than corresponding to a pentahydrochloride but as the temperature is lowered more gas is absorbed and the colour fades through orange and yellow, till in bath of liquid air it is perfectly white.—J. T. D.

Triphenylmethane Series; Some Reactions in the —— E. Vongerichten and K. Weilinger. Z. Farben- u Textil-Chem., 1904, **3**, 217—218.

When *p*-triaminotriphenylmethane and *p*-triaminotritolyl methane are heated respectively with toluidine and anilin hydrochlorides, transformation occurs, toluidine being replaced by aniline, or *vice versa*. When *p*-diaminoditolylmethane and the corresponding diphenylmethan derivative are treated in a similar manner, howeve Vongerichten and Bock (Z. Farben- u. Textil-Chem., 19 **2**, 249) have shown that the final product in either case i *p*-diaminophenyltolylmethane. The authors have no examined the behaviour of *p*-diaminotriphenylmethan and find that when heated with a strong excess of toluidine hydrochloride and *o*-toluidine, it is convert into *p*-diaminoditolylphenylmethane; and also that th latter when heated with aniline hydrochloride and anilin is again converted into *p*-diaminatriphenylmethane.—A. S.

Naphthyldiphenylmethane, Dinaphthylphenylmethane, an Trinaphthylmethane Series; Dyestuffs of the —— E. Noelting. Ber., 1904, **37**, 1899—1920.

The author obtains dinaphthylphenylmethane dyestuffs b condensing dimethyl-*p*-aminobenzaldehyde and its nitro derivatives with secondary alkylnaphthylamines and oxidising the leuco bases so obtained, and also by preparin diaminonaphthylphenylketones and condensing these wit secondary α-naphthylamines. Naphthyldiphenylmethan dyestuffs were obtained by condensing the above-mentione ketones with tertiary amines of the benzene series an dyestuffs and leuco bases of the trinaphthylmethane grou by the action of carbon tetrachloride on secondar α-naphthylamines or their *o*-formic acid esters. Th diaminonaphthylphenyl ketones were obtained by heatin econdary α-naphthylamines with dimethyl-*p*-aminobenzo-ethylanilide and phosphorus oxychloride and hydrolysing e aurammonium compound so formed with alcoholic alkali ydroxide or concentrated sulphuric acid according to the uations:—

$$(1)\ 3(CH_3)_2NC_6H_4.CO.N(CH_3)(C_6H_5) + 3POCl_3 = 3(CH_3)_2NC_6H_4.CCl_2.N(CH_3)(C_6H_5) + 2P_2O_5\,;$$

$$2)\ (CH_3)_2NC_6H_4.CCl_2.N(CH_3)(C_6H_5) + C_{10}H_7.NHR = (CH_3)_2NC_6H_4.C\vdots\{N(CH_3)(C_6H_5)(Cl)\}\{C_{10}H_6.NHR\} + HCl\,;$$

$$(3)\ (CH_3)_2NC_6H_4.C\vdots\{N(CH_3)(C_6H_5)(Cl)\}\{C_{10}H_6NHR\} + H_2O = (CH_3)_2NC_6H_4.CO.C_{10}H_6.NHR + C_6H_5NHCH_3 + HCl.$$

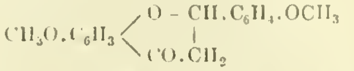
These ketones are weakly basic and dye in yellow shades, it cannot be considered to be real dyestuffs. They are duced by sodium amalgam in alcoholic solutions to the rresponding hydrols (carbinols) which dye silk and tannin-ordanted cotton in violet blue to green shades. On treating e aurammonium compounds with ammonia or the ketones th ammonium chloride and zinc chloride, Auramines are tained, dyeing in yellowish-orange shades, which are more able to acids than ordinary auramine but are readily nverted by alkalis into the corresponding ketones. yestuffs of the dinaphthylphenylmethane and trinaphthyl-ethane series have no practical importance on account of eir insolubility and relatively high cost of production. he replacement of one benzene nucleus by a naphthalene cleus in Crystal Violet changes the shade to blue. On placing the second and third benzene nuclei by naphtha-ne nuclei, the blue becomes greener at each step, but the fference in shade is not so marked as at the first stage. he presence of a nitro group in the benzene nucleus renders e shade of the dyestuff more violet. When naphthyldi-enylmethane dyestuffs are treated with acetic anhydride d sodium acetate, or acetic anhydride and a little sul-uric acid, the secondary aminonaphthyl group is acetylated d green dyestuffs are obtained, the solubility in water ing considerably increased. The acetyl group is split off acids or alkalis. The nitrosamine of Victoria Blue is own to be a green dyestuff. The author finds that the trosamines of the three other naphthyldiphenylmethane estuffs prepared by him are also green in shade. Thus e shade is changed to green on either acetylating or trosating a secondary amino group, and the relations are actly analogous to those observed with Pentamethyl iolet. On acetylating dinaphthylmethane dyestuffs which ntain two secondary amino groups with acetic anhydride d a little sulphuric acid, red diacetylated dyestuffs are rmed. On acetylating with acetic anhydride and acetic id, green mono-acetylated dyestuffs are obtained. Similar lations were also observed with the trinaphthylmethane estuffs. Both groups of dyestuffs also yield red dye-uffs with 2 mols., and green dyestuffs with 1 mol., of trous acid.—E. F.

iphenylmethyl. M. Gomberg. Ber., 1904, **37**, 1626—1644. This J., 1903, 1343 and 621; also 1901, 33 and 114.

a solution of tri-*p*-tolylcarbinol chloride, prepared from bon tetrachloride and toluene with aluminium chloride an inert solvent such as benzene, be treated with molecular ver in absence of air, the solution acquires an orange our, and an unsaturated compound is formed. On naining for some time in absence of air, the solution es its colour, and hexatolylethane, $(CH_3.C_6H_4)_3\vdots C.(C_6H_4.CH_3)_3$, is formed by polymerisation of the tri-olymethyl, which is presumably formed in the first tance. When tri-*p*-tolylcarbinol chloride is acted on by lecular silver, in presence of a current of air, in benzene ution, the orange-coloured substance is decolorised ost as fast as it is formed, and a crystalline deposit of a oxide $(CH_3C_6H_5)_3.C.O.O.C.(C_6H_5.CH_3)_3$, is obtained. can be separated from the carbinol and hexatolylethane dissolving the latter substances in ether, and can n be recrystallised from benzene. The same peroxide s obtained in fairly good yield by treating tri-*p*-tolylcarbinol chloride in benzene solution with an aqueous sodium peroxide solution in presence of a little acetic acid. The peroxide is readily hydrolysed by means of aceto-sulphuric acid to the corresponding carbinol, whilst with hydrochloric acid tri-*p*-tolylcarbinol chloride is regenerated. Di-*p*-tolylphenylcarbinol chloride was prepared from *p*-bromotoluene and methyl benzoate. Its behaviour towards metals is quite analogous to that of the tritolyl compound. By the action of air and molecular silver, 70—80 per cent. of the peroxide can be obtained. The solutions of di-*p*-tolylphenylmethyl are less red (more orange) in shade than those of tri-*p*-tolylmethyl. This peroxide can also be obtained by the action of sodium peroxide on the carbinol chloride. Diphenyl-*p*-tolylcarbinol chloride was found to be best prepared by the Friedel-Crafft reaction from toluene and benzophenone dichloride. The latter substance reacts in this manner with exceptional ease, forming analogous derivatives with chloro-, bromo-, and iodo-benzene, naphthalene, &c., and substituted benzophenone dichlorides show a similar activity, so that the most diverse derivatives of triphenylcarbinol chloride may be conveniently prepared in this way. Diphenyl-*p*-tolycarbinol chloride resembles in its action on metals the triphenyl compound rather than its higher homologues. With zinc it reacts energetically, forming a syrupy double salt and an unsaturated compound which absorbs iodine and is quickly oxidised in the air to a peroxide. A solution of the carbinol chloride treated with molecular silver acquires an orange yellow shade rather darker than that from the triphenyl- and less red than that from the di-*p*-tolyl-phenyl-compound. The peroxide was prepared by both methods used in the case of the two other tolyl-derivatives; *p*-chloro-, *p*-bromo-, and *p*-iodotriphenylcarbinol chlorides were obtained by the action of chloro-, bromo-, and iodobenzene on benzophenone dichloride in presence of aluminium chloride; *p*-chlorotriphenyl carbinol chloride was also prepared by the action of benzene on *p*-chlorobenzophenone chloride, and was identical with the substance obtained by the other method. All three *p*-halogen-substituted triphenylcarbinol chlorides behave towards metals in a manner analogous to the tolyl-compounds. With molecular silver the chloro-compounds yielded a wine-red, and the bromo- and iodo-compounds an orange-red coloration. On exposure to air these unsaturated compounds formed peroxides insoluble in ether. Tri-*p*-chlorotriphenylcarbinol chloride was obtained by the action of chlorobenzene on carbon tetrachloride. With molecular silver a benzene solution of this substance gives a Bordeaux Red coloration, finally changing to a Magenta violet which is so deep that a three per cent. solution is quite opaque. In presence of air the colour disappears and a powdery product can be isolated, probably the peroxide. Diphenyl-α-naphthyl carbinol chloride was obtained by the action in carbon bisulphide solution, of naphthalene on benzophenone dichloride in presence of aluminium chloride. With molecular silver in benzene solution it yields a deep brownish-yellow solution with green fluorescence. It is decolorised by the air with astonishing rapidity, and a crystalline peroxide is deposited. Trinaphthylcarbinol and its chloride were obtained by the action of naphthalene on carbon tetrachloride in presence of aluminium chloride, but could not be obtained in a colourless form, so their behaviour was not further studied. Tri-*p*-nitrotriphenylcarbinol chloride was obtained in an impure form from its carbinol, by the action of phosphorus oxychloride or pentachloride in nitrobenzene solution. The carbinol is not acted on by dry hydrochloric acid gas in benzene solution, nor by acetyl chloride. The carbinol chloride gives with molecular silver in benzene solution, on gentle warming, a blue green liquid, and on further warming, the colour changes to magenta violet. On cooling, the bluish-green coloration returns. On exposure to air the corresponding peroxide is formed. All the triphenylmethyl derivatives described above, with the possible exception of the tritolyl compound, absorb iodine, forming colourless compounds. As the faculty of forming peroxides disappears, for instance, by polymerisation on standing, the faculty of absorbing iodine disappears also, and the solutions become colourless. The author finds that triphenylmethyl exists in its solutions in a dimolecular condition, but he considers this to be merely a case of association and formulates it as $(C_6H_5)_3:C-$ and the peroxides as $R_3C.O.O.CR_3$.—E. F.

2.2′-Dihydroxyflavonol; Synthesis of ——. A. Katschalowsky and St. v. Kostanecki. Ber., 1904. **37**, 2346—2351.

On condensing quinacetophenone monomethyl ether with *o*-methoxybenzaldehyde, 2.2′-dimethoxyflavanone—

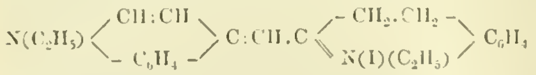


$$CH_3O.C_6H_3\left\langle\begin{array}{l}O - CH.C_6H_4.OCH_3\\ \qquad\quad | \\ CO.CH_2\end{array}\right.$$

is produced. Isonitroso-2.2′-dimethoxyflavanone, obtained by treating this compound with amyl nitrite and hydrochloric acid, is converted by treatment with sulphuric acid into 2.2′ dimethoxyflavonol, which is demethylated by means of hydriodic acid, 2.2′-dihydroxyflavonol being formed. It dyes mordanted cotton much deeper shades than do 2.3′- or 2.4′-dihydroxyflavonol (see this J., 1901, 367). The mordant-dyeing properties of this compound show that those of Morin are due, not only to the chromogen group  $\begin{array}{c}C.OH\\ | \\ CO\end{array}$ and to the hydroxyl group in the *peri* position to the keto group, but also to the *anchi*- (or 2′) hydroxyl group.—T. F. B.

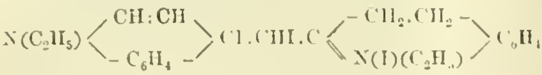
Cyonine Dyestuffs; Constitution of ——. A. Miethe and G. Book. Ber., 1904, **37**, 2008—2022.

The authors find that Ethyl Red, the dyestuff obtained by the action of alkali hydroxide on a mixture of quinoline ethyl iodide and quinaldine ethyl iodide in alcoholic solution, has the formula $C_{23}H_{25}N_2I$. The best yield is obtained by using a mixture of 2 mols. of quinoline ethyl iodide with 1 mol of quinaldine ethyl iodide. An alcoholic solution of quinoline ethyl iodide alone yields no dyestuff with alkali hydroxide. Ethyl Red combines with 2 atoms of iodine to form a perfectly stable compound, soluble with difficulty in water and in alcohol, but readily soluble in acetone to a deep red solution. This addition compound possesses none of the properties of a periodide such as quinoline periodide. For instance, its solution in acetone shows no blue coloration with starch solution. From the above considerations the authors deduce the constitutional formulæ—



$$N(C_2H_5)\left\langle\begin{array}{c}CH:CH\\ \\ -\,C_6H_4\,-\end{array}\right\rangle C:CH.C\left\langle\begin{array}{c}-\,CH_2.CH_2\,-\\ \\ N(I)(C_2H_5)\end{array}\right\rangle C_6H_4$$

for Ethyl Red ; and



$$N(C_2H_5)\left\langle\begin{array}{c}CH:CH\\ \\ -\,C_6H_4\,-\end{array}\right\rangle CI.CHI.C\left\langle\begin{array}{c}-\,CH_2.CH_2\,-\\ \\ N(I)(C_2H_5)\end{array}\right\rangle C_6H_4$$

for the iodo-addition product. By the action of alkali hydroxide in alcoholic solution on quinaldine ethyl iodide alone, a homologue, $C_{21}H_{27}N_2I$, of Ethyl Red is formed, which differs from the latter in shade and is a far less efficient sensitiser of a silver-bromide-gelatin plate. By the action of 1 mol. of silver nitrate, Ethyl Red is converted into the corresponding nitrate $C_{23}H_{25}N_2\ (NO_3)$ which is an excellent sensitiser for photographic plates, which it clouds far less than the original Ethyl Red, and has the further advantage of being very soluble in water and in alcohol.

—E. F.

English Patents.

Disazo Colouring Matters [*Azo Dyestuffs*]; *Manufacture of* ——. G. W. Johnson, London. From Kalle and Co., Biebrich-on-the-Rhine. Eng. Pat. 12,120, May 27, 1903.

See Fr. Pat. 332,714 of 1903; this J., 1903, 1290.—T. F. B.

Azo Colouring Matters; Manufacture of New ——, *and of Intermediate Products for the Production of such Colouring Matters.* H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 16,581, July 28, 1903.

See Fr. Pat. 331,140 of 1903; this J., 1904, 16.—T. F. B.

Anthraquinone Derivatives; Manufacture of New —— [*Nitroanthraquinonesulphonic Acids*]. H. E. Newtor London. From Farbenfabr. vorm. F. Bayer and Co. Elberfeld, Germany. Eng. Pat. 17,565, Aug. 13, 1903.

See Fr. Pat. 334,576 of 1903; this J., 1904, 57.—T. F. B.

Azo Dyestuffs: Manufacture of New ——, *and of Product to be used in the said Manufacture.* J. Y. Johnson London. From The Badische Anilin u. Soda Fabrik Ludwigshafen-on-the-Rhine, Germany. Eng. Pat. 16,995 Aug. 4, 1903.

The new azo dyestuffs are 2-hydroxy-1-azo derivatives o naphthalene, and are prepared from 2-4 dichloro-1-naphthyl amine, by acetylating it, sulphonating, splitting off the acetyl group, diazotising the dichloronaphthylaminemonosulphonic acid, and treating the diazo solution with a substance capable of neutralising the acid, *e.g.*, sodium acetat or carbonate, chalk, magnesia, whereby one of the chlorin atoms is replaced by a hydroxyl group, and a hydrox chlorodiazonaphthalenesulphonic acid or its inner anhydrid is produced. The latter, when coupled with β-naphthol gives a dyestuff which is soluble in water, and dyes wool i an acid bath brownish-violet shades, changing on treatmen with potassium bichromate or a mixture of a chromate an a chromium salt, into a deep bluish-black, having a blu "overhand" appearance, and very fast to washing, milling "potting," and light. Other hydroxy derivatives o naphthalene, *e.g.*, the 2.7- or 1.5-dihydroxynaphthalene may be substituted for the β-naphthol.—A. S.

United States Patents.

Orange Sulphur Dye [*Sulphide Dyestuff*]. W. Emmeric Assignor to Farbw. vorm. Meister, Lucius und Brüning Hoechst-on-the-Maine, Germany. U.S. Pat. 760,11 May 17, 1904.

"Toluylene-diurea" is heated with sulphur. The product is a dark reddish-brown powder, soluble in sodium hydroxide solution and in sodium sulphide solution with brown colour. On evaporating the sodium sulphide solution the dyestuff is obtained in a form soluble in wate the solution dyeing cotton in fast, bright, orange shades.

—E. F.

Azo Dyestuffs: Preparation of ——. W. Loeb, Bonn Assignor to C. F. Boehringer und Soehne, Mannheim Waldhof, Germany. U.S. Pat. 761,310, May 31, 1904.

A mixture of an aromatic amine, potassium nitrite, an an acid "coupling compound," or one of its salts, i submitted, in aqueous solution, to the anode action of a electric current. For example, "Ponceau 2 G." is prepare by electrolysing a mixture of 10 parts of aniline, 9·1 part of potassium nitrite, 32·7 parts of β-naphtholdisulphon acid, and 100 parts of water, using a platinum cathode.

ling or Fulling and Washing and Scouring Textile iece Goods; Machines for ——. T. Lumb, T. Walaw, and D. White, Morley, England. Eng. Pat. 12,342, ay 30, 1903.

pressure of the upper squeezing roller is regulated, rding to the cloth under treatment, by means of levers adjustable weights. A pair of vertical corrugated rs are placed between the "draught board" and the ezing rollers; these serve to break up longitudinal es in the cloth. The draught board is connected by s with a clutch on the driving pulley, and if a knot in abric prevents it passing freely through the openings, e draught board, the latter is moved and throws the ng pulley out of gear and thus stops the machine. leaving the squeezing rollers, the cloth is again ed out by an arrangement of "rams" which works versely. When used as a milling machine, the hinged is held up to form a trough under the squeezing s; for use as a scouring machine the hinged floor at right angles, so that the piece can travel round endless band.—A. B. S.

o-dyed Woollen Goods; Process for Increasing the stness to Wear of ——. O. Imray, London. From Peterhauser, Höchst-on-the-Maine, and F. Rechburg, rsfeld, Germany. Eng. Pat. 14,840, July 3, 1903.

wool is mordanted with metallic salts, such as potasbichromate, before dyeing with indigo.—A. B. S.

Designs Impressed on Fabrics; Method of Fixing or Protecting ——. L. J. Chischin, Moscow. Eng. Pat. 18,599, Aug. 28, 1903.

See Fr. Pat. 335,238 of 1903; this J., 1904, 115.—T. F. B.

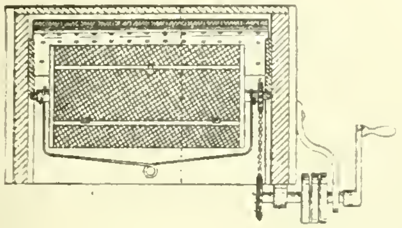
Soap for Dyeing and Cleaning; Manufacture of ——. A. J. Boult, London. From C. W. Horton, Cleveland, U.S.A. Eng. Pat. 28,508, Dec. 28, 1903.

A mixture of water and a coal tar dyestuff is incorporated with the soap while still in a plastic condition.—C. A. M.

United States Patents.

Dyeing; Machine for ——. C. W. Herbine and H. Rech, Reading, Pa., U.S.A. U.S. Pat. 760,118, May 17, 1904.

A machine for dyeing hosiery or yarn, comprising a tank with a curved bottom, a perforated false bottom, a removable perforated cylinder revolving in guide-bearings in either end of the tank, with a handle for lifting the cylinder, and machinery for revolving it.—E. F.



Wool-Fat; Process of Recovering ——. C. E. Swett, Assignor to R. H. Hutchison. U.S. Pat. 761,265, May 31, 1904. XII., page 719.

French Patents.

Dyeing, Bleaching, &c., Yarns; Method of and Apparatus for ——. W. Reid. Fr. Pat. 339,322, Jan. 2, 1904.

Yarns are spirally wound upon two reels fitted into a frame, which is capable of being revolved while it is moved along above, or is immersed in a dye- or other bath. Springs or other devices are employed to maintain the yarns—*e.g.*, wool yarns—under a constant degree of tension, while allowing them to contract, during any of the operations to which they are subjected. Two grooved shafts, placed on opposite sides of the dye- or other tank, cause a number of the frames successively first to advance some distance, and then to return almost the same distance, until the carriage which conveys them has reached the ends of the shafts, when the movement is reversed, and the frames are caused to return in the same manner. The reels may be made flat to facilitate their passage, in the frames with the yarns upon them, between squeezing rollers, for the purpose of removing the excess of liquor from the yarns, or they may be hollow and perforated, to admit of the introduction of a closed steam pipe into them for drying purposes. Arrangements for simultaneously raising or lowering a number of frames out of or into a dye, &c. tank, are also claimed.
—E. B.

Textiles in Hanks; Machine for Mechanically Dyeing ——. E. Dittmar. Third addition, dated Jan. 11, 1904, to Fr. Pat. 315,658, Nov. 6, 1901.

The rods which carry the hanks (see this J., 1902, 547, and 1903, 416) are made of bamboo or rice-cane.—T. F. B.

Dyeing with Aniline Dyestuffs; Solid Compound for ——. G. Rowland. Fr. Pat. 339,869, Jan. 25, 1904.

See Eng. Pat. 1502 of 1904; this J., 1904, 543.—T. F. B.

Dyeing and Bleaching of Cotton in Bobbins; Machine for ——. Soc. Schwcb. Frères and A. Wioland. Fr. Pat. 339,946, Jan. 27, 1904.

The bobbins are arranged side by side in a closed vessel. The spaces between the bobbins are filled by means of

diaphragms, so that no liquid can pass, except through the substance of the bobbins. The closed vessel is exhausted by an air pump, and then the dyeing or bleaching liquid is run in and circulated continuously by means of a pump. The dye vessel can be heated if desired by a steam pipe.
—A. B. S.

Rice Flour; Treatment of —— for use in Finishing Yarns and Textiles. Soc. anon. des Rizeries Françaises. Addition to Fr. Pat. 334,369, Aug. 1, 1903. XIX., page 725.

VII.—ACIDS, ALKALIS, AND SALTS.

Alkali Carbonate and Calcium Carbonate; Decomposition of Mixtures of ——, at High Temperature in vacuo. P. Lebeau. Comptes rend. 1904, **138**, 1496—1498.

The dissociation of alkali carbonates, which occurs when they are heated *in vacuo* (this J., 1904, 60) is facilitated by admixture with calcium carbonate. Complete dissociation of the carbonates of cæsium, rubidium, potassium, and sodium, occurs under these circumstances at 1000° C. This temperature is above that at which calcium carbonate alone dissociates, and the dissociation pressure throughout is lower than that of calcium carbonate at the same temperatures, suggesting the existence of double carbonates of the alkali metal and calcium. The residue after complete dissociation consists of pure lime (the alkali metal oxide having volatilised) in irregularly shaped transparent fragments, without action on polarised light, much less readily attacked by reagents than that obtained by simple calcination of the carbonate. Mixtures of lithium and calcium carbonates give a different result, the residue always containing lithia as well as lime.—J. T. D.

Barium Sulphate of the Lozère District. Guédras. Comptes rend., 1904, **138**, 1410.

The most distinctly crystalline deposits of barytes in the Lozère district are found near Altier, arrondissement de Mende. The mineral is very rich in copper, containing up to 10 per cent. of that metal, and also contains considerable quantities of tin. The vein is a very thin one. In the commune of Villefort there is a vein of barytes charged with galena; this barytes occurs in form resembling chalk. A portion of this vein is poor in galena and assumes a very definite form; the cleavages are perfect and show a vitreous, pearly lustre, which is lacking in the other barytes of the district; this lustre contributes largely to its industrial value. In both these deposits the embedding rock is composed of silky schists, stained with malachite in contact with the vein of barytes.—J. F. B.

Basic Ferric Phosphite. E. Berger. Comptes rend., 1904, **138**, 1500—1501.

Freshly precipitated ferric hydroxide dissolves in phosphorous acid, but the solution is decomposed completely by water in sufficient excess, giving a white precipitate. This precipitate, washed with water, slowly gives up phosphorous acid, and the residue when no more phosphorous acid can be washed out, dried first on a porous plate, and finally *in vacuo* over sulphuric acid, has a perfectly fixed composition. The results of analysis, and the reducing action of the salt on permanganate prove that no ferrous salt is present, and that the substance is basic ferric phosphite, $(PO_3H)_6Fe_4.Fe(OH)_3.5H_2O$.—J. T. D.

English Patents.

Sulphuric Anhydride; Manufacture of ——. W. P. Thompson, London. From G. Wischin, Munich, Germany. Eng. Pat. 12,419, May 30, 1903.

The mixture of sulphur dioxide and air or oxygen is led through an annular section containing contact material, the outside of which section is exposed to a cooling atmosphere, and then consecutively through a similarly packed wider annular section, enveloped by the first section, with or without the interposition of a comparatively narrow intervening space. No external source of heat is used, except that the gases are admitted in a hot state. Several forms of apparatus are described, but in all, the first, relativel narrow annular section (in which the reaction is mo vigorous) serves as a heating jacket to the wider, interic annular section or sections.—E. S.

Sulphuric Acid; Manufacturing ——. H. H. Niedenfüh Berlin. Eng. Pat. 1066, Jan. 15, 1904.

The gaseous sulphurous acid used in the chamber proce of manufacturing sulphuric acid is cooled before enteri the chamber by being utilised in concentrating the chamb acid, or by special cooling devices, and is purified, especial from arsenic, &c., by passage through washers, filters, or tl like. The denitration is effected by the action of cool sulphurous acid gases. A pressure generator is arrange before a special denitrating device, and between that a the part of the plant in which the acid is concentrated, order to increase the relative efficiency of the denitrat and " of the nitric acid in the chamber, and for decreasi the quantity of nitric acid necessary for carrying ou t reaction."—E. S.

Cyanides; Manufacture of ——. J. Tcherniac, Freibu Germany. Eng. Pat. 17,419, Aug. 11, 1903.

In manufacturing cyanides by oxidising a thiocyan (sulphocyanide) by nitric acid, &c., as directed in Eng. P 17,976 of 1902 (this J., 1903, 1045), it is now directed pass the washed gaseous mixture, containing hydrog cyanide and nitric acid vapour, over a salt or oxide (su as anhydrous sodium sulphate or alumina) which reacts combines with nitric acid, but has little or no effect hydrogen cyanide. The absorption of the hydrogen cyani is effected by an alkali hydroxide heated to a temperatu below its melting point, but above that at which the wat generated by the reaction is completely vaporised. using caustic soda for this purpose, it is first heated about 200° C., and finally to about 300° C.—E. S.

Glauber Salts and Ferrous Sulphate; Production of — from Nitre-cake or Acid-sodium-sulphate. C. L. Park London. Eng. Pat. 9619, April 27, 1904.

Iron, or iron oxide, or spathic iron ore, is added in exc to solution of nitre-cake (acid sodium sulphate) of sp. 1·275—1·300. Glauber's salt is crystallised out of t settled and cleared solution, and the mother liquid concentrated to obtain crystalline ferrous sulphate. T process may be modified by neutralising the acid liq by the iron or the like, at two stages of the operati Reference is made to Eng. Pat. 24,639 of 1903; this 1904, 252.—E. S.

French Patents.

Ammonium Nitrate; Process for Extracting —— fr Sodium Nitrate and Ammonium Sulphate. E. Nauma Fr. Pat. 339,733, Jan. 20, 1904.

A mixture of solutions of sodium nitrate and of ammoni sulphate is boiled, and the sodium sulphate which salts is removed. At a certain stage of the process the solu is cooled sufficiently to become saturated with ammoni nitrate: a double salt containing ammonium sulphate th separates, and the mother-liquor, after concentration desired, is rapidly cooled in a prescribed manner, subject to external disturbance, to obtain a deposition ammonium nitrate, which may be refined.—E. S.

Zinc Sulphide and other Sulphides; Process of Extract ——. G. D. Delprat. Fr. Pat. 339,920, Jan, 26, 19

Sodium Ferrocyanide; Manufacture of ——. Administion des Mines de Bouxviller. Fr. Pat. 339,996, Jan. 1904.

Sodium chloride is added to a hot, strong solution calcium ferrocyanide, and the crystals of sodium fer cyanide that form are salted out from the mother-liq of calcium chloride formed; or may be crystallised fr the concentrated liquor on cooling. Reference is mad Fr. Pat. 156,416 of 1883.—E. S.

des of Nitrogen; [Electrical] Manufacture of ——. iemens Bros. and Co. Fr. Pat. 339,730, Jan. 20, 190 I. A., page 717.

VIII.—GLASS, POTTERY, ENAMELS.

ta Pottery; Body of ——. H. Matsumoto. Mem. oll. Science and Eng. Kyoto Imp. Univ., 1903, 1, —86.

ata pottery body is composed of Shigaraki, Majeko, aye, and Mitsuishi clays, fired at the temperature of r cone 020—022; and the glaze is compounded of kusa stone and the ash of *Distylium racemosum*, and ed at cone 7. The ware is pale straw colour, the body us and non-transparent but hard, and the glaze is tely crazed (or "shivered"). In analysing the materials, lays were washed through a sieve with 60 meshes per cm. ted in this manner Shigaraki clay leaves 30 per cent. of ue, whilst the washed portion consists of 63·13 per . of clay substance, 12·19 per cent. of quartz, and 8 per cent. of felspathic detritus. Shiraye clay leaves er cent. of residue, and contains 97·05 per cent. of substance, 1·22 per cent. of quartz, and 1·73 per cent. elspar; whilst Majeko clay, which is sandy, leaves er cent. of residue, and is composed of 90·83 per cent. lay substance, 5·58 per cent. of quartz, and 3·6 per . of felspar. The author found it advantageous to omit Mitsuishi clay-stone. The Awata glaze consists of:— a, 53·00 per cent.; alumina, 11·11; iron oxide, 1·41; 14·24; magnesia, 0·30; soda, 2·53; potash, 2·32; on ignition, 14·77 per cent. On making up a series of es of the foregoing materials and a very pure quartz, uthor found that to give a good glaze the body should ain 30—40 per cent. of quartz to 20—12 per cent. of ar; or 40—50 per cent. when the felspar is between nd 6 per cent. On the other hand, the poor colour and of plasticity preclude the use of these bodies for fine . If, however, the ware is fired in the biscuit kiln at 11, it will carry the glaze without crazing, provided the contains 56·38—64·77 per cent. of kaolin, 7·11—8·21 lspar, and 36·51—27·02 of quartz. Thus, the relative ortions of quartz and felspar of those bodies which the glaze without "crazing," are:—"For 2·5—6 per of felspar, more than 10—30 per cent. of quartz, but han 30—45 per cent. of quartz; for 6—12 per cent. of ar, more than 30 per cent. of quartz."—C. S.

English Patents.

Glass; Apparatus for the Manufacture of ——. Rowart, Anvelais, and L. Francq, Obourg, Belgium. g. Pat. 9295, April 22, 1904. Under Internat. Conv., ril 27, 1903.

wer chamber, in which air is maintained under com- on, contains a vessel charged with molten glass, and unicates at the top by a long narrow opening with an chamber, which is exhausted and kept cold by a rating liquid circulating in compartments on each Through stuffing-boxes in the detachable top cover chamber pass vertical rods carrying clamps at their end, which carry between them a strip of glass. The containing the melted glass is carried by the plunger draulic cylinder, which raises it in the chamber until rrow opening of the top is slightly immersed in the At the same time, the rods in the upper chamber wered, so as to cause the glass strip held by the to pass through the opening and dip into the melted which adheres to it. On raising the rods, the glass ill draw up a portion of the melted glass through the g, the glass being at the same time forced upwards difference of the air pressures in the two chambers. glass rises in the form of a thin sheet, it is quickly d, and is then detached from the melted glass by g the vessel containing the latter. The rods, r with the formed glass sheet, are removed from the hamber by taking the cover off it. (See also Eng. 33 of 1904, this J., 1904, 660.)—A. G. L.

Drying and Baking Kilns for Ceramic Ware and the like. F. Dinz, St. Jean des Vignes, France. Eng. Pat. 12,861, June 8, 1903. Under Internat. Conv., Dec. 17, 1902.

