

THE J. PAUL GETTY MUSEUM LIBRARY

AN

ILLUSTRATED WEEKLY MAGAZINE,

FOR THE

Architect, Engineer, Archaeologist, Constructor, & Art-Lover,

CONDUCTED BY

GEORGE GODWIN, F.R.S., F.S.A.

*Honorary Member of various Societies; Author of "History in Ruins," "Town Swamps and Social Bridges,"
"Another Blow for Life," &c.*

"Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruit, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private princedom, may, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned."

"Architecture can want no commendation, where there are noble men, or noble mindes."—SIR HENRY WOTTON.

"Our English word To BUILD is the Anglo-Saxon Bylðan, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places."—DIVERSIONS OF PUBLEY.

"Art shows us man as he can by no other means be made known. Art gives us 'nobler loves and nobler cares,'—furnishing objects by the contemplation of which we are taught and exalted,—and so are ultimately led to seek beauty in its highest form, which is GOODNESS."

VOLUME FOR 1867.

ILLUSTRATIONS.

ACADEMY OF DESIGN, National, New York; by Mr. P. B. Wight, Architect, 29; Carved Capitals, &c., 21; Andernach Church, 908; Apollo as Mithras,—Sun Worship, 249; Architecture, Domestic, Ancient, Cologne, 44; Architecture, Nagas in Cambodia,—the Temple of Nakhon Wat, 224; Architecture, Terra Cotta, of North Italy, 510; Arques, Normandy, Castle of, Plan, 667; Albert Hall of Arts and Sciences, the Royal, Kensington, 368; Albert National Memorial, Hyde Park, wrought metal Spire, 590; Cross on a large scale, 591; Altar erected by the Fourth Cohort of the 4th Leg., 243; Altar-table and Reredos, Westminster Abbey; Professor G. G. Scott, R.A., Architect, 321; Altar to Many Gods, found at Meryopt, 242; Altar to the Unknown God, Antiochians, 242; Church, in the Cathedral, and in the Church of St. Severin, Erfurt, 471; Angers Cathedral, 663; Ancion Mart, Tokenhouse Yard, London; by Mr. G. Somers Clarke, Architect, 601;

BANK OF AUSTRALIA, the London Chartered, Sydney; Mr. J. F. Hilly, Architect, 97; Plans, 89; Barry, the late Sir Charles, Works of, 572; Bell Tower of Rathhaus, Rothenburg, Bavaria, 470; Boiler House and Shaft, British Department, Paris Exhibition, 234; Boxgrove Church, Hereford; Mr. G. G. Scott, Architect, 451; Brompton Cemetery, a Tomb in, 10; Bronze and Iron Work, Ancient, 331; Bronze Measure, Ancient, Ochenlurch, A.D. 143, 820; Buildings designed for Sefton Park; see "Sefton Park";

CAPITALS, Carved; see "Carved Capitals"; Carlton Club House, Junior, Pall Mall; Mr. David Brandon, Architect, 531; Plans, 530; Carved Capitals, &c., of the National Academy of Design, New York, 21; Carved Pupit, St. Mary's Church, Taunton; Mr. R. Ferrey, Architect, 608; Carving, Details of, Rochester, West Hants, Sussex; Messrs. G. & H. Godwin, Architects, 350; Castle of Arques, Normandy, Plan of, 507; Cathedral, Angers, 968; Cathedral, Linz, on the Danube, Plan of, by Mr. Stadtz, Architect, 802; Cathedral Perch, Angular, Rathbon, 699; Cathedral, Rathson, as proposed to be completed; Mr. Demizinger, Architect, 501; Cemetery, Brompton, a Tomb in, 10; Cemetery, March, New Isle of Elm, Cambridge; Mr. G. W. Stephenson, Architect, 623; Chapel Memorial, Yale College, Connecticut; Messrs. Vaux, Withers, & Co., Architects, 748; Chartered Bank of Australia, the London, at Sydney; Mr. J. F. Hilly, Architect, 87; Plans, 98; Chateau Gaillard, Plan of, 644; Church, Andernach, 908; Church Doorways, as proposed to be completed; Mr. Demizinger, Architect, 909; Church, Fünfhaus, near Vienna; Herr Friedrich Schmidt, Architect, 609; Church Institute, Leeds; Messrs. Adams & Kelly, Architects, 41; Church, St. Saviour's, Aberdeen Park, Highbury; Mr. W. White, Architect, 501; Church, St. Saviour's, American Park, Highbury, Interior View of, 550; Churches, Single Spon, Ancient,—Angers Cathedral, Notre Dame de la Colature, Le Mans, 663; Churches, Modern, German:—Fünfhaus Church, near Vienna; the Lazaristenkirche, Vienna; Herr Friedrich Schmidt, Architect, 609; Cle 2 Tower of the Rathhaus, Prague, 113; Cle 2 Buildings, Maxine Hall and, Dublin; Mr. Edward Holmes, Architect, 713; Plans, 712; Club House, the Junior Carlton, Pall Mall; Mr. David Brandon, Architect, 531; College Chapel, Yale, Memorial, Connecticut; Messrs. Vaux, Withers, & Co., Architects, 748; College, International, Spring Grove, Middlesex; Messrs. Norton & Masey, Architects, 131; Plans, 130; College, London of International Education Society; see "College, International, Spring Grove";

Colony, St. Saviour's, Ardingly, Sussex; Messrs. Slater & Carpenter, Architects, 837; Concrete Cottages, Selling, Kent; Mr. B. Adkins, Architect, 74;

Cork Warehouse, Lanct-street, Southwark; Mr. Joseph S. Mory, Architect, 78; Courthouses, New Greenock, Scotland; Messrs. Peddie & Kincaid, Architects, 41; Messrs. Fennie, of India Office, Westminster; Mr. M. Digby Wyatt, Architect, 783; Court, Inner, of India Office,—part of Upper Story enlarged, 782; Court, New Supreme, Auckland, New Zealand; Mr. Edward Ramsey, Architect, 170; Courts of Justice, see Courts of Law; Courts of Law, the proposed, design for, 112; Courts of Law, the proposed, design for, in the Strand, 151; Courts of Law proposed, design for; by Mr. E. M. Barry, A.R.A., 191; Courts of Law, the proposed, design for; by Mr. Lockwood, View in the Strand, 205; Courts of Law, the proposed, design for,—Mr. Lockwood's Key Plan, 208; Courts of Law, the proposed, design for; by Mr. G. G. Scott, R.A.,—View in Strand, 225; Court, Raphael Brandon, Architect,—The Strand and West Fronts, 238; Courts of Law, the proposed, design for; by Mr. W. Burgess, Architect, 311; Courts of Law, the proposed, design for; by Mr. G. E. Street, A.R.A., 845; Cross on wrought-iron spire of Albert National Memorial, Hyde Park, 590; Crags, Wilford's, Hesham, 243;

DARNICK TOWER,—South East view, 730; Decorations, mural, at Sir Walter Trevelyan's, Wallington, 919; Design for laying out Sefton Park, Liverpool; by Messrs. Edward André and Lewis Inquest, 829; buildings for, 627; Design for house, on a large scale, 591; Design for proposed Law Courts; see "Law Courts"; Design for proposed National Gallery; see "National Gallery"; Design, the National Academy of New York; Mr. P. B. Wight, Architect, 29; carved capitals, &c., 21; Domestic Architecture, Ancient, Cologne, 44; Doorways, Church, Gorman, 79;

ELMDALE HOUSE, Clifton Downs, Bristol, Messrs. George & Henry Godwin, Architects, 765; plan, 764; Exchange, Home and Mail, Southwark Street, Borough; Mr. R. H. Moore, Architect, 731;

ESCADE of the new Opera house, Paris, M. Garnier, Architect, 748; Faint, St. Thomas's Church, Dudley, 680; Fiest, the River, 570; Font, Lambung Cathedral, 908; Fonts, Modern,—St. Mary's, Acton; Christ Church, May Fair, London; Messrs. Penniss, Architects, 260; Fishbans Church, near Vienna; Herr Friedrich Schmidt, Architect, 909;

GAILLARD, Chateau, Plan of, 644; Gates, the Norwich,—Paris Exhibition, 683; Gallery, National, the proposed, design for; by Mr. E. M. Barry, A.R.A., 371; Plan of Principal Floor, 370; Genesis (The), of the Roman Camp, 243; Grey Towers, Nantrop; Mr. John Ross, Architect, 923; Ground Plan, 924;

HALL, Masonic, and Club Buildings, Dublin; Mr. Edward Holmes, Archt., 213; Plans, 712; Hall of Arts and Sciences, the Royal Albert, Kensington, 363; Hop and Malt Exchange Building, Southwark-street, Borough; Mr. K. H. Moore, Architect, 731; Hospital Ventilation, Arrangements for, Chertsey Union, 330; Hotel, Proposed, opposite the entrance to the Central Park, New York; Messrs. Bryant & Gilman, Architects, 571; House, Barbican; Mr. Robert Walker, Architect, 159; House, Elmdale, Clifton Downs, Bristol; Messrs. Godwin, Architects, 765; Plan, 764; Hurricane, the "Solent" in the, 905; Hyde Park Corner as it is and as it might be, 238;

INDIA OFFICE, Westminster, Inner Court of; Mr. M. Digby Wyatt, Architect, 783; India Office, Inner Court of,—part of Upper Story enlarged, 782; Institute Schools, Kirkdale, for the Parish of Liverpool, Messrs. J. J. Pettus & Son, Architects, 310; Plan of Ground Floor, 310; Institute, Church, Leeds; Messrs. Adams & Kelly, Architects, 41; Institute, Church, Leeds,—Interior of Lecture Hall, 60; International College, Spring Grove, Middlesex; Messrs. Norton & Masey, Architects, 131; Plans, 130; International Memorial Church, Kingsland-road, London; Mr. Henry Fuller, Architect, 431; Plan of Church and Lecture Room, 430; Iron and Bronze Work, Ancient, 331; Iron Work, Details of, Rochester, West Hants, Sussex, 350;

JUNIOR CARLTON CLUB HOUSE, Pall Mall; Mr. David Brandon, Architect, 531;

LAW COURTS, the proposed, Plans of, 112; Law Courts, the proposed, Design for, by Mr. Alfred Waterhouse, Architect,—View in the Strand, 151; Law Courts, the proposed, Design for, by Mr. G. G. Scott, R.A.,—View in the Strand, 225; Law Courts, the proposed, Design for,—Mr. Lockwood's Key Plan, 208; Law Courts, the proposed, Design for, by Mr. W. Burgess, Architect, 311; Law Courts, the proposed, Design for, by Mr. J. F. Hilly, Architect, 97; Plans, 98; Law Courts, the proposed, Design for, by Mr. Raphael Brandon, Architect,—the Strand and West Fronts, 238; Law Courts, the proposed, Design for, by Mr. W. Burgess, Architect, 311; Lazaristenkirche, Vienna; Herr Friedrich Schmidt, Architect, 908; Leeds New Mechanics Institution and School of Art; Mr. Cuthbert Brodric, Architect, 696, 697; Linz Cathedral, on the Danube, Plan of; Mr. Stadtz, Architect, 802; London Chartered Bank of Australia, Sydney; Mr. J. F. Hilly, Architect, 97; Plans, 98; London University, Burlington Gardens; Mr. Pennethorne, Architect, 835; Plan of Ground Floor, 834;

MALT AND HOP EXCHANGE, Southwark-street, Borough; Mr. R. H. Moore, Architect, 731; Messrs. Elmdale, Clifton Downs, Bristol; Messrs. George & Henry Godwin, Architects, 765; Plans, 764; Mansion, Grey Towers, Nantrop; Mr. J. Ross, Architect, 923; Mansion, Northornham, Battle, Sussex; Messrs. Eubenson, Brock & Webb, Architects, 41; Plan of Ground Floor, 410; Mansion, Parkfield, Pershore road, Birmingham; Mr. Cranston, Architect, 873; Mansion, Rochester, West Hants, Sussex; Messrs. George & Henry Godwin, Architects, 277; Plans, 276; Details of Carving and Iron Work, 380; March New Cemetery, Isle of Ely, Cambridge; Messrs. G. W. Stephenson, Architects, 682; Market, Smithfield Meats and Poultry—Central Roadway; Mr. Horace Jones, Architect, 251; Mart, Auction, Tokenhouse Yard, London; Mr. G. Somers Clarke, Architect, 891; Masons Hall, 31; Clark Buildings, Dublin; Mr. Edward Holmes, Architect, 713; Plans, 713; Mansion, Ancient Broken, Ochsenfurth, A.D. 1483, 829; Meat and Poultry Market, Smithfield—Central Roadway; Mr. Horace Jones, Architect, 251; Mechanics' Institution and School of Art, Leeds, new; Mr. Cuthbert Brodric, Architect, 696, 697; Memorial Chapel, Yale College, Connecticut; Messrs. Vaux, Withers, & Co., Architects, 748; Memorial Church, International, Kingsland-road, London; Mr. Henry Fuller, Architect, 431; Plan of Church and Lecture Room, 430; Messrs. Goddard & Son, Architects, designed by Messrs. Goddard & Son, Architects, 351; Metal Work, wrought, in the Paris Exhibition;—Spire of the National Memorial of the Prince Consort,—and the Cross, on a large scale, 591; Mile Castle, Castle Nick, 242; Mortuary House, Parish, and Inquest Room, Ground Floor, 410; Mural Decorations at Sir Walter Trevelyan's, Wallington, 919; Museum of H.R.H. the Duke of Saxe Coburg Gotha, in Gosh; Mr. Franz Neumanns, Architects, 491; Plan, 490;

NAGA ARCHITECTURE in Cambodia,—the Temple of Nakhon Wat, 224; National Academy of Design, New York; Mr. P. B. Wight, Architect, 29; Carved Capitals, &c., 21; National Gallery, the proposed, design for; by Mr. E. M. Barry, A.R.A., 371; Plan of Principal Floor, 370; Normanham, Battle, Sussex; Messrs. Habershon, Brock & Webb, Architects, 41; Plan of Ground Floor, 410; Notre Dame de la Colature, Le Mans, 663;

OPERA HOUSE, Paris, the New, Esquade of M. Garnier, Architect, 749;

PARISH SCHOOLS, intended, St. Saviour's, Paddington; Mr. Edward Roberts, Architect, 2;

Parkfield, Pershore road, Birmingham; Mr. Cranston, Architect, 873; Pastoral Staff, Modern, 180; Paxton Memorial, designed by Messrs. Goddard & Son, Architects, 351; Parish, Anglican, Rathson Cathedral, 699; Poultry Market, Smithfield, 410; Central Roadway; Mr. Horace Jones, Architect, 251; Prince Consort National Memorial; see "Albert";

Palnit, Carved, St. Mary's Church, Taunton; Mr. B. Ferrey, Architect, 608;

RAILWAY STATION, the Toowoomba, Queensland, Australia; designed by Messrs. J. & H. Fisher, 391;

Rathaus Bell Tower, Rothenburg; Messrs. G. G. Scott, R.A., Architects, 451; Rathaus, Prague, Clock Tower; Rathson Cathedral, Angular; Poulton Cathedral, Anglepo; Rathson Cathedral, as proposed, design for; by Messrs. G. G. Scott, R.A., Architects, 451; Reredos and Altar Table, West Hants, Sussex; Mr. G. G. Scott, R.A., Architects, 351; Reredos in Christ Church, Mayfair; Messrs. Francis, Architects, 225; River, the, 570; Rochester, West Hants, Sussex; G. & H. Godwin, Architects, 276; Details of Carving and 350; Roman Wall and Roman Art; Altar to many Gods, found at the Mile Castle, Castle Nick; Crypt, Hesham. Altar to the God, Antiochians. Altar erected by the Fourth Cohort of the Sun; St. Saviour's Church, Ardingly; Messrs. Slater & Carpenter, Architects, 837; St. Alban Hall of Arts and Sciences, London, 368;

ST. ANDREW'S CHURCH, Haywards, London; Mr. Charles F. Hilly, Architect, 97; St. George's Church, Worthing, Sussex; George Trautett, Architect, 459; St. Mary Redcliffe Church, Bristol; Mr. G. G. Scott, R.A., Architects, 451; St. Martin's Church, Cologne; Mr. Stadtz, Architect, 802; St. Saviour's Church, Aberdeen Linn; Mr. W. White, Architect, 510; St. Saviour's Church, Aberdeen Elm; Mr. W. White, Architect, 510; St. Saviour's Church, Ardingly; Messrs. Slater & Carpenter, Architects, 837; St. Serge Church, Angers, France, Interior of, 511; Schools, Lower and Middle Class, Ground Plan of, 336; School of Art, New, and Mechanics' Institution, Rochester, West Hants, Sussex; Mr. Cuthbert Brodric, Architect, 696, 697; Schools, New Infant, Kirkdale, for the Parish of Liverpool; Messrs. J. J. Pettus & Son, Architects, 310; Plan of Ground Floor, 310; Schools, Parish, intended, for St. Padington; Mr. Edward Roberts, Architect, 2; Sedilia and Reredos, proposed, St. Sefton Church, Liverpool, Design for; Messrs. Edgar, André Hornblower, 628; Buildings designed for, 627; Single Spon Churches, the Ancient Cathedral, Notre Dame de la Colature, Le Mans, 663; Smithfield Meat and Poultry Market, London; Mr. Horace Jones, Architect, 251; "Solent" (The), in the Hurricane, Spire in Wrought Metal Work of Albert Memorial, Hyde Park,—and on a large scale, 591; Stall Doors, New, Chichester Cathedral; Standard Theatre (National), Shoreham-by-Sea, Sussex; designed by Messrs. Fisher, 391; States, Modern Pastoral, 190; Sun Worship; Apollo as Mithras, 249; Supreme Court, Auckland, New Zealand; Edward Ramsey, Architect, 170; Synagogue, an Ancient, at Worms, 276;

TEMPLE OF NAKHON WAT, Cambodia, 224; Terra Cotta Architecture of North Theatre, National Standard, Shore Tomb in Brompton Cemetery, 10; Tomb, Middleton Cheney, Oxon; Wilkinson, Architect, 391; Toowoomba Railway Station, Queensland, Australia, designed by Messrs. J. & H. Fisher, Architects, 391; Tower, bell, of Rathaus, Rothenburg, 470; Tower, Clock, of the Rathaus, Prag; Tower, Darnick, south-west view, 730;

UNIVERSITY OF LONDON, B. Gardens; Mr. Pennethorne, Architect, 835; Plan of ground floor, 834;

VENTILATION, arrangements for, Union Hospital, 330; entilation of rooms,—plan of top, 330;

WAREHOUSE, Cork, Lanct Street; Mr. Joseph S. Mory, Architect, 78; Wilford's Crypt, in Hesham, 242; Works, late Sir Charles Barry, 470; Worms, an ancient Synagogue at, 276; Wrought metal work in the Paris Exhibition of the National Memorial of Prince Consort, Hyde Park,—and on a larger scale, 590;

YALE COLLEGE MEMORIAL, Connecticut, Messrs. Vaux, Withers, Architects, 748;

THE BUTTERFLY

Social Progress in 1866.

AST-FLYING Time, while bringing its changes, leaves its memories also. As occasion first arises to replace by a new series of figures the familiar date which has lately headed our pages, we are led to glance with somewhat more than usual gravity both at the past and towards the future; to inquire what the outgoing year has left behind in the shape of solid acquirement and material progress, and what reason may be safely assigned for the hope and promise of its successor.

Especially does the season call on those public writers whose

object is not the mere perfunctory production of a certain number of columns of letter-press, but who have the higher aim of doing service to their contemporaries and to their country by their consistent advocacy of right principles and the faithful pursuit of truth, to review the field of their exertions, and to see what progress has been effected by their labours. Not that it is often given to any individual workman of this honourable guild to trace the results of his own toil, or to attribute the success of any great principle to the service of his own pen. At all times in human history new veins of thought, whether in theory or in practice, have been contemporaneously reached by independent workers. The priority of a few days may be disputed by the friends of Newton and Leibnitz, of Le Verrier and of Adams, but the fact of the independent original discovery effected by the owners of these great names admits of no denial. Speke and Grant pushed their explorations in one portion of the great river system that feeds the Nile, while Baker, in another locality, made discoveries as to the cause of the annual flood that shed far more light on the solution of this great geographical problem than did even his heroic persistence till he bathed in the waters of

the larger of the two headwater lakes. There is honour enough for each patient investigator,—honour that is in no way diminished by being shared. Thus if we see that the principles of politics, viewed as a science, in contradistinction to the maxims of politics viewed as a trade, or politics followed as a hobby, are becoming more and more appreciated by the intelligence of the day, we are ready to congratulate our brother writers, and to congratulate our fellow-countrymen, without yielding to the weak selfishness that is always crying out, "You have stolen my thunder," or "You have taken the path which I was the first to point out."

In the practical comprehension of many of the principles that underlie a healthy social life, the very building principles of society, we think that a marked progress has been made in 1866. Distinct from the subjects of building as a craft, of architecture and of engineering as sciences, of pictorial and plastic art as methods of adornment and as means of education, are those questions in the treatment of which the engineer or the architect has to deal with politics, strictly so called, that is to say, with the cardinal points on which the welfare of the community hinges. Such is the true political spirit which distinguishes the founder of a city from the constructor of a row of houses,—the man who would build his fame from the man who seeks only to fill his pocket. The sanitary state of towns, involving the important questions of drainage, of water-supply, of ventilation, of consumption of smoke,—the provision of homes for the poor, and of hospitals for the sick,—the communications of town and of country, internal and external, including roads, footways, railways, telegraphs, docks and harbours, locomotive and water-going steam engines,—the supply of food, and the improvement of agriculture,—the supply of clothing, and the progress of manufactures,—the defence of the great centres of national life, involving questions of arms and of fortifications, of monster guns and of iron-clad steamers,—and the direction of the intelligence and the industry of the country in those channels which alone lead to a sound and permanent prosperity;—these are the main divisions of that practical political science which ranks among its disciples all men of earnest thought, from the statesman who moulds petty communities into great states, to the practical mechanic who discovers that chilled iron will advantageously replace the costlier material of steel.

In some of the subjects which we have thus cursorily indicated we think that the year 1866 has witnessed an appreciable progress; the public mind is far more fully awake than at any former time to the importance of sanitary questions. We will not refer to the numerous disabled pumps that disfigure the metropolis in support of this assertion, though even here both scientific labour and social courage have been

needed in dealing with a convenient and popular source of danger. But generally speaking, the vital importance of a pure water-supply has been constantly kept before the public. A knowledge has been attained on the subject which must, to some extent, influence all future legislation. Reports on the sanitary state of certain districts, reports on the purity of water, reference of the mortality of cholera to a great predisposing cause,—impure sources of service,—have not only filled the public journals and occupied the public mind, but we are beginning to see the benefit of the attention already given to the subject in the stately walls that bid fair to girdle the Thames, in the re-appearance of fish in its waters, and in the fact that the mortality from cholera during its presence in London in 1866 was at the rate of 8 in the 10,000 in place of the 120 in the 10,000 that fell before the visitation in the year 1849.

In the vital question of national defence, we have the satisfaction of feeling that, in the event of war, our troops will not be matched against an enemy possessing a weapon so confessedly superior to their own as to convert a fight into a *battue* at their expense, as was the case with the brave Danes at Düppel and with the imperial troops at Sadowa. But the satisfaction due to our tardy adoption of a breech-loading rifle is alloyed by the remembrance of the melancholy death of the inventor, whose plan we adopted, a death hastened, or altogether caused, not, we candidly believe, by human malice, but certainly by the malignity of red tape. We trust that among the millions whose sleep will be all the easier, if not all the sounder, for the eight years' toil of Mr. Snider, will be found some to inquire what tardy reparation may yet be offered to his representatives. For larger arms, as well as for the vessels that are to carry them afloat, we can only say that experiment and discussion have been actively, if not very systematically or successfully, pursued; and that if no one should attack us till we have made up our minds on the subject, and then carried out the result of our deliberations, we shall probably be in a very imposing position of defence when that time arrives. The greatest boon of the year in this respect is the application of the process of chilling to iron shot and shell, and the advantage thus secured to offensive operations. We have learned, too, at some cost, in the instance of the *Northumberland*, how not to lay the ways for launching an armoured vessel.