Trucks filled with the products to be baked are pushed into a tunnel kiln in a continuous train. Each truck is provided with a grate and ash pit, to prevent the fuel from coming into contact with the material to be baked. Blinds are introduced between the trucks before their admission and discharge, so as to avoid loss of heat and entry of cold air. Two galleries are arranged laterally, through which a current of air circulates, which is heated by contact with the hot walls of the kiln, and serves both for the combustion of the ignited fuel in the grates, to which it is guided by special covers, and also to the storing of the products awaiting admission to the kiln. A part of this air-current is also used to dry materials arranged in suitable galleries.—A. G. L.

English Patents.

Carborundum Articles; Manufacture of ——. O. Imray, London. From the Carborundum Co., Niagara Falls, U.S.A. Eng. Pat. 9963, April 30, 1904.

In making carborundum articles, the use of a binding agent may be dispensed with by adding sufficient water to the carborundum—part, at least, of which should be in the form of fine powder—moulding and drying the articles as usual, and then subjecting them for some time to the action of an oxidising flame at a temperature of 2500° F., whereby the grains become oxidised superficially, and adhere together. Either crystalline or amorphous carborundum may be used. Bricks, &c., may be faced with carborundum in a similar manner.—A. G. L.

Cement and Limes; Impt. relating to ——. A. Deuaeyer, Brussels. Eng. Pat. 9765, April 28, 1904.

Five per cent., or more of sodium or potassium silicate is added to the Portland or other cement, either before or after burning; in the latter case the silicate should be in the form of a fine powder.—A. G. L.

United States Patent.

Fireproofing Solutions [for Wood]; Process of Making ——. A. W. Baxter, London. U.S. Pat. 761,870, June 7, 1904.

See Eng. Pat. 20,592 of 1902; this J., 1903, 998.—T. F. B.

French Patents.

Fireproof Varnish: Manufacture of ——. Eymer-Ges. Fr. Pat. 339,641, Jan. 16, 1904.

The varnish consists of alkali silicates ("soluble glass") and asbestos or other fireproof material mixed with vegetable or mineral oils, or with oily substances such as glycerin.—A. G. L.

Building Materials, Artificial; Mechanical Manufacture of ——. P. Deuil père and P. Deuil fils. Fr. Pat. 339,727, Jan. 23, 1904.

The moulding of the bricks, &c., is effected in a hydraulic press. The size and form of the mould can be altered by means of suitable packing material, an even pressure being exerted by employing, at will, one or more compressing pistons.—A. G. L.

X.—METALLURGY.

Gold on the Rand Goldfields; Metallurgy of ——. C. Dixon and M. Torrente. Electrochem. Ind., 1904, 2, 215—220.

The authors give a full account of the recent advances and present position of the treatment of gold on the Rand.

The treatment of slimes, the zinc and electrolytic precipitation of the gold from the cyanide solutions, and the working up of by-products such as occur particularly in the cyanide treatment, are all dealt with.—R. S. H.

Gold-Silver Alloys; Solubility of —— in Potassium Cyanide Solutions. J. Yokobori. Mem. Coll. Science and Eng., Kyoto Imp. Univ., 1903, **1**, 65–71.

In view of the fact that native gold invariably contains a certain proportion (varying from 6 to 60 per cent.) of silver, the author examined the action of potassium cyanide solutions of different strengths (from 0·1 to 0·5 per cent.) on pure gold, gold-silver alloys containing 10, 20, 30, 40, 50, 60, 70, 80, and 90 per cent. respectively of silver and pure silver. The results are given in a series of tables. In the weaker solutions (0·1 and 0·2 per cent.) the amounts of gold and silver dissolved from the alloys vary in an irregular manner, except that with 0·2 per cent. cyanide solution the percentage of gold and silver dissolved in a given time appears to decrease gradually as the proportion of silver in the alloys increases. With the stronger cyanide solutions the solubility of both gold and silver appears to be nearly at the maximum when the alloy contains equal proportions of the two metals. The author also examined the effect of zinc shavings upon cyanide solutions. 5 grms. of the shavings were immersed in 100 c.c. of the cyanide solution, and the strength of the latter determined after 24 and 48 hours. With a 0·1 per cent. solution, the strength, after 24 and 48 hours' contact with zinc, varied from 0·070 to 0·077 and 0·064 to 0·072 per cent. respectively, whilst without zinc the corresponding figures were 0·096 and 0·092. With a 0·216 per cent. solution the figures were 0·163—0 164 and 0·08—0·136 per cent. with zinc, and 0·210 and 0·202 without zinc. With a 0·3 per cent. solution, the figures were 0·228—0·23 and 0·112—0·180 per cent. with zinc, and 0·290 and 0·274 without zinc.
—A. S.

Zinc Blende; Smelting of ——. C. Ritter. Z. angew. Chem., 194, **17**, 774.

The elimination of sulphur during the roasting of blende depends largely upon the state of division of the ore, which should be in grains not larger than 1—3 mm. in linear dimensions. If finer than this it lies light and requires more room in the furnace. This preliminary treatment of the blende before reduction is more costly than that necessary for calamine; but unless it be thoroughly carried out, much zinc remains in the residues. The addition of calcined calamine to roasted blende in the melting furnace seems to assist in expelling the zinc; for while a 25 per cent. blende smelted alone yielded 81 per cent. of its total zinc, a mixture of this blende with an equal weight of a 15 per cent. calamine yielded 91 per cent. of the total zinc. Flue-dust, or zinc-white, similarly smelted, yielded practically all its zinc; so that the fineness of division of the ore in the smelting furnace has an important bearing on the yield.—J. T. D.

Aluminium; Alloys of —— with Bismuth and with Magnesium. H. Pécheux. Comptes rend., 1904, **138**, 1501—1503.

By the method formerly used (this J., 1904, 577), bismuth-aluminium alloys were obtained containing 75, 85, 88, 91 per cent. of aluminium; densities 2·86, 2·79, 2·78, 2·74 respectively. The alloys are sonorous, brittle, fine-grained and homogeneous, silver-white, and have melting-points between those of their constituents, nearer that of aluminium. They are not oxidised in air at the temperature of casting; but are rapidly attacked by acids, concentrated or dilute, and by potassium hydroxide solution. The filed alloys behave like those of tin-aluminium (this J., 1204, 603), but still more markedly. Magnesium-aluminium alloys were obtained with 66, 68, 73, 77, 85 per cent. of aluminium; densities 2·24, 2·27, 2·32, 2·37, 2·47. They are brittle, with large-granular fracture, silver-white, file well, take a good polish, and have melting-points near that of aluminium. They are difficult to cast, being viscous when melted; and when slowly cooled form a grey spongy mass which cannot be re-melted. They do not oxidise in air at the ordinary temperature, but burn readily at a bright red heat. Th are attacked violently by acids and by potassium hydroxi solution; decompose hydrogen peroxide, and slowly deco pose water even in the cold.—J. T. D.

English Patents.

Alloys having Pyrophoric Action; Manufacture Metallic ——, and their Application to the purposes Ignition and Illumination. C. F. A. von Welsba Vienna. Eng. Pat. 16,853, July 31, 1903.

See Fr. Pat. 337,320 of 1903; this J., 1904, 484.—T. F.

Melting Furnaces. J. B. Orbison, San Francisco. Eng. Pat. 9445, April 25, 1904.

The furnace, which is especially adapted for melting br and like alloys, with the use of liquid or gaseous fuel mounted on trunnions, one of which is hollow for introd tion of a jet of flame, and has arrangements permitting to be mechanically oscillated. A gaseous fuel burner co municates with the hollow trunnion, and the bottom of furnace is provided with a dam disposed longitudina opposite a charging way at the top of the furnace, o which dam the metals flow alternately from right to and the reverse, as the furnace oscillates, until they thoroughly mixed.—E. S.

United States Patents.

Metals; Extracting —— from Ores. W. E. Greenaw Denver, Col., U.S.A. U.S. Pat. 761,164, May 31, 190

Chlorine, obtained by electrolysing sodium chloride absorbed by water; the chlorine solution is agitated w the ore in a closed vessel for some time; the solutio then displaced by fresh chlorine solution injected u pressure, followed by agitation. Finally the "desi metals" are precipitated from the solution filtered from ore.—E. S.

Gold Separating and Recovering Apparatus. W. Land San Francisco. U.S. Pat. 762,174, June 7, 1904.

The apparatus for the separation of gold from sand c prises a chamber containing mercury having a co bottom with a discharge passage, a receptacle fitted to depending from the conical bottom, and having cocks opposite ends; a vertical cylinder of smaller diame through which material is delivered and submerged in mercury; revolving scrapers extending over the up edge of the mercury chamber, and by which the mate after rising through the mercury, is discharged; an exte annular receiving trough, and an air-tube located wit and above the trough, having jet openings through w an air-blast may be discharged outwardly.—E. S.

Minerals; Apparatus for the Concentration of —— means of Oil. J. W. van Meter and M. P. Boss, Francisco. U.S. Pat. 762,774, June 14, 1904.

Oil, pulped ore, and water, are supplied by a rotary di butor, divided into two compartments, to the first of a se of communicating vessels, each of which has a bo discharge for the water and gangue, and means for m taining a water-bed to support the oil in its course. distributor is disposed in the upper part of the vesse discharge near its axis, so that the rotary movements of contents induced by the distribution of the material tend to throw the pulp outwardly against the walls of vessel, and facilitate the separation of the gangue. Th are means at the end of the series of vessels to separate upper and lower portions of the oil, the upper oil b returned to the first vessel by a pipe communicating the lower compartment of the distributor.—E. S.

citing Fluid for Electrical Batteries. G. F. Atwood, Assignor to Primary Power Co., Wakefield, Mass. U.S. Pat. 761,642, June 7, 1904.

E solution in which the positive pole is immersed is the ne as that described in Eng. Pat. 28,057 of 1903 (see J., 1904, 377), except that instead of 16 lb. of nitric l and 4½ lb. of sulphuric acid, 142 lb. of nitric acid are d.—T. F. B.

ode and Process of Making same. H. Blackman, New York. U.S. Pat. 762,227, June 7, 1904.

: anode for electrolytic apparatus consists of a cast e of iron that has been exposed at a high temperature uperheated steam until the exterior is converted into gnetic oxide of iron of sufficient thickness to protect the erlying iron during electrolysis. A protecting layer of s, or a vitreous glaze, is fused as a band around the tracted portion of the anode which is to be exposed at surface of the electrolyte.—E. S.

attery; Electrical ——. J. R. Lord, San Francisco. U.S. Pat. 762,425, June 14, 1904.

: anode is composed of an electrical conductor upon or nd which is placed, or deposited during the previous of the battery, a quantity of a compound of an anode al. The conductor serves as the negative pole, and is placed in such a position that any solids, chemically precipitated from the electrolyte, may fall upon or in electrical proximity to it, and thus form additional anode active material. The electrolyte is composed of one or more salts of one or more anode metals, together with one or more salts of one or more alkali metals in solution. Any suitable compound is used as a depolariser, and the cathode may be of any conducting substance chemically unattacked by the electrolyte, the whole of the materials being placed in a suitable containing vessel.—B. N.

French Patent.

Oxides of Nitrogen; Manufacture of —— [*Electrical*]. Siemens Bros. and Co. Fr. Pat. 339,730, Jan. 20, 1904.

AIR, or a mixture of nitrogen and oxygen, is caused to traverse an electric arc formed between electrodes of carbon combined with metallic salts, and especially with calcium fluoride. To avoid, as far as possible, the formation of carbon monoxide, the electrodes are formed with only enough carbon, mixed with the fluoride or other salt, to render them sufficiently conducting: or the gaseous mixture is so directed as to ensure the least possible contact of the mixture with the incandescent points of the carbons. Compare Fr. Pat. 335,453, 1903; this J., 1904, 193.—E. S.

(*B.*)—ELECTRO-METALLURGY.

Gold; Electrolytic Refining of ——. F. Wohlwill. Electrochem. Ind., 1904, **2**, 221—224.

A SOLUTION of gold chloride containing free hydrochloric acid or a suitable chloride is used as electrolyte. If the temperature is kept up to the normal value (67° C.) and sufficient free acid is present, no chlorine appears at the anode but the gold goes regularly into solution. Moreover, when these conditions are fulfilled, a sufficiently high current density can be used to make the operation of refining as rapid as the old chemical process, which it has entirely displaced in Germany and in the U.S.A. Mint at Philadelphia. The present paper refers chiefly to the separation of gold and platinum, which is readily effected by the electrolytic method. Any platinum present in the impure gold anodes passes into solution, but is not deposited at the cathode, and consequently accumulates in the electrolyte; it is removed by precipitation with ammonium chloride from time to time. Platinum is said to be much more widely distributed than is generally supposed, and occurs in small but appreciable quantities in nearly all silver Palladium can be separated in a similar manner, and in view of its occurrence in the Sudbury nickel ores attention is drawn to this point.—R. S. H.

Siemens Process for Winning Copper; Studies on the ——. M. De K. Thompson, Jr. Electrochem. Ind., 1904, 2, 225—231.

THE Siemens and Halske process of recovering copper from roasted sulphide ores, consists in leaching the finely powdered ore at 90° C. with ferric sulphate solution, containing free sulphuric acid. The ferric sulphate is reduced to ferrous salt, and copper enters solution as sulphate. Subsequent electrolytic treatment in a diaphragm cell deposits copper at the cathode and oxidises ferrous to ferric sulphate at the anode. (See Eng. Pats. 14,033 of 1886 and 3533 of 1889; this J., 1887, 734; 1890, 396.) The author has carried out a laboratory investigation of the several stages of this process. The dissolving action of ferric sulphate on cupric and cuprous oxides and sulphides was studied in detail, and then a natural copper ore was submitted to treatment. Copper pyrites before roasting is not appreciably attacked by ferric sulphate, but after roasting, in which it seems to be converted chiefly into oxide, it dissolves readily. The electrolytic treatment was carried out separately to study the anode and cathode reactions. At the cathode it was found that copper could be deposited in a firm adherent form from an acid solution of ferrous and copper sulphates until the concentration reaches a very low value, *e.g.*, with a current density of 0·47 amp. per 100 sq. cm., until the concentration of copper in solution was 0·5 per cent., at which point the metal begins to be spongy. The oxidation at the anode, using carbon electrodes, is at first very efficient, but as the concentration of ferrous sulphate decreases, the process gradually falls off in efficiency.—R. S. H.

Fused Zinc Chloride; Preparation of Pure ——, and its Electrolysis. S. Gruenauer. Z. anorg. Chem., 1904, **39**, 389—476.

Lorenz (this J., 1896, 279) has shown that zinc chloride, even after it has been kept in the fused state until evolution of steam can no longer be detected, still retains a certain proportion of water and cannot be satisfactorily electrolysed.

Preparation of Pure Zinc Chloride.—The author finds that by the following method pure anhydrous zinc chloride can be prepared, which on electrolysis behaves quite satisfactorily, giving at once zinc and chlorine. 40 grms. of zinc chloride are dissolved in 20 c.c. of hydrochloric acid of sp. gr. 1·19 and the solution evaporated in a tube of refractory glass, through which a current of dry hydrochloric acid gas is passed at the rate of 350 bubbles per minute. The temperature is gradually raised, and after some time the mass solidifies; at the moment of solidification, hydrochloric acid gas is evolved from the mass. The solid zinc chloride is fused as rapidly as possible, and the current of hydrochloric acid gas kept passing through. Any steam which condenses in the apparatus is driven over by means of a second gas burner. The dehydration of the zinc chloride is complete in 75 minutes. Attempts to substitute carbon dioxide and air for the hydrochloric acid gas gave unsatisfactory results, and the author considers it probable that the zinc chloride forms with the hydrochloric acid an addition compound, which is again split up at the temperature at which the mass solidifies. This method of dehydration can be applied to concentrated solutions of zinc chloride, and is not affected by the presence of foreign substances. It is probably applicable for the preparation of all anhydrous hygroscopic chlorides, *e.g.*, carnallite, calcium chloride, and the chlorides of the rare earths.

Electrolysis of Pure Anhydrous Zinc Chloride.—The carbon electrodes used should be dried in an air-bath, not by ignition in the Bunsen flame. The current-yield increases with increasing current-density, but the differences are very small with currents of more than 1·5 ampères. With increase of temperature (from 525° C. to the boiling point of zinc chloride, 732° C.) the current-yield falls, the more rapidly the nearer the boiling point of the electrolyte is approached. By fractional electrolysis of a mixture of iron and zinc chlorides, pure iron and pure zinc can be obtained, but the complete separation of the iron only takes place gradually, the last traces of iron being especially difficult to separate. With a mixture of equimolecular amounts of zinc and potassium chlorides the current-yields are much higher than with pure zinc chloride; for example, with 0·5 ampère, the yields were 59 and 23 per cent. respectively. This increased yield is due to the fact in the presence of alkali chlorides, the formation of "metal fog" in the electrolyte is prevented. The current-yield increases with increasing current-density, but the differences are inconsiderable with a current of more than 2 ampères. This mixture of zinc and potassium chlorides gives yields which approach those required by Faraday's law. With a mixture of equimolecular amounts of zinc and sodium chlorides, the current-yields are higher than with pure zinc chloride, but not so high as with the corresponding mixture of zinc and potassium chlorides. The variation of yield with current-density is the same as with the latter mixture. A mixture containing 35·36 per cent. of sodium chloride gives better yields at the higher current densities (1 ampère and above) than the equimolecular mixture. The fact that the addition of sodium chloride to zinc chloride improves the current-yield is of importance, as it points to the advantage of recovering zinc electrolytically from the waste zinc chloride liquors from dyeworks, which contain considerable quantities of sodium chloride.

Formation of "Metal Fog" in the Electrolysis of Fused Zinc Chloride.—The conditions which most favour the formation of "fog" are low temperature and high current-density. By raising the temperature a melt containing "metal fog" becomes clear, but the "fog" appears agai if the temperature be lowered. (See also this J., 190 670, 1001, 1021; 1902, 975; 1903, 1053.)—A. S.

ENGLISH PATENTS.

Electro-depositing Metals on Parabolic Reflectors an Analogous Articles; Improved Method of, and Mean for ——. B. J. and A. Round, Birmingham. Eng. Pa 9531, April 28, 1903.

The parabolic reflector, or other article with a concave analogous form, is made the cathode and rotated in th electrolyte, or a relative rotary motion is maintained betwe the cathode and anode, the latter consisting of a sheet silver beneath and extending into the crown of the anod and made to conform in shape with the inside contour the surface of the article to be silvered. The cathode suspended in the electrolyte in an inverted position, and, means of a small vent in the crown, the escape of gas provided for, and the space between anode and cathod remains filled with the electrolyte.—B. N.

Tantalum and like difficultly Fusible Metals: Manufactu of Homogeneous Masses of ——. C. D. Abel, Lond From Siemens and Halske Act.-Ges., Berlin. Eng. P 26,775, Dec. 7, 1903.

See Fr. Pat. 337,607 of 1903; this J., 1904, 494.—T. F.

FRENCH PATENTS.

Electric Arc Furnaces. Soc. de Métal. Électro-Thermiqu Fr. Pat. 339,593, Jan. 14, 1904.

In order to concentrate the heat from open arcs upon a material to be heated by radiation, the cover of the furna is brought as near the electrodes and the hearth of t furnace as possible. A double-walled cover is provid with a closed gas space between the two sections, the in wall being made of graphite, the outer of refractory brick The material to be fed into the furnace passes down lo inclined shoots at each end of the furnace, which serve al for leading off the gases from the heated zone. Two a are employed, one towards each end of the furnace, so th their heating effect serves both for the material on t hearth of the furnace and for that passing down the shoo towards this hearth.—R. S. H.

Furnace; Rotatory and Oscillating Electric ——. I. Braun. Fr. Pat. 339,942, Jan. 27, 1904.

An inner retort is made of refractory material and h protuberances on its inner surface to assist in the mixing the materials during the rotation of the furnace. T retort is surrounded by the resistance material, the latt being made in the form of plates so as to ensure the ce axis of the retort being kept in its true position during t movement. The resistance material is in contact wi electrodes of graphite, which are separated from o another by insulating walls of highly refractory mater such as carborundum or "siloxicon," and the furna is finally surrounded by a water jacket. The furnace provided with an air-box communicating by blast p with the interior of the retort, so as to supply materia with or without air, capable of assisting in the reactio By means of wheels gearing with endless screws, the f nace may be given two movements, one of rotation arou the axis of the furnace, and an oscillatory movement arou an axis at right angles to the axis of the furnace.—B. N.

Metals, such as Lead and Silver: [Electrolytic] Extr tion of —— from their Ores. Accumulatoren.-fabr Act.-ges. Fr. Pat. 339,849, Jan. 23, 1904.

Sulphide or other ores either before or after oxidation treated with such a molten halogen salt as is capable reacting with them to form the corresponding zinc or sil compound. The fused product is submitted to electroly and the metal collected at the cathode.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Mustard Oil as a Lubricant. A. Rohrbach. Organ f. Oel- u. Fett-Handel., 1904, **57**, [24].

Tests of mustard oil gave the following results:—Sp. gr., 0·916 at 15·5° C. Viscosity (Engler), 0·90 at 20° C., 0·40 at 40° C., 0·21 at 60° C., 0·14 at 80° C., 0·11 at 110° C., 0·09 at 150° C. The lubrication tests in the Martens' machine gave the following increases in temperature:—Under a load of 10 kilos. per sq. cm., at a peripheral velocity of 0·5 metre per second, 2·9° C., and at 2 metres 2·7° C.; under a load of 40 kilos., 9·8° C., and 22·1° C. respectively. At 9° C. the oil becomes slightly turbid. The flashing point (Pensky) is above 220° C.; acidity, 0·062 per cent. calculated as sulphur trioxide. The oil will stand heating to 180° C. without frothing. It furnishes a clear solution in benzene, and does not "gum" when spread out in thin layers and exposed to the air for 6 days.—C. S.

United States Patents.

Vool-fat: Process of Recovering ——. C. E. Swett, Providence, R.I. Assignor to R. H. Hutchinson, New York. U.S. Pat. 761,265, May 31, 1904.

he washings from the wool are treated with an alkali anganate or permanganate and then with an acid, and the agma rising to the surface is freed from excess of water nd extracted with a volatile solvent.—C. A. M.

Extracting Oil: Apparatus for ——. M. Kirshner, ynchburg, Va., U.S.A. U.S. Pat. 761,686, June 7, 1904.

rotating drum is situated in an outer casing. On the urface of the drum are a number of pockets to receive the aterial, which is compressed by plungers, situated in the ckets. Means are provided for actuating the plungers, r collecting the expressed oil, and for removing the sidue.—W. H. C.

atty Acids; Process of making ——. W. Connstein, Assignor to Verein Chem. Werke Act.-Ges., Charlottenburg, Germany. U.S. Pat. 762,026, June 7, 1904.

ee Fr. Pat. 328,101 of 1902; this J., 1904, 69.—T. F. B.

French Patent.

ats; Process of Treating —— *in the Stearine Industry.* L. F. Fournier et Cie. Fr. Pat. 339,385, Jan. 6, 1904.

current of compressed air is passed through the fatty ubstance heated to about 115° C. This is stated to celerate the process and improve the yields when used conjunction with different methods of saponification.
—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

russian Blue in Spent Oxide, &c.; Determination of —— *by Feld's Method.* R. Witzack. XXIII., page 728.

English Patent.

Binding Media for Oil Colours. J. E. Kollinger, Munich, Germany. Eng. Pat. 17,120, Aug. 6, 1903.

See U.S. Pat. 738,456 of 1903; this J., 1903, 1096.—T. F. B.

French Patent.

Lakes [from Azo Dyestuffs]: Process for Preparing New ——. Soc. anon. Prod. F. Bayer et Cie. Fr. Pat. 339,606, Jan. 14, 1904. IV., page 713.

(B.)—RESINS, VARNISHES.

Colophony: Distillation of —— *with Zinc Dust.* C. Stiepel. Augsburger Seifensieder-Zeit., 1904, **31**, 262. Chem.-Zeit., 1904, **28**, Rep., 179.

A quantity of colophony was melted, the amount of zinc dust necessary to neutralise the resin-acids (about 10 per cent.) added, and the mixture distilled in a small cast-iron retort. The course of the distillation and the products obtained were the same as by the usual distillation process, but the distillate was almost entirely free from acid.—A. S.

French Patent.

Fireproof Varnish: Manufacture of ——. Vymer-Ges. Fr. Pat. 339,641, Jan. 16, 1904. IX., page 715.

(C.)—INDIA-RUBBER, &c.

Litharge and Vulcanisation. E. Schulze. Gummi-Zeit., 1904, **18**, 749—751.

The rôle litharge plays in rubber mixings, to which it is added to aid vulcanisation, is commonly supposed to be that of a sulphur carrier, but, in the author's opinion, the effect is to be traced to purely physical causes. On the mixing rolls the sulphur and litharge particles become surrounded by a film of rubber. Where a sulphur particle alone is enclosed, the sulphur would combine with the rubber, forming normal soft rubber, and if more sulphur than is necessary for vulcanisation be present, the excess dissolves in the rubber substance, passes through without further combination, and is absorbed on coming into contact with particles of litharge. In the case of particles of sulphur and litharge being enclosed together, the sulphur will first combine with the litharge. The lead sulphide formed has no effect on the vulcanisation, but both it and litharge hasten vulcanisation very considerably by acting as conductors of heat. That such a mixing is a good conductor (comparatively) is shown by the fact that motor tyres made therewith become hot in use much more quickly than other tyres. The hardening effect of litharge is due probably to the saponification of the rubber resins, lead salts being formed of a higher melting point than the original resins.—J. K. B.

United States Patent.

Vulcanised Rubber: Regenerating ——. R. B. Price, Chicago. U.S. Pat. 762,843, June 14, 1904.

Ground waste rubber is boiled with a saturated or supersaturated solution of caustic alkali with or without pressure.
—J. K. B.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Tanning Materials: Composition of Liquors of similar Concentration from different ——. J. Paessler. Günther's Gerber-Zeit., 1904, 21—23. Z. angew. Chem., 1904, **17**, 789.

In liquors of 2° Baumé were determined the contents of tannin and of non-tannin substances, and in liquors containing 2 per cent. of the tannin substance were determined the content of non-tannin substance and the specific gravity. It was found that:—1. The specific gravity is dependent upon the content both of tannin- and of non-tannin substance; the ratio of tannin- to non-tannin substance varies widely in different materials. 3. The specific gravity of the non-tannin substances is higher than that of the tannin-substances.—J. T. D.

Pickling Method; Improved ——. A. Seymour-Jones. Collegium, 1904, 186—187.

Formic and acetic acids are proposed as substitutes for sulphuric acid in the usual acid and salt pickle, so as to avoid the destructive action of the last-named acid. Skins were limed and carried to the drenching and scudding stage, and then paddled in 0·25 per cent. solution of formic acid at 70° F., and left to soak in the acid for 24 hours. They were then paddled in a saturated solution of common salt and again left to soak for 24 hours. The result, as regards colour, was excellent. These skins were sent on a journey of 57 days, and all the time exposed to the worst conditions. Half the skins were then tanned out under the conditions laid down in the Society of Arts Report on Leather for Bookbinding (this J., 1901, 819, and 1902, 128), and proved most successful. The remainder, after eight months, were still unchanged, and no mould appeared at any time. The cost of this process is about the same as when sulphuric acid is used. White pyroligneous acid (distilled to free it from iron), diluted to contain 0·1 to 0·2 per cent. of acetic acid, has proved equally efficient and somewhat cheaper.—R. L. J.

Tannin Determination [*Filtration of Quebracho and Mangrove Extracts*]. K. Schorlemmer. XXIII., page 730.

Chromic Oxide in Chrome Leather; Note on the Determination of ——, *and Separation of the same from Aluminium Oxide in presence of Aluminium Salts.* H. R. Proctor. XXIII., page 729.

United States Patent.

Paper Pulp; Manufacturing —— [*and Extracting Tannin*]. O. Carr. U.S. Pat. 762,139, June 7, 1904. XIX., page 725.

French Patents.

Tannage of Skins: Process and Plant for Quick ——. H. de Marneffe. Fr. Pat. 339,428, Jan. 8, 1904.

Hollow box-like structures are formed by attaching the skins to deep rectangular frames. These are packed into a closed casing or container, each box being connected to a vent pipe passing outside the container. Tanning liquors are pumped into the container, percolate through the skins and pass by the vent pipes into a tank, from which the pump again circulates them. When tanning is complete, the skins are stuffed, fat-liquored, &c., in a similar manner, without further disturbance or handling.—R. L. J.

Rice Flour; Treatment of —— *for Use in Finishing Yarns and Textiles.* Soc. anon. des Rizeries Françaises. Addition to Fr. Pat. 334,369 of Aug. 1, 1903. XIX., page 725.

XV.—MANURES, Etc.

Commercial Manures; Influence of Lime on the Efficiency of the Phosphoric Acid of ——. B. Schulze. Fühling's Landw.-Zeit., 1904, **53**, 183; Chem.-Zeit., 1904, **28**, Rep., 158—159.

The author's experiments give the following results:—(1) The phosphoric acid of bone-meal (whether free from gelatin or not) exerts on a soil poor in lime an action similar to that of the phosphoric acid soluble in citric acid. (2) Simultaneous liming influences the action of the phosphoric acid soluble in water but little, that of the acid soluble in citric acid more, and that of the phosphoric acid of bone-meal still more. (3) When the phosphoric acid manure is applied in the spring, the greatest harm is effected by the use of quicklime in the spring, then comes autumn application of quicklime, next the use of calcium carbonate in spring, and finally calcium carbonate applied in the autumn, which has the least injurious action. (4) The phosphoric acid of bone-meal varies in its action according to the time and form of the liming, yet the beneficial action of the phosphoric acid and the amount of it assimilated are always so much diminished as to show that bone-meal and lime should never be applied to the same crop. (5) One of the causes of the diminution in crop produced by lime lies in the action of the latter on the phosphoric acid of the soil, which is rendered difficultly soluble. Experience shows that the acid compounds of the soil are indispensable in rendering useful difficultly soluble phosphates.—T. H. P.

Calcium Sulphide for the Destruction of Cuscuta [*"Dodder Weed"*] *and other Parasites in Agriculture.* F. Garrigou. Comptes rend., 1904, **138**, 1549—1550.

The author has employed powdered calcium sulphide with great success for the destruction of blights and parasitic weeds among vegetables, fodder, and garden plants. For the "dodder weed" in fields of lucerne calcium sulphide is superior to any other destructive agent, and kills the weeds in 48 hours. It kills insects on beans, peas, and rose-trees. In order to ensure its full activity it is necessary either that the weather should be moist, or that the powder should be moistened after it has been applied, thereby liberating sulphuretted hydrogen.—J. F. B.

French Patents.

Ammonium-Magnesium Sulphate: Manufacture of ——, *and the Application of this Salt as a Manure in Agriculture.* J. D. D. Thierry. Fr. Pat. 339,116, Jan. 7, 1904.

Ammonium-magnesium sulphate is formed by passing ammonia gas into a strong solution of magnesium sulphate, mixed with the proper proportion of sulphuric acid, and removing the crystals that form. Or, solution of ammonium sulphate and of magnesium sulphate, in atomic proportions, are mixed, and the crystals that form are withdrawn, the mother-liquor being used in making fresh solutions. The application of the salt as a fertiliser is also claimed.—E. S.

Sodium Bisulphate: Industrial Utilisation of —— [*Manure*]. L. A. Angibaud. Fr. Pat. 339,820, Jan. 2 1904.

Fish waste, or other animal garbage, is immersed in boiling strong solution of nitre-cake, or in the same in a molten state. The syrupy liquid thus produced is worked up with powdered fossil or other phosphates, and the mass is allowed to cool and consolidate in heaps, when it may be powdered for use as a manure.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Diffusion; Chemical Treatment during ——. A. Besson. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1126—1133.

The author determined the quality of diffusion juice when the chips had been subjected to preliminary treatment or when chemicals had been added to the water used. Diffusion with ammoniacal or amine solutions has practical interest in consequence of the tendency to use for diffusion the alkaline condenser waters in order to save the heat. The introduction of ammoniacal waters was found to be prejudicial, the purity of the raw juice being sensibly diminished and the defecation and carbonatation scums being increased in quantity and in viscosity, although the juice is slightly lighter in colour than ordinarily. Pure amines act favourably on the juice, but the ordinary amines containing ammonia produce unfavourable effects. Certain factories use sodium bisulphite as an antiseptic in the diffusion battery, chiefly at rasping stations, to disinfect the battery, render the juice more stable and diminish the production of gas. The first effect of bisulphite solutions is to decolorise the chips and the juice; the purity is not decidedly altered, and no invert sugar is formed. In carbonated juice a little more lime is present, and the juices frequently become cloudy after filtration and possibly have a greater tendency to form incrustations. It would be better to use a solution of sulphurous acid made on the spot; 0·4—0·5 grm. of sulphur dioxide may be used without fear of inversion. The rendering of juice neutral by the addition of chalk does not appear to give purer juice. Sodium bicarbonate (0·5 grm. per litre) gives a slight improvement in purity, but when the chips are made alkaline with sodium carbonate or aluminate, the purity is diminished. The effects obtained by using alkaline and acid oxidising reagents may be explained by the above results. Chips treated with carbon dioxide give up an enormous amount of gas during diffusion, and the purity is sensibly lowered. The abundant disengagement of gas in carbonic diffusion may serve to explain abnormal evolution of gas when beetroots that have been long stored are worked up. The lessened vitality of the beets in silos badly ventilated, allows of an accumulation of the gas produced by the respiration of the roots, and this gas is subsequently given off in the battery.—L. J. de W.

Incrustation [Sugar Works]; Use of Aluminium and its Compounds for Preventing ——. A. Besson. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1136—1137.

As the efficacy of aluminium salts in preventing the formation of an incrustation during concentration is dependent on the alkalinity of the juice, it is preferable to use some compound containing a feeble and volatile acid, and bisulphite of aluminium specially prepared in concentrated solution is found to answer, while at the same time the juice gets the benefit of a slight sulphiting. The quantity to be added to second carbonated uice with an alkalinity of 0·15 to 0·20 is 0·01 to 0·02 grm. of alumina per litre, the juice being then concentrated vithout further filtration. The larger amount of reagent liminishes the alkalinity about 0·07. The lime and silica ıre thrown out as a granular, non-incrustant silico-aluminate of lime.—L. J. de W.

Mangifera Indica" L. [Mango Tree]; The Gum of ——. P. Lemeland. J. Pharm. Chim., 1904, **19**, 584—593.

The gum of the mango tree is sold as an astringent drug n India. It occurs in lumps varying in size from that f a nut to that of a small egg, of an amber to reddish-ellow colour, almost transparent and showing a brilliant onchoidal fracture. The sample studied contained 16·57 er cent. of moisture and the mucilage was only partially oluble in water. Calculated on the dry substance, the oluble portion amounted to 39·36 per cent. The soluble ortion possessed a rotatory power $[\alpha]_D = -25·33°$. The um contains a directly oxidising enzyme (aëroxydase). Vhen hydrolysed by 3 per cent sulphuric acid, the gum, in ne air-dry state, yielded 71·42 per cent. of reducing sugars lculated as invert sugar, which included 73·33 per cent. f galactose and 35·09 per cent. of pentoses. Arabinose as isolated from the latter in the crystalline condition. The ortion of the mucilage insoluble in water yielded 86·28 er cent. of reducing sugars, calculated on the substance ontaining 10·51 per cent. of moisture. These sugars in-uded 32·08 per cent. of galactose and 42·87 per cent. of entoses.—J. F. B.

United States Patent.

chroo-dextrin; Process of Making ——. G. Reynaud, Paris. U.S. Pat. 761,542, May 31, 1904.

chroo-dextrin, it is stated, may be prepared from "acid ats" by mixing the peat with 3—5 times its weight of ıter and heating the mixture under a low pressure in a gester to a temperature of 110°—150° C. for 30—60 inutes, according to the degree of acidity of the peat, ereby converting the amylaceous matters of the peat into xtrin.—J. F. B.

French Patent.

ar; Boiling and Crystallisation of ——, *at a High Temperature.* J. B. L. Aurientis and R. Fontenilles. Addition, dated Nov. 11, 1903, to Fr. Pat. 326,433, Nov. 18, 1902. (See this J., 1903, 812.)

e present addition deals with the crystallisation of sugar tained in saturated syrups at a temperature higher than C., with the addition of grain sugar ("semoule") in ying proportions according to the degree of saturation the syrup. The residual syrup from each operation is ed for melting a fresh quantity of sugar similar to that ich yielded it, so as to avoid second and third runnings gars.—T. H. P.

XVII.—BREWING, WINES, SPIRITS, Etc.

Enzyme, [Anaëroxydase]; Study of the Action of an Indirect Oxidising ——. E. Bourquelot and L. Marchadier. Comptes rend., 1904, **138**, 1432—1434.

The oxydases proper [aëroxydases] take up oxygen from the air and transfer it to certain oxidisable bodies; the indirect oxydases [anaëroxydases] on the other hand only exert an oxidising action in presence of hydrogen peroxide or similar bodies, which they decompose. The authors have studied the action of the anaëroxydase present in an infusion of oatmeal upon vanillin in presence of hydrogen peroxide. The experiments were carried on at a temperature of 30°—33° C. for 24 hours. The product of the oxidation was identified as *dehydrodivanillin*, which is the same product as is formed by the action of the aëroxydase of gum upon vanillin. The aëroxydases and anaëroxydases possess certain other properties in common; in particular, the presence of as much as 50 per cent. of alcohol does not interfere with their activity, but minute proportions of hydrocyanic acid paralyse them. The authors take the view that the aëroxydases are composed of a mixture of two enzymes, one a *hydroxydase*, capable in presence of air of converting water or certain other bodies into the corresponding peroxides, and the other an indirect oxydase decomposing these peroxides with liberation of active oxygen (compare this J., 1903, 384).—J. F. B.

Yeast; Toxic Action of Chromium Compounds on ——. E. Pozzi-Escot. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1141—1142.

Experimenting on a bottom fermentation beer yeast at 19°—20° C., the author finds that the toxic action of chromium compounds depends on the nature of the combination of the chromium in the compound, the action being a maximum for chromic acid and a minimum for salts of chromium. The effect of 0·1 grm. of chromic acid per litre is clearly marked even in presence of a large quantity of yeast; chrome alum only begins to produce an effect when 3·5 grms. per litre are added, and the growth is still active when 10 grms. are present.—L. J. de W.

Zymase and Alcoholic Fermentation. P. Mazé. Comptes rend., 1904, **138**, 1514—1517.

The decomposition of sugar into alcohol and carbon dioxide is a very general phenomenon in living cells under normal conditions. Zymase is an enzyme of aerobic life and its action on sugar is to be regarded as a digestive phenomenon. In *Eurotiopsis Gayoni* (see also this J., 1902, 287) the zymase is found exclusively in contact with air in strictly aërobic cells; their richness in zymase decreases with the age of the cells, and it soon disappears entirely. The formation of zymase in absence of air, in plants which apparently have lost their zymase, should be considered not as the result of an effective production, but as a regeneration, more or less slow and incomplete, of zymase which has lost its activity. In normal life the zymase is destroyed after it has acted, probably by oxidation, and alcoholic fermentation in anaërobic life is to be regarded as the continuation of an enzymic action originally aërobic. Under anaërobic conditions the zymase is enabled to accumulate, and continues to produce alcohol after the yeast has ceased to multiply and assimilate that product. As regards the mechanism of the action of zymase, the author expresses a view identical with that formulated by Buchner and Meisenheimer (this J., 1904, 252).—J. F. B.

Pure Yeast System; Application of Hansen's —— *for English Stock Beers.* N. H. Claussen. J. Fed. Inst. Brewing, 1904, **10**, 308—315.

The system of single-cell yeast has not hitherto gained a footing in England for the manufacture of stock beers, owing to the fact that the type of secondary fermentation peculiar to English beers cannot be effected by the same yeast as carries out the primary fermentation. Hitherto, the existence of specific secondary yeasts has only been assumed, but the author has now discovered a new, non-

sporulating, budding fungus, belonging to the Torula group, which possesses the peculiar property of conditioning beer in such a way as to create the typical English flavour and condition. This fungus, to which the name of Brettanomyces is given, exists in several varieties, some of which are harmful. It produces a slow fermentation in wort or in beer fermented by ordinary brewers' yeast; the carbon dioxide produced by its action is retained very firmly, and forms a copious and lasting foam. A somewhat considerable amount of acid is formed, accompanied by ethereal substances, which at once call to mind the flavour of stored English beer. If a few drops of a pure culture of Brettanomyces be sown in a bottle of pasteurised beer and stored at a temperature of 75°—85° F. for 10—14 days, the beer acquires the English character. The beer employed for this purpose should have reached a certain limit of attenuation during primary fermentation. The author suggests that Brettanomyces is a minor constituent of English pitching yeast, or may enter the beer at some stage as an infection, and that its presence is indispensable for the secondary fermentation. He proposes that the question of single cell yeast for English beers should be re-opened, that the primary fermentation should be conducted with pure beer yeast, and that pure cultures of selected varieties of Brettanomyces should be employed for secondary fermentation.
—J. F. B.

Malting and Brewing; Transformation of the Albuminoids during ——. F. Weis. Z. ges. Brauw., 1904, **27**, 385—389, 405—407, 420—423, 440—445.

After giving an account of the nature and proportions of the different nitrogenous constituents of barley and malt, so far as they are known, the author discusses the action upon them of the proteolytic enzymes of the malt. Green malt contains a coagulating enzyme, similar to rennet, which coagulates milk, and two proteolytic enzymes, one resembling pepsin and the other trypsin. Referring to a previous paper (this J., 1901, 141), written before the dual nature of the proteolytic enzymes of malt was recognised, the author describes how he now uses stannous chloride for precipitating the true albumins, zinc sulphate for precipitating the albumins and albumoses, and tannic acid for precipitating all albuminoid derivatives higher than the amides and similar simple products. The comparison of the nitrogenous contents of the filtrates from each of these precipitates then enables him to differentiate between the products of the action of the peptic enzyme and those of the tryptic enzyme. The first stage of proteolysis [of wheat glutin] by malt, corresponding to the action of the peptase (degradation down to albumoses), proceeds with considerable rapidity; the action is notable even at low temperatures and acquires its greatest intensity at 51° C., at which temperature it is nearly twice as strong as it is at 35° and at 60° C. The tryptic proteolysis (degradation from albumoses down to products unprecipitated by tannic acid, *e.g.*, amides) takes place very much more slowly than the peptic proteolysis. The action at temperatures below 15° C. is almost *nil*, and it proceeds with greatest intensity at 45°—50° C., but the action at 35° C. is very little weaker than at 47° C. Both enzymes cease to act at temperatures about 70° C. In practice, therefore, the result of the proteolysis will be different according to whether the mash is started at 35° C. and raised only slowly or whether it is started at 50°—60° C. The proteolytic enzymes are unaffected by the kilning process; their action is not confined to albumins of the same origin but extends to other albumins, of animal or vegetable origin, which may be added to the mash. There is little doubt that the germinating power of barley depends to a great extent on the activity of the proteolytic enzymes, and these should therefore play a part in the determination of the malting value of barley. Analyses of malt mashes on the large scale, starting at 35° C. and rising only slowly, showed that no notable increase in the proportion of albumoses took place during mashing. The proteolytic action was most intense during the second and third hours of the mashing, but the increase of total nitrogen was mainly accounted for by an increase of products of the lowest types [amides and the like]. A considerable amount of soluble albumin survived the mashing, whence it is concluded that a portion of the malt-albumin is practically unattackable by the proteolytic enzymes. It may b assumed that the rapidly acting peptase has converted al that it is capable of attacking during the period of germination on the floor and that the bulk of the proteolysis durin mashing is performed by the tryptase. The slow metho of mashing with low initial heats is not favourable to th presence of a high proportion of albumoses in the wort; i albumoses be required, all the above observations indicat that Windisch's high temperature, rapid-mashing proce should be followed. Another possible means of raising th proportions of albumoses is to add to the mash unmodifie materials of an albuminoid nature capable of proteolys by the peptase. The author found that the addition o wheat flour did indeed increase the proportions of solubl albumins and albumoses in the worts whilst decreasing th proportion of amides, the total nitrogen remaining the sam as with malt alone. The addition of maize flour, on th other hand, caused a decrease of the amounts of tota nitrogen, soluble albumins, and albumoses, whilst increasin relatively the proportion of amides. It is pointed out tha from a practical point of view the addition of wheat flour out of the question, but if it be desired to brew a wort containing a minimum proportion of total nitrogen withou reducing that of the amide yeast-foods, the addition of ra maize may lead to that result.—J. F. B.

[Wort] Coolers; Use and Abuse of ——. L. Briant. J. Fed. Inst. Brewing, 1904, **10**, 286—298.

The results of the passage of the wort through the op cooler are discussed under the following heads:—

Infection.—The temperature at which the wort is gen rally discharged from the cooler is 165° F., but after abo two-thirds of the total quantity have run off, the temperatur will have sunk to 140° F., and the last few barrels may hav cooled down to 120° F. before they are discharged. Th number of infecting organisms which enter the wort in th cooler is enormous, even under favourable conditions, bu the damage done by infection does not become serio unless the temperature becomes dangerously low befor the wort has been run off. It is advisable, therefore, sterilise the last few barrels of wort from the cooler by re boiling before passing on to the refrigerator. The chi sources of infection are the proximity of orchards an stables and the entrance of dust from the barley and ma machinery; it is sometimes advantageous to enclose th cooler room and to admit to it nothing but filtered air.

Deposition of Sludge.—The wort leaves the hop-back a clear condition, but as the temperature falls a floccul deposit separates out in variable amounts. This depo contains, in addition to mechanical impurities, albumino matters, hop-resins, and mineral matters. It is desirabl but not perhaps absolutely essential, that this sludg should not be allowed to pass on to the fermentation tuns.

Hot Aëration.—One of the most important objects the cooler is to enable the wort to combine at a high temperature (180°—190° F.) with a suitable quantity of oxyg This object can, however, be attained very effectively b the injection of air into the main through which the h wort is being pumped. In large ordinary coolers it sometimes advisable to run the wort continuously thro them, withdrawing it at the surface. In the case of do coolers, a thin film of wort may be exposed to the air in th top vessel, whilst it is run continuously into the deep protected, lower vessel for sedimentation.—J. F. B.

Top-Fermentation Beers; Chilling and Filtering of —— *III.* H. van Laer. J. Fed. Inst. Brewing, 1904. 1 347—355.

The author describes, and reports favourably on, the Wittmann system of collecting the aromatic gases of ferment tion, and applying them for the carbonation of beer (th J., 1904, 618). In order to obtain a fine aroma in chille and carbonated beers, the author strongly recommends th Continental practice of passing the boiling wort from th coppers on to dry hops in the hop-back.—J. F. B.

Fermented Beverages: Native African ——. H. van Lae Ann. de la Brass., 1904, **7**, 241—244.

The natives of Africa prepare a number of fermente drinks by spontaneous fermentation, the yeasts being eith present in the raw materials used or introduced by insects. The author divides these drinks into two classes—"wines" from materials containing directly-fermentable sugars; and "beers," the preparation of which entails the collaboration of an amylase. *Masanga* is a wine made from sugarcane by the natives of the Upper Congo. Just before the flowering season, ripe juicy canes are cut into 2-inch lengths, and crushed in a mortar, the pulp being strained, and the filtered juice diluted with water, and left to ferment spontaneously, in jars, for 24 hours, in a shady place. The product is sweet, with a small amount of gas, very agreeable flavour, although rarely bright. Left for a day in bottle, it acquires good condition, but it soon turns sour. The sample examined by the author contained 14·72 grms. of dry extract per litre, 25 of alcohol, 1·656 of mineral matters, 2·4 of volatile acids (as acetic acid), 9·3 of non-volatile acids (as lactic acid), no saccharose, and only traces of glucose and proteids. It manifested slight dextro-rotation. The sediment contained numerous microbes, and a small spherical yeast with thick-walled cells, often grouped in pairs and fours. *Malafou* is the fermented juice of the oil palm, from incisions in the bark. The wine is colourless, opalescent, and contains 16·86 grms. of dry extract per litre, 38·2 of alcohol, 2·9 of mineral matters, 4·2 of volatile acids, 9·99 of non-volatile acids, and 7·1875 of proteids, but no saccharose or glucose. The gravity at 15° C. is 1·00168, and it has a slight dextro-rotation. The sediment consisted of microbes and various yeasts with granular cell contents. *Tokko* is a sorghum or millet beer prepared by the Sakarras, the grains being malted in a primitive fashion, dried in the sun, crushed with a little water, and afterwards diluted and heated in earthen pots. This treatment seems to facilitate conversion, the malt having only a feeble diastatic power. When cold, the mass is left to ferment spontaneously for 24 hours. The beer contains 31·87 grms. per litre of dry extract, 31·12 of alcohol, 5·687 of proteids, 0·36 of acetic acid, and 1·665 of lactic acid, but no reducing substances. It is yellow in colour, with peculiar odour and acid flavour. The sediment contains microbes, yeast cells, and cells of Schizosaccharomyces Pombe, with numerous unaltered granules of starch, indicating the absence of any high temperature in the manufacturing process. The first stage of fermentation is evidently alcoholic, the diastase and ferments acting concurrently, until the increased acidity cripples the small amount of amylase present; and the fatty acids in the beer are probably due to lactic ferments, since Mycoderma aceti would have reduced the proportion of alcohol. The Matabele boil a mash of sorghum, millet, or maize in large earthen pots. After cooling for 24 hours, and when fermentation has commenced, a quantity of malted sorghum, equal to about one-third of the original raw material, is added, and fermentation proceeds briskly. In three days after boiling, the liquid is strained through hempen bags, and is ready for consumption. The taste is acid and refreshing, something like weak cider. The author has malted sorghum and millet by steeping for three days in a 0·5 per cent. solution of salicylic acid at 25° C. Spread out to a depth of 8—10 cm. between filter paper, the grains begin to "chit" in two days. In nine days the malt is finished, and when dried in the air, crushed, and mixed with water, gives only a very imperfect conversion, even after five days at 60—68° C.—C. S.

Wine Brandies; their Derivation, Adulterations, and Analysis according to "Chemical Functions" by the Paris Municipal Laboratory Method. J. Pharm. Chim. 1904, **19**, 484—491 and 593—604. (See also this J. 1903, 433).

Spirits may be classified under two heads:—natural alcohols and industrial alcohols. The natural alcohols are distilled from the fermented juices of grapes and other fruits and sugar cane: their character depends on the romatic "impurities" derived from the plants from which hey are prepared. The industrial alcohols are used only in heir purified form as "neutral alcohol"; they are obtained rom beet-root, potatoes, grain, and other amylaceous materials.

Wine Brandies.—These are produced mainly in the West and South of France; the most famous are those made in the Charentes district from white wines yielded by grapes of the "Folle blanche" variety, the best being the *Grande Champagne* of the Cognac district. The Charentais stills are of a special type, and the method of distillation is characteristic of the district (see also *loc. cit.*). The brandy "*bonne chauffe*," leaves the stills at an alcoholic strength of 70°; it then undergoes an ageing process for five years in presence of air, during which period its alcoholic strength decreases by volatilisation to about 50°. In other districts of France, brandies are made on a different principle, mainly from grapes of the Picpoul variety. Wine brandies contain all the volatile principles of the grape; the "Folle blanche" grape, especially, is very rich in a perfumed essential oil consisting of ethyl and amyl esters of the higher acids of the fatty series, and a small proportion of hydrocarbons. This oil is also prepared commercially as a "sauce" or Cognac bouquet for aromatising the industrial alcohols. It is prepared by distilling the lees and pips of the grapes with steam; also synthetically from castor oil. The natural brandies also contain volatile by-products [higher alcohols, esters and acids], formed by the action of the yeast and bacteria, also furfural produced during distillation. These latter products are present in very small quantities, and their proportions are always well balanced in a normal spirit. From the oak casks are extracted astringent [tannin], colouring, and aromatic [vanillin] matters. A little cane-sugar is generally added after the ageing period. The proportion and nature of the above "impurities" determine the value of the brandy, and afford a basis for the diagnosis of adulteration. Genuine Cognac, being intensely aromatic, is generally blended with industrial alcohol to an extent depending on the price at which it is to be sold. This adulteration never escapes detection by the Paris method, which is also perfectly certain in the detection of brandies compounded artificially.

Marc Brandies and Mixed Fruit Brandies.—Marc brandies are absolutely toxic on account of the exceptionally heavy proportions of impurities. The methods employed for their distillation vary greatly, and their composition varies correspondingly. Two sorts of marc are treated; the residue remaining after the wine has been racked off is distilled direct, whilst the marc from which the juice has been expressed before fermentation is broken up, treated with water, and fermented before being distilled. Adulteration rarely proceeds beyond blending with neutral alcohol. Artificial marc brandies are always compounded with the "head" products from the distillation of natural marcs, which are readily detected by analysis.

—J. F. B.

Alcohol; Denaturing ——. R. Duchemin. Rev. Gén. de Chim., March, 1904.

After discussing the merits and disadvantages of the various denaturing agents for alcohol which have been proposed, it is concluded that "methylene 90° regie" (a product of wood distillation of sp. gr. 0·830, and containing 65 per cent. of methyl alcohol) is preferable to any other agent hitherto suggested. It is proposed to add 10 per cent. of this product to the alcohol, and it is adduced that the denaturation could be profitably carried out; the denaturing agent costing about 100 frs. per hectolitre. Other advantages claimed are, that it cannot be separated from the denatured spirit; it does not affect the wicks of alcohol lamps; it possesses a very dissagreeable taste without having a very bad odour. It is also pointed out that it would encourage the wood distilling industry.—T. F. B.

Brandy; its Relation to the British Pharmacopœia and Chemical Valuation. J. C. Umney and C. T. Bennett. Chemist and Druggist, 1904, **64**, 968—970.

It has recently been decided in law that as brandy is largely used as a medicine, it ought to comply with the definition given in the "B. P.," *viz.*, "a spirituous liquid distilled from wine and matured by age, and containing not less than 36½ per cent. by weight or 43½ per cent. by volume of ethyl hydroxide." It was also recommended that the maximum proportion of esters in brandy should be 80 parts per 100,000 of absolute alcohol. Results obtained by the authors and given in the following table show, however, that the commercial value of brandy is in no way proportional to the amount of esters it contains.

Description.	Money Value.	Volatile Esters per 100,000 of absolute alcohol.
Splendid old Petite-Cognac champagne, vintage 1875	100	132
A leading Cognac shipper's three star brandy..	56	92
" " " " ..	50	121
Two-thirds high class Cognac, one-third medium value wine-brandy other than Cognac	25	94
Superior Cognac brandy, vintage 1900..	23	115
All pure wine-brandy (75 per cent. Cognac, 25 per cent. other than Cognac)	20	81
Two-thirds high class Cognac brandy, one-third high-class wine-brandy other than Cognac ..	20	133
Medium pure Cognac	20	106
Low-grade pure Cognac	17	92
Half wine brandy, Cognac, half wine brandy other than Cognac	17	72
Low-grade Cognac brandy, vintage 1900	15	60
Half Cognac wine-brandy, low grade, half wine-brandy of other countries, very low grade	15	77
25 per cent. wine brandy, Cognac, 75 per cent. guaranteed (but very low grade) wine-brandy other than Cognac	10	47
33·3 per cent. wine-brandy, Cognac, 33·3 per cent. wine-brandy other than Cognac, 33·3 per cent. grain spirit	10	61
Half low-grade wine-brandies, Cognac, half ditto other than Cognac	7	66
Guaranteed wine brandy of very low grade ...	6	37
All grain spirit flavoured to represent brandy..	5	13

It is pointed out also that it would be very difficult to distinguish between a genuine brandy and one prepared by the addition of blended synthetic esters to a mixture of genuine brandy and so-called "silent" spirit. For judging as to the genuineness of a sample of brandy, it is necessary to make determinations of all the "impurities," *viz.*, higher alcohols, aldehydes, acidity and esters.—A. S.

Mineral Enzymes; Preparation of Artificial ——. J. Bonnet. Fr. Pat. 339,460, Jan. 9, 1904.

WHEN a solution of a manganese salt is made slightly alkaline in the presence of an organic colloid, capable of preventing the precipitation of the manganese hydroxide, a product is obtained which behaves as a carrier of oxygen in a manner similar to that exerted by an oxidising enzyme. These artificial oxydases are prepared by mixing a solution of an albuminous substance (*e.g.*, white of egg, gelatin, serum, &c.) or of certain colloids (*e.g.*, gums, dextrins, &c.) with a solution of a metallic salt (manganese, iron, copper, &c.) in presence of a small quantity of alkali, alkaline-earth salt, or organic base. The products may be employed either in the de-oxidised state, in the oxidised state, in a state of sterilisation after heating, or in the solid state as obtained by precipitating the solutions by means of alcohol. —J. F. B.

Fermentation of Liquids. G. Johnson and P. R. Hare. Fr. Pat. 339,513, Jan. 14, 1904. Under Internat. Conv., May 4, 1903.

(*A.*)—FOODS.

Coffee Berry; Composition of the Inner Husk of the ——. B. von Bittó. J. Landw., 1904, **52**, 93. Chem.-Zeit., 1904, **28**, Rep., 159.

ANALYSIS of the inner husk of the coffee berry (*Coffea arabica*), which contained 11·18 per cent. of moisture, gave the following percentage numbers, calculated on the dry matter:—Ash, 2·96; ethereal extract, 1·29; nitrogenous substances, 6·19; nitrogen-free extractive matters, 23·26; crude fibre, 66·28; crude protein (by Stutzer's method), 4·43. The fat is faint yellow in colour, and when melted only solidifies gradually. On analysis the following results were obtained:—Köttstorfer's (saponification) value, 141·2; acid value, 82·7; free fatty acid, expressed as palmitic acid 37·81 per cent.; glycerides, as tripalmitin, 28·03 per cen The husk contains no cholesterin, but gives 0·022 per cent of organic phosphorus, corresponding with 0·58 of lecithin. The caffeine present amounts to 0·35 per cent. of the dry matter, and the pentosans to 21·50 per cent. The ash is very hygroscopic, and at the ordinary temperature dissolves in water to the extent of 48·59 per cent.—T. H. P.

ENGLISH PATENTS.

Meat Preparations; Manufacture of ——. A. R. da S. Braga, Sao Paulo, Brazil. Eng. Pat. 7896, April 5, 19

A QUANTITY of the fruit of the papaw family (*Car papaya*), cut into small pieces, is placed in water containing one per 5,000 parts of hydrochloric acid, and after some time the liquid is squeezed out. To this liquid minced meat is added, and after disaggregation of th fibres, which may be hastened by stirring, has taken place the mass is dried by heating in a current of air, an pulverised. The proportions of water and fruit vary, according to the quantity of the meat, but the acid must always be used in the smallest possible proportion t facilitate pulverisation. Such a meat preparation, whether powdered or not, is said to keep well.—T. H. P.

ENGLISH PATENTS.

Sewage; Method and Means for Treating ——. J. Hewes Leicester. Eng. Pat. 13,560, June 17, 1903.

THE crude sewage is passed through a small chamb provided with valves into settling-tanks, preferably arrange side by side. The clear liquid passes over a weir at th other end of the tanks into a precipitation tank, where it treated with suitable chemicals. The sludge from th settling-tanks is allowed to pass into chambers arranged a the side of the tanks, where it is dried. The dry sludge incinerated in closed retorts, and the products of distillat collected. Lime is added to the incinerated retort resid and the mixture used as a sewage precipitant or "bo powder."—W. P. S.

Distillers' Refuse; Sewage and the like; Treatment of —— L. Cameron, London. Eng. Pat. 14,536, June 30, 19

THE liquid is aerated in a rectangular tank, wherein it circulated by means of a paddle-wheel. The tank has partition down its centre, but not extending the who length of the tank, thus leaving a space vacant at each end The paddle-wheel is placed in one of the side spaces. Whe oxidation is complete, the acidity of the liquid is neutralise with lime, and alum is added. After settling, the sludge removed, mixed with peat, sawdust, or coal dust, and form into bricks for use as fuel.—W. P. S.

Filter [for Water]; High Pressure ——. W. S. Haws London. Eng. Pat. 12,297, May 29, 1903.

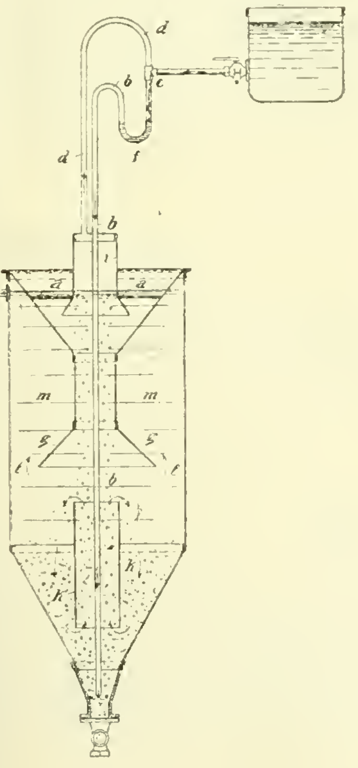
SEE Fr. Pat. 335,676 of 1903; this J., 1904, 265.—T. F. B.

urified and Sterilised Water, as well as of Distilled Water; Process for the Simultaneous Production of ——. A. Baudry, Kieff, Russia. Eng. Pat. 21,668, Oct. 8, 1903.

HE water is passed down a fractionating column, steam eing passed in near the bottom. The volatile impurities long with any oily matter in the steam pass away at the p, whilst the solids separated are drawn off at the bottom. he sterilised and purified water is drawn off at an interediate stage. The steam passing away is sent through a econd column, where it is partially condensed, and distilled ater is obtained. The rest of the steam along with the olatile impurities serves for a preliminary heating of the ater to be treated and then passes away. Should the volatile npurities be valuable they can be recovered by means of a pplementary condenser. The process of drawing off the quid from an intermediate section of the column can be plied to the separation of mixtures of liquids of different iling points, such as crude petroleum, &c.—W. H. C.

ectification of Water; Process and Contrivance for the Solution, with the aid of Compressed Air, of Chemicals for the ——. E. Krause, Düsseldorf, Germany. Eng. Pat. 9038, April 20, 1904.

IE cylindrical solution vessel, with a conical bottom and th the internal construction shown, is utilised as follows. e water passes from a store tank through the U-bend *c*, *b*, at such a rate that it draws air from the pipe *d* with it.



s air then passes to the bottom of the vessel, and in ng, agitates the hydroxide of lime or barium used, and motes solution. The rising bubbles of air are caught by inverted funnels *g*, *g* and *i*, and pass up to the pipe *d*, be used over again. The solution clarifies in rising ough the undisturbed portion *m*, *m*, and overflows through The same air being used over and over again, obviates difficulties due to the presence of dissolved carbon ide, this being absorbed by the lime at the beginning. —W. H. C.

XIX.—PAPER, PASTEBOARD, Etc.

English Patent.

Sulphates and Carbonates of Lime; Treatment and Utilisation [in Paper Manufacture] of Artificial ——. A. Monin, Lyons, France. Eng. Pat. 12,391, May 30, 1903.

See Fr. Pat. 320,430 of 1902; this J., 1903, 42.—T. F. B.

United States Patents.

Paper Coating or Enamelling Composition. W. A. Hall, Bellows Falls, Vt., U.S.A. U.S. Pat. 761,374, May 31, 1904.

The coating composition consists of a solution of casein in alkali, mixed with a solution of modified starch, serving as an adhesive or binder for the enamel base, *e.g.*, china clay. —J. F. B.

Paper Pulp; Manufacturing ——. O. Carr, Buenavista, Va., U.S.A. U.S. Pat. 762,139, June 7, 1904.

The process for extracting tannin and manufacturing paper-pulp from woods containing tannin consists in reducing the wood to chips having a length of fibre sufficient for paper-making and fine enough parallel to their fibres for efficient diffusion. The tannin is then extracted and recovered, and the exhausted chips are converted into pulp.—J. F. B.

French Patents.

Dyestuff [and Fibre for Paper Making] from Asphodel Roots. A. Badoil and J. E. Valadon. Fr. Pat. 333,478, Nov. 28, 1903. IV., page 712.

Rice-Flour; Treatment of ——, *for Use in Finishing Yarns and Textiles.* Soc. Anon. des Rizeries Françaises. Addition, dated Dec. 2, 1903, to Fr. Pat. 331,639, Aug. 1, 1903. (See this J., 1904, 59.)

This addition deals with the application of rice-flour, prepared as described in the original specification, to the sizing and smoothing of paper pulp, the couching of paper in white or coloured sheets, leather dressing, the preparation of vegetable gums in the form of paste and generally for all dressings of a similar kind.—T. H. P.

Viscose; Heater for the Treatment of ——. Soc. Franc. de la Viscose. Fr. Pat. 339,564, Jan. 13, 1904.

In the purification of viscose, by heating it at a definite temperature for a certain time until it coagulates and becomes insoluble in the saline washing liquids employed for extracting the by-products, it is essential that every portion of the mass should be continuously subjected to an invariable temperature. The apparatus in which this treatment is effected consists of a hemispherical vessel surrounded by a water-bath which is heated by a steam coil. In the vessel is mounted a vertical shaft carrying three superposed stirring arms provided with scrapers, and designed in such a way that the mass, as it coagulates, is reduced to fine granules. The water in the water-bath is likewise agitated mechanically in order to ensure uniform distribution of the heat. The saline solution is introduced just before the mass coagulates.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Chloroform; Preservation of ——. Témoin. Chem. and Druggist, 1904, **64**, 973.