The absence from our Cabinet of that important officer, a Minister for Public Works, has led during the past two years to the application of the cumbersome and expensive expedient of a Royal Commission in three several instances. The Railway Commission and the Coal Commission have as yet given no utterance as to their labours; the River Commission, as our readers are aware, have added to their hurried

report,—hurried, as we have reason to believe, not by their own fault,—much valuable information, to which we have more than once taken occasion to refer. It is to be hoped that the instructions to the Railway Commission are such as to allow the commissioners to deal, so far as recommendation of legislative or administrative measures goes, with such gross cases of railway swindling as have shaken the public confidence, and impaired the national credit, within the past year. The press has shown no hesitation in publishing facts which need no comment, and which of themselves form an unqualified condemnation of their perpetrators, however high the names of these persons may have previously stood. But it is only very recently that there has appeared in any portion of the public press any active support of the opinion, which we felt it our duty in the first instance to express, that illegal acts for the purpose of raising money should not only be called by their right names, but should be visited with their appropriate penalty. The unexampled chronic panic which has reigned since the month of May seems not unlikely to continue, so long as financiers who execute on a large scale operations of a nature smaller attempts at which are visited with impunity. The wise and liberal legislation of which the tendency is to render deba a point of honour, and to refuse to allow the officers of the law to aid the reckless and imprudent creditor, will fail in its object, or will do more harm than good, unless it be accompanied by increased stringency in all cases of actual fraud. If a bankrupt business is to be bought and sold for a premium of half a million sterling; if debentures are to be issued contrary to legal provision; if in any instance one of the harpies who make many poor in order to make one or two very rich is detected in passing the strictest limit of legality, the atonement due to wronged society should be exacted; nor should it be left to individual sufferers to set in motion the sharp machinery of the criminal law in a case of swindling any more than in a case of violence.

A suggestion has come before the public, rather as the convenient discovery of a political secret than as a positive proposal, to supplement the best managed of English institutions, the Post Office, by the committal of telegraphy to the same able and successful management. English habit and English prejudice are, or rather were, very strongly opposed to the interference of Government in matters that have been of late years handed over altogether to private enterprise. But the conspicuous failures of private enterprise, the waste and loss incurred in the construction and management of railways, the disregard of public convenience which railway boards display, the want of provision for obvious need, or of mutual arrangement where both public and proprietary are the sufferers, as in the ill-considered tangle of conflicting railways that obstruct one another at London Bridge, the collapse of limited companies, stand in such strong contrast with the cheap, punctual, profitable working of the Post Office, that a change in public opinion is far from improbable. If a Government official do wrong, there is, at all events, some responsible person to attack, some one who cannot dive for shelter beneath the green cloth of a "board," and in all cases where regularity of administration is the main requisite, we think it probable that the most regular and capable administrators will be those chosen by the Government of the country. To the report of the Railway Commission, we shall look for much valuable information on this head. The enforcement of a uniform, intelligible system of accounts, showing to the plain sense of men of moderate skill in calculation the two great facts of the worth and cost of their property, and of the gross and net amount of their income, with stringent and easily recoverable penalties against those who should withhold or "cook" such half-yearly accounts, is another point which recent great scandals and misfortunes should induce the public loudly to demand.

That peculiar feature of the national character which renders Englishmen in the mass so patiently submissive to unnecessary and avoidable inconvenience, provided that it arises from want of forethought, arrangement, or organization, still marks many of the habits of London. No provision has yet been made for the accommodation of the immense and overgrown street traffic, increasing at the rate of $3\frac{1}{2}$ per cent. per annum, and driven into fresh eddies by the opening of each additional railway

station. The stream of passengers from east to west that converges at St. Paul's and at the Mansion House is yet forced through the narrow channel of Cheapside. The powers that rejoice in covering the carriageways at inconvenient seasons with 4-in. cubes of broken granite have successfully resisted the attempt to introduce the steam-roller, although the macadamisers of Hyde Park have amused themselves with the solemn promenade of a horse-roller, somewhat more efficient than a child's perambulator.

The scavenging of the streets in muddy weather is still committed to volunteers, who levy a black mail at every crossing, at a cost of time and of labour ample to effect the decent and efficient cleansing of the thoroughfares. Our main highways are still, as of old, obstructed from time to time by the sudden appearance of men armed with planks and barrows, who proceed to pull up the pavement, or to pull down the houses, or to sink mines and tunnels beneath the carriage-way, with as imperturbable serenity as if the thoroughfare of a crowded city was the natural scene of action for the "navvy." Still, as of old, gang succeeds gang, and no sooner is the road relaid over the sub-railway than it is taken up again for the water-works; no sooner is it replaced by the water-works than it is afresh invaded by the gas folk. Still do English architects persist in building houses without chimneys,—that is to say, without chimneys that will free the apartments from smoke; and the habitation of any new building is announced by the outbreak on the roof of those enrious, varied, and unmechanical crows, tubes, and wriggling spouts in which the smoke doctor and the chimney quack delight. Still do we persist in sending a large percentage of our costly coal through these wonderful structures, to pollute the air we breathe, and in getting rid by the same means of the greater part of the heat produced by the consumption of the remainder. Last, we are submitting to the greatest injury that can be inflicted on the atmosphere of London by failing to preserve Hampstead Heath, which is now invaded by the builders, and thus about to poison, with the products of animal, vegetable, and mineral combustion, the one pure fresh wind that sweeps through the streets of London.

In addition to the large increase in our power of national defence which we owe to Mr. Suider and to Major Palliser, the chief features of our national advance in 1866 are the union of the Old and the New World by the Atlantic cable, and the opening of a sure and providentially arranged system of railway accommodation for a portion of the suburban traffic of the metropolis by the completion of the Victoria Bridge. The patient courage, the devotion of time, of science, and of capital that have achieved the great work of telegraphic union, and the yet more surprising feat of the recovery of the lost cable from the bed of the Atlantic, have been gratefully acknowledged by the Queen, and are receiving an ample and well-earned need of pecuniary recompense. The public have not, in this instance, been the sole gainers by the enterprise of the Company; and many who would never have contributed even a word of encouragement during the hard times of the undertaking may now grumble that the convenience of the submarine wires is not more appropriated to the amusement of the readers of daily newspapers than to the commercial service of the Company and their customers. In this, as in other cases, we hold that the true rule is the establishment of such rates of charge as will best remunerate the proprietors of the telegraph. We should think that rates considerably lower than those now charged would ultimately follow from the application of this rule, but that is a point on which the first half-yearly reports will furnish better materials for judgment. At all events, the Atlantic telegraph is not likely to fall into the condition of that which transmits from Bombay messages so utterly unintelligible that the persons who are expecting the information they ought to convey are unable to decipher their meaning. The very recent date at which the great Victoria Bridge has been opened enables us to do little more than chronicle the fact that the science and experience of one of the few remaining lieutenants of Robert Stephenson has been wisely appealed to by the directors of the three lines the enormous traffic of which converges on this important point, to an extent that will require the passage of nine hundred trains daily over the Thames. The care which has been given to attain the result on which we have so often insisted as indispensable, the

perfect independence of the routes for the several streams of traffic, so that the swift through trains shall not have their progress throttled by the risk of collision with the frequent short local service, has yet to be appreciated by the public; but it is clear that the servants of the company have in this instance,—and in this instance, with one exception, that of the Metropolitan Railway, alone,—a fair chance of a painful and satisfactory discharge of their duties.

When the absolute block that followed the opening of the Cannon-street Station, a block which twelve months previously we predicted in these pages, and the present imperfect service from the Charing-Cross Station, which entirely prevents the company from carrying the enormous traffic, which the employment of due provision, such as that designed by Sir Charles Fox, would have secured, come to be contrasted with the service that is now practicable at the Victoria Station, the public will feel the force of the arguments we have urged, and will insist that time shall be no longer scandalously wasted, nor human life recklessly endangered, because railway companies run across their own lines in the way in which the Legislature has prohibited them from crossing the less important and less frequented routes of the country highways.

A feature not less important than hopeful marks the closing month of 1866. The voice of common sense, and of that wise charity that begins at home, has begun to make itself heard above the false rant. The working men of Stavely have heard the voice of the delegates of the strikers in the very words which we ventured to put into the mouths of these evil missionaries. The fact that the iron producers of Belgium are so well prepared to run a dead heat with those of England that the latter can no longer afford to carry the dead weight applied by bad regulations of trades unions or of political unions is becoming daily more clear to those most deeply interested in its existence. The strong mother-sense of the straightforward English workman has been appealed to, and the appeal has been answered by the workman himself, in all the nervous unlettered eloquence of Bunyan,—“I have a union of my own at home, a wife and six little ones, and that is the union I mean to stick to.” Let this spirit, and this intelligence, awake and spread; let the working men pause before they forsake the anvil, the bench, the loom, for pot-house agitation. Let them determine that every man shall have perfect liberty of action; that no rules to keep all down to one dead level be permitted; that every man be enabled to do his best; and we may fearlessly raise our old cry of “England against all the world.” “So England to herself do prove but true.”

THE FIRE AT THE CRYSTAL PALACE.

A RUDE practical commentary on a vulgar idea concerning the “ferro-vitreous” method of building, was made on Sunday afternoon last; when the northern end, called the Tropical Department, of the Crystal Palace, was almost entirely destroyed by fire; and invaluable specimens illustrative of some of the chief arts and sciences were buried under heaps of broken ironwork, or consumed and lost. Such a combination of delight for the eye, with educational agencies, there had never been before, at one spot, in or near London; and there is not now in any capital in Europe. Here, rather than in portions of the building appropriated often, as they are at this moment, or in great part, to the less instructive of the items of attraction, was realized something that approached to the original ideal of some of those individuals who were the founders of the Crystal Palace Company, or advisers of the first Board of Direction. The beauty of nature and of art; appliances for education and study; the nucleus of a collegiate institution; books and news; in short, the Academic Grove, the Museum, and the London Club, were there together; there, even in winter, within the walls of glass, was moderate warmth; and in summer was a balcony where the visitor to the reading-room might sit in the open air, with book or paper, or enjoying one of the finest prospects in England. London had no public reading-room so comfortable or so beautifully provided; and one of the recommendations of the room, as well as of its adjuncts, the lectures and classes, consisted in the fact that the advantages could be had by ladies. The temporary deprivation, and in many respects total loss, as regards the Tropical Department of the

Crystal Palace, is therefore of serious importance to families resident in the vast suburb that has grown about the Crystal Palace, and which extends now from London to Croydon. The destruction of the building would have had an important effect on the value of land and houses in the neighbourhood; and the entire destruction would certainly have taken place, had the wind, instead of being from the west or south-west, been in an opposite direction. Architects have to regret the partial destruction of the Alhambra Courts, to which Mr. Owen Jones gave so much assiduous care, after years of study of the original models,—and which if they became the most popular of the Fine Arts Courts, had been the most costly in their wall-decoration; and they will regret the greater havoc that the fire has made in the Byzantine Court (one of Mr. M. D. Wyatt's reproductions), and the total destruction of the Assyrian Court,—the embellishment of Mr. Fergusson's theories,—of the collections of models of building-contrivances, engineering works, and ships, and of the Indian and Chinese collections. The great seated figures copied from the temple at Ahoi Simbel are greatly disfigured, or in part destroyed; and the avenue of lions *couchant* is gone, along with the greater portion of the marble-margined fish-canal. The northern one of the two bronze fountains by Monti is represented by a shapeless mass. One loggia of the cloistered walk, enclosing the Byzantine Court, copied from the Church of St. Mary at Cologne, indeed remains, or on the western side, with its ceiling unharmed, and the painted decoration even, of its exterior, scarcely injured; whilst in the centre itself of the court still stands the fountain of Derbyshire marble produced after that of Heisterbach on the Rhine. But the remaining sculpture in this northern end of the Palace, excepting the southern one of the bronze fountains, is either lost or greatly injured: the valuable copies of the *Ægina* marbles have wholly disappeared. The recumbent effigies of the Crusaders, in the Byzantine Court, are covered with rubbish; and some of the copies obtained at so much pains from Fontevrault, of the tombs of the Plantagenets, may perhaps need to be again compared with the originals ere they can be restored satisfactorily. The casts of fonts and other works important to the history of British and Irish art lie broken to fragments, and mixed with indescribable rubbish out of which protrude leaves of the files of the *Times* or the *Monitor*. Even southward of the glass- and canvas-screen, in parts of the building which remained intact,—excepting as to glass-breakage, and as to flooring removed in order to cut off the southward extension of the conflagration,—sculpture was thrown down, in the haste about saving the holy of the building, and property belonging to the numerous stall-keepers, and in removing the Christmas-tree which stood near the screen ready to add its fuel to the fire. In this way alone, much loss is to be regretted: albeit many of the casts in the Palace have long been undergoing such marked deterioration, added to what they received during the original construction of the building, as to suggest the desirableness of procuring fresh casts from the originals. The whole collection of living animals, excepting a very small number of the birds, is destroyed. It included a chimpanzee, and a young hippopotamus; the latter, alone of the specimens of different kinds destroyed, was valued at £1,000.