The author states that chloroform to which 0·4 per cent. of sulphur has been added, undergoes no alteration on keeping, even when exposed to light.—A. S.

Bromoform; Electrolytic Preparation of ——. E. Müller and R. Loebe. Z. Elektrochem., 1904, **10**, 409—415.

The authors have improved upon the method of Coughlin (this J., 1902, 186) in dispensing with a porous septum. The most favourable composition of the electrolyte is

125 grms. of potassium bromide, 375 c.c. of water, 50 c.c. of acetone, 5 grms. of potassium bicarbonate, and 1 grm. of potassium chromate. The latter ingredient serves to inhibit cathodic reduction. A good current-efficiency (90—95 per cent.) can only be secured by allowing free bromine to separate out with the bromoform, and to this end a plentiful supply of carbon dioxide is bubbled through the liquid during electrolysis.—W. A. C.

Guaiacol with Lead Peroxide; Distillation of ——. R. Pschorr and M. Silverbach. Ber., 1904, **37**, 2149—2152.

When phenol is distilled with lead peroxide, diphenylene oxide is produced. The authors have found, however, that when guaiacol is subjected to the same treatment it is converted into veratrol, with the simultaneous formation of catechol (pyrocatechin), the bulk of which remains behind in the form of the lead salt and is carbonised, whilst the veratrol distils over. The lead peroxide acts in this case merely as a base, and the same reaction takes place on the distillation of the sodium salt of guaiacol, but with a smaller yield. By an analogous process the lead salt of ethyl vanillate yielded the corresponding ester of veratric acid, and the lead salt of the monomethyl ether of resorcinol yielded the dimethyl ether on distillation.—J. F. B.

Lupinidine and Sparteïne. R. Willstätter and W. Marx. Ber., 1904, **37**, 2351—2357.

In 1880, Liebscher isolated from the seeds of the yellow lupin two alkaloids—the crystalline oxygenated lupinine and the liquid, oxygen-free lupinidine to which the formula, $C_8H_{15}N$ was assigned. The authors have prepared the latter base from the mother-liquors after the separation of the lupinine. From their analyses of the pure alkaloid they conclude that the above formula is erroneous, and that lupinidine has a composition corresponding to the formula $C_{15}H_{26}N_2$. They also find that lupinidine is identical with the alkaloid sparteïne isolated by Stenhouse in 1851 from the broom tree. The alkaloids occurring in the various species of lupin are as follows:—Lupinine, $C_{10}H_{19}ON$, in *Lupinus luteus* and *L. niger*. Sparteïne, $C_{15}H_{26}N_2$, in *L. luteus* and *L. niger*. Lupanine, $C_{15}H_{24}ON_2$ [racemic and lævorotatory forms] in *L. albus*, *L. angustifolius* [blue lupin], and *L. perennis*.—J. F. B.

Orange Flower; Distribution of Certain Organic Matters in the ——. E. Charabot and G. Laloue. Comptes rend., 1904, **138**, 1513—1514.

The greater portion of the essential oil of the orange flower is located in the petals, which also contain the highest percentage of oil. During the period of blossoming the percentage of oil in the flower and the weight of oil contained in a single flower increase considerably; the formation or accumulation of the odorous substances in the flower is most intense when that organ is in the stage of full development. During the development of the blossom the essential oil becomes richer in terpenic esters, methyl anthranilate, and total alcohol; the esterification continues in the blossom, but with far less intensity than in the leaf and stem. The proportion of geraniol in the oil increases during blossoming, whilst that of the linalool decreases. In the full-blown flowers there is no marked difference in composition between the oil extracted from the petals and that obtained from the other parts of the blossom, but the former is slightly richer in methyl anthranilate than the latter.—J. F. B.

Camphor Group; Investigations in the ——. J. W. Brühl. Ber., 1904, **37**, 2156—2178.

A contribution to the study of the simplest substitution compounds of camphor, especially the halogen derivatives, their synthesis and orientation. A comparison is drawn between the action of bromine and iodine on oxymethylene-camphor in presence of an excess of alkali. The first product in either case is bromo- or iodo-formyl-camphor, but the bromo-formyl-camphor is less stable in presence of excess of alkali than the iodo derivative. The former breaks down with the production of *o*-mono-bromo-camphor and alkali formate, and addition of more bromine has no further effect; the iodo-formyl-camphor, on the other hand, resists the action of the alkali and yields *o*-*o*-diiodo-camphor when the equivalent quantity of iodine is added, no trace of the mono-iodo-camphor being produced.
—J. F. B.

Camphor Derivatives; Physiological Action of Certain ——. J. W. Brühl. Ber., 1904, **37**, 2178—2183.

Camphocarboxylic acid is practically devoid of physiological properties, but the action of its esters in an homologous series resembles that of camphor, and increases in inverse proportion to their solubility in alkali (see this J., 1902, 1409). The present paper deals with the action of the homologous series of oxyalkylidene camphors [acylcamphors]. The lowest member, oxymethylene-camphor, is readily soluble in an equivalent quantity of alkali; the sodium salt is poisonous in a general manner, but it is totally devoid of the specific properties of camphor, and is to be classed with camphocarboxylic acid. It possesses a feeble bactericidal action. The solubility of the next members of the series in alkali decreases with increase of the molecular weight, and these bodies are comparable with the esters of camphocarboxylic acid. Like the latter, oxyethylidene-camphor and oxypropylidene-camphor, possess the specific toxic properties of camphor. They are nerve poisons, and set up the typical "cramping" actions; they take effect more rapidly than camphor. Oxyethylidene-camphor is the more powerful of the two. Mono- and di-iodo-camphor were tested for their antiseptic properties, both being odourless bodies. Mono-iodo-camphor acts as an irritant towards the more sensitive mucous membranes, but its antiseptic power is only slight. Di-iodo-camphor is more powerfully irritant, and cannot be used on open wounds; it might possibly be of value when an initial irritant and a secondary resorbent action is required.—J. F. B.

Oxalacetic Ester; Product of Spontaneous Decomposition of [Detection of] ——. L. J. Simon. XXIII., page 730.

"Mangifera Indica," L. [Mango Tree]: The Gum of ——. P. Lemeland. XVI., page 721.

English Patent.

3.4-*Diamidobenzoic Acid; Manufacture of Alkyl Esters of* ——. O. Imray, London. From E. Ritsert, Frankfurt-on-Maine, Germany. Eng. Pat. 16,684, July 29, 1903.

See U.S. Pat. 761,998 of 1904; following this.—T. F. B.

United States Patents.

Halogen Tertiary Butyl Alcohol; Process of Making ——. T. B. Aldrich, Detroit, Mich., U.S.A. U.S. Pat. 761,188, May 31, 1904.

A ketone, or a mixture of ketones such as is produced by dry distillation of salts of monobasic fatty acids, is halogenised (*e.g.*, with a hypochlorite) in such a way as to produce a mixture of about equimolecular parts of free ketone and substitution product, which is then condensed to form the halogenated tertiary butyl alcohol. Thus, trichlorotertiary-butyl alcohol is produced by treating acetone with bleaching powder in presence of water, and condensing the product with alkali hydroxide.—T. F. B.

Halogen Tertiary Butyl Alcohol; Process of Making ——. T. B. Aldrich, Detroit, Mich., U.S.A. U.S. Pat. 761,189, May 31, 1904.

A ketone and a halogen substitution derivative thereof is condensed, by means of less than 10 per cent. of alkali hydroxide, to a halogenated tertiary butyl alcohol. By condensing a mixture of acetone and bromoform with less than 10 per cent. of sodium hydroxide, distilling the mixture under reduced pressure to remove the excess of acetone and bromoform, and then distilling the residue with steam, tribromotertiary butyl alcohol is produced.—T. F. B.

.4 - *Diaminobenzoic Acid; Alkyl Esters of ——, and Process of Making same.* E. Ritsert and W. Epstein, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst on the Maine, Germany. U.S. Pat. 761,998, June 7, 1904.

(4-)Aminobenzoic acid is esterified, and an acidyl group ntroduced, and the acidyl compound then nitrated, 3-nitro-acidylaminobenzoic ester resulting; the acidyl group is liminated and the product reduced, 3-4-diaminobenzoic sters being produced as white, easily crystallised substances, arly easily soluble in water, and readily soluble in alcohol nd in ether.—T. F. B.

icorice Root; Process for Extracting Juice from Dried ——. F. Evers, Düsseldorf, Germany. U.S. Pat. 762,032, June 7, 1904.

ee Eng. Pat. 1180 of 1904; this J., 1904, 383.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Cyanine Dyestuffs: Constitution of ——. A. Miethe and G. Book. IV., page 712.

French Patent.

igment [Photographic] Process: Film for the ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 339,654, Jan. 16, 1904

elluloid or collodion is incorporated with oils, fats, axes, resins, high boiling-point hydrocarbons, &c., and rmed into sheets, which are covered with a film of gmented gelatin in the usual manner. For example, kilos. of celluloid and 600 grms. of castor oil are mixed gether in presence of alcohol, acetone, &c., and formed to sheets. Photographs produced by this method, when ripped from their celluloid backing and fixed to paper, do t present the excessive glossiness exhibited by prints oduced on prepared celluloid.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives: Twenty-eighth Annual Report of His Majesty's Inspector of ——. 1903.

ere have been no modifications of the law during the ar. The number of deaths (5) from accidents by fire explosion in the manufacture of explosives was below average for the decade (6·4). The total number of tories under continuing certificate or license is 1 7. e quantity of foreign blasting explosives imported during past two years was as follows:—

—	1902.	1903.
	Lb.	Lb.
roglycerin explosives.....	1,839,277	2,330,582
er explosives............	12,000	168 + 2 cases

f the above 2,330,582 lb. of nitroglycerin explosives orted during 1903, however, 1,460,000 lb. were transpped from British ports for other countries. The nber of detonators imported during the year was over millions, of which more than 4 millions were tranpped for other countries. Dr. Dupré's report shows t of 379 samples of licensed explosives examined by , 339 were passed and 49 rejected. He has continued work on the sensitiveness of nitroglycerin to shock. en placed between sheets of lead it does not explode n struck by a 2 lb. weight falling from a height 46 inches. Sheet lead of even 0·01 inch thickness tly reduces its liability to explosion. Picric acid, on other hand, when placed upon a steel anvil could not exploded by a blow from a 2 lb. weight falling from a ght of 46 inches. When thin sheet lead (0·01 inch) placed upon the anvil and the picric acid put on this, a w from a 2 lb. weight falling from a height of only 18 inches readily exploded it. An investigation was made as to the effects of heat, of acids, and of alkalis on trinitrotoluene and Aniline Black. The former, when heated, takes fire at about the temperature at which gunpowder explodes. The latter has to be heated to dull redness before it fires. A mixture of the two substances, however, takes fire at a temperature lower than either of its constituents separately. The addition of sulphuric acid or of solid caustic potash to trinitrotoluene just melted over a steam bath produced no appreciable rise of temperature. Should, however, the trinitrotoluene be raised to 160° C. the addition of caustic potash produced instant ignition and sometimes an explosion. Two new tests are described for investigating the stability of nitro explosives. The first consists in heating from 2—2·5 grms. of dry guncotton, contained in small weighing bottles, to a temperature of 130° C. Two equal portions are heated for half an hour, the bottles fitting fairly well into copper tubes immersed in an oil-bath. After weighing, the bottles are replaced in the bath and again heated and weighed, one after the lapse of 2 hours, the other after 4 hours. The loss in weight will, it is anticipated, give a measure of the stability of the explosive. In the second test the explosive (2—2·5 grms.) is introduced into a glass tube, 12 ins. long, 0·6 ins. diameter, and of about 50 c.c. capacity. This tube is connected with a receiver kept exhausted to 1 m.m. of mercury, and also with a barometer tube dipping into mercury. After the tube containing the explosive has been exhausted it is placed in an oil-bath at 130° C. The mercury in the barometer tube soon begins to fall, and after the lapse of ¼ hour the vacuum is restored. This process is repeated after the lapse of another ¼ hour. The results of the first half hour, though noted, are usually not included in the subsequent records. After this, however, the real test begins, and the number of mm. the mercury falls every ¼ or ½ hour is recorded, the vacuum being restored after each observation. The time allowed to elapse between the observations is governed by the amount of gas evolved, the object being to retain a moderate vacuum (from 1/100—1/50 of an atmosphere) throughout the experiment. By a simple cooling arrangement applied to the upper part of the heating tube, any nitroglycerin in the explosive is condensed, and the test is thus applicable to nitroglycerin explosives.

Captain Desborough's report on the Testing Station, Woolwich, shows that out of 22 explosives submitted, 13 successfully passed the test. A gas-leak detector has been added to the gallery in order to locate the actual places at which leakage occurs, and it has also been useful in detecting the presence of unconsumed coal-gas after a shot has been fired in which there has been doubt as to ignition. The only new departure in explosives has been the combination of nitroglycerin with ammonium nitrate. The only notable change with accessories has been the substitution of a waxed for an ordinary paper wrapper in a non-detonating explosive, and it was found that the wax-coated explosive was much less sensitive to ignition from an external spark. Experiments were carried out as to the physical effect produced on ammonium nitrate explosives by subjecting them to extreme cold—in surrounding the cartridges with solid carbon dioxide for 12 hours. The results obtained, showed that when the explosive was contained in a paper wrapper it became so hard as to render the insertion of a detonator impossible, whereas the samples contained in metal wrappers did not change their physical condition. From experiments carried out the conclusion is drawn that the visibility of sparks or glow on firing an explosive in a bore-hole is not of necessity any criterion as to the liability to fire gas, but the appearance of flame (as opposed to glow) or of sparks due to the combustion of projected explosive indicates the existence of a very grave danger.—G. W. McD.

Explosion of Gunpowder; Circumstances attending an ——, which occurred in the Mixing House of the Factory of Messrs. Curtis and Harvey, Ltd., at the Marsh, Faversham, on Feb. 2, 1904. By Capt. M. B. Lloyd, H.M. Inspector of Explosives.

800 lb. of roughly mixed powder exploded in the mixing machine. It is considered that "the explosion was most probably caused by a foreign substance introduced into the ingredients in course of being mixed in the machine, and

that this was most likely to have been a small piece of cement from the lining of the wall which was detached from a faulty place." The possibility of lubricating oil, in the present case, olive oil, in contact with ground charcoal having caused spontaneous ignition of the charcoal was investigated. Two thermometers, one clean and one oiled with the olive oil, were placed in charcoal contained in cardboard cylinders surrounded with cotton wool, but no increase of temperature could be detected.—G. W. McD.

Explosion of Nitroglycerin; Circumstances attending an ——, *in the Separating House of the Factory of Messrs. Curtis and Harvey, Ltd., at Cliffe, Kent, on Feb.* 18, 1904. By Major A. Cooper-Key, H.M. Inspector of Explosives.

About 2,000 lb. of nitroglycerin were in the house at the time, and dense nitrous fumes were noticed coming from the building for some seconds before the explosion took place. It is considered probable "that the accident was caused by the spontaneous decomposition of the charge of nitroglycerin in course of separation owing to the presence in one of the ingredients of an impurity undiscoverable by the analysis of a sample, and that the fatal results were due to the men in charge failing to make use of the drowning tank until the heat from the decomposition caused an explosion." Experiments showed that the gases evolved in the "fuming off" of nitroglycerin consisted of nitrogen trioxide and peroxide (48·7 per cent.), nitric oxide (40·7 per cent.), carbon monoxide (3·2 per cent.), carbon dioxide (1·4 per cent.), and nitrogen (6 per cent.), and Major Cooper-Key considers that the failure to drown the charge was not due to the workmen being instantaneously and unexpectedly overcome by the carbon monoxide in the fumes. It is recommended that arrangements should be made in nitroglycerin works to enable a charge to be drowned in a period measured by seconds instead of by minutes.—G. W. McD.

United States Patent.

Gunpowder. A. H. Robinette, Fostoria, Ohio, U.S.A. U.S. Pat. 761,403, May 31, 1904.

"An explosive powder, consisting of nitrate of potash, ferrocyanide of potash, chlorate of potash, yellow prussiate of potash, and granulated sugar.—C. A. M.

Explosive Cartridge. G. Cornara, Mantova, Italy. U.S. Pat. 762,229, June 7, 1904.

See Eng. Pat. 30,253 of 1898; this J., 1899, 175.—T. F. B.

Explosive Compound. W. A. Spore, Argenta, Ill., U.S.A. U.S. Pat. 762,446, June 14, 1904.

The explosive consists of corn-pith, potassium chlorate, and a nitrated-turpentine binding material.—G. W. McD.

Explosive, and Method of Making same. E. Steele, Mill Valley, Cal., U.S.A. U.S. Pat. 762,447, June 14, 1904.

See Fr. Pat. 336,783 of 1903; this J., 1904, 386.—T. F. B.

Nitrocellulose; Art of Purifying ——. F. I. du Pont, Wilmington, U.S.A. U.S. Pat. 762,757, June 14, 1904.

Nitrocellulose is immersed in water, and is subsequently brought in contact with a further amount of water containing a gas in solution, under pressure, in such a manner that the escaping gas passes through the nitrocellulose.
—G. W. McD.

French Patent.

Explosive. J. Bührer. Fr. Pat. 339,552, Jan. 13, 1904.

Paraffin (6 parts) is heated to 65° C., and mononitrotoluene (7 parts) is dissolved in it at this temperature. Trinitrotoluene (1 part), iron filings (16 parts), and potassium chlorate (70 parts), are then added successively, and incorporated at a temperature of 55° C. Other metals, in a fine state of division, such as copper, zinc, &c., may be used in place of iron.—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Soapstone Fibres. K. E. Guthe. Nature, 1901, 70, 132 Pharm. J., 1904, 72, 852.

If steatite or soapstone be fused in a gas-oxygen jet, clear bead is obtained from which very fine fibres can easil be drawn. These fibres show approximately the sam elastic fatigue and tensile strength as fused quartz fibres the same dimensions, and can be used instead of the latte for suspensions.—A. S.

INORGANIC—QUALITATIVE.

Indium [*Separation from Aluminium*]. C. Renz. Be 1904, 37, 2110—2112.

The author draws attention, in view of recent publicatio to his former work on indium. Indium chloride in solutio in absolute alcohol gives, with pyridine, a crystalline precip itate of $InCl_3.3C_5H_5N$, slightly soluble in alcohol, insolub in ether, melting at 253° C. Indium hydroxide, in presen of a little ethylamine hydrochloride, is insoluble in ethy amine (the presence of the hydrochloride prevents th hydroxide from passing through a filter), and this insol bility can be used to separate indium from aluminium. I ammonia, however, indium hydroxide is somewhat solubl The author first described the preparation of crystallise indium oxide and its volatility at high temperatures. Whe heated strongly in an iridium capsule, it sublimes percep tibly without previous fusion, and the residue contai brilliant minute crystals belonging to the regular system, well as crystals of another shape. Possibly the two a In_3O_4 and In_2O_3, corresponding to Fe_3O_4 and Fe_2O_3. Th crystalline form of In_2O_3 is distinguished from the amo phous by being quite insoluble in hot concentrated su phuric acid. Metallic indium combines readily wit selenium and tellurium.—J. T. D.

INORGANIC—QUANTITATIVE.

Prussian Blue in Spent Oxide, &c.; Determination of — *by Feld's Method.* R. Witzeck. J. Gasbeleucht., 190 47, 545—547.

The author confirms Feld's observation that methods for th determination of Prussian blue, in which the crude cyanid material is first decomposed by heating with a solution caustic alkali, give results which are too low, on account the formation of thiocyanate. Feld (this J., 1903, 106 has described processes which are applicable to the ex amination of such materials. These methods have bee largely used by the author, and are recommended as acc rate and rapid. The formation of thiocyanate is entirel avoided. The author uses a simple distillation apparatu the distillation flask being furnished with a tap-funnel an the main receiver connected to a safety bulb-tube. F determining the total cyanogen content, 2 grms. of th sample of spent oxide (or 0·5 grm. in the case of cyanid mud) are rubbed down finely with 1 c.c. of N/1 ferro sulphate solution and 5 c.c. of 8N sodium hydroxide solutio for five minutes. 30 c.c. of 3N magnesium chloride solutio are then added slowly, with continuous stirring, and th whole is washed into the distillation flask (which is of 700 c. capacity), with enough hot water to bring the volume about 200 c.c. After five minutes' boiling, 100 c.c. boiling N/10 mercuric chloride solution are added the boiling liquid, and the mixture is boiled 10 minut longer. All the cyanogen present is now in the form mercuric cyanide. The flask is attached to the condense 30 c.c. of 4N sulphuric acid are added, and the liquid distilled for 20—30 minutes, the receiver and bulbs contai ing 20 c.c. of 2N sodium hydroxide solution. If the distilla be turbid, owing to the presence of sulphur, about 0·5 grm. lead carbonate is added, the liquid is agitated, filtered, an an aliquot portion taken for titration. The titration is pe formed by adding 5 c.c. of 4N potassium iodide solution an then N/10 silver nitrate solution, until a yellowish turbidi appears. 1 c.c. of N/10 silver nitrate solution = 0·009556 grm. of Prussian blue (Fe_7Cy_{18}). The whole analysis takes about 1½ hours.—H. B.

Calcium; Separation of —— from Magnesium. C. Stolberg. Z. angew. Chem., 1904, **17**, 741—744 and 769—771.

A critical bibliography is given of the methods of separation of calcium and magnesium which have been more or less widely adopted, and experiments are quoted which show that the almost universal oxalate method gives accurate results, provided that:—(1) The solutions are sufficiently diluted; (2) a sufficient quantity of ammonium chloride is present; (3) the precipitation is effected at the boiling temperature, and a large excess of ammonium oxalate is used; (4) the precipitate is allowed to stand for 12 hours before filtering; (5) the precipitate is redissolved in hydrochloric acid and reprecipitated in the same manner as at first. The time required for this method, however, induced the author to investigate the method based on the different solubilities of the sulphates in alcohol; and after many attempts with ethyl alcohol of various strengths, and with mixtures of methyl and ethyl alcohols, the following method was adopted:—The mixed salts, in not too dilute solution, are evaporated with excess of sulphuric acid and the whole of the excess of sulphuric acid is driven off by careful heating. The sulphates are digested on the water bath with water more than enough to convert the magnesium sulphate into the hydrated salt $MgSO_4.7H_2O$, and when this is complete, methyl alcohol, to which has been added 10 per cent. by volume of absolute ethyl alcohol, is added, in quantity sufficient to dissolve the magnesium sulphate. After a few minutes the whole is iltered, and the filter thoroughly washed with a mixture of 5 volumes of absolute alcohol and 95 volumes of methyl lcohol. The magnesium sulphate is completely dissolved; whilst the calcium sulphate remains absolutely insoluble. The filter is dried at 105° C., separately incinerated, the ash gnited with 2—3 drops of sulphuric acid, the precipitate dded, ignited, and weighed. The filtrate is diluted with water (to prevent separation of difficultly soluble lower ydrates, which is apt to occur if the alcohol be at once vaporated), heated on the water-bath till the alcohol is all riven off, and the magnesia either determined as pyrohosphate or calculated from the determination of the lphuric acid as barium sulphate. The results are accurate, d a calcium determination can be easily carried out in an our.—J. T. D.

ercury; Separation of —— from Molybdenum and Tungsten, by means of Hydrazine. P. Jannasch and W. Bettges. Ber., 1904, **37**, 2219—2228.

rom Molybdenum.—To the solution contained in a deep rcelain basin add 2—3 grms. of tartaric or citric acid, d make up to about 100 c.c. Heat the covered basin to out 80° C., add 2 grms. of hydrazine sulphate dissolved 30—45 c.c. of strong ammonia, and heat for 15 minutes, rring frequently. Pour off through a double filter, wash decantation with a solution of 1 grm. of hydrazine phate in 100 c.c. of water to which 20 c.c. of strong monia have been added, and determine the mercury in filtrate. Collect the precipitate on the filter, add c.c. of strong ammonium sulphide solution, keep warm the colour changes from yellow to red, and cautiously l excess of hydrochloric acid; heat, with stirring, for —15 minutes on the water-bath, filter, wash with water taining hydrochloric acid and hydrogen sulphide, dry; arately incinerate the filter at a low temperature in a celain crucible with perforated lid, add the precipitate, e the crucible in a nickel dish, and ignite in a stream oxygen till the sulphide is completely converted into xide.

rom Tungsten—Proceed, for the mercury, exactly as a ve, save that the addition of tartaric or citric acid is not n essary. Boil down the filtrate to 50 c.c., add, very c iously, fuming nitric acid till the hydrazine is destroyed, b down, transfer to a weighed porcelain crucible, com e the evaporation to dryness, heat in an air-bath, and th to redness over a flame, and weigh. This method is obviously available only when the filtrate from the mercury contains no fixed substance other than tungstic acid. Attempts to determine tungsten in tungstates by precipitation as sulphide, or as tungstic acid or anhydride by direct precipitation with acids, all failed. With the aid of hydrazine, however, the latter mode of precipitation was made quantitatively accurate. The tungstate is dissolved in about 50 c.c. of water, heated to boiling, and a mixture of 2 grms. of hydrazine hydrochloride dissolved in 10 c.c. of water with 22 c.c. of concentrated hydrochloric acid, is added. (The acid may be added first and the hydrazine solution immediately after, but the hydrazine must not be added before the acid.) A precipitate forms, at first, whitish, but gradually becoming deep yellow, citron-yellow, and green. The liquid is gently boiled, with frequent stirring, for 20—25 minutes, and evaporated to about half its bulk. The precipitate is allowed to settle, poured through a double filter (putting back any turbid filtrate till quite clear), washed thoroughly with 1:10 nitric acid, the filter and moist precipitate ignited in a porcelain crucible, and the residue moistened with a few drops of nitric acid, and again ignited till constant in weight.—J. T. D.

Palladium; Determination of —— and Separation from other Metals by Means of Hydrazine. P. Jannasch and W. Bettges. Ber., 1904, **37**, 2210—2219.

Pure palladium was prepared from the commercial metal by dissolving in nitrohydrochloric acid, evaporating to dryness, taking up with water and hydrochloric acid, diluting considerably, and precipitating at the boiling temperature with hydrazine sulphate. After digesting at 100° C. for some time, the precipitate was filtered off, dried and ignited. This precipitate, however, contained copper (which was removed by a repetition of the process) and oxygen, the latter in variable amount, corresponding in some instances with Pd_2O. By ignition in hydrogen the oxygen is removed, and pure silver-grey metallic palladium obtained. For the determination of palladium, 0·3—0·5 grm. of the pure metal is dissolved in *aqua regia*, the solution evaporated, and the residue taken up with a little water, and 20 drops of dilute hydrochloric acid, heated till solution is complete, diluted to 120 c.c., and heated to boiling. The solution of 1 grm. of hydrazine sulphate in 20 c.c. of water is added, the liquid heated on the water bath for 20 minutes, allowed to stand in the cold for two hours, filtered through asbestos in a hard-glass tube, the precipitate well washed with hot water, dried at 120°—130° C., and ignited in hydrogen. When water ceases to be formed, the hydrogen stream is stopped, and the palladium allowed to cool in the desiccator and weighed.

Separation from Potassium or Sodium.—Proceed exactly as above. Boil down the filtrate to 50 c.c., add cautiously a few c.c. of fuming nitric acid to destroy the hydrazine, evaporate to dryness, take up with a little dilute sulphuric acid, and evaporate, weighing the potassium or sodium as sulphate.

Separation from Magnesium or Zinc.—The palladium is determined as above. The magnesium or zinc can be precipitated directly by means of sodium phosphate and ammonia or sodium carbonate respectively, without removing the hydrazine.

Separation from Iron.—Determine palladium as above. Destroy the hydrazine, and precipitate the iron with ammonia.—J. T. D.

Chromic Oxide in Chrome Leather; Note on the Determination of —— and Separation of the Same from Aluminium Oxide in the Presence of Aluminium Salts. H. R. Procter. Collegium, 1904, 192.

The Procter and Griffith method of fusing the ash from chrome leather with a mixture of sodium carbonate and *magnesia levis* (this Journal, 1900, 223) has been thoroughly confirmed as regards accuracy, and for convenience and rapidity leaves little to be desired. Should aluminium be present it is perfectly easy to reduce the solution with alcohol, weigh the mixed oxides, and deduct the weight of chromium calculated from titration as stated by Appelius (this Journal, 1904, 552); or precipitate the alumina at once from the acid solution by ammonia and ammonium chloride, with the usual precautions to avoid precipitation of chromic acid.—R. L. J.

ORGANIC—QUALITATIVE.

Indophenine Reaction. L. Storch. Ber., 1904, **37**, 1961.

The effect of oxidising agents in promoting this reaction for thiophene (blue coloration with isatin and pure sulphuric acid) seems to be solely due to the heat developed. The same effect is produced by adding water or by simply warming the mixture without addition of water.—E. F.

Oxalacetic Ester; Product of Spontaneous Decomposition of —— [Detection of]. L. J. Simon. Comptes rend., 1904, **138**, 1505—1508.

Oxalacetic ester on keeping undergoes spontaneously a change, resulting, in the probable formation of a dihydroxyquinonic derivative. Such a sample gives with alkalis a deep violet coloration, which deepens gradually, and is destroyed by excess of the reagent. The same coloration can be obtained at once by substituting alkali borate or formate for the hydroxide, and the solution can then be boiled with excess of the reagent without fear of destroying the colour. This reaction may be used to identify oxalacetic ester.—J. T. D.

ORGANIC—QUANTITATIVE.

Tannin Determination; [Filtration of Quebracho and Mangrove Extracts]. K. Schorlemmer. Collegium, 1904, 137—144.

Two litres each of various quebracho and mangrove extracts were prepared as for analysis by the method of the Internat. Assoc. of Leather Trades Chemists, halved int portions A and B, and the times occupied in filtering th various fractions recorded (see table). The chief points o interest were (*a*) the length of time, usually several hours required to filter a quantity of these apparently clear liquid through the "S. and S. No. 605 hard" paper and (*b*) th irregular behaviour, with these materials, of these papers though they were all taken from one and the same packet The 500 c.c. fractions, less 50 c.c. removed to determine the contents, were passed each through a second filter II. A. o II B., as in the method for finding the "correction facto of the filter-paper," and here the time required was usuall a matter of minutes. In the first filtration, substances ar removed which, even after the factor has been applied represent appreciable percentages of insoluble matters (se last col. in table), although, with two exceptions, all th liquors appeared too clear to require filtration. Four different values for insoluble matter were obtained from on and the same extract (Expts. No. 8 and 9), as the result o four trials *viz.*, 8.A., 8.B., 9.A., 9.B. In four instance weighed filter papers were employed and the dried deposits after removal of soluble matter by washing, determined b difference. The weights so obtained bore a definite relatio to the times required to filter, being greater as the latte were longer. The value of applying a correction factor i the analysis of these materials would appear to be smal because (1) filtered and unfiltered liquors behave differentl towards the papers and (2) the papers themselves sho large differences in behaviour. The percentage of tota soluble matter determined by evaporating 50 c.c. fron filtrate (*b*) was in most cases identical (occasionally higher with the result deduced from filtrate (*a*) plus the correctio factor. In the table the figures in brackets are difference (losses) in mgrms. per 50 c.c. from the contents of 50 c.c. o original unfiltered liquor. In other words, the losses i filtrate (*b*) are almost the same as the losses in filtrate (*a* after correction by the plus amount due to the factor, so that equally true results might be obtained more simply by rejecting a larger quantity of filtrate, say 400 c.c., than at present customary, before collecting for evaporation.

—R. L. J.

Table showing the times required to filter (in hours) and refilter (in minutes) Quebracho and Mangrove Liquors.

——		Filter I.					Filter II.		(6)	(7)
		(1) First 250 c.c. Hours.	(2) Next 50 c.c. Filtrate (*a*).		(3) Next 500 c.c. Filtrate (*b*).		(4) First 250 c.c. Mins.	(5) Next 50 c.c. Filtrate *c*. Mins.	Correction Factor ($b - c$). + mgrms.	"Insolubl Matter." Per Cent

Glycerin [in Wine]; Determination of —— by the Lime and by the Iodide Method. J. Schuch. Z. landw. Versuchsw. in Oesterr., 1904, **7**, 111. Chem.-Zeit., 1904, **28**, Rep. 158.

The differences, expressed in grams of glycerin per litre of wine, between the results obtained by the lime method and by the iodide method of Zeisel and Fanto, are stated as follows:—For white wines, − 0·35 to + 0·20; for red wines, −0·51 to + 0·77; for sweet wines, − 1·21 to + 1·21. These differences, even in the case of sweet wines, are not sufficiently great to cause the lime method to be replaced, especially as the glycerin obtained by the iodide proce can only be regarded as "crude glycerin." The li method has the advantage of allowing a number of dete minations to be carried on simultaneously, without delayi the other determinations of a wine analysis. To do tl with the iodide method necessitates the use of a numb of expensive pieces of apparatus.—T. H. P.