Even the architect, or decorative artist, should regret the disappearance of the hulk of the plants; which were many of them from the celebrated collection of Messrs. Loddige, and perhaps cannot be replaced. In the library were about 6,000 volumes of books, including most of those which were consulted by Mr. Jones, Mr. Wyatt, and their associates, in the production of the Fine Arts Courts.

Of that portion of the building which was the scene of the fire, nothing remains but foundations, and the columns and coupled arch-ribs of the intersection of the nave and transept, or excepting here and there a column hardly noticeable in the general scene of ruin. But the nave, southwards from the transept, to the screen, is much of it perfect; although the ridge-and-furrow roofing over the courts on each side is gone, leaving such decoration as might be made to serve again, exposed to the destructive effects of the present weather. The Hall of the Abencerrages indeed retains its ceiling; and the East-room, southward of it, is almost unimpaired, even to the casts and the model of the original Alhambra: but the Hall of Justice, and the room of the divans, have their tiled flooring sunk down

amongst the ruins of the supporting construction, and their finishing coats of ornamental plastering peeled off to a large extent by the heat; the Court of the Lions is strewn with fragments of the red tiles of the corridor-roofing; and the colouring and gilding of the walls, when not peeled off, are much discoloured, as also is the marble of the fountain. But for the discolouration, much of the decoration here might be restored, at considerable deduction from the original cost of the whole. A portion of the Roman Court, within the screen, or next the Alhambra, is also injured; whilst, on the other hand, so much of the Mediaeval Courts as are within the screen may be described as perfect. The great heat of the fire is made evident by the remains of three hells, of Eastern manufacture, which hung near the gallery-stairs that led up to the Indian and Chinese collections. The material of them is found fused into irregular shapes.

Besides the Tropical Department of the main building, generally known to the public, there was a considerable extension of the basement northwards in the direction of the tower; and from this extension there was another eastward, forming the wing corresponding in position with that which is entered from the station of the West End and Crystal Palace line of railway. The north-eastern wing was divided into two principal portions, of which the easternmost was at a lower level than the other, that is to say, at the foot of the terrace. This latter portion, forming the orangery, and which is the part of the structure that was blown down by a storm some few years since, remains perfect or nearly so: the remainder of the wing, and the connecting line to the main building, form part of the general ruin. One part of the connecting line was used for storage of articles that were some of them inflammable; and the adjoining portion of the wing was used as the carpenter's shop. The great flue from the boilers of the Tropical Department ran in the direction of the tower, to the staircase of which the chimney-shaft forms the newel. This flue, carried on arches, horizontally, through the distance leading up to the storage-space, and through that very space itself, is supposed to have had much to do with the disaster, whether otherwise arising from spontaneous combustion, or from generation and explosion of some kind of gas. The truth is, however, that so many conditions and circumstances were existent to produce the fire, and there is so much difficulty in making out what was the plan of the basement, from the ruins, that we are not able to say much more as to the cause of the fire, than that any one of the conditions and circumstances might have set the train going. This only we know from the drawings of the building as it was first erected, and from what those who have visited the Palace are, most of them, acquainted with: that immediately behind the basement which forms the ground-story on the garden side, is a long roadway of communication between the two ends of the building,—in which way is the flue before referred to, or two flues similar to one another, each communicating with the chimney of a water-tower,—and that behind this space, must be another (taking, in part, the slope of the hill,) in which are to be found the supports to the iron columns, and those to the boarded flooring, the service-piping generally of the building, the hot-water piping to heat the Tropical Department, and whatever stores may be kept accessible by the traps that are to be noticed by visitors. As important perhaps as anything else, there must be in this space a great collection of dust, and, with it, some refuse, to be set on fire easily, or by spontaneous combustion accelerated by heat,—this refuse resulting from use of that really ingenious adaptation from conservatory-flooring, made by Paxton in the 1851 building,—which flooring he expected could be kept clean by the sweeping-machine,—and which he found required little more than was effected by the dresses of the ladies, even before the perfect adaptation of the garments, as recently, to street-sweeping purposes. The supports to the columns are, of course, brick; but those to the flooring, like the flooring itself, seem to be entirely of timber. This flooring was, if we remember rightly, laid down much of it after the mechanical system of building which came in with Crystal Palaces, or by mere extension of square feet of construction, without regard to possibility of modification according to size of what might have to be placed at some spot, or to weight that might have to be supported. Giving all praise to Paxton as the author of one of the finest pieces of effect that has been pro-

duced in building,—namely, the perspective of the interior of the Sydenham structure,—the fact remains, that there was no architect's work in the building, pervading it, as there should have been; and that the architects who were employed on the Fine Arts Courts were not the architects of the foundation on which they built. The tile-flooring of the chief portion of the Alhambra Courts was, from all present appearance, laid on the wooden boarding,—instead of as Mr. Owen Jones, we may be sure, would have laid it, on brick-arching or solid concrete. But above all, the hot-water piping seems to have been laid with wooden flooring in dangerous proximity to it, that is to say, in oblivion both of the increased susceptibility to fire, by desiccation,—of which the fact might have been obvious,—but of the fact, authenticated by experience, that heat will travel to a considerable distance along hot-water pipes, even those which are at low pressure.

When the news came to the London railway-stations, on Sunday afternoon, that the Crystal Palace was on fire, and (as the report said) half burnt down, we suspect that the first impression of three persons out of four, not architects, was one of wonder what there could be in the structure to cause a conflagration. Certainly, we have the best means of knowing what were actual words of some persons. It should be apparent now to all, not only that there was a considerable amount of inflammable material in the structure, and in the contents of the building, but that, further, there is something appertaining to parts of the construction that people usually feel convinced are "fire-proof," which are not correctly so designated, and which even contain elements of destruction. That the flooring of the Tropical Department of the Crystal Palace was of wood, as is the flooring of the rest of the building, may have been known to all; and many persons must have noticed places where the heat, coming through the flooring, was, comparatively with the rest of the space, intense. Those, however, who had examined the construction of the building were well aware that wood entered, in a very important degree, into the formation of the roofs and external enclosure, and into the framework of the Fine Arts Courts, as it does into the large amount of the fittings and furniture. Of course, many of the exhibited articles are inflammable.

The Handel Orchestra, alone, seems calculated to produce, should it catch fire, almost as great a conflagration as that of a theatre: indeed now, whilst the Christmas festivities are going on, there is, or including the concert-room, an amount of material destructive and to be destroyed, such as should demand incessant watching, like what there is in places of public entertainment in Paris, and, in case of fire, instant action aided by far more accurate knowledge of the conditions of inflammability and fire-conductivity than prevails generally with the constructors and the guardians of whatever public or private buildings. As to the original Crystal Palace, the opinion of the best authority on the subject of fires and fire-prevention, the late Mr. Braidwood, was very plainly expressed; and it is much to be regretted that his several statements respecting "fire-proof" construction itself, are not universally known. They are exceedingly important as bearing upon the inquiry into causes of the calamity at Sydenham, and as supplying the explanation of the picture presented by the ground over which the conflagration raged; where the utter destruction is what could not have been equalled by the burning of a building constructed with brick-piers and the best kind of timber-flooring, pugged and nuder-ceiled. For absolute safety, indeed, neither the system of construction adopted in different portions of the British Museum, nor the modified Crystal Palace system of the South Kensington Museum, can be considered absolutely safe; and it is to be regretted that the exigencies of lighting debar us from what seems to be the only construction that is really fire-proof, that of brick-vaunting, and solid filling-in wherever there might have been hollow space in other methods of construction, as in the formation of roofs. We cannot have features which were those of the Roman baths: yet something might have been utilized of their lessons, even in the Sydenham building; and the utilization would have involved, to say the least, avoidance of the plank and timber-supported flooring in the Tropical Department of the building. To Mr. Braidwood's conclusions we shall return.

Our own observation of the fire did not com-

menace much before half-past five o'clock, when men of the A division of police, under Chief Superintendent Walker, arrived from London. The two figures from Ahoo Simhel were then burning and exposed to view; and that end of the transept, like the eastern end, and the whole of the portion of the Palace north of the transept, had fallen. Soon after seven o'clock, the writer was able to pick his way to where firemen of the London Brigade stood with the branch-pipe playing upon the wreck of the Alhambra and Assyrian Courts, and thence over broken columns and girders, past the end of the building, to the top of the wall of the place where the stores had been. Here the fire still blazed, as well as far beyond in the remains of the carpenter's shop. The fire was being revived by the rising wind; but the stream from a 1½-in. jet-pipe, or nozzle, was being directed with little telling effect. It seems wonderful that no life was lost; but the danger of buildings of iron construction is well known, at least to the successor of Mr. Braidwood and his men. Still, even at the place of comparative safety at which we stood, a stumble over the hose would have pitched one headlong into the furnace that there was some 15 ft. below; and the man at our side seemed careful to direct the attention of any of his comrades, approaching, to the danger that was in their path. The balcony at the top of the tower was hurling like a beacon-light; and large fragments were falling, or being thrown down. Some of the lower floors were reported to have been on fire; but the writer saw no evidence of this in the bottom-story, which he was able to enter at the hour mentioned in one of the newspapers as the time at which the whole was on fire. If as little reliance is to be placed on published reports of the commencement of the fire, as we have found it to be given to some of those referring to its termination, there should be no dependences upon the newspapers when attempting to give particulars of occurrences not witnessed by the reporter himself, with the time duly noted. The writer of the summary of news in the leading-article portion of one paper, stated that the fire extended to the Handel orchestra. The truth is: it never extended southward of the great screen, excepting as to some trifling breakage of glass; and, as we have seen, in the nave it did not get near to the screen.

The fire was discovered by the small number of persons within the building, somewhere before two o'clock, and, independently, about the same time, by many persons outside. The latter saw an unusual appearance in the smoke of the chimney; and it is affirmed that the effect was not that of an ordinary foul fire, as also that from the great draught through the flue, the flue could not have become foul. An explosion seems to have been heard by a person passing the building; but whether the gas came from the mains, or was generated in a banked-up fire that might have been practically a retort, is not clear, more than the way in which the mixture with atmospheric air took place. It seems that, on the discovery, the policeman and fireman inside, immediately set to work; and those outside endeavoured to gain admittance. Some time was lost before much of the large water-service of the Palace could be brought to bear on the fire. As usual in such cases, wrenches of plugs and cocks were not at hand at the moment when they were wanted; and canvas-hoses proved too weak for the strain upon it. Nevertheless, some accounts say that the fire was practically got under before the first engine from a distance, one from Croydon, arrived, about four o'clock. Captain Shaw, with his men and engine, did not arrive before half-past four o'clock; or, according to one account, the time would be even later. The delay in this case is attributed to the present system of electric telegraphy; according to which, communication by the wire either is not permitted during hours when it might be especially wanted, or is made to consume more time than a despatch by train or horse conveyance. The north-east corner of the main building, or some place near thereto, is indicated by all observers as the spot where the fire broke out. Thus, as to the main building, the fire spread westward and southward, or against the wind; and the fact of the general westerly direction taken receives confirmation from the direction in which the fallen columns lie, that is with their heads towards the east. Coming to the great stem of the *Wellingtonia gigantea*, the flames no doubt shot up the hollow, to the roof. The Queen's apartments, and the rooms for classes, in the north-eastern angle, must have

been soon destroyed. The great heat acting upon the screw-ends of bolts such as form the main strength of the Paxton girders, allowed the ends to be drawn out of the nuts; and cast-iron cracked, from several causes, such as the diminution of strength which is one effect of heat, from subjection to cross-strain and torsion which the forms had not been designed to resist, or from the application of water. Wells and flanges of wrought-iron became bent like ribbons. Of these effects of the fire on iron, the ruins afford ample illustration. Even the columns still carrying arch-ribs, about the intersection of the nave and transept, seem out of the perpendicular: so that they should scarcely be used again, excepting after being taken apart, and separately examined by competent persons. The official statement of the evening of the fire, that the "iron framework of the tropical end is mostly standing, and apparently not severely injured," must have been written after a view from the screen only; for, certainly, the bulk of the columns are down, as well as the roofing that they carried. One of the measures attempted to stop the progress of the fire, was the cutting across the whole building, as by taking out boards of the ground-flooring, and of the flooring of the galleries. This cutting-out, of course, should have extended to the woodwork of the roofs and sables, as perhaps to some extent it did. According to the appearance of things, however, at the building now, the operation described could have stayed the fire only at some distance southward of the screen; whilst, actually, much of the nave northward has been saved.