XXIV.—SCIENTIFIC & TECHNICAL NOTE

Suspensions or Colloids; Flocculation of ——, and Agg tination of Bacteria. H. Bechhold. Z. physik. Che 1904, **48**, 385—423. (See also this J., 1901, 688.)

The author's experiments related to:—(1) The flocculati by various electrolytes of suspensions of mastic, bacte (chiefly typhus bacteria cultivated on bouillon, killed with "formol" and washed in a centrifugal apparatus with distilled water) and agglutinin-bacteria (typhus bacteria treated with the serum of a goat which had been inoculated with typhus bacteria); and (2) the influence of various colloids of the first order (gelatin, serum, gum arabic, &c.) on the action of the electrolytes. The results may be summarised as follows :—Below a certain concentration of the electrolyte and of the suspension, no flocculation takes place even on prolonged contact. Above these limiting concentrations, within certain limits, the rate of flocculation increases with the concentration of the electrolyte and of the suspension. No essential difference can be observed between the flocculation of bacteria, agglutinin-bacteria, and unorganised suspensions or colloids. The flocculation of bacteria and of agglutinin-bacteria, like that of true suspensions by electrolytes, depends upon the valency of the cation, its rate of migration and decomposition-potential, and the ionisation of the electrolyte. The flocculation of bacteria suspensions cannot be effected by mono- and di-valent cations of high decomposition-potential. The flocculation of unorganised suspensions or colloids of the second order (inorganic colloids) can be prevented by colloids of the first order (albumin, gelatin, &c.), but the latter have no influence on the flocculation of agglutinin-bacteria. The irregular action of salts of trivalent cations in effecting flocculation, is ascribed to the envelopment of the suspension by colloidal aluminium hydroxide, ferric hydroxide, &c., produced by hydrolytic dissociation. By treating bacteria with lead nitrate, alcohol, acids, &c., products are obtained which, with regard to their behaviour towards electrolytes, form intermediate steps between bacteria and agglutinin-bacteria. When a bacterial suspension is subjected to the action of an electric current, the bacteria, like all true suspensions, migrate to the anode. Agglutinin-bacteria are agglutinated by the electric current. With regard to flocculation by salts, agglutinin-bacteria behave like unorganised true suspensions, whilst bacteria ehave like unorganised suspensions to which a colloid of he first order has been added.—A. S.

THE SCHUNCK RESEARCH LABORATORY AT MANCHESTER.

The chemical research laboratory, including a library of chnical works and periodicals and a fine collection of emical specimens, relating more particularly to that partment of organic chemistry embracing the colouring atters, which the late Dr. Edward Schunck, F.R.S., queathed to the Owens College, and which has been ansferred from Kersal, Manchester, to the college ground, as formally opened on Friday, July 1st, by Dr. W. H. rkin, Sen., F.R.S. At the same time the extensions of e College laboratories connecting them with the Schunck boratory were declared open. The Vice - Chancellor Dr. Hopkinson) and Prof. H. B. Dixon, F.R.S., spoke of e distinction which Schunck gained by his researches, and the great value which his gift would be to the Manchester niversity.

In his address, Dr. Perkin briefly reviewed Dr. Schunck's rk, especially in connection with vegetable colouring tters. He remarked that, great as were the difficulties h which Dr. Schunck had to contend in his pioneer rk on the constituents of certain plants, the problems ch organic chemistry has still to solve, and especially se which deal with physiological chemistry, will be found offer still greater difficulty. The future progress of siological chemistry may be said to depend largely on acquirement of an accurate knowledge of the nature of ch, albumin, and their decomposition products. When estigating problems dealing with the constitution of ural products, it should always be borne in mind that ure not only builds up its complicated substances from simplest materials, but that all its operations are carried at ordinary temperatures and without the use of erful reagents.

medallion portrait of the late Dr. Schunck, which . Schunck has presented to the University, was unveiled her son, Mr. Charles Schunck, and was formally accepted r. E. J. Broadfield on behalf of the University Court.

New Books.

Radium, and other Radio-Active Elements. A popular account treated experimentally. By Leonard A. Levy and Herbert G. Willis. Percival Marshall and Co., 26-29, Poppin's Court, Fleet Street, London, E.C. 1904. Price 2*s.* 6*d.*

8vo volume, containing introduction, 97 pages of subject-matter, an appendix of eight pages, and a total of 26 illustrations. The leading subjects treated of are as follows :—I. Discovery of Radium ; its Extraction. II. The Radium Emanation. III. and IV. Physical Effects (Electrical and Magnetic). V. Chemical Effects. VI. Actions on Animal Life and Living Tissues. VII. Other Radio-active Elements. Appendix. Experimental Apparatus.

Subject List of Works on Electricity, Magnetism, and Electro-Technics in the Library of the Patent Office. [Pat. Office Library Series, No. 14 ; Bibliogr. Series, No. 11.] Darling and Son, Ltd., His Majesty's Stationery Office, 34-40, Bacon Street, London, E. Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C. 1904. Price 6*d.*

Die Farben-Photographie [Photographische Bibliothek, Bd. 19]: eine gemeinverständliche Darstellung der verschiedenen Verfahren, nebst Anleitung zu ihrer Ausführung. Von Dr. E. König. Gustav Schmidt's Verlag, Berlin. 1904. Price M. 2.50.

Small 8vo volume with coloured frontispiece, preface, introduction, and 87 pages of subject matter, containing two illustrations. The subjects treated of are the following.—Direct Methods of Colour Photography—1. Becquerel's Process. 2. Lippmann's Process. 3. The Bleaching-out Process. 4. Joly's Method. Indirect Methods of Colour Photography.—Section I.—The Three-Colour Printing, or Subtractive Method of Tricolour Photography. 1. Photographic Apparatus (Camera). 2. Light Filter. 3. Plates and Sensitisers. 4. Exposure and Development. 6. Finishing of Copies. Appendix. Two-Colour Photography. Section II.—The Additive Method of Tricolour Photography by Optical Synthesis. 1. Theoretical. 2. Guide in the Preparation of Partial Pictures. 3. Guide to Preparation of the Chromoscope.

Die Herstellung von Diapositiven [Photographische Bibliothek, Bd. 20], zu Projektionszwecken (Laternbildern), Fenstertransparenten und Stereoskopen. Von P. Hanneke. Gustav Schmidt's Verlag, Berlin. 1904. Price M. 2.50.

Small 8vo volume with preface, introduction, and 126 pages of subject-matter, containing 25 illustrations, and followed by an alphabetical index. The following are the subjects mainly treated of :—I. The Preparation of Diapositives on Chlorobrominated Silver Plates. II. Preparation of Enlarged or Reduced Diapositives. III. Diapositive on Silver bromide-gelatin Plates. IV. Diapositive on Collodion Plates. V. Diapositive on Albumin Plates. VI. Diapositive on Chloride of Silver Plates for Copying out. VII. Diapositive by the Pigment Process. VIII. Stereoscopic Diapositive. IX. Coloured Diapositive. X. Appendix.

Trade Report.

I.—GENERAL.

Canada ; Tariff Changes in ——.

Bd. of Trade J., June 23, 1904.

A memorandum (No. 1,284 B), issued by the Canadian Commissioner of Customs, gives in detail the tariff changes as set forth in the resolutions introduced by the Minister of Finance in the Canadian House of Commons on 7th June.

The resolutions, which are now in force (but which are still under discussion in the Canadian House of Commons), contain the following passages :—

1. Resolved, That it is expedient to amend "The Customs Tariff, 1897," to the following effect :—

Notwithstanding anything contained in Schedule D (which refers to the British preferential tariff), the maximum duty on the under-mentioned articles when imported under the British Preferential Tariff shall be as follows :—

	Rate of Duty.
Table ware of china, porcelain or other clay.....	15 % *ad val.*
Common and colourless window glass...........	7½ % ,,

Item 203 of Schedule A. shall be repealed and the following substituted therefor :—

203.	Plate glass not bevelled, in sheets or panes not exceeding 7 sq. ft. each, n.o.p.	10 % *ad val.*
203*a*.	Plate glass not bevelled, in sheets or panes exceeding 7 sq. ft. each, and not exceeding 25 sq. ft. each, n.o.p.	25 % ,,

Items 22, 151, 170, 171, 172, 173, 175, and 178 of Schedule A. shall be repealed and the following substituted :—

22.	Paraffin wax candles	25 % *ad val.*
151.	Paraffin wax.............................	25 % ,,
170.	Illuminating oils, composed wholly or in part of the products of petroleum, coal, shale, or lignite, costing more than 30 cents. per gall.	20 % ,,
171.	Lubricating oils, composed wholly or in part of petroleum, costing less than 25 cents. per gall.	2½ cents per gall.
172.	Crude petroleum, gas oils (other than benzine and gasoline), above 40° Beaumé gravity, at 60° temperature...............	1¾ cents per gall.
173.	Oils, coal, and kerosine distilled, purified or refined, naphtha and petroleum, and products of petroleum, n.e.s.	2½ cents per gall.
175.	Lubricating oils, n.e.s., and axle grease.....	20 % *ad val.*
178.	Vaseline, and all similar preparations of petroleum for toilet, medicinal, or other purposes	25 % ,,
	Molasses, the produce of any British country entitled to the benefits of the British Preferential Tariff, in the original package in which it was placed at the point of production, and not afterwards subjected to any process of treating or mixing; the package also to be free: Provided, however, that this shall not apply to molasses to be used for the purpose of distillation..............................	Free.

2. *Resolved*, that the following articles now dutiable shall be transferred to the free list :—

Whale oil soap	Free.
Plain, basic photographic paper, baryta coated, for albumenizing or sensitizing	,,
Hydrofluosilicic acid	,,
Glass cut to size for the manufacture of dry plates for photographic purposes, when imported by the manufacturers of such dry plates for use exclusively in the manufacture thereof in their own factories........................	,,
Ferment cultures to be used in butter-making..	,,
Quassia juice	,,
Crude petroleum, fuel and gas oils, 43° Beaumé gravity, or less, at 60° temperature, 0·8233 sp. gr.	,,

II.—FUEL, GAS, AND LIGHT.

CALCIUM CARBIDE INDUSTRY; PROSPECTS OF —— [IN GERMANY].

P. Wangemann. Chem. Ind., 1904, **27**, 318—322.

The consumption of carbide in Germany during 1904 will be, it is estimated, about 20,700 tons, whilst the production will be 13,300 tons, leaving 7,400 tons or about 35·7 per cent. of the total to be imported. In discussing the prospects of the carbide industry, attention is drawn to the new fields opened out for calcium carbide by the introduction of dissolved acetylene (see this J., 1901, 1196; 1903, 288), and of calcium cyanamide prepared from calcium carbide and atmospheric nitrogen (this J., 1903, 794, 809).
—A. S.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PARAFFIN LIQUID AND "PARAFFINUM MOLLE": U.S. CUSTOMS DECISION.

April 26, 1904.

It was held, providing it could be shown that, in "paraffinum molle," ceresin was the component material of chief value, the merchandise was free of duty. The Board of General Appraisers, after thoroughly considering the question of value, decided that the paraffin liquid was composed entirely of petroleum, and, being produced from Russian petroleum, was subject to a countervailing duty equal to that imposed by Russia on imports of the same character from the United States; and, in the case of "paraffinum molle," since the mineral wax or ceresin was present only to the extent of one-fifth, the remaining four-fifths of paraffin liquid were sufficient to render the merchandise subject to the same countervailing duty. (Compare this J., 1903, 930.)—R. W. M.

MINERAL WAX: U.S. CUSTOMS DECISION.

May 17, 1904.

A waxy substance, called ozokerite, containing resins and pitch, was held to be dutiable at 20 per cent. *ad valorem* as a "manufactured article unenumerated."—R. W. M.

IV.—COLOURING MATTERS AND DYESTUFFS.

SULPHIDE DYESTUFFS: U.S. CUSTOMS DECISION.

April 21, 1904.

Sulphaniline Black, Sulphaniline Brown and Sulpho Black T G were decided to be dutiable at 30 per cent. *ad valorem* as "coal tar colors or dyes," under paragraph 15 of the present tariff. The claims of the importers for assessment of duty at 20 per cent. *ad valorem* under the same paragraph as "coal tar preparations," or at 25 per cent. *ad valorem* as "chemical compounds," under paragraph 3, were unsupported by evidence and overruled.—R. W. M.

TETRACHLOROPHTHALIC ACID: U.S. CUSTOMS DECISION.

April 22, 1904.

It was decided that tetrachlorophthalic acid was dutiable at 25 per cent. *ad valorem* as an "acid not otherwise provided for," under paragraph 1 of the present tariff. The claim for assessment of duty at 20 per cent. *ad valorem*, as a "preparation of coal tar" was overruled.—R. W. M.

LOGWOOD BLACK: U.S. CUSTOMS DECISION.

April 22, 1904.

Logwood Black was decided to be dutiable at ⅞ cent per lb. as "logwood extract," under paragraph 22 of the tariff. The assessment of duty at 30 per cent. *ad valorem* as a "colour" was overruled.—R. W. M.

V.—PREPARING, BLEACHING, Etc., TEXTILES, YARNS, AND FIBRES.

BLEACHER'S BLUE: U.S. CUSTOMS DECISION.

Duty was assessed on bleacher's blue at 30 per cent. *ad valorem* as a "coal tar color," under paragraph 15 of the present tariff. On appeal from a decision of the Board of General Appraisers, affirming the above assessment, the United States Circuit Court reversed the decision, and held that bleacher's blue was dutiable at 20 per cent. *ad valorem*, under the same paragraph as a "preparation of coal tar, not a color or dye."—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

BARYTES: U.S. CUSTOMS DECISION.

April 25, 1904.

The Treasury Department holds that barytes separated by crushing and jigging from the accompanying worthless rock is dutiable at 75 cents per ton, as "barytes unmanufactured," and not at 5 dols. 25 cents per ton, as "manufactured barytes."—R. W. M.

MANGANESE BORATE: U.S. CUSTOMS DECISION.

May 9, 1904.

The United States Circuit Court of Appeals at Philadelphia decided that manganese borate used chiefly as a drier for varnish is dutiable at 25 per cent. *ad valorem* as a "chemical compound or salt," under paragraph 3 of the present tariff, and not at 3 or 4 cents per lb., under paragraph 11, according as the contents of anhydrous boric acid is above or below 36 per cent. The Court held that the article is not a borate material, but a product of the borate materials enumerated in paragraph 11.—R. W. M.

BORAX GLASS POWDER: U.S. CUSTOMS DECISION.

April 29, 1904.

Powdered borax glass, which on analysis was shown to contain 66·86 per cent. of anhydrous boric acid, was held to be dutiable at 5 cents per lb. as "borax," under paragraph 11 of the present tariff.—R. W. M.

COPPER ACETATE: U.S. CUSTOMS DECISION.

May 20, 1904.

Copper acetate was held to be dutiable at 25 per cent. *ad valorem* as a "chemical salt" under paragraph 3 of the present tariff. The claim that it was free as "verdigris or subacetate of copper" under paragraph 694 was overruled.
—R. W. M.

X.—METALLURGY.

OUTPUT OF CERTAIN MINERALS AND METALS IN THE WORLD IN 1902.

Bd. of Trade J., June 16, 1904.

The colonial and foreign section of the Mines and Quarries Report for the year 1902 contains a table showing the utput of certain minerals and metals (contained in or btained from ore raised) in the British Empire and in oreign countries during the year 1902. The following is brief summary of the table in question :—

—		United Kingdom.	British Colonies and Possessions.	Foreign Countries.	Total.
oal......	Met. tons	230,739,359	25,264,052	547,153,634	803,157,045

MINES OF BRITISH COLUMBIA.

U.S. Cons. Reps., No. 1977, *June* 13, 1904.

From the annual report of the Minister of Mines of British Columbia for 1903, just issued, it appears that the total production of the mines of the Province show a very slight increase over the year previous, being of the value of 17,495,954 dols., compared with 17,486,550 dols. in 1902. Excepting copper and coke, which show an increase, there is a falling off in all products, as shown by the following table :—

Description.		1902.		1903.	
		Quantity.	Value.	Quantity.	Value.
Gold :—			Dolls.		Dolls.
Placer	Ozs.	53,657	1,073,140	53,021	1,060,420

ALLOYS: U.S. CUSTOMS DECISION.

May 20, 1904.

An alloy consisting of iron, manganese, and aluminium, and used for hardening bronze, was held to be dutiable at 8 cents per lb. under paragraph 172 as an "alloy in which aluminium is the component material of chief value." Another alloy, consisting of copper and tin, used to manufacture anti-friction bearings, was decided to be dutiable at 20 per cent. *ad valorem* as a "metal unwrought," under paragraph 183.—R. W. M.

XII.—FATS, FATTY OILS, Etc.

SPERMATINE: U.S. CUSTOMS DECISION.

May 5, 1904.

A waxy substance, which was stated to be obtained from brown coal in central Germany by extraction with benzine (petroleum spirit) and subsequent distillation and refining was held to be free of duty as "mineral wax," under paragraph 695 of the present tariff. The assessment of duty at 20 per cent. *ad valorem* as a "manufactured article unenumerated," was overruled.—R. W. M.

ADEPS LANÆ CUM AQUA: U.S. CUSTOMS DECISION.

This substance was decided to be dutiable at 25 per cent. *ad valorem* as a "medicinal preparation, not alcoholic." The claim for assessment of duty at ½ cent per lb. as "wool grease," was overruled, on the ground that it was not the wool grease of commerce, and on the authority of a decision of the United States Circuit Court of Appeals.—R. W. M.

XIII. C.—INDIA-RUBBER, Etc.

RUBBER; EXPORT TAX ON —— IN BRAZIL.

U.S. Cons. Rep., No. 1977, *June* 13, 1904.

Until lately the State of Amazonas has imposed an export tax on all rubber coming into its jurisdiction from up the Amazon river. This export tax has now been reduced from 20 per cent. of the declared value to 15 per cent., and the owner or purchaser of rubber grown outside of the state of Amazonas is at liberty to ship his rubber from Manaos or Para, as he pleases.

The amount of rubber affected by the new regulation is estimated at not less than 7,000 tons. Of this quantity, it is believed that 5,000 tons will come to Para.

XVI.—SUGAR, STARCH, Etc.

CHARCOAL: U.S. CUSTOMS DECISION.

May 4, 1904.

Charcoal, used for decolorising purposes, was held to be dutiable at 20 per cent. *ad valorem*, as a "manufactured article unenumerated." The assessment of duty at 35 per cent. *ad valorem*, as an "article composed of carbon," was overruled.—R. W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

Duty-Free Spirit Question in Russia.

Z. Spiritusind., 1904, **27**, 249.

The reported Russian law to the effect that the use of duty-free technical spirit would be given a three years' trial, is confirmed, the matter being now in the hands of the Minister of Finance. The Minister called together in February, at St. Petersburg, a Congress of Distillers who were to make themselves individually conversant with the progress in the use of technical spirit, and express their opinions as to the best method of organisation for the sale of the spirit. The Minister proposed the formation of co-operative associations of distillers for the sale of technical spirit and for promoting the use of such spirit. These associations would be responsible for the observance of the strict regulations drawn up by the Minister for the sale and control of the spirit. The Congress declared themselves generally in agreement with the proposals of the Minister. They considered it desirable that each association of distillers should be limited to a definite radius; that the associations should combine to form unions and that periodic "union congresses" be held; and finally that a permanent board with full powers should be formed in St. Petersburg. The responsibility for the observance of the regulations as to the sale of the spirit could only be undertaken by the associations, if they were granted exclusive rights with regard to the sale of technical spirit. The Congress elected a committee for the defence of the interests of the spirit distillers, and this committee was charged with the drawing up of rules for the new associations to be formed for the sale of technical spirit. They also resolved to petition the Government:—(1) to remit the customs tax on engines, burners, lamps, &c., designed for the use of denatured spirit, provided similar goods are not manufactured in Russia; (2) to reduce the tariff for the transport of denatured spirit; and (3) to discontinue the inspection and control of manufacture in the case of agricultural distilleries and to introduce a scheme of obligatory mutual insurance of such distilleries. The Minister is continuing his efforts to discover a suitable denaturing process. Apart from the prize of 50,000 roubles (see this J., 1903, 1109), the professors of the Kiew Polytechnicum are experimenting with ketones. The Minister of Agriculture is also interesting himself in the use of technical spirit, and in conjunction with the Imperial Russian Technical Society, has resolved to organise in the course of the year an exhibition in St. Petersburg on the lines of the one held in Vienna.

—A. S.

Alcohol Tax in U.S.A.

On May 23, 1904, the United States Circuit Court decided that the local taxes on alcohol in France, known as the *octroi*, or *droit de ville*, which are not collected on merchandise exported, are not part of the dutiable value of merchandise imported into the United States.—R. W. M.

XX.—FINE CHEMICALS, Etc.

Saccharin in Glycerin: U.S. Customs Decision.

May 7, 1904.

A preparation consisting of 20 per cent. of saccharin and 80 per cent. of refined glycerin was decided to be dutiable at 1 dol. 50 c. per lb. and 10 per cent. *ad valorem* as "saccharin" under paragraph 211 of the present tariff, on the ground that the saccharin was the component material of chief value.—R. W. M.

Chrysarobin: U.S. Customs Decision.

June 1, 1904.

It was decided that chrysarobin, extracted from Goa powder, is dutiable at 25 per cent. *ad valorem*, as a "medicinal preparation."—R. W. M.

Opium Powdered: U.S. Customs Decision.

May 6, 1904.

It was decided that powdered opium was dutiable a "opium crude," at 1 dol. per lb. under paragraph 43 of th present tariff. The claims of the importer that it wa dutiable at $\frac{1}{4}$ cent per lb. and 10 per cent. *ad valorem* under paragraph 20 as a "drug, advanced in value o condition," or at 25 per cent. *ad valorem* as a "medicina preparation," under paragraph 68, were overruled.

—R. W. M.

Heroine and Heroine Hydrochloride: U.S. Custom Decision.

April 22, 1904.

Heroine and its hydrochloride were decided not to be tru salts or alkaloids of opium, but new chemical bodies derive from morphine. For this reason the Board of Genera Appraisers reversed the assessment of duty at 1 dol. pe ounce, as "salts or alkaloids of opium," under paragrap 43, and sustained the claim of the importers that bot were dutiable at 25 per cent. *ad valorem*, as "medicina preparations in the preparation of which alcohol is used.

—R. W. M.

Synthetic Oils: U.S. Customs Decision.

June 2, 1904.

Synthetic oils of jasmine, "amber," bergamot, and nerol were held to be free of duty under their respective name as provided for in paragraph 626 of the present tariff.

—R. W. M.

Orange Flower Water: U.S. Customs Decision.

April 20, 1904.

In accordance with a decision of the United State Circuit Court, the Board of General Appraisers held tha orange flower water is dutiable at 25 per cent. *ad valore* as a "medicinal preparation, not alcoholic," unde paragraph 68 of the present tariff.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," an [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, a asterisk is affixed. The dates given are (i) in the case of Applic tions for Patents, the dates of application, and (ii) in the case Complete Specifications Accepted, those of the Official Journa in which acceptances of the Complete Specifications are advertise

Complete Specifications thus advertised as accepted are open inspection at the Patent Office immediately, and to oppositi within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 13,481. Sulman and Kirkpatrick-Picard. Remov of precipitates from liquids. June 14.

„ 13,638. Dewar. Method of absorbing gases, a the application thereof to the production of hi vacua and the separation of gases. June 16.

„ 13,765. Johnson. Apparatus for separating co slack, ores, minerals, or substances of differe specific gravity. June 17.

„ 13,892. Gayley. Appliances for extracting mo ture from air and feeding such air to bl furnaces or converters.* June 20.

„ 14,042. Parsons. Production of high vac June 21.

„ 14,067 Kaehl. Centrifugal separating apparat [Ger. Appl., July 31, 1903.]* June 21.

„ 14,337. Bigàllet, Olivo, and Maurin. Tuyères melting furnaces or cupolas, and the method charging such furnaces. June 25.

[A.] 14,621. Bonnet. Apparatus for mixing, emulsifying, and homogenising liquids.* [Fr. Appl., July 1, 1903.] June 29.

[C.S.] 17,348 (1903). Holt. Means of softening and filtering water for steam boilers, economisers, bleaching, dyeing, &c., and apparatus therefor. July 6.

, 14,355. Gersabeck. Process for generating air-gas.* June 25.

, 14,383. Poetter. Gas producers.* June 25.

, 14,389. Gerdes. Manufacture of fuel blocks or briquettes. June 25.

, 14,445. Boult (Lomax). Method of purifying illuminating gas.* June 27.

14,500. Carter and Fowler. Method of chemically treating arc-lamp carbons, whereby all wastage is stopped on same while lamp is burning, &c., &c. June 28.

14,563. Warren and Skinner. Apparatus for generating combustible gas from liquid hydrocarbons. June 28.

14,718. Carpenter. Apparatus for use in the gasification of coal or other materials in the production of illuminating and heating gas.* June 30.

[C.] 13,763 (1903). Crossley and Rigby. Regulation of gas producers. June 22.

13,764 (1903). Crossley and Rigby. Gas producers. June 22.

14,014 (1903). Cory. Artificial fuel. June 29.

14,663 (1903). International Oxy-generator Syndicate, Ltd., and Rosenberg. Oxy-hydrogen combustion apparatus. July 6.

[C.S.] 17,103 (1903). Timmis. Means for getting more perfect combustion of fuel in the fire-chambers of boilers, and also for the prevention of smoke and sparks. July 6.

„ 17,215 (1903). Westinghouse (Gow). Method of and apparatus for the manufacture of gas. July 6.

„ 22,451 (1903). Evered and Co. (Weiblen). Incandescent mantles. June 29.

„ 8311 (1904). Kurzwernhart. Siemens regenerative furnaces. June 29.

„ 8325 (1904). Bühlmann. Process of manufacturing incandescent mantles. June 22.

„ 12,231 (1904). McLean and Paterson. Treatment of peat. July 6.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 14,417. Paterson. Process for recovering phenol from carbolic solutions. June 27.

[C.S.] 13,473 (1903). Thompson (Ges. z. Verwertung der Boleg'schen Wasserlöslichen Mineralöle und Kohlenwasserstoffe). Production of lubricants. June 22.

„ 17,973 (1903). Aminaff. Dry distillation of organic substances. June 29.

„ 2102 (1904). Coulson. Method of solidifying tar. June 29.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 13,941. Lake (Oehler). Manufacture of mordant dyes.* June 20.

„ 13,956. Johuson (Badische Anilin und Soda Fabrik). Manufacture of hydroxethylaniline and derivatives thereof. June 20.

„ 14,289. Vidal and Juuius. Reducing nitrosed or nitrated aromatic compounds whereby iron oxides are produced which may be used as oil colours, &c. June 25.

„ 14,506. Heys (Sansone). Production of indigo derivatives and sulphur colours, and their use in printing and dyeing. June 28.

„ 14,566. Lorrain (Bell). Dye-compound.* June 28.

„ 14,634. Newton (F. Bayer and Co.). Manufacture and production of new colour-lakes. June 29.

[C.S.] 14,768 (1903). Ellis (Chem. Fabr. vorm. Sandoz). Manufacture of azo dyestuffs. June 22.

„ 17,792 (1903). Ransford (Cassella and Co.). Manufacture of a new acetdiamidophenolsulphoacid and of colouring matters therefrom. June 22.

„ 18,283 (1903). Imray (Meister, Lucius und Brüning). Manufacture of a tetrazo-phenolsulphonic acid. July 6.

„ 10,678 (1904). Lake (Oehler). Halogenised nitrocompounds. July 6.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 13,302. O'Brien (L'Huillier). Dyeing, and apparatus therefor.* June 13.

„ 13,382. Long and Kay. Cleaning and permanently restoring colour in fabrics. June 14.

„ 13,484. Dolder. Process for the dyeing of cotton and the like in the form of cops, spools, &c., with alizarin red. June 14.

„ 13,485. Thompson (Wickels Metallpapierwerke). Method of producing a silky appearance on cotton and other fabrics. June 14.

[A.] 13,773. De Keukelaere. Process for treating flax, jute, and similar fibres for the purpose of bleaching. June 17.

„ 13,867. Muntadas y Rovira. Process and apparatus for the bleaching of fabric and yarn. [Ger. Appl., June 18, 1903.]* June 18.

„ 13,879. Bailey and Casson. Manufacture of artificial silk threads. June 20.

„ 13,895. Kemp (Morley). Dyeing machine for dyeing raw cotton, loose wool or silk, rags, mungo, yarns of all kinds, and slubbing. June 20.

„ 14,182. Greenwood. Mercerising and lustreing textile fibres and fabrics. June 23.

„ 14,202. Roberts and Mitchell. Extracting or carbonising in all classes of pieces of cloth or yarn made from änimal fibre. June 23.

„ 14,869. McWhirter. *See under* IX.

[C.S.] 13,556 (1903). Reid. Method and apparatus for treating spun fibres with liquids for dyeing, bleaching, and other purposes. June 22.

„ 14,191 (1903). Berger. Apparatus for the treatment of wool slivers. June 29.

„ 14,472 (1903). Burdick and Pervilhac. Process for colouring, decorating, or printing textiles, paper, &c. June 29.

„ 17,616 (1903). Hoyle and Barker. Production of bleached yarn, and appliances therefor. June 22.

„ 9311 (1904). Stöhr. Apparatus for dyeing hanks of yarn. June 29.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 13,565. Castiglioni and Calastretti. Process for reducing sulphates of the alkaline earths and of the alkalies to sulphides, and for reducing metallic oxides to metals. [Italian Appl., June 20, 1903.]* June 15.

„ 13,827. Grossmann. Method of obtaining ferrocyanide and ammonia compounds from crude coal-gas. June 18.

„ 13,875. Levi. Production of alumina and alkali from alkaline silicates of alumina, such as leucite. June 18.

„ 13,955. Johnson (Badische Anilin und Soda Fabrik). Manufacture of reducing agents. June 20.

„ 13,981. Behrens and Behrens. Processes for manufacturing carbonic acid.* June 20.

„ 14,431. Pictet. Apparatus for the separation of oxygen and nitrogen from air. [French Appl., June 27, 1903.]* June 27.

„ 14,464. Lake (Dr. Alb. R. W. Brand and Co.). Recovery of carbonic acid from waste gases. June 27.

„ 14,848. Artigue. Apparatus for the commercial manufacture of oxygen. [French Appl., July 6, 1903.]* July 1.

„ 14,859. Hargreaves. *See under* XI.

[C.S.] 14,213 (1903). Price. Apparatus for the separation of oxygen and nitrogen from air. July 6.

„ 18,594 (1903). Newton (F. Bayer and Co.). Manufacture and production of nitrous anhydride and nitrites. July 6.

„ 20,069 (1903). Davis. Manufacture of alkaline prussiates. June 29.

„ 26,007 (1903). Brothers. Manufacture of crystalline gypsum for filling purposes. June 29.

„ 28,400 (1903). Hunt. *See under* XI.

„ 28,682 (1903). Soc. pour l'Exploitation des Procédés Georges Claude. Process and apparatus for separating gaseous mixtures, applicable for the separation of oxygen and nitrogen from liquid air. June 22.

„ 10,538 (1904). Alsop. Method of generating a gaseous medium from air. June 22.

VIII.—GLASS, POTTERY, AND ENAMELS.

[C.S.] 18,255 (1903). Carolan (General Electric Co.). Methods of sealing metal into glass or other vitreous material. June 29.

„ 18,290 (1903). Dansette. Ceramic tiles, plates, &c. June 29.

„ 28,790 (1903). Foureault. Apparatus for manufacturing glass sheets or plates. June 29.

„ 10,649 (1904). Dolley and Belknap. Ornamental glass. June 22.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 13,644. Baudry. Process of making Portlan cement from slag. June 16.

„ 14,138. Boult (Buffard). Luting or cemen June 22.

„ 14,183. Conti-Vecchi. Process of and means fo impregnating wood with antiseptic and lik substances or liquids.* June 23.

„ 14,297. Rynd. Preparation of pipeclay. June 2

„ 14,869. McWhirter. Apparatus for heating, steaming, and chemically treating wood and fabrics different kinds, and for drying such article July 2.

[C.S.] 14,366 (1903). Wirtz. Process for obtaining a sul stitute for emery and like substances from sla June 29.

„ 16,412 (1903). Winstanley. Process of and m chines for preparing lime and Portland cemen June 22.

„ 18,064 (1903). Williams. Manufacture of ceme for use in repairing retorts, &c. June 29.

„ 7343 (1904). Neusch (Westdeuts Thomas-phosph Werke). Asphalt composition for floors and like. June 22.

„ 7736 (1904). Spatz. Manufacture of firepro stone or stoneware and mortar. June 29.

„ 10,040 (1904). Devillers. Process for the manufa ture of slabs or sheets imitating marble. July

„ 11,218 (1904). Wulf. Manufacture of a floor cove ing. June 22.

X.—METALLURGY.

[A.] 13,328. Pelletier and Semprun. Solder for alu nium or its alloys.* June 13.

„ 13,462. Fris. Treatment of earths containing g or other precious metals or gems. June 14.

„ 13,565. Castiglioni and Calastretti. *See under* V

„ 13,578. Elmore. Process for separating cert constituents of subdivided ores, &c., and ap ratus therefor. June 15.

„ 13,579. Cowper Coles and Co., Ltd., and Cowp Coles. Deposition of metals or metallic co pounds on metals or metallic articles. June 1

„ 13,648. Woods. Utilisation and separation refuse metals. June 16.

„ 13,730. Lewis. Metallic alloys. June 17.

„ 13,744. Flewin. Gold extractor and concentra June 17.

„ 14,213. Simpkin and Ballantine. Manufacture briquettes. June 23.

„ 14,214. Simpkin and Ballantine. Means for phosphorising iron ores and concentrates. June

„ 14,302. Cameron. Process for the production oxydulated iron. June 25.

[C.S.] 13,454 (1903). Huntington and Heberlein. Pro for treating sulphide ores or compounds pre ratory to smelting. June 22.

„ 14,013 (1903). Cory. Treatment of ores. June

[C.S.] 17,445 (1903). Rouse and Cohn. Method of converting into briquettes or lumps, iron sand, whether natural or prepared by reducing iron ore or iron wastes. June 22.

„ 18,763 (1903). Savelsberg, Wannschaff, and Allgem. Elektro-Metallurgische Ges. Extraction of heavy metals by means of chlorine. June 22.

„ 19,366 (1903). Abel (Siemens und Halske Akt. Ges.). Reducing metallic compounds and fusing metals, in particular nickel and iron, in the electric furnace. June 29.

„ 7981 (1904). Mercadier. Manufacture of spongy porous lead and of articles therefrom. June 22.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 13,579. Cowper-Coles. *See under* X.

„ 13,759. Borchers and Hupperts. Production of titanium from its oxygen compounds electrolytically. [German Appl., June 18, 1903.]* June 17.

„ 13,952. Imray (Soc. Anon. d'Études Electrochimiques). Apparatus operating with automatic regulation for submitting gases and vapours to the action of the electric arc. June 20.

„ 14,058. Potthoff. Solutions for the electro-deposition of metal.* June 21.

„ 14,059. Potthoff. Apparatus for electro-galvanising.* June 21.

„ 14,128. Leitner. Preliminary treatment for accumulator plates. June 22.

„ 14,147. Cowper-Coles and The Metals Corporation, Ltd. The electrolytic deposition of metals. June 22.

„ 14,504. Hargreaves. Electrolytic cells. June 28.

„ 14,859. Hargreaves. Manufacture of carbon. July 2.

[C.S.] 17,885 (1903). Wood-Smith. Apparatus for ozonising air and other gases. June 22.

„ 19,366 (1903). Abel (Siemens und Halske Akt. Ges.). *See under* X.

„ 28,400 (1903). Hunt. Process for the production of hydroxides and oxides of metals by electrolysis. June 22.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 13,451. Zimmermann and Stöhr. Manufacture of a floating soap.* June 14.

„ 13,529. Smith. Treatment and refining of oils and fatty substances. June 15.

„ 13,983. Stockhausen. Compounds of sulphonated oils and fats, and the method of producing same. June 20.

„ 14,482. Wheelwright and Fiske Apparatus for cooking garbage and offal, and removing the oil therefrom.* June 27.

„ 14,483. Wheelwright and Fiske. Apparatus for cooking garbage or offal, and removing the oil therefrom.* June 27.

„ 14,709. Wheelwright and Fiske. Apparatus for removing oil or grease from garbage and offal.* June 30.

, 14,808. Mitchell. Manufacture of soap. July 1.

S.] 15,457 (1903). Macalpine. Appliance for use in refining oils. June 29.

, 4867 (1904). Hearson (Frank and Ziegler). Process for the extraction of fat or wax like substances from hydrous materials. June 22.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(*A.*)—PIGMENTS, PAINTS.

[A.] 13,923. Lekeu and Tonglet. Paint, and the manufacture thereof.* June 20.

„ 14,289. Vidal and Junius. *See under* IV.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 14,130. Southworth. Process for treating raw or partly dressed hides. June 22.

„ 14,203. Castet. Process and apparatus for the extraction of tannin at a low temperature and at a low pressure. June 23.

[C.S.] 11,094 (1904). Lewis. Manufacturing soluble albumen from milk. June 22.

XV.—MANURES, ETC.

[A.] 13,361. Mathesius. Process of manufacturing an artificial manure. [German Appl., June 13. 1903.]* June 13.

„ 13,664. Hammerschlag. Manufacture of artificial manures or fertilisers. June 16.

„ 13,842. Meusel. Manufacture of fertilisers and cattle foods.* June 18.

XVI.—SUGAR, STARCH, GUM, ETC.

[A.] 13,833. Stein and Loewenthal. Manufacture of sugar and other food for diabetics. June 18.

„ 14,205. Lichtenstein. Manufacture of caramel or caramel solution. June 23.

[C.S.] 19,499 (1903). Calico Printers' Assoc., Browing, and Barlow. Production of soluble starch or dextrin. June 29.

XVII.—BREWING, WINES, SPIRITS, ETC.

[A.] 14,028. Schneible. Art of brewing.* June 21.

„ 14,382. Hunt. Maturing and improving the aroma of raw whiskey and other spirits and also certain wines. June 25.

„ 14,472. Moberts. Manufacture of beer. June 27.

„ 14,827. Hunt. Treatment of whiskey and other spirits. July 1.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—FOODS.

[A.] 13,333. Dreaper. Manufacture of food substances. June 13.

„ 13,689. Foelsing. Preservative for food.* June 16.

„ 13,715. Hutmaker. Milk foods. June 17.

„ 13,833. Stein and Loewenthal. *See under* XVI.

„ 14,010. Lehman. Process for humanising cows' milk and condensing it to a dry state. June 21.

„ 14,588. Beadle and Stevens. Manufacture of foodstuffs. June 29.

[C.S.] 5102 (1904). von Dalfsen. Production of an article of food from sweet cassava. June 22.

„ 11,094 (1904). Lewis. *See under* XIV.

(*B.*)—SANITATION; WATER PURIFICATION.

[A.] 13,436. Vial. Water clarification. June 14.

„ 13,588. Henderson. Treatment of sewage. June 15.

[A.] 14,003. Schweitzer. Apparatus for treating sewage. June 21.
,, 14,452. Kloeters. Disinfection. June 27.
,, 14,482. Wheelwright and Fiske. *See under* XII.
,, 14,483. Wheelwright and Fiske. *See under* XII.
,, 14,484. Wheelwright and Fiske. Removing liquids from solids, applicable for the treatment of garbage, &c.* June 27.
,, 14,709. Wheelwright and Fiske. *See under* XII.
[C.S.] 18,569 (1903). Fidler. Method of and apparatus for removing sludge, &c. from settling tanks. July 6.
,, 18,570 (1903). Fidler. Settling or precipitating tanks. July 6.
,, 11,900 (1904). Bordigoni. Bacterial or septic tank treatment of sewage. July 6.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 14,447. Hennessen and Spix. Process of manufacturing figured glazed paper.* June 27.
[C.S.] 16,604 (1903). Stearn and Topham. Manufacture or treatment of filaments from viscose. June 29.
,, 16,605 (1903). Stearn and Topham. Apparatus for pumping and controlling the passage of liquids or semi-liquids, and more especially of solutions of cellulose, in the manufacture of filaments. July 6.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 14,014. Boehm (Merck). Manufacture of barbituric acid and intermediate products. June 21.
[C.S.] 14,189 (1903). Lienau and Naschold. Purification of pinene hydrochloride. July 6.
,, 14,758 (1903). Bouveault and Blanc. Manufacture of alcohols and alcohol derivatives applicable as perfumes, flavourings, &c., and of primary alcohols generally. June 22.
,, 18,245 (1903). Newton (F. Bayer and Co.). Manufacture of a pharmaceutical compound. June 22.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[C.S.] 18,370 (1903). Bloxam (Neue Photographische Ges.). Reproduction of pictures or the like by aid of catalysis. June 22.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 13,562. Moller. Manufacture of nitro-glycerine. June 15.
,, 14,480. Ceipek. Explosives. June 27.
[C.S.] 14,825 (1903). Lake (Alf. Nobel and Co.). Explosives. July 6.
,, 12,238 (1904). Reine. Means for igniting fuses. July 6.

Printed and Published by Eyre and Spottiswoode, East Harding Street, London, E.C., for the Society of Chemical Industry.—P 13

JOURNAL OF THE
Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 14.—Vol. XXIII. JULY 30, 1904. No. 14.—Vol. XXIII.

Subscription of Members 25/- per annum ;
Entrance Fee 21/- ;
Election by the Council.

Price to Non-Members 36/- per annum ;
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each ; 1902 *et seq.*, 1/9 each.

he Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
F. Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.

UNCIL FOR YEAR ENDING JULY 1904.

President : Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.

Vice-Presidents:

of. P. Phillips Bedson.
of. Marston T. Bogert.
Carey.
. John Clark.
Grant Hooper.
an Levinstein.
Dr. R. Messel.
W. H. Nichols.
Dr. F. B. Power.
Prof. H. R. Procter.
Dr. Jos. W. Swan, F.R.S.
Thos. Tyrer.

Ordinary Members of Council:

. Edw. Divers, F.R.S.
. J. Grossmann.
Hemingway.
of. W. R. E. Hodgkinson, Ph.D.
vid Howard.
. J. Lewkowitsch.
N. H. Martin.
Max Muspratt.
B. E. R. Newlands.
Prof. W. J. Pope, F.R.S.
Frank Scudder.
Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

CANADIAN.	
of. W. R. Lang.	Alfred Burton.

Hon. Local Secretary:
Alfred Burton, 42, Front Street West, Toronto.

The following take office in Sept. next:—*Chairman:* F. J. Smale. *Vice-Chairmen:* W. H. Ellis and Thos. Macfarlane. *Committee:* Jeffrey H. Burland, G. P. Girdwood, W. R. Lang, and A. McGill.

Liverpool Section.

Chairman: *F. H. Tate.*

Vice-Chairman: *C. Longuet Higgins.*

Committee:

Percy Bateson.
J. Campbell Brown.
G. C. Clayton.
A. Foden.
G. Watson Gray.
Max Muspratt.
E. L. Peek.
Julius Raschen.
Alf. Smetham.
H. B. Stocks.
J. W. Towers

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:
W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

The following take office in Sept. next:—*Chairman:* Eustace Carey. *Vice-Chairman:* Frank Tate. *Committee:* T. Lewis Bailey, J. T. Conroy, G. Watson Gray, and C. L. Higgins.

London Section.

Chairman: *Walter F. Reid.*

Vice-Chairman: *A. Gordon Salamon.*

Committee:

J. N. Connah.
E. Divers.
Bernard Dyer.
M. O. Forster.
R. J. Friswell.
Oscar Guttmann.
Otto Hehner.
J. T. Hewitt.
J. Lewkowitsch.
A. R. Ling.
W. S. Squire
F. Napier Sutton.
L. T. Thorne.
Thos. Tyrer.

Hon. Local Secretary:
Julian L. Baker, 7, Addison Road, Bedford Park, W.

The following take office in Sept. next:—*Chairman:* A. Gordon Salamon. *Committee:* H. G. Colman, D. L. Howard, Wm. Pearce, Boverton Redwood, and Charles Wightman.

Manchester Section.

Chairman: J. Carter Bell.

Vice-Chairman: *G. H. Bailey.*

Committee:

J. Allan.
R. Clayton.
G. J. Fowler.
B. Hart.
W. E. Kay.
H. Levinstein.
K. Markel.
W. J. Pope.
F. Scudder.
T. Stenhouse.
H. L. Terry.

Hon. Local Secretary:
Julius Hübner, Ash Villa, Cheadle Hulme, Cheshire.

The following take office in Sept. next:—*Vice-Chairman:* F. Scudder. *Committee:* W. H. Coleman, J. Grossmann, W. B. Hart, K. Markel, H. Porter, and W. Thomsen.

Newcastle Section.

Chairman: J. T. Dunn.

Vice-Chairman: W. L. Rennoldson.

Committee:

A. Allhusen.
P. P. Bedson.
H. S. Collins.
T. W. Hogg.
H. Louis.
N. H. Martin.
John Pattinson.
W. W. Proctor.
Harry Smith.
A. Spiller.
J. E. Stead.
C. E. Stuart.

Hon. Local Secretary and Treasurer
F. C. Garrett, Durham College of Science, Newcastle-on-Tyne.

The following take office in Sept. next:—*Committee:* Ellwood Holmes and Geo. Sisson.

New York Section.

Chairman: *V. Coblentz.*

Vice-Chairman: Russell W. Moore.

Committee:

H. C. Aspinwall.
L. Baekeland.
C. F. Chandler.
G. Drobegg.
W. F. Fuerst.
E. J. Lederle.
Wm. McMurtrie.
Wm. H. Nichols.
T. J. Parker.
Clifford Richardson.
W. J. Schieffelin.
G. C. Stone.
D. Woodman.

Hon. Treasurer: R. C. Woodcock

Hon. Local Secretary:
H. Schweitzer, 40, Stone Street, New York, U.S.A

The following take office in Sept. next:—*Chairman:* C. Chandler. *Committee:* V. Coblentz, A. H. Elliott, E. G. Lov
H. A. Metz, F. Schniewind, and C. B. Zabriskie.

Nottingham Section.

Chairman: J. T. Wood.

Vice-Chairman: S. F. Burford.

Committee:

L. Archbutt.
F. J. R. Carulla.
R. M. Caven.
F. Stanley Kipping.
G. D. Lander.
H. B. Mayfield.
J. O'Sullivan.
J. M. C. Paton
A. L. Stern.
G. J. Ward.
J. White.

Hon. Treasurer: S. J. Pentecost.

Hon. Local Secretary:
S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

The following takes office in Sept. next:—*Committee:* J. Goldn

Scottish Section.

Chairman: *T. L. Patterson.*

Vice-Chairman: *D. J. Playfair.*

Committee:

H. Bumby.
D. B. Dott.
Thos. Ewan.
J. Arnold Fleming.
W. Frew.
G. H. Gemmell.
Jas. Hendrick.
Jas. Hope.
H. Ingle.
D. S. Jerdan.
W. G. Johnston.
J. Falconer King.
J. G. F. Lowson.
J. S. Macarthur.
J. McCulloch.
M. A. Parker.

Hon. Secretary and Treasurer:
Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow

The following take office in Sept. next:—*Chairman:* R. Thomson. *Vice-Chairman:* J. S. Macarthur. *Committee:* W. Curphey, L. Dobbin, Robt. Hamilton, T. L. Patterson, and D Playfair.

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.
J. F. Elliott.
F. B. Guthrie.
L. Meggitt.
J. Morison.
A. A. Ramsay.
J. A. Schofield.
R. Greig Smith.
H. G. Smith.
T. Steel.

Hon. Local Secretary:
T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S

Yorkshire Section.

Chairman: *Jas. E. Bedford.*

Vice-Chairman: G. W. Slatter.

Committee:

C. S. Bedford.
E. A. Brotherton.
John W. Cobb.
W. M. Gardner.
A. J. Murphy.
H. R. Procter.
F. W. Richardson
Geo. Ward.
H. A. Watson
Thorp Whitaker
J. B. Wilkinson

Hon. Local Secretary and Treasurer:
T. Fairley, 17, East Parade, Leeds.

The following take office in Sept. next:—*Chairman:* H. Procter. *Committee:* W. Ackroyd, J. E. Bedford, F. Bran
B. A. Burrell, and A. Smithells.

N.B.—The names in *italics* are those of members of Committee who retire from their respective offices at the end of the current sess

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who propose to attend the meeting are requested to inform he General Secretary, as soon as possible, by what steamer hey will travel. The principal boats will be met on arrival t New York by a representative of the Reception Committee, who will escort the guests to the Hotel Seville, Iadison Avenue and 29th Street, which will be the ociety's Headquarters in New York. A similar system ill be observed at all the other cities visited by the special rain. A revised programme appeared in the March 31st ssue.

In accordance with the provisions of Rule 18 of the ye-laws, notice is hereby given that those members whose ames are printed in *italics* in the list of Council will retire om their respective offices at the forthcoming Annual leeting.

Mr. Wm. H. Nichols has been nominated to the office of resident under Rule 8; Dr. Edw. Divers, Prof. W. R. aton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. arker have been nominated Vice-Presidents under ule 8; and Sir Wm. Ramsay has been nominated a Vice-resident under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have een nominated for re-election to their respective offices.

ST. LOUIS EXHIBITION.

Copies of the Catalogue of the British Chemical Exhibits the St. Louis Exhibition, with descriptive articles by perts, may be obtained by members on application at e office of the Royal Commission, 47, Victoria Street, estminster, price 1*s*. each.

TAX-FREE ALCOHOL.

The following resolution, passed by the Chemical Section the London Chamber of Commerce and approved by e Council of the Chamber, has been endorsed by the uncil of this Society:—"That the Chancellor of the chequer be urged to appoint a departmental committee, luding recognised commercial and scientific representa-es, to examine and report upon the best method of viding untaxed alcohol for manufacturing and other rposes, such as power, heating, and lighting."

COMMUNICATIONS.

Authors of communications read before the Society, or of its Local Sections, are requested to take notice that ler Rule 43 of the Bye laws the Society has the right of ority of publication for three months of all such papers. ringement of this Bye-law renders papers liable to be cted by the Publication Committee, or ordered to be tracted for the Journal, in which case no reprints can urnished to the author.

List of Members Elected

22nd JULY 1904.

deis, R., Aüssig, Austria, Chemical Manufacturer.

l, Prof. Hubert C., Laboratory of Medical Chemistry, University of Minnesota, Minneapolis, Minn., U.S.A., Chemist (State Board of Health).

brough, Col. John, Blanefield, Stirlingshire.

Clarke, A. R., 613–617, Eastern Avenue, Toronto, Canada, Leather Manufacturer.

Danker, Dan. J., 247, Atlantic Avenue, Boston, Mass., U.S.A., Dyestuff and Chemical Manufacturer.

Ermen, Walter F. A., 11, Park Road, Pendleton, Lancashire, Analytical Chemist.

Gyr, Dr. K. H., c/o Messrs. Joseph Fison and Co., Ltd., Ipswich, Analytical Chemist.

Hamilton, E. H., Anaconda Copper Mining Co., Anaconda, Montana, U.S.A., Assistant Superintendent

Holloway, E. G., 447, Belle Plain Avenue, Chicago, Ill., U.S.A., Chemist.

Hooker, A. H., c/o Heath and Milligan Manufacturing Co., 170, Randolph Street, Chicago, Ill., U.S.A., Manufacturing Chemist.

Kaye, Thomas, Westerfield, Perth, Scotland, Analytical Chemist.

Litter, Hans, Farbenchemisches Laboratorium der Kgl. Technischen Hochschule, Dresden, Germany, Chemist.

Liverseege, J. F., Council House, Birmingham, Public Analyst.

McKenna, A. G., 506, Hawkins Avenue, Braddock, Pa., U.S.A., Metallurgical Chemist.

Marschall, Adolf J., Little Falls, N.Y., U.S.A., Chemist.

Mighill, Thos. A., 127, Purchase Street, Boston, Mass., U.S.A., Chemist.

Rostosky, Dr. Leopold, Tiergartenstrasse 28, Dresden Alt, Saxony, Chemist.

Shedden, Frank, 5, Belvidere Road, Walsall, Science Master.

Southerden, Frank, 75, Barry Road, Dulwich, S.E., Teacher of Chemistry.

Wackenreuter, A.G., 134–136, Kinzie Street, Chicago, Ill., U.S.A., Colour Manufacturer.

Wedekind, Rud., Uerdingen a/Rhein, Germany, Manufacturer of Alizarin and Bichromates.

Whittier, Chas. T., 322, Warren Street, Jersey City, N.J., U.S.A., Manager.

Wünsche, Fritz, Reichenbachstrasse 25 p., Dresden-Altst., Germany, Chemist.

Zimmele, H. B., 621, Main Street, Niagara Falls, N.Y., U.S.A., Technical Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Adgate, M., l/o Syracuse; Naugatuck, Conn., U.S.A.

Arnott, G. W. Campbell, l/o King Street East; 114, Victoria Street, Toronto, Canada.

Bloxam, W. Popplewell, l/o India; 73, Walpole Road, Boscombe, Hants.

Boyes, Herbert J. S.; Journals to Alameda Barão de Piracicala, Sao Paulo, Brazil.

Cayvan, L. L., l/o Hôtel Normandie; 19, West 17th Street, New York City, U.S.A.

Clapperton, Jas., jun., l/o Glasgow; retain Journals.

Clayton, R. H., l/o Cheetham Hill; Woodleigh, Blackfield Lane, Kersal, Manchester.

Crowther, J.; all communications to South Australian School of Mines, Adelaide, South Australia.

Fawcett, J. H., l/o Italy; c/o Bank of Australasia, 4, Threadneedle Street, E.C.

Filcock, P., l/o Cumberland House; Sunny Bank, Prestbury Road, Macclesfield.

Gibb, Thos., l/o Mount Perry; Wilford, Doraoch Terrace, Brisbane, Queensland.

Granger, Dr. J. Darnell, l/o Acton; 25, All Saints' Street, Nottingham.

Hall, Wm. F. (of Selukwe); retain Journals.

Harvey, C., l/o Manor Park; 17, Alloa Road, Goodmayes, Essex.

Hewitt, A. H. (of Hong Kong); Journals to Springvale, near Gurnard, Isle of Wight.

Hicks, Edwin F., l/o New York; c/o P. Blakiston's Son and Co., 1012, Walnut Street, Philadelphia, Pa., U.S.A.

Jackson, Edw., l/o Grove Avenue; Ravens Cliff, Oxford Road, Moseley, Birmingham.

Jessop, L. V., l/o Victoria Park; Holmlea, Woodville Road, Leytonstone, Essex.

Jones, T. Tolley, l/o Little Collins Street; Australian Explosives and Chemical Co., Ltd., 138, Queen Street, Melbourne, Victoria.

Lindmueller, Chas., l/o Cleveland; c/o United Zinc and Chemical Co., Argentine, Kas., U.S.A.

Marsden, Dr. Fred., l/o Leeds; 4, Swinton Grove, Manchester, S.E.

Mayer, And., jun., l/o Braddock; 104, St. Mark's Avenue, Brooklyn, N.Y., U.S.A.

Meyer, Aug. R.; Journals to c/o United Zinc and Chemical Co., Kansas City, Mo., U.S.A.

Proctor, C.; all communications to 27, London Road, Forest Hill, S.E.

Runting, D. A.; all communications to Moreland Grove, Coburg, Melbourne, Vic., Australia, Analyst.

Scrymgeour, Wm., l/o Kalgoorlie; Fraser's Gold Mine, Southern Cross, West Australia.

Stevens, Dr. Henry P., l/o Ash; Laboratory, 15, Borough, London Bridge, S.E., Analytical and Consulting Chemist.

Sturrock, Capt. G. C.; Journals to Aruvankad, Nilgiris, India.

Warnes, A. R., l/o London; c/o North West Soap Co., Ltd., 63, Garden Reach, Calcutta, India.

Wilson, Gordon; Journals (temporary) to Promontorio, Estacion Chinacates, Durango, Mexico.

MEMBER OMITTED FROM LIST.

1900. Garrigues, W. E., 66, Beaver Street, New York City, U.S.A., Chemical Engineer.

Death.

Allen, Alf. H., Broomfield Road, Sheffield. July 14.

New York Section.

CORRECTION.

ANALYSIS OF COMMERCIAL ACETATE OF LIME.

BY W. M. GROSVENOR, JUN.

(This J., May 31, 1904, 530—535.)

The author desires to state that when he referred to th Distillation Method as having been originated by Freseniu and modified by Stillwell and Gladding, he was unaware tha the method was really first devised by Dr. H. Endemann i 1874 and published in Dr. Waly's "Industrial Record" n 1875. It may also be found in Prof. Chandler's "America Chemist" for 1876.

Obituary.

ALFRED H. ALLEN, F.C.S., F.I.C.

Original Member of the Society of Chemical Industry. Also Member of Publication Committee, and formerly Member of Council.

Alfred Henry Allen, born at Southwark, London, on January 17th, 1846, was the son of George Allen, an eminent architect. He was educated at a private school in Brighton, and subsequently became a student at the College of Chemistry and Agriculture at Kensington, under the late Mr. John Nesbit, and at the Royal College of Chemistry and School of Mines under Hofmann and Tyndall. He studied metallurgy and practised assaying under Percy, and attended geology and mineralogy classes at University College, London, under Morris. He began his professional career as assistant to the late Dr. A. H. Hassall, but resigned that position in order to go to Sheffield as analytical assistant to the late Dr. James Allan. On the death of the latter Allen became the residuary legatee, and, though very young, resolved to continue the practice on his own account. Later on, he was appointed lecturer in chemistry and physics at the Sheffield School of Medicine, then situated in Surrey Street, and also lecturer on chemical and physical science at Wesley College. He was President of the Society of Public Analysts in 1887 and 1888, and was also an original Fellow and a Member of Council of the Institute of Chemistry. He served for four years on the Council of this Society, and, from 1888 up to his death, on its Publication Committee.

In 1873, when the Sale of Food and Drugs Act came into operation, Allen was made public analyst to the Corporation of Sheffield and also to the West Riding of Yorkshire. These appointments, together with similar ones in connection with other boroughs, he held up to the time of his death. Always a conscientious and impartial officer, he prided himself on the fact that no one had ever been unjustly punished through his evidence.

In the revision of the Foods Acts, &c., Allen gave evidence before several Royal Commissions and Departmental Committees. Amongst these may be mentioned the Select Committee on British and Foreign Spirits, the Commission on Arsenical Poisoning, the Departmental Committee on Beer Materials, and the Board of Agriculture Departmental Committee on Milk and Cream. In the last-mentioned case the standard ultimately fixed was that advocated and used by him for many years. When the consideration of butter substitutes resulted in the passing of the Margarine Act, it was at his suggestion that the title "margarine" was adopted. The Danish Government many years ago invited him to inspect the farms and inquire into the whole question of butter production in Denmark. The results of his investigation are embodied in his report to that Government.

During the epidemic of lead poisoning in Sheffield, fifteen years ago, Allen did an enormous amount of special work connected therewith. His theory as to the cause of the action of Sheffield water on the lead service pipes proved to be correct, and his simple method of preventing further mischief, by the addition of chalk to the water of the reservoirs, is in use at the present time.

Always busy with the affairs of his many offices, he yet found time to devote to scientific research, and has left after him a monumental work, which will serve to keep his name in respectful and grateful remembrance. Many important papers were contributed by him to this and other scientific journals, but their contents represent only a fraction of the extensive original work carried out for and published in his great undertaking just referred to, the eight volumes of his treatise on Commercial Organic Analysis, which has long been accepted as a standard work by chemists everywhere. It should never be forgotten that this invaluable treatise, so admirable in its arrangement, so accurate in its facts, and so generally reliable in its statements, is very much more than a handy and useful compilation from the published works of other chemists, containing as it does on every page the evidence of its author's thought and investigation. Having in mind what he accomplished in developing and systematising commercial organic analysis, it will assuredly be felt by many that he might well be styled the Fresenius of that large branch of chemical analysis.

Another example in this direction may be found in his valuable work on the "Chemistry of Urine," published in 1895. It was written in great measure, so its author informed the writer, as the outcome of an earnest study of the dread complaint (diabetes) which was undermining his own health and powers. In the preface to this work he makes pathetic reference to the subject.

Many will remember how much A. H. Allen's genial presence and powers of entertainment were in request at the social gatherings of the Annual General Meetings in the earlier years of the Society, and what a pervading sense of the incompleteness of those social gatherings in later years was caused, when ill-health enforced his absence from them.

Allen's mental characteristics were a wonderful memory, great keenness of intellect, and ability for rapid grasp of intricate questions. His name will ever be honourably identified with most of the legislation for securing pure food and drugs for the people.

ATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

—PLANT, APPARATUS AND MACHINERY.

odium Hydroxide; Formation of —— from Sodium Carbonate in Boilers fed with Water containing the latter. J. Brand. Z. ges. Brauw., 1904, **27**, 456—458.

well-water containing 23·5 parts of sodium carbonate 100,000 was employed as boiler feed water. At the end 14 days an incrustation appeared on the fittings, consting of 84·8 per cent. of sodium carbonate, 1·6 per cent. sodium hydroxide, 5·48 per cent. of sodium sulphate, d 7·36 per cent. of water. In 45 days the incrustation attained such dimensions that injury to the boiler was feared, and the water was therefore mixed in equal proportions with one containing alkaline earth carbonates (16° of hardness). After another week the water in the boiler was examined, and was found to contain 1,667 parts of solids per 100,000 parts, including 1,176 parts of sodium carbonate, 362 parts (21·7 per cent. of the total) of sodium hydroxide, and 100 of sodium sulphate. The sediment deposited from the slightly turbid sample consisted solely of calcium and magnesium carbonates. The probable explanation of the formation of sodium hydroxide is that under the high temperature and pressure in the boiler, the magnesium carbonate present is converted into hydroxide, which reacts with the sodium carbonate, the double decomposition being continually repeated; or, it may be that, as stated by Küster and Grüters (this J., 1903, 417), the sodium carbonate parts with its carbon dioxide under certain relative conditions of tension and partial pressure.—C. S.

English Patent.

Centrifugal Machines [Separators] and the like. A. J. Boult, London. From the Firm F. Meyer's Sohn, Tangermünde, Prussia. Eng. Pat. 15,862, July 17, 1903.

See Fr. Pat. 334,041 of 1903; this J., 1904, 14.—T. F. B.

United States Patent.

Granular Materials; Apparatus for Washing ——. G. M. Hoffman and J. T. Gibson, New York. U.S. Pat. 762,309, June 14, 1904.

In order to clean filtering material, such as sand, it is forced by suitable means, together with water, into a hopper working in an immersion pit, and provided with air-lift mechanism, and delivered into a second hopper. The second hopper is provided with an immersion pit and air-lift apparatus, has an overflow for the water, and means for adding additional wash-water to the second immersion pit.—L. F. G.

French Patents.

Muffle Furnace; Circulating ——. E. Ufenast. Fr. Pat. 340,045, Jan. 30, 1904.

The furnace is embedded in the ground, and not arched, being covered in at the top with firebricks. Coal is fed through holes in the roof on to grates of firebrick, and the products of combustion are made to circulate through longitudinal and transverse passages, and to play around the central muffle on all sides. The circulation is regulated and effected by suitable screens, and the coal gases are led away by an iron pipe from the top of the furnace.—L. F. G.

Filters; Method of Constructing ——. Berlin-Anhaltische Maschinenbau Akt.-Ges. Fr. Pat. 340,147, Feb. 3, 1904.

See Eng. Pat. 15,948 of 1903; this J., 1904, 600.—W. H. C.

Dryer; Cylindrical —— for the Direct Heating of Substances in a Continuous Current [of Gas]. M. Hecking. Fr. Pat. 340,260, Feb. 8, 1904.

See Eng. Pat. 25,209 of 1902; this J., 1904, 13.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Illuminating Gas; Condensation of ——. H. G. Colman. J. Gas Lighting, 1904, **86**, 760—763.