Reverting to the inquiry into the origin of the fire, let us observe that this is one of the cases that might be well met by an inquest, such as the inquests that Mr. Payne, some years ago, held on fires in the City of London, and like the inquest on the fire of Covent Garden Theatre. At the latter inquiry, Mr. Braidwood gave very important evidence, tending to show the exceeding importance of *spontaneous combustion* as a cause of fires, and other evidence bearing upon the inflammability of desiccated woodwork. Some time ago, a valuable collection of Notes on Spontaneous Combustion, giving what were well-authenticated instances, and what were regarded as such by Mr. Braidwood himself, was published by Mr. Wyatt Papworth. The entire experience shows that whilst spontaneous ignition is generally accelerated by heat, it may take place in sawdust in contact with vegetable oil, in cotton, cotton-waste, hemp, and most other vegetable substances, and in dust-hills under particular conditions. Sometimes, heat makes the whole difference between an immunity for years, and a conflagration in the same number of hours. Paint-stores have caused many serious fires. Rags with which oil has been wiped up have proved very dangerous. Dust-bins have caused heavy losses, as in one instance where 30,000, to 40,000, were lost from hot ashes being thrown into a dust-bin. Mr. Braidwood said, "No collection of rubbish or lumber of any sort should be allowed to be made in any building of value."

Can it be said of the Crystal Palace that this condition of the maintenance of a "building of value" has been observed. As to flues, Mr. Braidwood said that none should be permitted to be used from furnaces or close fires, unless prepared for the purpose; otherwise the flue might be dangerous throughout its course. As to heating by hot air, steam, and hot-water, he spoke of them as "objectionable,"—one of the reasons being that the pipes are kept out of sight as much as possible. He said,—"By this means they are constantly liable to produce spontaneous ignition; for, there appears to be some chemical action between heated iron and timber, by which fire is generated at a much lower temperature than is necessary to ignite timber under ordinary circumstance." He quite recognized that fires may occur even from pipes that are left open; and he showed that the heat of water at the furnace may be more than 212°. Some fires from hot-water pipes have been known to occur after ten years of apparent safety. It is for those who are acquainted with what was the state of the furnaces, flues, stores, hot-water-piping, timber-flooring, and space below the floor of the Tropical Department, to say how

far any of the conditions here pointed to were existent in the Crystal Palace.

As to the sufficiency of iron-construction, useful information may be got out of a comparison of Mr. Braidwood's views with those of Mr. Fairbairn. The latter authority stated, in 1837, at the meeting of the British Association for the Advancement of Science, that cold-blast iron suffered a loss of strength amounting to 10 per cent., by an increase of temperature equal to 164°, and hot-blast a loss of 15 per cent., by an increase equalling 168°. Cases have occurred in which such an increase as the last-stated, or from 21° degrees to 190°, would have been sufficient to cause the ruin of a building. The iron beams of a floor have been known to give way from the mere heat of burning materials on tiles which the beams carried. And, a chapel at Ildington being burned down in 1838, it was found that of thirteen cast-iron columns supporting the galleries, only two were perfect,—most of the others being broken into small pieces, and in some parts melted,—and that, although the pillars had been strong enough to support the galleries when filled with people, as the fire reached them they crumbled under the weight of the timber only, albeit lightened as the latter was by the fire. A knowledge of such facts will help to explain much of the appearance of the iron-work fractured, and lying amongst the general rubbish, that forms the sad spectacle which there is now on Sydenham-hill, and may serve to emphasize what would be our recommendation touching any proposed restoration of the Tropical Department, already sufficiently adverted to.

No more need be said unless in expressing hope that the directors will see their way to the restoration of as much as may be restored of the beautiful effects of nature and art-work, and the educational advantages that the Crystal Palace lately had, combined with such improvements as may lessen the chance of another disaster.

SEWERS IN PARIS.

The great general collecting sewer of the left bank of the Seine commences at the junction of the Quai Henry IV. and the Boulevard Bourdon. It follows the line of the quays, crosses the Place du Chatelet, and, opposite the Pont de la Concorde, turns at right angles towards the north, passes under the Rue Royale, continues under the lower portion of the Boulevard Malesherbes, leaving Moneau on the left, and debouches at Asnières below the bridge over which passes the departmental road of Argenteuil. Its development is about 5½ miles; the inclinations 1 in 2,500 from the Boulevard Bourdon to the Rue de la Pepinière, and 1 in 2,000 from that point to the Seine. In section, the height is 15 ft. 1 in. from the bottom of the invert of the canal to the crown of the arch, which is elliptic; the width is 18 ft. 5 in. at the springing. The canal at the level of the *bonnettes* on each side is 11 ft. 6 in. wide, and 4 ft. 5 in. deep. The masonry is of *maillères*, laid in hydraulic mortar, the whole being lined with Vassy cement. There is no dressed stone used in the construction.

This sewer receives, at the Boulevard Haussmann, what is termed the collecting sewer of the hill-side. Running parallel to the circular railway, this latter turning off from the route Impériale, No. 34, or Avenue de Vincennes, traverses the Rue du Faubourg St. Antoine, at the commencement of the Rue de Montreuil; after having touched upon the Boulevard du Prince Eugène, the Rue du Faubourg Poissonnière, at 400 metres from the boulevard, and the Place du Havre, it gains the *deboche* above mentioned in the neighbourhood of the Rue de la Pepinière. Thanks to the 2 metres difference of level between the Place du Chatelet and Asnières, the level of the invert of the new sewer can be made 2 metres lower than that of the ancient sewers, and the cellars can be drained in that part of Paris which lies beyond the so-called hill-side collector.

The Sebastopol sewer, which establishes a junction, under the boulevard of that name, between the great collector of the right bank, and the containing collector, allows the surplus and storm waters of a great portion of this side of the river to be poured into the Seine. Besides this there is the Rivoli sewer, another affluent of the great collector, which can divert the overflows to the Seine, when otherwise the streets would be flooded, at the Quai de la Con-

* Fire Prevention and Fire Extinction; by James Braidwood, First Superintendent of the London Fire Brigade. Including fire-proof structures, fire-proof safes, public fire-brigades, private means for suppressing fires, fire-engines, fire-ambulances, portable fire-escapes, water-supply. With illustrations. London: Bell & Daldy, 1858.

ference, and thus relieve that part of the great collector which lies below the Place de la Concorde.

In sewers through which a large body of water flows, cleansing them by manual labour and sweeping is out of the question; so recourse is had to a boat provided with a vertical board which exactly fits the section of the canal. This board is placed at the head of the boat, and is pierced with holes; it can be raised or lowered at pleasure. Carried by the current, this board or sluice forms an obstacle to the passage of the water, and there results an eddy which gives an impulsive force to the board, so that it pushes before it the solid matter deposited on the invert, but restored to a state of suspension by the fillets of water which pass through the holes.

The result is, as experience has proved, that this sluice-board amasses before it the sandy deposits, leaving a horizontal column in suspension, generally from 100 to 150 mètres long. If a pole be immersed in the water above stream, it will touch the bottom, and the masonry will be found clean and free from all deposit. On the other hand, if the pole be placed at the other end of the boat, it will penetrate a heap of mucky deposit, and stand upright of itself; it will also remain upright, and drift along with the boat and the heap of deposit.

Thus the boat travels of itself, under the superintendence of two workmen. Its rate of moving is variable, and does not exceed in general two feet a minute. In winter these boats, which have relays at every two kilometres, work day and night, and it is not too much for the requirements of the cleansing.

In the canals of small section, as that of Sebastopol, the boat is replaced by a chariot, running on rails laid on the banquettes, and carrying also a flushing board. The deposits of the sewers are carried down as far as Asnières, where a sort of bar or delta is being formed, which must be removed by dredging, and can be utilised for agricultural purposes.

The quantity of water passing through the great sewer is, as may be supposed, extremely variable; it is generally 1 mètre per second, giving 4 cubic mètres or 140 cubic feet per second. This velocity, according to the usual hydraulic data, should roll stones the size of an egg, but the viscous nature of those sewage deposits—street-sweepings containing much organic matter—prevents the water from carrying off anything that is not mechanically stirred up into it.

These sewers are liable to inundations like rivers, by sudden torrents of rain, so that the vault is widened out at every 2 kilometres, and stairs or ladders are provided leading to safety-chambers.

The total length of all the sewers in Paris is, up to the present time, 294 miles.

Great exertions are made to terminate the great collecting sewer of the left (south) side of the Seine. It will absorb the Bièvre river, cross the Seine by two tubular siphons of enormous diameter at the Pont de l'Alma, follow the Avenue Josephine, pass under the Place de l'Étoile, and, traversing the district of Courcelles, will fall into the Seine at Asnières, a little above the point where the Chemin de Fer de l'Ouest crosses the river. Thus the Bièvre will join the Seine seven miles lower down the river than it does at present.

OFFERED PRIZES FOR DOING GOOD.

THE PARIS EXHIBITION.

OUR readers know that a distinct order of reward has been instituted "in favour of persons, establishments, or localities, which, by a special organization or special institutions, have developed a spirit of harmony among all those co-operating in the same work, and have provided for the material, moral, and intellectual well-being of the workman," and that these rewards consist of ten prizes, of the total value of 4,000*l.*, or 400*l.* each, and twenty honourable mentions. One grand prize of 4,000*l.* may, in addition, be awarded to the person, establishment, or locality, distinguished under this head, by a very exceptional superiority. At the first meeting of the International Jury, held in Paris, on the 1st of December last, certain principles were adopted, and we print them as serving further to define the object:—

"1st. The jury may doubtless take into account among the facts presented for its consideration, the spirit of charity and beneficence; but it is not specially charged to reward acts of that character.

2nd. To constitute them the basis of a claim to reward, the facts adduced must have been the consequence of a free and spontaneous initiative, and not of legislative enactments.

3rd. It will not suffice that the work be praiseworthy in itself; it must at the same time be compatible with sustained and progressive prosperity.

4th. The circumstances of the position in which competitors may be found should be duly considered. To have maintained intact traditional circumstances of harmony and happiness, whilst progressing in agricultural or industrial pursuits, is a good ground of claim; but the introduction of improvements where antagonism and suffering previously existed is not less meritorious.

5th. The jury has not thought it right to exclude from the competition individuals or societies which, although not engaged in agricultural or manufacturing pursuits, have founded durable and prosperous institutions, contributing to the propagation of good feeling and happiness, of which it is desirable to seek the best examples."

We are anxious that these prizes should be widely known of, and well understood, so that claims may be made for as many organizations and individuals in Great Britain as fairly comply with the conditions. Blank forms are obtainable, we believe, at the South Kensington Museum, and the claim must be lodged there on or before the 20th inst.

THE MONUMENT FOR THE CANADIAN VOLUNTEERS KILLED BY THE FENIANS.

THE citizens of Toronto having determined, at a public meeting, to erect a monument to the memory of the volunteers killed at Limeridge, on the 2nd of June last, in repelling the Fenian scoundrels, appointed a committee to carry out the arrangements. In answer to advertisement the committee received sixteen separate designs, from which they selected one by Mr. C. E. Zollikoffer, of Ottawa, as first in order of merit; and awarded to it the first premium, the second being given to Mr. J. Smith, of Toronto. The selected design, which is to be erected on a site in the Queen's Park, Toronto, is a square temple, formed by twelve Corinthian columns on pedestals (three at each angle 90°), which carry an entablature and pediment on each of the four faces. The tympana of the pediments are to be filled with the royal coat of arms, the arms of the province, and the arms of the citizens of Toronto and Hamilton respectively.

Within the inclosed area at the four angles formed by the columns will be life-sized statues illustrating the four branches of military service; and in the centre will be a sarcophagus, supporting a figure of Britannia reclining on a demi-lion couchant, mourning the loss of her subjects. The roofs of the four pediments carry at their intersection a pedestal, with a crowning figure of "Victory" 12 ft. in height.

The whole of the carving will be executed in freestone from Nova Scotia; the shafts of the columns and the sarcophagus will be of Amprur marble, and the remainder in Hailton freestone. The floor will be laid with encaustic tiles. The monument will be placed effectively on a wide spreading basement, consisting of a sloping embankment, with steps in the centre of each face, and on that a pyramidal flight of steps, which continue up between the pedestals (or rather the broken podium) on which the columns stand, so that the floor of the monument will be level with the bases of the columns.

While we give praise to this "planting" of the monument, and to the general proportions of the structure as a whole, we must raise a voice against the crowning figure and pedestal standing on the roof as they do. The apparent weakness of the arrangement will be excessively unsatisfactory and disagreeable. If carried out it will be a lasting offence to every tasteful eye in Toronto. We trust this observation will lead Mr. Zollikoffer to reconsider and alter this portion of his design.

ART NOTES FROM FLORENCE.

WHEN on the 15th of December the Italian Parliament was opened by the king, in the Great Hall of the Palazzo Vecchio, a brilliant sun and most mild temperature contributing to the happy auspices of the day, as well as to the beauty of the scene presented in the line of streets from the Pitti Palace to the Piazza della Signoria, all the ingenuity and taste of the Florentines in decoration, all possible devices, trophies, banners, and tri-colour hangings, had been profusely prepared for the occasion. In the centre of the great piazza stood a lofty mast, with the national standard, and around its

basement statues of Prudence, Justice, Temperance, and Fortitude, prepared in the usual style for such ephemeral art-works. In the loggia of Oragna was a gorgeous display of all the Italian banners and embroidered epigraphs, that seemed to convert those majestic arcades into a festive pavilion. But in the midst of the ornamentation for the day, under the vaults of Oragna's structure, stood a nobler object now attracting more attention than all the apparatus of fête, for on the morning previously had been uncovered the colossal group, by Fedi, of Pyrrhus sacrificing Polyxena, raised on its basement here so long since as the 2nd of October, but up to this time concealed by a high wooden shed, within which were finished the works for encrusting that basement with marble. It comprises four figures—the Pyrrhus carrying the hapless girl to the altar for sacrifice; the Hecuba prostrate, in vain intercession for her child; and a youthful son of Priam stretched in death, as just struck down at the conqueror's feet. It occupies the extremity of the loggia, near the Palazzo Vecchio, in position correspondent to that of Gian Bologna's "Centaur," at the other side; and it is only to be regretted, that in this otherwise most favourable location, a part of the group is concealed to the spectator standing in front of the archway, at whose centre it rises, as seen from the piazza, by the intervening figure of Cellini's "Persons" above the parapet between the great pilasters. This admirable group having been, long since, purchased by subscription of the citizens to become a public ornament to Florence, and destined by the Municipality for its actual place, the voice of criticism has already been heard from various quarters, and little notice has been taken of it by the journals since its exposure, except simply to announce the fact. We happened to find ourselves on the piazza at the moment of the uncovering, about eight o'clock on a dull, wet morning, and were surprised to see so little attention excited, so complete an absence of *éton*, in the whole proceeding. As to the merits of the work we have formerly expressed ourselves.

In tragic power, movement, and just equilibrium, in all the technical qualities, it strikes us as faultless; in the heroic beauty and action of the Pyrrhus, the sad loveliness of his victim, and the pathetic character of the mother's figure, the story is conveyed with dramatic truthfulness. But the subject is revolting, and, perhaps, incapable of being exalted by any merits of treatment; and as the most historic centre of the Italian capital, an episode in the siege of Troy, and one that illustrates the withering force of superstition alone, redeemed by nothing of patriotism or magnanimity, seems to the last degree unsuitable. As a classic motto for such a group, we can think of no line more appropriate than—

"Tantum religio potuit suadere morosus."

And, to criticise details, the fault generally found is one that all may perceive in the disproportionate slowness and diminutiveness of Polyxena compared with the warrior who raises her figure with the left arm while aiming a blow with his sword (an unnecessary atrocity) at the prostrate Hecuba; also, a heavy and clumsy appearance in the drapery that covers the lower part of the mother's figure; and a certain rhetoric action in the left arm and hand of this unfortunate young princess, as she vainly struggles in the grasp of her destroyer. But neither these, nor the more serious moral objections to be urged, can forfeit for Fedi's work the high place now assigned to it by public opinion, nor prevent us from awarding the tribute of praise due to the classic grandeur, the blending of power and grace, in the whole composition.

A detail now observable, and a novelty since we saw this group in the studio, is the tinting of the nude parts with a pale pinkish colour, *approaching*, though, indeed, but faintly, to that of flesh, and which adds a warmth without impairing the purity of effect. We may describe this more precisely by stating that, from a distance, it is but the natural hue of the marble, only, from nearer points of view, what is artificial strikes the eye.

The other monumental sculpture of recent origin in Florence, the colossal "Dante," on the piazza S. Croce, by Pazzi, was uncovered so far as to display the principal figure, though not the reliefs and accessories, a few days ago; and we understand that the artist will soon have ready the four bas-reliefs illustrative of the "Divina Commedia," for the basement, and the lions to

be placed at its angles. Public criticism has found fault with the mournful and severely indignant expression of the head as insinuated to the triumphs of apothosis, in which the poet is here before us; and the more youthful, the more serene type supplied in Giotto's fresco might have been preferable for the Dante of this movement; but it should be remembered in Pazzi's justification, that his statue was not begun or ordered for the appropriation by which it has been finally honoured,—an afterthought not to be foreseen in an undertaking guided by personal feeling. The Minister of Public Instruction has interceded for the careful preservation due to several frescoes by Poccetti and his school in the vaults of rooms lately abandoned, after being used for custom-house purposes, in the Casino Mediceo, a once grand-ducal palace on the piazza S. Marco; and the municipality has exerted itself for a like interest, ordering the transfer to the Mediceo Museum in the "Pretorio" of a Crucifixion, in fresco, attributed to Andrea del Castagno, and of unquestionable merits, hitherto left in a niche under glass on a wall of a fortifying cincture soon to be taken down, near Porta San Gallo. The same minister lately ordered, and with laudable purpose, the drawing up of a map of excavations, to serve as guide, not only for all places where such labours have yet commenced, but for all to which it is judged that explorers should direct their attention, in hope of archaeological discovery; and antiquarians of repute—Conestabile, Fiorelli, Spano—have already pledged their assistance for this desirable object. In the range of such discoveries we hear of diggings carried out with valuable results by an enterprising arch-priest of Vado, near Savona, who, on his own risk and speculation, as it seems, began the works near his church for seeking the extant remains of Vado-Sabazia, a Roman city, soon brought to light in various interesting ruins and antique implements; an aqueduct with leaden conduits passing under a mountain to the extent of 1,400 metres; the pavement of streets, still with the ruts of carriage-wheels, and besides piles of formless ruin; some marble busts of different size, amphore, specimens of glass manufacture noticeable among those of antique produce, marble lamps, epigraphs, and coins in chronological series from Tiberius to Valentinian. Amidst other circumstances of public life, such a treasure-trove might have excited greater interest and been more fully reported on; as it is, we must satisfy ourselves with very scanty notices in journals respecting the hitherto labours and successes of the reverend *padre*, among those relics of Vado-Sabazia, which have followed the vicissitudes of one antique object, the Iron Crown of Italy, to which intrinsic importance is attached; and have now to mention its restitution with much official pomp and ceremony, received by capital clergy, the Prefect of Milan, and the local magistrates, to the basilica of Monza, 7th of December; also, the presentation to the King of a casket to contain his own wrought with much artistic skill by Montinari, of Perugia, from which town it was brought to Florence by a deputation of chief citizens. The idea of a preparatory exhibition at Florence, of works to be sent to Paris, is quite abandoned. An English artist, long resident here, Mr. Bunney, has been exhibiting a set of water-colour landscapes and peasant-life scenes, from subjects in and around this city, prior to their being sent to London, for the display in Piccadilly; altogether a pleasing series of records of Tuscany. Mr. Stark, another English artist long here, who is considered to have imitated the colouring of Titian with signal success in his numerous copies from that master, has lately finished an original picture, "Venus standing in a Shell," that evinces his best capacities, and has been much praised.

THE STAGE AND MUSIC.

The Haymarket.—A promising boy leaves the quiet home, goes to college, and is a "man" exposed to many temptations and left to himself for defence. He is led into extravagances, falls into debt, makes the acquaintance of money-lenders, loses his chance for "honours," and half ruins his father. This is the story (it has occurred in hundreds of instances, and will occur in hundreds more), well told by Mr. Tom Taylor in his new comedy, "A Lesson for Life," now being acted at the Haymarket, Mr. Sothorn playing the hero, *Harry Vivian*, Mr. Chippendale his father, and Miss Moore, with much delicacy,

a ministering angel in the shape of his cousin. Mr. Sothorn shows himself in this piece an admirable actor. His ease and naturalness of manner in the lighter parts of it are perfect; but when he desires to become more impressive, he is more artificial, and must guard himself against seeming to "preach." Mr. Walter Gordon plays with great heartiness an under-graduated friend of *Vivian's*. The piece is well written, sound in structure, and very interesting. Mr. Compton, Mr. Howe, and Mr. Kendal, a promising young actor, help in it.

The Princess's.—Mr. Planche's capital extravaganza, "The Invisible Prince," has been revived here very successfully, Mrs. John Wood playing the principal character with great dash and cleverness, and Mr. G. Honey, the very had *Prince Furibondo*, with much original humour. This piece was first played twenty years ago, and when we say that it has been reproduced without the alteration of a line, and goes admirably, the difference in the extravaganzas of those days and the burlesques of these is made evident. The piece has been produced by Mr. Vining, with rich appointment, and Mr. F. Lloyds has painted for it some capital scenes. We must note especially the last, the elegance and beauty of which are remarkable.

A Concert for Charity.—The proceeds of a concert, to be given by Mr. Henry Leslie this (Saturday) evening, the 5th, in St. James's Hall, are to be applied to charitable purposes. All the artists, including Madame Sainton-Dolly, Madame Lemmens-Sherrington, Mr. Santley, and other eminent singers, will give their services gratuitously.

THE ACCIDENT ON THE METROPOLITAN RAILWAY.

The inquest on the three persons killed by the fall of a girder from the Smithfield market works on the metropolitan railway has resulted in a verdict of manslaughter against the foreman, Wilmot, and the ganger, Chaney. It appears that no arrangement whatever existed for staying proceedings while a train was passing below, although the steam of the engine prevented the workmen from even seeing what they were about at the moment. From the evidence it seems clear that the girder was pulled, by a donkey engine, too far across the other girders, till it lost its balance and canted over; and there was not even a check rope to regulate the speed or the progress of the girder. It was admittedly improper to use the donkey engine at the moment of the misadventure, and it pulled the girder several feet forward at a time when it ought not to have gone more than one foot.

ACCIDENTS.

Manchester.—A partition wall, in the rear of the warehouse of the Messrs. Berken, Brothers, Oxford-street, has fallen, killing one man almost instantaneously, and injuring six others seriously. The seven men were labourers in the employ of Mr. Davis, contractor, and they were engaged at the time in removing a quantity of *debris* that was lying about, preparatory to an extension of the premises that have their front in Bale-street. The partition wall, the only one which has been left standing, was about 40 ft. in length by 20 ft. in height; and this served as a front, two stories high, to some premises in the inner portion of the property.

Edinburgh.—The temporary service bridge at Abbeyhill, erected for the formation of the new branch of the North British Railway from Edinburgh to Leith and Granton, has fallen, burying in its ruins two men, a couple of horses, and two wagons filled with sand. The bridge was constructed of beams, about 15 in. square, covered with sleepers and rails, for the purpose of conveying earth and other material to form the embankment now in progress. Mr. Grainger, the contractor for the works, had given strict orders that not more than one wagon should pass across the bridge at a time, which order being neglected was the cause of the bridge giving way. On the men being taken out, it was found that both were only slightly injured; neither were the horses much injured.

Leeds.—During a late gale of wind and rain an iron church, in course of construction, on Hunstlet-moor, for temporary use until the completion of the permanent stone church now being erected there, was blown to the ground.

The temporary edifice was being built of galvanised iron, for the accommodation of about 300 people, at a cost of about 300*l.*, and the skeleton of the structure had been fixed and the roof covered in, but the whole of this was demolished, and part of the woodwork permanently injured. The damage done is estimated at about 30*l.* or 40*l.*

Durham.—A labourer employed in building the Gaol wall was standing on a plank on the scaffold, when he got too near the end of the plank, which toppled up and precipitated him on to the ground, from a considerable height. He fell upon his head, which was much cut.

Ardingly, Sussex.—An inquest has been held into the circumstances attending the death of a bricklayer, who was killed by falling from a scaffold. Deceased was working on the scaffolding of some new huts, and was in front of a fireplace laying bricks. While stooping to take up mortar, he fell forward to the ground, face first. A surgeon deposed that he saw deceased, but could distinguish no bruise or fracture whatever. In his opinion deceased died from breaking his neck by the fall. The jury returned a verdict of "Accidental death."

THE THOMAS MEMORIAL, LLANDAFF CATHEDRAL.

A MONUMENT in memory of Mr. Henry Thomas, many years chairman of Quarter Sessions, Breconshire, has been erected in Llandaff Cathedral.