In this paper attention is chiefly devoted to a consideration of the function of condensers as scrubbers in which the gas is subjected to the washing action of the liquid products separating from it during the process of cooling, and of the best means of carrying out most efficiently the objects of condensation, namely, to cool the gas to atmospheric temperature and at the same time to retain in it as much of the lowest boiling tar constituents as can be permanently carried during distribution, and to effect as complete a removal as possible of naphthalene and all higher boiling substances. In the analogous process of fractional distillation, where the vapours evolved on boiling a mixed liquid are subjected to fractional condensation to remove higher boiling constituents, the principle universally adopted is to allow the products separating in the still-head to flow backwards against the current of ascending vapour, and it is therefore contended that the same process is also the most suitable in condensing illuminating gas. In the latter case, however, the conditions differ in several respects from those existing in fractional distillation. The vapours are there diluted with large volumes of permanent gases, thus lowering the rate at which the solvents act upon the vapours present; water is also continuously condensing, and, as it does not mix with the tar, tends to form a coating over it, and prevents the latter acting upon the gas. Further, owing to the rapid cooling which takes place in the earl stages after the gas leaves the retort, large quantities of th tar separate as a fog, a considerable portion of which i carried forward mechanically with the gas right throug the condensing apparatus, and must be removed as soon a possible, if the above counter-current system is to be full carried out. In order to effect this removal the autho proposes to treat the hot gas as it leaves the hydraulic o foul main, in a modification of the "cyclone dust collector," by means of which these heavy tar particles are removed The apparatus consists of a short, wide cylinder, to th bottom of which is fixed an inverted cone, the tar flowin away from the lowest portion of the latter by means of seal pot or siphon. The gas enters the cylinder at tangent, takes a spiral course through the apparatus, an leaves by means of the outlet main fixed in the centre o the cylinder. Owing to the whirling motion thus set u the heavy solid and liquid particles are driven by centrifugal force to the circumference of the cylinder and cone where they coalesce and flow away through the sipho This apparatus, as erected at the Tottenham Gas Works effects a practically complete removal of the tar-fog fro the hot gas; the quantity of tar thus separated amounted t 2 galls. per ton of coal carbonised, or one-fifth of the tot tar production. When the separator is at work the quantit of tar condensing during the subsequent cooling stages onl amounts to about one-third of a gallon per ton, and is a thi liquid containing a much higher proportion of low-boilin constituents than ordinary coal-tar. The results obtaine so far indicate that when the heavy tar-fog is remove from the hot gas in this manner, the gas after coolin contains a larger quantity of benzene and toluene and les naphthalene than is the case when the centrifugal separato is not employed.—H. G. C.

Formaldehyde; Presence of —— in the Products of Combustion of Ordinary Fuels. A. Trillat. Comptes rend 1904, **138**, 1613—1615.

Air, carefully freed from any trace of formaldehyde, wa passed over burning combustibles in a heated tube, and th products were collected and examined for formaldehyd In all cases (coal, peat, various woods or products of thei distillation, papers, pure cellulose, cork, india-rubbe tobacco) formaldehyde was found, in amounts varying fro 1/10,000 to 1/100,000 of the weight of substance burn Wood and cellulose gave the largest amounts. The benzen hydrocarbons also yielded formaldehyde, in amounts increasing with their complexity. In all cases the material with which the combustible materials are in contact affe the yield of formaldehyde considerably; copper, fo example, favours its production much more than porcelai The existence of formaldehyde in the atmosphere is n doubt attributable to its formation in combustions.

English Patents.

Liquid Fuel; Impts. in Furnaces Heated by ——. A Barron, Mexboro'. Eng. Pat. 15,726, July 16, 1903.

The liquid fuel is blown in by compressed air, and to secur greater heat the flame passage is made longer than usu and flared towards the interior.—C. S.

Carburetted Water-Gas; Apparatus far the Manufactur of ——. W. R. Addicks, New York. Eng. Pat. 10,12 May 3, 1904.

See U.S. Pat. 758,882 of 1904; this J., 1904, 602.—T. F. B.

Gas; Manufacture of ——. H. W. Woodall, Wimborn and A. McD. Duckham, Upper Parkstone, Dorset. Eng Pat. 16,497, July 27, 1903.

Coal is distilled continuously in a vertical retort, the lowe open end of which dips into a water sump, from which th

:e is removed continuously by means of a conveyor. e steam produced, passes up through the retort, forming :er-gas, which is either led off along with the coal-gas or wn off separately. The retort is heated most intensely its upper end, by means of combustible gas, the products combustion being led down a flue surrounding the retort, as to maintain the coke at a high enough temperature to ompose the steam. Coal is fed into a little shoot within top of the retort, by means of a rotating gas-tight ding drum, in such a manner that the shoot and the ort are always full of coal. The position of the bottom the shoot determines the top level of the coal in the ort. The gas is drawn off from the top of the retort as ıal.—H. B.

United States Patents.

el; Manufacture of Artificial —— by Distillation. . T. Davis, San Francisco. U.S. Pat. 763,267, June 21, 904.

mixture of crude petroleum and fine carbonaceous terial is agitated and exposed to a continuously inasing degree of heat, so as to distil off the lighter hydrobons and leave the heavier hydrocarbons associated with carbonaceous material. After cooling, the combustible iduum is pressed.—H. B.

Gas Furnace; Regenerative ——. E. Derval, Paris. U.S. Pat. 762,578, June 14, 1904.

e furnace is fitted with inclined retorts, each of which uilt up of curved sections so arranged that each section t an angle to the horizontal less than that of the next oining section above.—H. B.

ıs Producer. L. Wilson, Glasgow. U.S. Pat. 762,568, June 14, 1904.

e combustion chamber of the producer is formed of a ing, the lower half of which has a refractory lining. s is surrounded by an outer lined casing, an annular ce being left between the inner casing and the lining of outer casing. Within the annular space is a duplicate ed pipe for supplying heated air and superheated steam the combustion chamber. Midway up the combustion mber there are provided lateral exit pipes, through ch the hot gases are led into the annular space, and gases are finally drawn off at the top of the said space. —H. B.

Vater-Gas Generator. D. McDonald, Louisville, Ky., U.S.A. U.S. Pat. 763,313, June 21, 1904.

e generator is provided laterally at its upper end with a rt vertical stack, which communicates with the superter and contains two flues communicating with the rior of the generator at two different levels in its er part. By means of a rotatable valve at the top of stack, either of the two flues may be put in connection h the superheater.—H. B.

oke Oven; Electric ——. M. R. Conley, New York. U.S. Pat. 763,368, June 28, 1904.

ctric resistance plates are arranged in pairs in the r wall of the furnace body (which is of non-conducting erial), and on different horizontal planes, in order to n a series of heating zones. The oven is open at the and is closed at the bottom by swing doors which open he full sectional area of the oven.—C. S.

e; Process of Making ——. M. R. Conley, New York. U.S. Pat. 763,369, June 28, 1904.

: coal is introduced into an essentially air-tight oven previous abstract), which is heated by electrical resis es to a temperature higher than that of the ordinary oven.—C. S.

French Patents.

minating Gas; Manufacture of ——. B. Duttenhofer. Fr. Pat. 340,055, Jan. 30, 1904.

the prevention of the formation of tar and "graphite," n is passed into the coal in the retorts from the beginning of the distillation. It is claimed that the hydrogen supplied in the form of steam in this way combines with the carbon to produce hydrocarbons.—H. B.

Combustible Gas from Pulverised Combustibles; Process and Apparatus for the Production of ——. G. Marconnet. Fr. Pat. 340,075, Feb. 1, 1904.

A mixture of air and finely-pulverised combustible is aspirated in regulated quantities by each suction of the motor (or other apparatus to be supplied with the gas) into a shoot similar to that described in Fr. Pat. 337,514 (this J., 1904, 484), wherein the fuel is burned during its downward passage. From an ashbox at the foot of the shoot the gas produced is led off to the motor, a portion of this gas being withdrawn to feed the burners in the combustion shoot. The device for producing the mixture of air and combustible consists of a vertical pipe having a hopper at the top, from which the powdered fuel descends in a continuous stream. The pipe is connected on one side with the combustion shoot, and on the other with an air-supply pipe. At each suction of the motor, the air rushing through the descending stream of fuel carries over a determinate quantity into the shoot in the form of a cloud. The excess of fuel which accumulates at the foot of the vertical pipe is transferred to the hopper from time to time.—H. B.

Briquette Fuel; Process of Manufacturing ——. V. Conti and A. Levy. Fr. Pat. 340,244, Feb. 6, 1904.

The binding material employed to agglomerate the fuel (coal, lignite, wood, peat, spent tan, &c.) is magnesium oxychloride, in the proportion of about 3 per cent. To facilitate the volatilisation of the oxychloride it is mixed with 3 per cent. of its own weight of potassium bichromate, or double that quantity of sodium bichromate or potassium nitrate. The product is compressed and dried in the usual manner.—C. S.

Carbon or Fuel; Artificial ——, and Method of Manufacturing same. J. Auguiot. Fr. Pat. 338,776, May 1, 1903.

The ingredients of the product consist of powdered fuel materials, with a large proportion of petroleum or other mineral oils, the volatility of which is almost entirely nullified by an admixture of sodium oleomargarate, or of white soap in association with asphaltum or pitch. The following approximate proportions are given:—Crude petroleum, 50 parts; sodium oleomargarate, 6; asphaltum, 25; sawdust, 5; coal dust, 30 parts. The first three are incorporated by heating and continued stirring, and the sawdust and coal dust are afterwards stirred-in in succession. —C. S.

Siemens Regenerative Furnaces; Process and Apparatus for Avoiding Loss of Gas in ——. A. Kurzwernhart. Fr. Pat. 340,332, Jan. 25, 1904.

See Eng. Pat. 1890 of 1904; this J., 1904, 434.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Mineral Oil Industry in the Lüneburger Heide. Häpke. Chem.-Zeit., 1904, **28**, 618—619.

The occurrence of mineral oil at Wietze, a village standing on the small river of the same name in the neighbourhood of Celle, Hanover, has been known since the middle of the seventeenth century, but the first borings were not made till the end of the year 1880. The production of mineral oil at Wietze amounted in 1903 to more than 40,000 metric tons, of a value of about 3,200,000 M., whilst that of Ölheim was about 750 tons, of a value of 60,000 M. The oil occurs in two different zones, the upper one extending to a depth of 250 m. and the lower one to a depth of 350 m. The oil from the upper zone is thick, of a dark brown colour, sp. gr. 0·935—0·950, and is usually accompanied by a strong brine containing some magnesium chloride. On distillation it yields:—Benzine, sp. gr. 0·725, 0·5 per cent.; colourless kerosene ("petroleum"), sp. gr. 0·80, 6·0; kerosene with a faint yellowish tinge, sp. gr. 0·84, 6·0; spindle oil, 20·0; machine oil, 44; tar, 10·0 per cent. The tar on redistillation yields 70 per cent. of an oil containing paraffin, and 30 per cent. of coke. After separation of the benzine and kerosene, the machine oils are used almost exclusively as a wagon-grease. The oil from the lower zone is dark green in colour, and has the sp. gr. 0·885. On distillation it yields:—Benzine, sp. gr. 0·701 at 15° C., 1 per cent.: ligroïn, sp. gr. 0·727—0·730, 2—3; naphtha and kerosene ("petroleum"), 28; lubricating oil, 47; residue, 17; and loss, 4—5 per cent.—A. S.

"Naphtha" [Crude Petroleum] and Gas at Berekei (Daghestan); Examination of the ——. K. Charitschkoff. J. russ. phys.-chem. Ges., 1904, **36**, 321—326; Chem. Centr., 1904, **1**, 1627.

The deposit at Berekei has been worked for only a short time. The crude petroleum appears to be of good quality. It is characterised by its high content (36 per cent.) of light fractions ("petroleum"), its low content of middle fractions, and the relatively low viscosity of the residue. The residue has a calorific value of 10,520 calculated by Mendelejeff's formula; it contains no paraffin. The gas which accompanies the petroleum contains, when freed from air, 12·82 per cent. of carbon dioxide, 65·84 per cent. of methane, and 19·92 per cent. of ethane.—A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

Natural Dyestuffs still used in Dyeing, and their Valuation. von Cochenhausen. Z. angew. Chem., 1904, **17**, 874—886.

A long paper on the dyeing properties and methods of valuation of the chief natural dyestuffs still used in dyeing-operations.—A. B. S.

Rosanilines; Additive Ammoniacal Compounds of —. J. Schmidlin. Comptes rend., 1904, **138**, 1709—1711.

The mon-acid salts of rosanilines absorb 4 mols. of a
monia gas, producing colourless substances, apparent
similar to those formed when the tri-acid salts (this
1904, 710) absorb a fourth molecule of hydrochloric a
gas. These ammoniacal compounds are entirely additi
and lose all their ammonia *in vacuo*. The author conclud
that the mon-acid rosaniline salts are unsaturated molecul
and that the free affinities are chemically neutral, and
be satisfied by bases or by acids. No doubt the carbon
a neutral element—is the seat of these unsaturated affiniti
which appear to be satisfied by 4 mols. of either HCl or N
—J. T. D.

Azo Dyestuffs derived from 2:2-Dinaphthol. M. E. Poz
Escot. Comptes rend., 1904, **138**, 1618—1619.

The existence of azo-derivatives of β:β-dinaphthol is stro
evidence in favour of the linkage between the two naphth
nuclei being in the 3:3- and not in the 1:1-position, as
been supposed. The azo dyestuffs obtained have no practi
interest, although, in an acid bath, they dye wool a more
less deep red shade.—T. H. P.

Cyanomaclurin. A. G. Perkin. Chem Soc. Proc., 1904, **20**, 170.

Cyanomaclurin (Chem. Soc. Trans., 1895, **67**, 937), wh
exists in jackwood (*Artocarpus integrifolia*) in conjunct
with morin, crystallises from water in the anhydrous fo
and is now shown to be isomeric with the catechi
$C_{15}H_{14}O_6$. On fusion with caustic alkali, cyanomaclu
gives β-resorcylic acid (not cresorcylic acid as previou
suggested) and phloroglucinol, and with pine wood
hydrochloric acid it resembles the catechins in giving
phloroglucinol reaction. With boiling dilute hydrochl
acid, a brown amorphous compound is produced; this
identical in appearance with the so-called fourth anhydr
from Gambier catechin, and has the same percentage co
position. Cyanomaclurin thus appears to represent
catechin in which the catechol nucleus is replaced
resorcinol.

Catechins; Note on the ——. A. G. Perkin. Chem.
Proc., 1904, **20**, 171.

In a previous communication (Trans., 1902, **81**, 1160)
was pointed out that whereas Gambier catechu contain
catechin, $C_{15}H_{14}O_6$ (m. pt. 175°—177°), the pentabenz
derivative of which melts at 151°—153°, yet a catec
$C_{15}H_{14}O_6$, which was isolated from *Acacia catechu* melte
204°—205°, and gave a benzoyl compound melting
181°—183°. It is now found that the acacia catechin gi
an acetyl derivative, $C_{15}H_9O_6(C_2H_3O)_5$, forming colour
needles (m. pt. 158°—160°), and a tetramethyl et
$C_{15}H_{10}O_2(OCH_3)_4$, separating in colourless prisms (m.
152°—153°). The corresponding substances from
Gambier catechin (Kostanecki and Tambor, this J., 1
851) melt at 129°—130° and at 142°—143° respectiv
For acacia catechin the name "*acacatechin*" is proposed

Indigo; Constituent of Java ——. A. G. Perkin. Chem. Soc. Proc., 1904, **20**, 172.

Rawson (this J., 1899, 251) has shown that Java ind
contains a yellow colouring matter. This substa
$C_{15}H_{10}O_6$, forms yellow needles, melts at 276°—277°,
gives an acetyl compound, $C_{15}H_6O_6(C_2H_3O)_4$, which separ
in colourless needles, and melts, when crystallised f
methyl alcohol, first at 116°—120° and subsequentl
181°—182°. The colouring matter is identical w
kampherol (Chem. Soc. Trans., 1902, **81**, 587).

Indigo; Our present Knowledge of the Chemistry of —
W. P. Bloxam. Chem. Soc. Proc., 1904, **20**, 159—16

As the determination of the maximum amount of ind
obtainable at each successive stage of its preparat
("mahai") and of the quantity present in the leaf of
green plant depends on the purity of the indigotin emplo
as a standard, the author has estimated the percentag
nitrogen in the best specimens procurable, and has

und that they contain only about 90 per cent. of indigotin. nce the pure substances could not be prepared by the tion of solvents on cake indigo or the synthetical product. e crude indigo was sublimed under diminished pressure, d in this way a well-crystallised product was readily tained which gave the percentage of nitrogen required indigotin. This pure material, when sulphonated and bjected to analysis by the permanganate method, was und to give values ranging up to 300 per cent. of the ight of substance taken. As this method is used in linary technical analyses of indigo, this result explained extraordinary variations observed in the published ues given for cake indigo and the products obtained ring the successive stages of the manufacture ("mahai"). has also been found that the red substance occurring the cake obtained from plant-indigo, and known as ndirubin" or indigo-red, is not, as stated, a derivative of ligo, as it contains no nitrogen. This material, which y consist of a mixture of compounds, will be further estigated.

English Patents.

ridine Series ; Manufacture of Colouring Matters of the —— [Acridine Dyestuffs]. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 17,768, Aug. 17, 1903.

Monazo Dyestuffs ; Manufacture of ——. Soc. Anon. des Prod. F. Bayer and Co. Third Addition, dated Nov. 27, 1903, to Fr. Pat. 323,808 of Aug. 18, 1902.

The diazo derivatives of the *o*-aminophenolsulphonic acids or of their derivatives are combined with 1.5-aminonaphthol in acid solution. The resulting dyestuffs dye wool from an acid bath in various shades, ranging from violet to reddish-violet, many of which are converted into very fast blacks by an after-treatment with bichromate. The colours before chroming are usually violet or reddish-violet.

—A. B. S.

Basic Dyestuffs ; Production of New ——. Fabr. Bâloise de Prod. Chim. Fr. Pat. 340,130, Feb. 2, 1904.

The rhodamine bases of either the phthalic or succinic series are heated with halogen derivatives of fatty acids, *e.g.*, chloracetamide, either alone or in the presence of a diluent, as alcohol or glycerin. The dyestuffs can be precipitated from aqueous solution in the usual way by means of common salt.—A. B. S.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Half-Silk Dyeing ; Two-Colour Effects in ——. A. Sander. Färber-Zeit., 1904, **15**, 197.

To increase the affinity of the cotton for the dyestuffs, it is soaked for 10 minutes in a solution of sodium hydrate, 36° Tw., containing 100 c.c. of glycerin per litre, washed, acidified in a solution containing 50 c.c. acetic acid per litre, washed, and dyed. The cotton is dyed with sulphide dyestuffs at about 70° C. with the usual additions ; some casein is added to prevent the colour staining the silk. The material is then washed and the silk dyed with suitable acid or other dyestuffs.—A. B. S.

Dyeing Process ; Study of the Direct —— and of the Felting of Wool. E. Justin-Mueller. Bull. Soc. Ind. Rouen, 1904. Chem.-Zeit., 1904, **28**, Rep. 199—200.

The author regards the textile fibres as bodies of a colloidal nature, and arrives at the following conclusions with regard to their behaviour in the direct dyeing and felting processes. (1) Explanation of the effect of wetting the wool before steaming, in wool printing. Colloidal bodies only take up foreign substances when they are wet, or in the gel condition or one approximating thereto. Thus the wool takes up the dyestuff satisfactorily, only when it is wet; moreover, on steaming, the wet wool swells, and the dyestuff is converted by the moisture and steam into a dissolved condition, whereby its absorption is favoured. (2) In dyeing wool in an acid bath, the acid tends to convert the wool into the gel condition, in which it has much greater absorptive power for dyestuffs. That this is actually the case is readily perceived if in dyeing woollen yarn, the boiling is prolonged, or too much acid is added ; the yarn then becomes felted together, *i.e.*, it approaches the gel condition. (3) *Felting Process :* The wool and hair fibres are converted into the gel condition by the preliminary treatment, or by the acid or alkaline "fulling" ; then, by the mechanical action during the milling, the fibres in the gel condition become felted together. (4) The greater affinity of mercerised cotton for dyestuffs is also due to the tendency of the caustic soda to convert the cotton into the gel condition.

—A. S.

Printing Tissues; Application of the "Three-Colour Process" in Engraving Rollers for ——. M. J. Witwizki. Z. Farben- u. Textil-Chem., 1904, **3**, 237—241.

Much retouching of the negatives, or of the unetched dies, is necessary in order to obtain, along with secondary and tertiary shades of colour, pure primary hues, in printing with rollers (applying respectively red, blue, and yellow colours) engraved from negatives prepared by photographing richly-coloured designs or natural objects through light-filter colour screens (see this J., 1902, 47; 1904, 184, 560, and 604). Otherwise brownish-grey tones result. The solubility of the colour mixtures employed in tissue printing causes the prints produced to be less successful reproductions than those obtained by lithography, in which insoluble pigments are used, the colours in the fairly open parts running into one another in the former case, while in the latter case they retain to a much greater extent the detached stipple-form in which they are applied. In tissue printing the reproduction of objects in their natural colourings is less sought than their presentation in striking combinations of colour. The author agrees with Pietruszewskij (1) that natural objects cannot be properly depicted by means of three colours only; (2) that the results obtained by mixing colours optically are not identical with those obtained by mixing them in the form of pigments.
—E. B.

Dyeing [Mordanting] Process; P. Heermann's Study of the ——. L. Bloch. Bull. Soc. Ind. Mulhouse, 1904, **74**, 159—166.

The author has repeated a number of the quantitative estimations made by Heermann (this J., 1903, 361 and 623, and 1904, 57 and 438) in his study of the influences of (*a*) length of time of immersion, (*b*) temperature and (*c*) concentration of solution, and (*d*) basicity of the mordanting salt, upon the absorption of the hydrates of stannic tin, iron, chromium, and aluminium, by raw and by boiled off silk. Although the results do not exactly accord with Heermann's, the numbers obtained bear the same relations to one another. With regard to the process of mordanting (weighting) silk with stannic hydrate, which is very extensively practised in the silk-manufacturing centres, the author points out that even if it were definitely shown that an economy in tin is realised by the process of successive immersions in dilute baths, as would from Heermann's results appear to be the most advantageous method, there still remains the question whether the economy thus gained is not more than counterbalanced by the greater expense of working which is involved.—E. B.

Antimony Tannate Mordant; Half-Discharge for ——. H. Bourry. Bull. Soc. Ind. Mulhouse, 1904, **74**, 167—169.

To obtain so-called cameo effects upon cotton tissues, these are mordanted with tannic acid and tartar emetic, printed with a mixture of stannous chloride and ammonium sulphocyanide, and over-printed, during the same passage through the printing machine, with caustic soda lye, the stannous chloride mixture acting at the same time as a half-discharge for the mordant and as a resist for the caustic soda discharge. The proportions for the half-discharge mixture recommended by C. Favre and the author are 5·4 litres of starch and gum-tragacanth paste, 4 kilos. of stannous chloride, and 1·5 kilos. of ammonium sulphocyanide. The printed tissues are steamed for a short time, passed through a chalk bath, dyed with basic dyestuffs, washed, soaped, and cleared as usual. Another method for producing somewhat similar effects consists in printing the thickened caustic soda-lye discharge, steaming for 2—4 minutes, and over-printing with a thickened solution of stannous chloride. The tissues are then passed through a chalk bath and dyed, &c. A full discharge is thus obtained in the parts where the caustic soda has been applied, along with a half-discharge in the parts where the stannous salt alone has been printed.—E. B.

Dyestuffs for Wool; New Classes of —— and N
Reactions of Aldehydes. E. Noelting. Bull. Soc. I
Mulhouse, 1901, **74**, 171.

The author considers the reactions recently described l
Prud'homme (this J., 1904, 512) novel and interestin
The latter finds that a blue dyestuff is produced wh
diazotised "Magenta," decolorised with sodium hydr
sulphite, acts upon benzaldehyde. A number of oth
aldehydes tried by the author act similarly, *viz.*, the thr
nitrobenzaldehydes, the three hydroxybenzaldehydes,
tolnylaldehyde, *p*-chlorobenzaldehyde, *o*- and *p*-aminoben
aldehyde, benzaldehyde *o*-sulphonic acid, protocatechu
aldehyde, vanillin, isovanillin, methylvanillin, piperon
and phenylacetaldehyde. All these give blue dyestu
analogous to that obtained from benzaldehyde.—E. B.

Grease Oleines [Wool Oils] Distilled; Detection of Mine
Oil in ——. A. H. Gill and S. N. Mason. XXII
page 763.

English Patents.

Wool-washing Machinery; Impts. in ——. E. Lesena
Courcoing (Nord), France. Eng. Pat. 5201, March 2, 19

The application to a wool-washing machine "comprising
vat," of a mechanism consisting of combs, is claimed,
"tines" of which combs traverse the bottom of the vat a
carry the wool through the water, removing it at length
a carrier-hand, without raising it from the water in
process. The mechanism referred to, is described in det
comprising standards attached to the vat, bearings fit
in these standards and adjustable therein, shafts journal
in the bearings, sprockets carried by the shafts, cha
adapted to travel over the sprockets, and the con
depending from the links of the chains referred to. Gu
arms and blocks on the links, &c., regulate the position a
movement of the combs through the vats.—A. S.

Yarn Bleaching; Appliances for ——. W. H. Hoyle a
T. Barker, Bolton, England. Eng. Pat. 17,616, Aug.
1903.

The cotton is bleached as it comes from one of
"intermediate" machines, such as the "slubbing fram
so that it is only slightly twisted. The cotton is wou
on perforated vulcanite bobbins, which have a slit in
side, and can be slightly expanded by placing them on
slubbing frame bobbins, which have a key or rib which
into the slit. When wound, the vulcanite bobbins
removed from the frame bobbins and placed on tape
metal tubes to support them during the usual bleach
process. When the bleaching is complete, the materia
dried and the vulcanite bobbins replaced on the slubb
frame bobbins in readiness for the next spinning operatio

II.—ACIDS, ALKALIS, AND SALTS.

uric Acid Chambers; Oblong and Tangential ——. . Meyer. Z. angew. Chem., 1904, **17**, 926—929.

ply to Hartmann and Benker (this J., 1904, 488) criticisms are considered to be faulty, inasmuch as ompare sets of chambers in the two systems working totally different conditions. The Abraham circula- ppealed to so strongly by Hartmann and Benker, no exists; but whether, even in an oblong chamber, it is minant motion of the gases is very doubtful, and the considers the undirected whirls observed in a glass by Porter (and figured in this J., 1903, 476) to ent much more nearly the actual state of things. It sidered that in a tangential chamber, the Abraham tion must be practically non-existent, or there could the distribution of temperatures (wall, top, 63°; , 61°; centre, top, 56° C.) observed by the author. did it exist, the resulting cooling by the air-cooled walls of the chamber would be quite inadequate to the amount of heat required to keep the temperature to the proper optimum, with such intense working as in a modern tangential chamber. The author's con- g tubes are merely a means of getting the best work the system—a substitute, and, in the author's view, vantageous substitute, for more chamber space. The holds that a tangential chamber can be made ely higher than an oblong one; and he thinks the age of height has nothing to do with the Abraham tion, but arises from the fact that the condensed ts of acid have further to fall through the mist in the er, and thus in part aid its condensation, and in part he reaction by change of temperature and by aiding e of the gases and the mist. According to Lunge re two reactions concerned; each of these has its in- ent "temperature-optimum," and hence temperature- s through ranges embracing both of these optima will l the reaction. Height, if the author's view be correct, e of especial value where water-spray is fed into the r; but here also extreme fineness of division of ay is important.—J. T. D.

'ed Chlorides; Behaviour of Typical —— when 'ed in Hydrochloric Acid Gas. F. A. Gooch and . McClenahan. Z. anorg. Chem., 1904, **40**, 24—38.

a hydrated chloride is heated in air, the products may be, according to the temperature and the of the chloride, either the anhydrous chloride and or hydrochloric acid and the oxychloride, oxide, or de of the metal. The authors chose three typical l chlorides, *viz.*, barium chloride, $BaCl_2.2H_2O$, which gives off its water without loss of chlorine; magnesium chloride, $MgCl_2.6H_2O$, which loses part of its chlorine together with the water; and aluminium chloride, $AlCl_3.6H_2O$, which loses the whole of its chlorine in the form of hydrochloric acid together with the water; and examined their behaviour when heated in hydrochloric acid gas. They find that hydrochloric acid has no influence on the dehydration of barium chloride below 100° C. (the temperature at which the chloride is completely dehydrated). It has also practically no influence on the separation of the first 2 mols. of water from magnesium chloride, $MgCl_2.6H_2O$ (at about 100° C.); the further dehydration is, however, retarded between 100° C. and 130° C., but accelerated above 130° C. Hydrolytic dissociation of the magnesium chloride is not very considerable below 200° C. The dehydration of aluminium chloride, $AlCl_3.6H_2O$, is retarded by hydrochloric acid up to 130° C.; above this temperature, just as above 100° C. in air, water and hydrochloric acid are evolved simultaneously. These differences in the behaviour of hydrated chlorides are satisfactorily explained by the constitutional formulæ proposed by Cushman (Amer. Chem. J., **26**, 505), with tetravalent oxygen and trivalent chlorine. According to this view, the mols. of water which are not readily split off occur in the body of the complex molecule, whilst the mols. of water that can be easily removed, occur in the form of side chains.—A. S.

Arsenic Pentachloride; Non-existence of ——. W. R. Smith and J. E. Hora. J. Amer. Chem. Soc., 1904, **26**, 632—635.

Chlorine was passed into arsenic trichloride for varying times, so as to obtain products containing, for every atom of arsenic, from 3 to 9 atoms of chlorine. Since the freezing points of these products decrease quite regularly with increasing chlorine content, it is concluded that the substance obtained by passing chlorine into arsenic trichloride at − 34° C., and stated to be arsenic pentachloride, is merely a solution of chlorine in the trichloride. (See Baskerville and Bennett, J. Amer. Chem. Soc., **24**, 1070.) —T. F. B.

English Patents.

Salt; Manufacture of ——. H. Tee, Liverpool. Eng. Pat. 8117, April 8, 1903.

Impure or discoloured rock salt is melted in covered crucibles, each provided with a horizontal outlet pipe from the bottom, for running off deposited matter, and with another channel a little above the bottom, through which the purified salt may be run. Air, preferably highly heated, is blown through the molten salt for a considerable time, to oxidise the impurities. In some cases, a small proportion of lime, say from 0·1 to 1·0 per cent., is added to assist the separation of the oxidised iron. After settling, the molten clarified salt is run on to cooling floors, and granulated by suitable devices. In a modified process, the salt is melted by gases acting upon its surface, as in a metal reverberatory furnace.—E. S.

Sulphate of a Higher Oxide of Manganese; [Electrolytic] Manufacture of a ——. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 17,981, Aug. 19, 1903.

To obtain "manganese superoxide sulphate" [sulphate of the peroxide of manganese], a solution of manganous sulphate in sulphuric acid is electrolysed at a temperature of about 60° C., a lead cathode in sulphuric acid being used. The anode may be of lead; but if it be of manganese or ferro-manganese, a salt of manganese need not be dissolved in the acid, which is then taken of greater strength than in the former case. Another process consists in treating with "lead superoxide," a hot sulphuric acid solution of manganous sulphate. Or, to stated proportions of powdered potassium permanganate and of sodium sulphite, sulphuric acid of 70 per cent. is added. The required salt may be obtained in a solid form by adding, separately, powdered manganous sulphate and potassium permanganate to hot sulphuric acid of 55 per cent. On cooling, black manganese superoxide sulphate separates. —E. S.

Saturators for Sulphate of Ammonia. M. Schwab. Eng. Pat. 17,585, Aug. 13, 1903. III., page 746.

Gas; Process and Apparatus for Separating Mixtures of ——, applicable for the Separation of Oxygen and Nitrogen from Liquid Air. Soc. pour l'Exploitation des Procédés Georges Claude, Paris. Eng. Pat. 28,682, Dec. 30, 1903. Under Internat. Conv., Jan. 3, 1903.

See Fr. Pat. 328,245 of 1903; this J., 1903, 950.—T. F. B.

Nickel Hydroxide; Recovering [from Nickel-Ammonium Chloride] ——. H. A. Frasch, New York. U.S. Pat. 763,053, June 21, 1904.

Nickel-ammonium chloride is subjected to dry distillation in presence of a "dehydrating agent," the ammonia evolved is collected, the residue is dissolved in a suitable liquid, and nickel hydroxide is precipitated. Or the nickel-ammonium chloride is suspended in a solution of calcium chloride, on heating which, a portion of the nickel separates as hydroxide, and the remainder is precipitated from the separated solution by a suitable agent. Ammonia is then recovered from the cleared solution by heating it with calcium hydroxide. —E. S.

Copper, Sulphate of; Method of Making ——. G. Gin. U.S. Pat. 763,478, June 28, 1904.

See Eng. Pat. 5230 of 1903; this J., 1904, 323.—T. F. B.

VIII.—GLASS, POTTERY, ENAMELS.

Porcelains; New Results Obtained in ——. F. Garros. Comptes rend., 1904, **139**, 68—70.

The author describes the properties of "asbestos porcelain," made by firing asbestos. This is particularly suitable for sterilising filters, and the extremities of the author's sterilising bougies which are made from it, while allowing liquid to pass freely, are said to completely retain the finest solid particles, including micro-organisms of all descriptions. A glaze preparation consisting of oxide of tin has been found very suitable for glazing the ends of these surgical bougies, alkaline glazes being too fusible. The degree of porosity of asbestos porcelain can be regulated by the temperature of firing. As this rises, the individual particles of asbestos contract, and the biscuit becomes more and more porous, and at the same time the translucidity increases up to 1400° C. Between this and 1650° C. incipient fusion occurs, with consequent decrease of porosity, but increase of solidity; and above 1650° C. "Asbestos Glass" is formed. Porous plates or cells for accumulators, of asbestos porcelain, exhibit a much lower resistance than other porous vessels; and insulators have been made, standing a firing at 1500°—1600° C., by a mixture of asbestos with an alumino-alkaline paste. The asbestos predominates in the biscuit for these insulators, while the same mixture with excess of the paste forms a most suitable glaze. Such insulators are very strong mechanically, and will bear without leakage very high electrical pressures. Copper can be joined to asbestos porcelain through the medium of the glaze. A new field in ceramics has been opened up, it is stated, by this work, and the author says that, amongst other applications, he has already produced porcelains from magnesia, talc, &c.—J. T. D.