The design and general execution of the monument are the work of Mr. Pritchard, architect. The reliefs were designed by Mr. Arnstead, and executed by Mr. Clarke, of Llandaff. The monument occupies a deep recess in the wall of the north aisle, beneath the first window from the west end. The recess is fronted by two low-pointed arches, having a rich moulding of sculptured flowers, and springing from a central and two lateral columns of dark variegated marble. The capitals, bases, and other mouldings are of colic, as are two outer piers which flank the whole, and support a square hood, the central spandrel of which is occupied by an armorial shield within a sunk foliated circle, while on either side are seated figures of Justice and Mercy, carved in relief. Within the recess is vaulted in two bays, with ribs along the lines of groining, springing from foliated corbels. Upon the raised floor is laid a coffin-shaped slab of black marble, upon which is inlaid a red cross, adorned with a nimbus, and having at its foot a Paschal Lamb in Sienna marble. The tympana, formed by the two vaulting bays, are occupied by carvings in high relief; one representing the Delivery of the Law by Moses, and the other the Judgment of Solomon. Below, between these and the floor, is the inscription.

A large three-light window above the monument is filled with stained glass by O'Connor, in memory of Evan, Henry, and Llewelyn Thomas, representing the three last generations of the family.

GREAT NORTHERN BRICK COMPANY.

This company, formed some twelve months since for the purchase and development of works at Arlesley, near Hitchen, for the manufacture of patent perforated and solid white-bricks, have now nearly completed their buildings, which are on an extensive scale. The machinery will consist of two horizontal high-pressure steam engines, working up to 50-horse power each, and having boilers 30 ft. long and 7 ft. diameter, with brick-machines, crushing-rollers, and appliances, and capable, it is stated, of making from 20 to 25 millions of bricks in a year. The bricks are dried by steam power in inclosed sheds. The whole of the shares of this company are sold. The works have been carried out at a cost of some 20,000*l.* Mr. C. N. Foster, of Whitefriars, was the general contractor. The engines, mills, clay-rollers, and machinery were supplied by Messrs. Garforth, of Dukinfield, Ashton-under-Lyne; the iron roofs by Messrs. Hemmings. The buildings, drying-sheds, kilns, and all arrangements of machinery and construction have been carried out from the designs and under the supervision of Mr. John Ellis, architect.

NATURE THE STANDARD OF TRUTH IN ARCHITECTURE.*

It is not in my power, and I doubt if it be in the power of any one, correctly to define the limits where architectural truth ends and falsity begins. It is said "there is no disputing in matters of taste;" and art is so much a matter of feeling that it would be impossible to set down fixed rules which would be universally acceptable. The very life of art depends upon its freedom; like knowledge, it has no limits but those of necessity; and good taste is shown by the moderation and propriety with which that freedom is used. I propose, therefore, to submit to you some of the restraints which you should put upon the freedom allowed you (for the mind is as easily enfeebled by too much latitude as by constant restraint); and in what way you should look to nature as your pattern and guide; and the reason why I would have you to look there for guidance is, that it is there, and there only, where you can find works which are in themselves perfect.

If art, then, is to be judged by the standard of nature, it should be true; for there is nothing false in nature,—absolute truth is an attribute of the Great Architect.

A fine building must have certain qualities to render it interesting and worthy of being ranked amongst the efforts of genius; and these qualities will depend upon the bent of the designer's mind; whether or not he is earnest in his profession, and looks upon it as a noble one, demanding some sacrifice on his part, or whether it is to him merely a means by which he may earn his daily bread. To the last class of architects I have nothing to say, they are tradesmen, and not artists; they will never produce anything great, for their selfishness is certain to show itself in their works; the hand cannot execute anything higher than the mind can inspire. Do not for a moment suppose I wish you to work for fame only, such is not the custom in these our days; but as surely as you keep a high aim in view, and have the ability to reach within a moderate distance of it, so surely will your reward be the greater, even in a pecuniary point of view.

The first thing to be considered in designing a building is its situation and purpose: if it is to be a large one, breadth and simplicity should be aimed at; if small, richness and elegance. Such, you find, is the characteristic of the works of nature. The vast expanse of the ocean stretching away to the horizon, the mighty mountains "baring their naked shoulders to the sun," the ragged rock, and the knotted oak, all teach the lesson that breadth and mass are the elements of the sublime. A large structure formed of numerous minute parts can never be grand; in its detail should be subordinate to mass, so that when viewed as a whole no part should obtrude itself upon the eye.

The mountain side is studded with harebells and mosses, lichens and heath; but these are unseen when its bulk fills the sight: it is only when you ascend its slopes and peer into its crevices that these present themselves to your notice; and when you reach the summit the barren rocks and everlasting snow repose there in solemn grandeur. Place, then, rich and minute ornaments on your grand structure where the eye can search them out and rest upon them without fatigue, and aim after broad lights and deep shadows.

And with what profusion does Nature deck her minutest creations: the spotted butterfly flitting from flower to flower on its fragile wings, the flowers on which it rests, touched with a delicacy the linnæus strives in vain to imitate, the spangled breasts and glittering wings of the feathered tribe, all point to the fact that small objects are those most richly decorated. Reverse this order of nature and you produce monstrosities; a butterfly the size of an eagle would be ridiculous—an eagle reduced to the size of a butterfly contemptible. Roslyn chapel increased to the dimensions of Durham cathedral, and the cathedral reduced to the dimensions of the chapel, would, in like manner, upset all ideas of fitness and propriety. And yet some of our modern designers do not perceive even this plain and palpable truth. In our ceremonies we see temples with columns the length of a walking-stick, and sarcophagi capable only of containing the dust of a sparrow. In close affinity to this is the practice of "using models of archi-

ecture to decorate architecture," which, says Mr. Ruskin, "is one of the chief follies of the Renaissance; and, in the present day, the practice may be classed as one which distinguishes the architects of whom there is no hope."

In nature you ever find that the means are the best adapted for the object in view. It is almost superfluous to illustrate this proposition. I need only refer you to your own bodies, "fearfully and wonderfully made." Can any of you suggest—dare any one of you think it possible he could improve upon that wonderful mechanism? Is not each part the most suitable for the functions it has to perform, each having a direct relation and proportion to the other, all being in harmony without and within? In how few instances do we find this to be the case in the buildings we see around us; the exterior often bears no relation to the interior, being often unsuited to the climate, and ill-fitted for the purposes for which it is intended. Look at that Doric temple, divided into numerous small rooms. It has an upper floor, though you would not think so till you found it out on entering the vestibule. See the vain attempt to hide the chimneys, features capable of great beauty, but not being classical ones, they must be ignored and, if possible, kept out of sight. It is a fine building, doubtless, displaying much classical refinement, but it is nevertheless a sham. Look we next at this other building; it is Gothic—Gothic with a vengeance! Every available angle has a little turret attached to it; the roof bristles with little domes of every variety of form; and you look in vain for any morsel of rich detail or carving on the face of the barren walls: these turrets are useless in themselves, worthless as a decoration, an excrescence better lopped off. Here, too, at the lodge you have them repeated on so reduced a scale that they had to be built solid. Is this art? is there thought displayed here? any attempt to adapt means to an end? I leave you to form your own individual judgments on the subject.

The Middle Ages were characterized by a restless and vigorous spirit, and earnest and truthful love of the beautiful, which found vent not only in architecture, but in the chivalric devotion to the fair sex, the pomp of the tournament, and the romance of the Crusades. And when Greece was at the acme of her greatness, when philosophy and patriotism were more loved than luxury and self-aggrandizement, art flourished and she produced marvels of beauty, subjects worthy of the closest study, full of the spirit of harmony, replete with subtle refinement. Think you the refined Greek would have stuck ugly black tubes on the roofs of his temples, for the smoke to escape through, had such been necessary? Would he not rather have sought bow to decorate what was a constructive necessity, and produced a "thing of beauty?" This is the spirit in which I would have architects act, not to copy Greek or Gothic, but to design what is required. If it is not in their power to do so, then it cannot be helped. The true artist will not content himself with merely copying details, but, having imbibed the spirit of the style, he will design for himself, producing new combinations, and securing variety and originality. In our ancient baronial mansions we find that the turrets were constructed for defensive purposes, and were accessible from within, and they now form snug retreats and convenient closets for their modern occupants; they were not excrescences, but useful features decorated.

It is not always possible to make a building outwardly express the purpose for which it is erected, but it is often made to appear what it is not. The facade of an Italian palazzo placed in front of a series of iron sheds roofed in with glass is made to do duty as a corn exchange, the one part having no relation to the other; here, if anywhere an architect has a subject on which to exercise his originality, he has no precedent to trammel him, no tradition to follow, and he has all the produce of the field as suggestive detail; but imitation is easier than creation, and up goes the false front! It is not necessary to truthfulness to exhibit construction. Nature clothes with beauty all that is unseemly, however necessary it may be, but she never places the covering appertaining to one object upon another; the skin of the leopard is never seen on the tiger, nor the bark of the oak upon the birch.

A perpetual exhaustless vitality is one of the most prominent characteristics of Nature: she hates uniformity, and delights in variety; each hill and valley has a different outline; no two

trees are alike; every sheep in a flock, the shepherd tells us, he can distinguish by beard-mark, and seldom indeed do we see two human beings so much resembling each other as to be scarcely distinguishable. It is not at all probable that a real "Comedy of Errors" will ever take place; two Dromios, each having an Antipholus for master, are not likely ever to be found in the history of our globe.

The craving after uniformity I conceive to be a most unhealthy sign. What a dull prosaic place this beautiful world would become if some folks had their will! But with all their striving they cannot produce perfect uniformity: nature rebels against it. The very stones from the quarry, to their great disgust, assume a variety of tints by exposure to the air. They erect uniform rows of buildings, and one inhabitant, requiring more accommodation, adds a story to his quota, and another erects a porch in front of his, and the cherished uniformity disappears. If you will put rows of houses in uniform, do let some individuality appear on the face of each dwelling. The eyes of all the soldiers in a regiment are not of the same colour, their noses and mouths are not all of the same contour, let the War Office regulations be as strict as they may; nor, were they so, would the corps appear to greater advantage, or the men be better soldiers. Give us, then, some variety in the window-dressings and doorways of our terraces and squares,—make them uniform in style, if you will; but give us some little variety in detail. And what sacrifices you have to make in order to produce this uniformity! Windows are placed where they are not wanted, and they are absent where required. Let us ascend this common stair. Here we are at the landing. What means this? Half of a window at our feet and half of another above our heads, and a solid wall where the greatest amount of light can be admitted. What means this absurdity? "Oh," you reply, "it is in order that the windows may appear on a uniform line in the street elevation." And is the effect good, after all, on the street front? I think not. In my humble opinion, a little variety in the line of windows would give some life to what is dull and monotonous. I could point to a public building in this city where a mock chimney-stalk is built upon an iron girder, merely because a true chimney occupies a similar position upon another part of the facade; and this very building has been held up as a specimen of common-sense, unpretending architecture.

It appears to me that we derive an amount of pleasure in contemplating a building corresponding to that which the architect derived in designing it, and to the amount of thought he displays in so doing. Speaking for myself, I can say that some buildings abounding in faults afford me more gratification than others which are comparatively free of such. I would rather see a work amenable to severe criticism than one which is commonplace and devoid of interest. Such I conceive to be the reason so much interest is attached to the works of the Medievalists, some of which, if repeated now, would be looked upon as rude and unworthy of notice. It is for the same reason that work cast from a mould and repeated is so lifeless as compared with the handwork of the artificer; and the too general use of the compasses in drawing mouldings and details produces a similar result. The sketch has more life and spirit than the finished drawing. Music produced by machinery may be perfectly correct, but it cannot be expressive. On the other hand, there is often too much effort and too little thought shown in our modern work; a small church has the details of a cathedral crowded into its moderate limits, the parts elbowing each other in the most uncomfortable fashion. The effort to be picturesque is seldom successful; picturesqueness is generally the result of accident, the work of different minds, a combination of grouping and light and shade, which was unforeseen; where, however, a picturesque result has been secured by the effort of the designer he deserves a high rank as an artist. A picturesque result may be very easily spoiled by the introduction of a fresh object into the scene; and this leads me to remark that there is often too little consideration shown by an architect for the works of his compeers: the aim seems to be how to overpower the existing work by the greater pretentiousness of the new; but, in most instances, the attempt recoils upon the delinquent, the result being altogether unsatisfactory. Strive rather to produce pleasing combinations; sacrifice some of your own prepossessions for the

* From a paper by Mr. W. G. Shields, read at a meeting of the Edinburgh Architectural Association.

sake of others, and you will, in the long run, derive greater satisfaction than by following the opposite course.