United States Patents.

Glass; Method of Drawing ——. J. A. Chambers, Alleghany, Assignor to Window Glass Machine Co., Pittsburg, Pa. U.S. Pat. 762,879, June 21, 1904.

Hollow glass cylinders are drawn by feeding molten glass into a receptacle, chilling the upper layer of the glass, and then lowering a "bait" into the bath, forming a neck and enlarged cap, after which the cylinder is drawn up. —A. G. L.

Glass Articles; Method of Drawing ——. J. A. Chambe Alleghany, Assignor to Window Glass Machine C Pittsburg, Pa. U.S. Pat. 762,880, June 21, 1904.

The glass articles are shaped by drawing them upwa from a bath of molten glass, and gradually and au matically increasing the speed of the drawing.—A. G. L.

Glass Sheets; Apparatus for Making ——. J. Broeg Greensburg, Pa. U.S. Pat. 763,633, June 28, 1904.

By means of vacuum action, glass from a bath of mol glass is caused to enter a cavity in a sectional head which an initial portion of the article to be cast is form A further portion of glass attached to the initial par withdrawn from the bath, and means are provided severing the drawn glass from the mass pendent thereon —A. G. I

Paving Flags from Destructor Slag; Manufacture of — The Engineer, July 8, 1894, page 41.

The Battersea Borough Council have installed a plant for manufacture of pavement flags from the clinker of their re destructor. The slabs are composed of two distinct layer material, an upper and thinner one, $\frac{3}{4}$ in. thick, consistin granite refuse dust and cement, and a thicker one m up of a mixture of three parts of clinker and six of cem The clinker is first ground in a mill and then mixed the cement and water. The mixture is fed into a mo given a facing of granite to add the appearance of st and subjected to a pressure of 500 tons in a special p similar in pattern to the presses used by other munic bodies. The slabs are 3 ft. by 2 ft., 2 ft. 6 ins. by and 2 ft. by 2 ft., by $2\frac{1}{2}$ ins. thick. Four unskilled men, said, can turn out 120 flags in eight hours.—A. G. L.

Gypsum; The Hydration of ——. P. Rohland. Thon Zeit., 1904, **28**, 942—944.

The author's experiments lead him to conclude that substance which, in the condition of a dilute solu increases the tension of solution (Lösungsdruck) of gyp must also accelerate its velocity of hydration.—C. S.

English Patents.

Lime and Portland Cement; Process of and Machine Preparing ——. T. Winstanley, Formby. Eng. 16,412, July 25, 1903.

For the simultaneous slaking and conveying of li number of trays are mounted on an endless conv Lime is placed on these trays, and water is then sprin on the lime, after which the trays are moved forwards to enter, one or more at a time, a chamber in which are exposed to the steam generated by the heat ev during the slaking. Steam may also be admitted outside if necessary. After leaving this chamber, the are moved forwards to a screening apparatus, into w they discharge their contents, the coarser particles b returned to undergo the same operation. The proces hydrating the free lime in Portland cement is the s except that no water is sprinkled on the trays, the ce being hydrated by moist air in the chamber.—A. G. L.

Asphalt Compositions for Floors and the like. F. N London. From Westdeutsche Thomasphosphat-W Berlin, Germany. Eng. Pat. 7343, March 28, 1904.

Powdered slag is added to melted asphalt compos filling materials, such as sand and gravel; and bin agents, such as tar, resinous products and oil, are a the whole is boiled and stirred, and then allowed to when a hard elastic product is obtained. Suitable pr tions are 80 per cent. of slag, 10 per cent. of as composition, and 10 per cent. of binding and filling mate —A. G.

cement is composed of 500 lb. of "prince metallic," . of japan, 100 lb. of white lead, 3 galls. of varnish, ls. of oil of citronelli, 10 galls. of coal tar, 1 gall. of tha, and 5 galls. of fish-oil. Ground slate may also be l.—A. G. L.

French Patent.

ks and Agglomerates from Waste Moulding-Sand of asswoorks; Manufacture of ——. Blottefière. Fr. Pat.),282, Feb. 9, 1904.

ENT is made from a mixture of 8 parts of chalk, 12 of ay, and 80 of waste glassworks sand, or of 12 parts of ., 20 of fireclay, and 68 of waste sand. The cement is d with an aggregate consisting of quartz, sandstone, ricks, &c., and the mixture subjected in moulds to aulic pressure, varying from 10 or 30 to 350 kilos. per m., according to the use to which the bricks are to it.—A. G. L.

X.—METALLURGY.

ls; Distillation of a Mixture of two ——. H. Moissan l O'Farrelley. Comptes rend., 1904, **138**, 1659—64.

URES of metals were heated in an electric furnace for og times, and the residues were analysed. In the of copper and zinc, and copper and cadmium, the and cadmium were completely expelled after very periods of distillation. In the case of copper and the same ultimate result was reached, though only a longer distillation, during which the percentage of gradually lessened. In the case of copper and tin, mixtures gradually increased in copper-content, some n-content, and some distilled without change of com- ion. (The latter alloy corresponds approximately to l's crystallised alloy, SnCu.) In the case of lead and the lead gradually lessens in amount, pure tin being ately left. A remarkable character of tin is the wide e of temperature through which the liquid metal exists; t it melts at the low temperature of 226° C., its boiling . is above those of copper and lead. The results of experiments show that the laws of ordinary fractional lation apply even in the case of the distillation of ures of metals.—J. T. D.

etals; Passivity of ——. W. J. Müller. Z. phys. Chem., 1904, **48**, 577—584.

view that the passive state of a metal is due to a ctive coating, whether of gas or of oxide, is not in dance with electrochemical theory, which does, how- support Schönbein's view that passivity is caused by teration or "state of molecular stress" in the surface e metal itself. Where a metallic anode dissolves, no sing action occurs at the anode; this phenomenon place only where the metal is passive, or where it ves as a polyvalent ion which, in solution, is con- l into one of lower valency. Passivity, then, according to the author's view, occurs in cases where the metal can form polyvalent ions, but where the potential difference requisite to cause these to enter into solution is so great that before it is reached the positive electrons themselves are torn away and enter the electrolyte, causing evolution of oxygen or oxidising actions at the anode. This represents the passivity of the noble metals, and of chromium, an element of stable passivity, which on dissolving as an anode, does so as hexavalent ions, at once decomposing water to form chromic acid and hydrogen ions. Lead under similar circumstances forms tetravalent ions, which in strong sulphuric acid dissolve to form $Pb^{iv}(SO_4)_2$, but in more dilute acid form lead dioxide, the corresponding plumbic acid being too weak to exist in the solution. The conversion of the passive into the active metal will clearly be favoured by the impact of anions on the passive anode, especially those which when discharged form substances of great activity from a purely chemical standpoint, such as chlorine and bromine; thus in hydrochloric acid, lead and iron readily lose their passivity, whilst the more stable passive chromium retains it. The recent discovery of Ruer that platinum can be dissolved or rendered active by an alternating current, especially if a continuous current be superposed, is entirely in accord with the present theory. In the case of iron, the passive ions are no doubt hexavalent, like those of chromium, as the passive iron behaves like a noble metal, and does not perceptibly dissolve, save where it has the opportunity (with strong alkali hydroxide electrolyte) of combining with hydroxyl ions to form ferric acid.—J. T. D.

Pig Iron and its Constituent Elements. H. L. Williams. Amer. Foundrymen's Assoc., June 1904.

The author discusses the effect of carbon, silicon, sulphur, phosphorus, and manganese upon the physical properties of pig iron and castings. The effect of silicon depends upon the amount of carbon present and the rate of cooling. Increase of silicon tends to soften iron containing a high proportion of combined carbon; more silicon is required in light castings than in heavy ones. Manganese increases the affinity of iron for carbon, and also reduces the proportion of sulphur. Heavy castings should contain 0·80 per cent., but light castings not more than 0·50 per cent. In chilling work, up to 3 per cent. of manganese may be used. Ordinary foundry castings should contain up to 0·50 per cent. of phosphorus, and ornamental work up to 1·25 per cent. Silicon should be added to iron containing an excessive amount of phosphorus. The amount of sulphur in iron should be low, not exceeding 0·09 per cent. in ordinary castings.—A. S.

Sulphur in Pig Iron; Irregular Distribution of ——. J. J. Porter. Amer. Foundrymen's Assoc., June 1904.

In the following table are shown the results of the determination of sulphur in pigs from a number of different foundry irons containing from 1·50 to 4·00 per cent. of silicon, about 1·50 of manganese, 0·40 of phosphorus, and about 4·00 per cent. of total carbon. The samples for analysis were taken at different depths, and the figures show the great importance of the method of sampling, and also that the point at which the percentage of sulphur is highest is not always at the top of the pig, as is generally supposed.

—	Percentage of Sulphur.				
	Pig A.	Pig B.	Pig C.	Pig D.	Pig E.
Hole No. 1 Top	0·115	0·058	0·066	0·165	0·116
„ 2.............	0·125	0·058	0·061	..	..
„ 3.............	..	0·052	0·061	..	..
„ 4.............	..	..	0·084	..	..
„ 5.............	..	..	0·059	..	..
„ 6—Bottom ...	0·040	0·030	0·029	0·175	0·103

The author also observed slight variations in the percentage of sulphur lengthwise of the pigs.—A. S.

Scrap Iron. W. G. Scott. Amer. Foundrymen's Assoc., June 1904.

The author classifies scrap iron as follows:—Light machinery scrap (gray iron); heavy machinery scrap (gray iron); stove plate scrap (gray iron); car wheel a chilled iron (gray iron); cast borings; malleable ir scrap; steel scrap; wrought iron scrap; and mix scrap; and gives general average analyses of the differ kinds.

——	Silicon.	Sulphur.	Phosphorus.	Manganese.	Carbon.	Graphite.

* Combined carbon.

—A. S.

Steel; Heat Treatment of ——. W. C. Roberts-Austen and W. Gowland. Engineering, 1904, **77**, 118—122, 138—142, 170—176, 184—189, 202—203, 205—208, 239—243, 289—292; Science Abstracts, 1904, **7**, B, 476—477.

Specimens of commercial rolled round bars of steels containing 0·130, 0·180, 0·254, 0·468, 0·722, 0·871, 0·947, and 1·306 per cent. of carbon, respectively, were tested, after being subjected to the following heat treatments:—(*a*) Annealing for ½ hour at 620, 720°, 800°, 900°, and 1100° C.; (*b*) soaking for 12 hours at 620, 720°, 800°, 900°, and 1200° C.; (c) quenching in water at 720°, 800°, 900°, and 1200° C.; (*d*) quenching in oil at 720° C.; (*e*) quenching in oil at 720°, 870°, and 1000° C., and reheating to 350° C.; and (*f*) quenching in oil at 800° and 900 C., and reheating to 600° C The tensile test pieces were ½ in. and $\frac{7}{16}$ in. diameter, elongation being taken over 2 in.; the "elastic limit" was deduced from autographic stress-strain diagrams. The results are given in a series of tables and of curve-diagrams showing the change of breaking-stress, "elastic limit," elongation, and contraction, with the percentage of carbon. Stress-strain diagrams are given for the annealed specimens and for those quenched in water. After annealing at 620° C., the 0·871 per cent. carbon steel showed a lower "elastic limit" than either the 0·722 or 0·947 per cent. specimens, although it gave the greatest breaking-stress both in this condition and as rolled. In the 0·947 and 1·306 per cent. carbon steels, the breaking-stress was diminished by annealing at 800° C. and to a less extent at 900° C., owing to segregation of cementite. All the high-carbon steels were more or less "burnt" when subjected to annealing and soaking at and above 900° C., probably owing to decomposition of cementite into ferrite and amorphous carbon. The heating-curve of a sample of cementite prepared by Abel's method, showed that two changes occurred at about 1100° C.; the residue, after the heating, contained free carbon. The following conclusions are drawn from the stress-strain diagrams. The amount and regularity of elongation at the yield-point are dependent upon (1) the non-homogeneity of the steel; it is always greater when the steel is made up of two constituents, such as ferrite and pearlite, or pearlite and cementite, than when it contains only a single constituent; (2) the annealing of the bar at a temperature below Ar_1; (3) the amount of ferrite present. Secondly, the amount of elongation which immediately precedes fracture varies with the homogeneous or non-homogeneous character of the steel, as in the first case. With similar thermal treatment, the steels containing most ferrite show greatest elongation. Annealing at 620° C. generally causes an increase of the elongation. The elongation is usually *nil* when the bar is composed of martensite, and always when "burning" has occurred.

—A. S.

Cementation of Carbon Steels and of Special Steels. L. Guillet. Comptes rend., 1904, **138**, 1600—1602.

The potassium carbonate contained in wood charcoal is a factor in cementation effected by this substance; and the diminution in the speed of cementation observed aft some time is due to the exhaustion of the potassium ca bonate by volatilisation. Barium carbonate has a simi influence to potassium carbonate, but does not volatili and the cementing power of a mixture of charcoal a barium carbonate remains constant. It is a matter indifference whether air or nitrogen fills the cementatio box. The speed of cementation, with a given mixtur depends on the composition of the steel. Manganes chromium, tungsten, and molybdenum (elements which ca substitute a portion of the iron in cementite) accelerate th action, as compared with that in the case of a carbon stee while nickel, titanium, silicon, aluminium, and tin (elemen which exist dissolved in the iron) retard it. The surface bars of steel which had been treated in the cementatio box was analysed immediately after cementation, and aft intervals of six and 12 months; the carbon contents we respectively, 1·35, 1·05, and 0·85 per cent. Thus γ-iro dissolves carbon even at the ordinary temperature; and doubt after a sufficient interval of time these bars wou have become homogeneous throughout. (See also this J 1903, 798.)—J. T. D.

Aluminium; Alloys of —— *with Magnesium and wi Antimony.* H. Pécheux. Comptes rend., 1904, **13** 1606—1607.

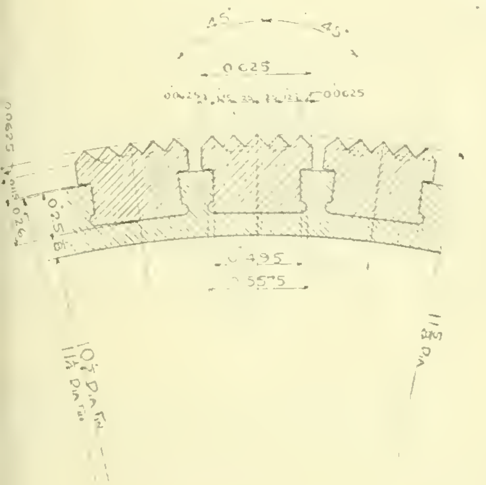
Aluminium-Magnesium.—While the author, operating b fusion in a crucible in presence of air (this J., 1904, 716 could not obtain stable alloys containing less than 65 p cent. of aluminium, Boudouard had formerly obtained n only $MgAl_4$ (81 per cent.) and $MgAl_2$ (70 per cent.), b also MgAl (54 per cent. of aluminium). The last tw however, were obtained by operating in sealed tubes fro which air was excluded.

Aluminium-Antimony.—Aubel has obtained the allo SbAl, melting at 1080° C.; Guillet the alloys SbAl, SbAl $SbAl_4$, and $SbAl_{10}$, which all ultimately fall to powder; an Gautier has studied the curve of melting-points, witho obtaining definite alloys. The author has now obtaine four definite alloys, $SbAl_{30}$, $SbAl_{35}$, $SbAl_{38}$, and $SbAl_{40}$, a melting between 750° and 760° C., and having, respe tively, at 23° C., the densities 2·736, 2·700, 2·662, an 2·592. They all expand on solidifying. They are n brittle, though they file badly, have a coarse-grained vesicul fracture, do not oxidise at the temperature of casting, d not decompose water in the cold, even after filing (SbAl decomposes it at 100° C.), but are attacked by mineral acid and by strong solution of potassium hydroxide.—J. T. D.

Zinc Ore; Magnetic Concentration of —— *in Virgini* C. Q. Payne. Eng. and Mining J., 1904, **77**, 1001—1003.

The material consists of limonite iron ore in conjunctio with hydrated silicate of zinc (calamine) and carbonate zinc (smithsonite). The ground ore is mixed with 8—1 per cent. of coal slack and roasted in a cylindrical rotatin reverberatory furnace. After cooling, the roasted materia is passed over a double cylinder magnetic-separator. Th nders are seamless drawn steel tubes, 16 ins. diameter, about $\frac{1}{16}$ in. thick, each containing a bipolar electronet, the curved face of each pole, 10 ins. wide, being ed close to the wall of the cylinder, along which it pies a certain arc. The upper cylinder is run at a d of 200 revolutions per minute, and produces a clean entrate containing about 48 per cent. of iron. The rial not attracted by the top cylinder passes on to the r one, where it is separated into clean zinc ore, and a in amount of iron "middlings," which are passed igh the separator again.

or the separation of limonite and calamine without ious roasting, a machine is used the design of which is d on the author's discovery that in the separation of feebly etic minerals, such as limonite, garnet, &c., a very rful or dense magnetic field is less effective than one in h the position of the lines of force are so controlled that t differences of magnetic density are established therein.



separating cylinders (see figure) of the machine are of non-magnetic material having a high electrical tance, and are provided, on their surface, with a series ooves, in which are fitted thin, soft steel plates having ed edges. When the cylinder is made to revolve in a etic field, the construction of its surface largely supes Foucault currents, which would cause resistance to otion, whilst the toothed edges of the plates cause the of force to be so divergent that the particles of limonite e attracted and held whilst in the field. The ore, after ; very finely ground, is made to pass through two ssive magnetic fields, arranged vertically. The upper is formed in an air-gap between two stationary electroets, each of which is placed inside a cylinder, the top eing the separating cylinder, and the lower one, of , the feed-cylinder. From the latter, the magnetic les, when brought into the field, are attracted by eparating cylinder, and are conveyed over a division The lower field is somewhat more powerful than pper one, and allows of the separation of very feebly etic ore particles or "middlings." It is established in -gap between two opposing pole-pieces, one of which nected with an external electro-magnet, and the other one contained within the separating cylinder. The ial is fed directly upon the upper part of the sepa- cylinder, and, by means of a non-magnetic guide- connected with the outer pole-piece, is conveyed into ld, which is situated just below the horizontal diameter cylinder.—A. S.

Gold-Mining: Application of Modern Theories of the Flow of Water. H. S. Hele-Shaw. J. Chem. Met. and Min. Soc. of S. Africa, May 1904, 420—426.

By means of ingenious experiments the author sets forth "a great and fundamental truth, *viz.*, that not only does water flow with turbulent motion, which we can expect in a viscous liquid, but" under certain conditions "it can be made to flow with the stream-line motion of a perfect and frictionless liquid." He also shows "that in all the operations of gold-mining, it flows with both these movements, the former in the general mass of liquid, the latter on the surface or skin containing vessel or channel."—J. H. C.

Cyanide Solutions; Determination of Working Constants in ——. G. W. Williams. J. Chem. Met. and Min. Soc. of S. Africa, May 1904. Part II., 412—419. (For Part I. see this J., 1904, 683.)

Methods for determining free cyanides, "protective alkali," carbonates, lime, sulphocyanides, gold, silver, zinc, cyanates, and sulphides are discussed, results of many experiments are detailed, and some improvements are suggested on methods previously described.—J. H. C.

English Patents.

Crucible Furnaces. M. Harvey, Walsall. Eng. Pat. 23,909, Nov. 4, 1903.

A portable furnace containing a crucible is fixed in an outer casing which forms a blast chamber, so that the contents can be poured without removing the crucible. The outer casing is provided with trunnions and is mounted on a carriage. Means are provided for leading the blast into the furnace, for charging the fuel, for tilting the whole, and a spout for pouring.—W. H. C.

Heavy Metals; Process for the Extraction of —— *by Means of Chlorine.* J. Savelsberg, G. Wannschoff, and Allgem. Elektro-Metallurgische Ges., Papenburg-on-the-Ems, Germany. Eng. Pat. 18,763, Aug. 31, 1903.

United States Patents.

Electrically Extracting Essential Oil; Process and Apparatus for ——. G. D. Burton, Boston, Mass., Assignor to Boston Leather Process Co., Portland, Me. U.S. Pats. 763,151-2, June 21, 1904.

The essential oil is extracted and distilled off by immersing bark, or other vegetable matter in a suitable menstruum through which an electric current is passed to raise the temperature to the desired extent. The apparatus is in the form of a closed still provided with connections for the electric current and with a condenser. The material to be treated, is contained in porous bags and is surrounded by the extracting solution which serves also to conduct the current.—R. S. H.

Treating Sewage; [Electrolytic] Apparatus for ——. W. J. Schweitzer. U.S. Pat. 763,026, June 21, 1904. XVIII. B., page 758.

(*B.*)—ELECTRO-METALLURGY.

Electro-Plating; Composition of Baths for ——. R. Namias. Monit. Scient., 1904, **18**, 487—488.

The following baths are recommended:—

Nickel.—Forty grms. of crystallised nickel sulphate, 25 grms. of ammonium chloride, 10 grms. of boric acid, and 10 grms. of citric acid per litre.

Silver.—The cyanide bath is made up to the formula $AgCN, 2KCN$. As it becomes alkaline in use, a little potassium cyanide and mono-potassium citrate are added from time to time.

Copper.—Solution A:—30 grms. of normal copper acetate, 30 grms. of sodium sulphite, 5 grms. of ammonium carbonate, and 500 c.c. of water. Solution B:—35 grms. of potassium cyanide and 500 c.c. of water. A and B are mixed warm.

Brass.—Fifty grms. of copper acetate, 25 grms. of zinc chloride, 250 grms. of sodium sulphite, 35 grms. of ammonium carbonate, and 100 grms. of potassium cyanide in 3 litres.

Gold.—To gold chloride solution ammonia is added, the precipitate is dissolved in 1 per cent. potassium cyanide, and the solution boiled. One grm. of gold per litre is the minimum.

Platinum.—A solution of potassium chloroplatinate, containing not less than 2 per cent. of the salt.

Iron.—Forty grms. of ferrous sulphate, 100 grms. of ammonium chloride, 100 grms. of ammonium citrate, and 1 litre of water. The citrate prevents anodic deposition of basic salt.—W. A. C.

Steel; "Ageing" of Sheet ——. T. S. Allen. Elec World and Engineer, 1903, **41**, 1048—1049. Scien Abstracts, 1904, **7**, B, 469.

The results of the author's tests on commercial sheet st for armature construction are given in a series of curv It was found that "ageing" takes place in all sheet st subject to a varying temperature, and especially in ste having a high initial hysteresis. Most of the samples w high initial hysteresis examined, "aged" at first, but af periods varying from 20 to 160 days, at a mean temperat of 93° C., the hysteresis showed a tendency to come do to near the initial value. The author concludes from results of the tests that annealing is useless for armat iron.—A. S.

Nickel Cathodes. D. H. Browne. Electrochem. I 1903, **1**, 348—349. Science Abstracts, 1894, **7**, 461—462.

The tendency of electrolytically deposited nickel to cr and curl off the cathode in a shape resembling shavings wood, is attributed to local irregularities in the electrol Artificial circulation of the electrolyte, the employment a uniform current-density throughout the electrolysis, the use of a graphitised cathode of rolled block tin recommended. Good results, so far as the flexibility the deposited nickel is concerned, were obtained un the following conditions:—Electrolyte, 70 grms. of nic chloride and 180 grms. of sodium chloride per litre; t perature, 70° C.; current density, 100—200 ampères sq. m. With regard to the curvature of the deposit, it observed that the curling was always in the direction of anode, and around the longer axis of the cathode. By use of a cathode plate of reversed curvature, it is st that the deposit when stripped from the backing, "spr into a perfect plane surface."—A. S.

Metal Extraction; Electric —— from Ores by Mean Insoluble Electrodes. S. Laszczynski. Elektroch Zeits., 1904, **11**, 54; Chem.-Zeit., 1904, **28**, Rep. 19

In cases in which the anodic oxidation of a cation is t prevented, the author surrounds the insoluble cat with a closely-fitting layer of porous material or fabric. —T. H. 1

Molybdenum; New Carbides of ——. H. Moissan K. Hoffmann. Comptes rend., 1904, **138**, 1558—156

Cast molybdenum, carbon, and excess of metallic alu ium, are heated together in the electric furnace; reaction must not be carried on too long, or the tempera (which is kept down by the volatilisation of the alumin will rise too high. The fusion is treated successively solution of potassium hydroxide, dilute sulphuric acid, concentrated hydrochloric acid, and the graphite separ mechanically. There remains a molybdenum carbid formula MoC; very hard, not decomposing water in cold, or steam at 600° C. It seems analogous to Willi tungsten carbide. Possibly it plays a part in the forma and behaviour of tungsten steels.—J. T. D.

English Patent.

Electro-Deposition of Metals on Aluminium, Alloy Aluminium, and other Metals. F. W. Croucher, F Hants. Eng. Pat. 13,182, June 12, 1903.

In order to ensure the adhesion of the deposited metal aluminium is prepared by treatment with a large numb special solutions intended to clean its surface, *viz.*, w oil soap, hydrochloric acid, potassium cyanide, phosp acid, sulphuric and nitric acids, potassium cyanide, am nium cyanide, ammonium chloride, and cyanide or bichl of mercury, and caustic potash; it is then passed thr suitable "striking" baths before being placed in depositing vat.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

rd ; Crystals obtained in the Belfield Test for ——. I. Kreis and A. Hafner. Z. Untersuch. Nahr.- u. enussm., 1904, **7**, 641—669.

e difference between the form of the crystals deposited n an ethereal solution of lard and from a solution of f fat was attributed by Hehner and Mitchell (Analyst, 328) to the presence of a greater proportion of stearic l in the beef crystals. The authors, however, have not n able to confirm the observations of Hehner and chell as to the gradual formation of needle-shaped stals from lard on recrystallisation, but invariably ained the chisel-shaped crystals. Their lard crystals ted at 45 to 47° C., then solidified as the temperature e, again becoming liquid at 61° C. The crystals from f fat melted at 43° and 58·5° C. After repeated crystaltion from ether the melting points of the crystals ame constant, at the temperatures recorded for the ed glycerides described in the author's former paper s J., 1903, 1136). The synthetical glycerides prepared lescribed before, were identical in every respect with these ural glycerides, and the authors therefore conclude that ir explanation of the difference between lard and mutton beef fat crystals in the Belfield test is that the latter sist of (impure) palmito-distearin, and the former of tadecylo-distearin. Pure heptadecylic acid, $C_{17}H_{34}O_2$, n the lard crystals melted at 55·5° C. It was more ible in 95 per cent. alcohol than either stearic or mitic acid, 100 c.c. dissolving 0·970 to 0·972 grm. at C.—C. A. M.

s ; Decolorisation of —— with Aluminium Magnesium Iydrosilicate [Florida Fullers' Earth]. Hirzel. Chem. Rev. Fett- u. Harz-Ind., 1904, **11**, 116—118, 145—146.

LLERS' earth is found in alluvial deposits of ½ to 4 metres thickness in the interior of Florida. It usually occurs ve a layer of sand, and beneath a layer of ½ metre humus and ½ to 2 metres of plastic clay. When bly dug out it is a moist greenish mass, which has e freed from clay and sand, and dried in thin layers ore it can be sold. During the drying process it loses ut 50 per cent. in weight, and leaves a white friable mass ch still contains from 15 to 18 per cent. of water. ally it is ground in a mill and sorted into different grades sifting. The commercial product is a neutral white or yish or yellowish white powder, which when dry is remely hygroscopic. Its average composition is as ows :—Silica, 56·53 ; alumina, 11·57 ; magnesia, 6·29 ; oxide, 3·32 ; calcium oxide, 3·06 ; water, 17·95 ; and alis, &c., 1·28 per cent. It is usually necessary to ydrate Florida fullers' earth before use. This is best e in a special apparatus from which air is excluded ar as possible, the powder being heated with continual tation at 300° to 500° C., until it assumes a greyish-blue de. This removes both the absorbed water and the mically combined water of hydration. For many pures it is sufficient to expel absorbed water by heating the vder at 120° C., though the product is a much less ective bleaching agent than that roasted at the higher perature. Preliminary experiments should be made h the oils or fats to be bleached, in order to determine most suitable temperature in each case. Thus, light eral oils, such as lamp petroleums and vaseline oil, are apletely decolorised at 12°—17° C., whilst 60° to 80° C. he most suitable temperature for finer vegetable oils, and to 125° C. for solid fats. In the case of the heaviest eral oils, such as cylinder oil, bleaching can only be cted at higher temperatures (140°—150° C.). The ount of earth required also varies with the different oils, e requiring 3 to 5 per cent., others 7 to 10 per cent., ilst others again need as much as 15 to 20 per cent., or re. Hard paraffin, after preliminary treatment with huric acid &c., is completely bleached by means of only to 2 per cent. of the earth. Cocoa nut oil, palm kernel mustard seed oil, and olive oil require 2 to 3 per cent., whilst rape oil arachis oil, cottonseed oil, and linseed oil need a greater proportion—usually 5 to 10 per cent. The earthy flavour left in edible oils after treatment with the fullers' earth can be removed by a short treatment with 10 per cent. of a 10 per cent. solution of sodium chloride, or with 1 to 1½ per cent. of powdered dry sodium bicarbonate. The method of treatment has also great influence on the results. The filtration method is simple and widely employed, but is open to the objections that filtration through a layer of 430 mm. is slow, that only the coarser grades of earth can be used, and that some method of heating the oil or fat during the filtration is necessary. In methods by mixing, the oil, brought to the right temperature, is mechanically mixed for about 20 minutes with the requisite proportion of earth, and then pressed in a filter press. The earth left in either process contains about 80 per cent. of its weight of oil. In the case of linseed or other drying oils the powder can be used in oil paints, whilst in the case of other oils the earth can be extracted with a suitable solvent. The oil thus obtained is of a dark colour, but can be bleached by means of more Florida earth. The residual earth can be regenerated by heating it to 400°—500° C., and the dark grey to black product thus obtained can be used again for bleaching purposes, preferably after the addition of 15 to 20 per cent. of fresh earth.—C. A. M.

Bating or Puering Skins; Process for ——. O. P. Amend, New York. U.S. Pat. 763,347, June 28, 1904.

Hides or skins are treated with a solution of an ammoniacal salt, small quantities of an acid such as hydrochloric acid being added at intervals so as to re-form the salts.
—R. L. J.

XV.—MANURES, Etc.

Sodium Nitrate on the Constitution of the Soil; Effect of the long-continued Use of ——. A. D. Hall. Chem. Soc. Proc., 1904, **20**, 154.

After a review of the results of the mechanical analysis of Rothamsted soils, it was observed that those which had been manured with sodium nitrate every year, gave abnormal results; a further series of fifteen soils was examined drawn from each of the Rothamsted fields where plots with and without sodium nitrate occurred. In general, the use of sodium nitrate has resulted in a lower proportion of "klay" being left in the surface soil. This result was most manifest in the mangel field, where cultivation is frequent, and was not apparent at all in the grass field, where the turf protects the soil from the washing action of the rain. The removal of the finest particles from the surface soil is attributed to deflocculation induced by the use of sodium nitrate and followed by the washing of the finest particles into the subsoil. This hypothesis is confirmed by chemical analysis of the "klays" separated in the mechanical analysis of some of the subsoils, which were found to be richer in fine particles beneath the soils receiving nitrate, and by the condition of the same soils in the field, which showed every evidence of deflocculation.

Soil Acidity; Comparison of Methods for the Determination of ——. F. P. Veitch. XXIII., page 762.

XVI.—SUGAR, STARCH, GUM, Etc.

Diffusion Juice; Cold and Hot Liming of ——. Prangey and de Grobert. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 1241—1247.

An examination of the properties of the principal constituents of the non-sugar portion of beetroot juice, leads to the conclusion that the raw juice should not be heated before carbonating, as, in presence of large additions of lime, there is danger of causing the melassigenic substances which have been rendered insoluble in the scums to re-enter into solution. The only objection to heating the unlimed juice is that the slight acidity (due chiefly to asparagine) may cause inversion, but this may be easily overcome by the addition of a very small quantity of lime to neutralise the acidity. When normal beetroots, which have been gathered only a short time, are being worked, erroneous procedure does not cause serious trouble, but it is quite otherwise if the roots have undergone alteration during storage.—L. J. de W.