The revival of ancient symbols in the decoration of our churches, is, I think, a species of untruthfulness. When these were in general use the laity were ignorant of the use of letters, the invention of printing had not opened the gates of learning to the masses, hence the necessity of teaching by means of symbolism. To the majority of the people of this century these symbols are a dead letter: to the antiquary and the archaeologist they form an interesting study, affording a pleasant field for investigation; reproduced in modern work, they are as much out of place as contorted figures introduced into new stained glass. There are some symbols, however, such as the lamb, the dove, and the cross, the meaning of which is obvious, and which are beautiful in form: to the introduction of such there can be no objection: I refer to those hieroglyphics which only the initiated can understand, which few take the trouble to decipher, and which are not good in form, or worthy of being used as simple decorative features. I make these remarks with diffidence, as it is much a matter of feeling, and some seem to derive pleasure, and it may be profit, from the practice.

Feeling is the source and fountain-head of all true beauty in art. The strictest adhesion to rule will not make a designer an artist: as well attempt to write a poem by rule as to design a beautiful structure by rule. Unless the poet's soul be in the man, his work will be prosaic. He must have experienced himself the sensations he wishes to create in others. A man may be deeply learned and a profound thinker; but, unless he is endowed with a peculiar organization, and has special qualities of mind, he will be deficient in taste, and remain blind to much that is beautiful in art, and which is keenly felt and easily discernible by a less gifted mind.

We are at the beginning of a great social era; social forms are rapidly changing, and wealth is increasing in the land to an unprecedented degree; the love of art is spreading, and the skill of the architect is more and more in request. It rests with yourselves what use you will make of your opportunities,—whether you will lead or be led by your clients, whether you quietly acquiesce in demands for what you know to be bad art, or whether you will strive to plant a little piety into the too general commonplace. Many of you whom I am addressing are at the outset of a noble profession. You will either leave behind you works which will be a source of pleasure to future generations, and which they will love and cherish, or things which will encumber the earth, and which they will be eager to clear off its surface as blemishes. Be earnest, be truthful; let everything you do be the best of its kind that you can do. Your productions should last for ages, and teach others as you have been taught. "The true secret of genius is to suffer no fiction to exist for us; to realise all that we know in the high refinement of modern life, in arts, in sciences, in hooks, in men; to exact good faith, reality, and a purpose; and first to last, and without end, to honour every truth by use."

SCHOOLS OF ART.

The Slough School.—At the annual meeting of this school the prizes and certificates gained by the students were distributed by Mr. H. W. Foley, M.P., who presided. The report of the Council stated that the works executed by the students during the year, showed that satisfactory progress had been made. The number of students continued to increase, but it was a matter of regret that so few glass-makers entered the classes. The present system of Government examination of drawings had been as beneficial to the students as to the school. The result of the elementary examinations at Oldswinford, under Mr. Rainbach, had been highly satisfactory. The report further stated that Mr. Keen had been appointed assistant-master, in the place of the late Mr. Rose.

The Chester School.—The students of this school recently presented to Mr. E. A. Davidson, their head master, a token of their regard on his leaving Chester, after filling the situation of head master of the school for nearly fourteen years. The chair was occupied by Mr. Griffiths, assistant drawing-master. An address to Mr. Davidson was read by one of the senior pupils, asking him to accept, as a small token of their

regard, a handsome inkstand, in walnut wood. A small silver plate on the inkstand bore the inscription. A number of gentlemen, also, who have been connected with Mr. Davidson in his capacity of a professor of drawing, together with a number of the elder pupils of the Chester School, have presented Mr. Davidson with an English skeleton timepiece, embellished with a figure (in gold) of her Majesty the Queen, and 50*l.*, in recognition of that gentleman's services as master of the School of Art. The Mayor presided.

The Manchester School.—The annual distribution of prizes awarded by the Department at South Kensington, to students in this school, took place in the lecture theatre of the Royal Institution; Mr. Thomas Bazley, M.P., president, in the chair. There was a numerous attendance of ladies and gentlemen. The Chairman said he could not omit noticing the works contributed by the female students: they were certainly running hard in the race, and he felt sure he should only be doing justice to the male students if he said that, in the spirit of gallantry, they would be glad to be eclipsed by their female competitors. To the teachers a great debt of obligation was due; and to Mr. Muckley, the head master, in particular, because he had not only been the instrument of teaching the young how best to pursue their studies, but had contributed beautiful works in the exhibition which now adorned the Royal Institution. He was glad to hear that at present the school numbered some 300 students, for every one of those students he regarded as a missionary of good and refining taste, as well as a missionary for the elevation of his fellow creatures. Mr. W. J. Muckley, the head master, then addressed the students on the subject of their studies. He said that patience must enter as an element into all their efforts. For the most part, success was measured in everything by the patient endurance one could bring into the composition of one's labours. It mattered not whether the student might be artificially engaged or otherwise, the ingredient of patience must be largely in the compound of all studies in order to ensure distinguished success. He spoke also of the essential necessity of progression, and passed on to notice the two classes of students—those whose tendencies were to become painters, and those who wished to apply their knowledge to purposes of decoration. Without wishing to dishearten any of the students under his care, he would ask them to consider to what their engagements in the institution were leading. He would have them recollect that the calling of an unsuccessful painter was one of much wretchedness. Europe was absolutely inundated with bad painters. The alternative was the taking up of that department of art (the humbler department, certainly), for which many of the students were capacitated—the art of applying the beautiful to the useful in the wide world of the decorative arts. The greatest geniuses in art had thought it worthy of their consideration to devote much of their time to the application of art to industry. The vast gatherings of merchandise in the various industrial exhibitions showed clearly enough how much might be done in this direction, notwithstanding the great growth of the ornamental arts during the last fourteen years. Many of the students of this institution had long made the decorative arts their exclusive study, and after a comparatively short career had, without difficulty, procured honourable appointments, and certainly much more remunerative than any engagement they could have obtained in connexion with other walks in art. Let them not forget that the Manchester School of Art possessed such machinery for the furtherance of the knowledge of ornament as no other school in the provinces had at command. Mr. Bazley distributed the prizes.

The Cork School.—The annual distribution of prizes and distinctions awarded for works executed by the students of this school, took place in the Rotundo of the Athenaeum. The premiated works and many others executed in the school during the year were exhibited, and attracted great attention from the large number of persons who visited the Rotundo. The master of the school (Mr. James Brennan) read the report for the past year, from which the following is taken:—

"The numbers attending the school for 1865, when contrasted with the present year, stand as follows—102 for the summer period of 1865, against 125 this year for the same period; and 149 for the winter session, against 115 this year, so that there is an increase in the number of students attending the school this year. Amongst the successes which students of the school have obtained this

year, I may mention the following. Two of our lady students, Miss Anne Baier and Mrs. Henry Hill, forwarded original paintings to the Exhibition of the Society of Female Artists, London, where the former lady was fortunate enough to dispose of one of her paintings to an English gentleman the first week of the opening. A number of drawings from the various schools of art were sent in to the International Horticultural Exhibition, for competition, and to one of our students, Mrs. Henry Hill, the second prize was awarded for drawings of orchids, London, taking the first prize, and Edinburgh the third. With regard to the prizes offered by the Department, the list has been increased and improved. They offer for next year a competition for gold medals, six of them for design, twenty silver medals, fifty bronze medals, and prizes of books in addition, perfect freedom being left to the student in the choice of subjects for competition in the various stages to which prizes attach."

IMPROVEMENT OF PRESTON HARBOUR.

PRESTON occupies a position of great business importance; but its river, the Ribble, like the Clyde of last century, is useless for vessels of any size worth speaking of. It appears, however, from a report to the Corporation, by Messrs. Bell & Miller, C.E.,* that for a sum of 110,000*l.* not only could the Ribble be effectively deepened so as to admit large vessels to the town, but from thirty to sixty acres of docks could be there secured in the vicinity of the present quays.

The report makes it quite clear that the improvement of the Ribble presents no difficulties compared with those which have already been overcome on the Clyde. Messrs. Bell & Miller point out, in the first instance, that in the Ribble (which is tidal, and seventeen miles in length from Preston to the sea) there are great facilities for forming and maintaining a comparatively straight and uniform channel of easy access. This they propose to do by deepening the river from Preston to Naze Point, and by removing a ridge or bar of marl and gravel at Bank Nook. The training walls of rubble which serve to contract the channel and guide the current terminate at present near Naze Point; but they propose that the south wall shall be carried some distance beyond Lytham Pier, where it may be said the sea channel begins. The river bed, we are assured, presents remarkable facilities for deepening, the levels are in every respect suitable, and the nature of the strata of the river bottom affords facilities for its removal, as it is composed of sand along nearly the whole of its course below Preston.

The cost of these improvements on the channel of the Ribble, the engineers estimate at 23,000*l.* If the lock of the proposed harbour be placed at Ashton quay, something like 36 acres of dock accommodation would be obtained, at a cost estimated at 74,000*l.*; but if the lock be placed at the point indicated lower down the river, a dock area of 60 acres would be obtained, at a cost of 80,000*l.*

The Ribble committee of the Corporation have had the report upon its improvement under consideration, but they have come to no resolution as yet on the subject.

Preston is an enterprising place. The inhabitants have spent large sums in the drainage and other improvements of their town, and it is only surprising that they have been so long in following such examples as those given by Glasgow and other important and thriving towns. The district of Lancashire in which Preston is situated is a very thriving and populous one, and the Ribble is quite as much fitted to be its outlet to the sea as the Clyde is of Glasgow. The advantages of such improvements as those contemplated would be immense, and it is to be hoped the people of Preston will not rest satisfied now till they be carried out.

NITRO-GLYCERINE.

AMONGST the latest batch of Acts passed during the last Session is one relating to the "Carriage and Deposit of Dangerous Goods," which is of some public importance. The frightful explosions of nitro-glycerine which have taken place abroad caused the late Government to bring in a Bill to regulate the transmission of this dangerous explosive. The Act is dated August 6*th*, and it provides that nitro-glycerine, or glonoinic oil, shall be deemed "specially dangerous;" and also gives power to her Majesty, by an order in council, to declare any other goods to be "specially dangerous," within the meaning of

* "Report to the Mayor and Corporation of Preston upon the Improvement of the River Ribble, and the Construction of Docks and other Works, at the Port of Preston." Bell & Bain, Glasgow. 1866.

the Act. No person is to deliver any specially dangerous goods to any warehouse owner or carrier, or deposit such goods on any quay or in any warehouse or ship, for transit, without distinctly indicating the nature of the contents on the outside of the package; and at the same time giving notice in writing to the owner of the warehouse or quay, or to the carrier, stating the exact nature of the goods, and also that they are specially dangerous. The infraction of the law is punishable by forfeiture of the goods and a fine of 500*l.*, or imprisonment, with or without hard labour, for any term not exceeding two years. Section 6 provides that no warehouse owner or carrier shall be bound to receive or carry any goods which are specially dangerous. With regard to the storage of nitro-glycerine, the 8th section provides that the "Act for the Safe Keeping of Petroleum" (25 and 26 Vic., c. 66) shall extend to nitro-glycerine, and shall have effect as if nitro-glycerine had been mentioned in addition to petroleum; with this difference, that the part of the Act which specifies the maximum quantity of petroleum to be kept without a licence shall not apply in the case of nitro-glycerine, "and any quantity whatever of nitro-glycerine shall be deemed to be subject to the provisions of the said Act." The same rule is also to apply to any other substances which shall hereafter be declared "specially dangerous" by an order in council. The Act will probably have the effect of entirely stopping the trade in nitro-glycerine in this country until its use has become a little more familiar.

A report on the dangerous nature of nitro-glycerine was presented to the underwriters by Captain Grant, one of the officers of Lloyd's Salvage Association, who placed himself in communication with Professor Abel, of the Royal Arsenal Laboratory, Woolwich. Appended to the report is a copy of a circular issued by the Prussian Government respecting the transport of nitro-glycerine. It is to be packed in bottles made either of tin or strong glass, which must be closed by a stopper of cork, not of glass, and they must be cased with cork, and have an inside lining of straw. As a further precaution, the bottles are to be packed with hay, straw, or the like, in tight wooden cases, and the packages are to be marked *Sprengel* (blasting oil). Particular care is to be exercised in the transit of nitro-glycerine during cold weather, as it freezes into a solid mass at low temperatures, and is then, it is said, peculiarly liable to explode by concussion. As regards the warehousing of blasting oil, the same orders have to be complied with as those applying to gunpowder and other explosive articles. The penalty for an infraction of these rules is not to exceed ten dollars (about 30*s.*), so that it will most likely be found cheaper to disregard the regulations, and, if detected, pay the fine. In the United States, the laws affecting the transport of this substance are very stringent. It must not be conveyed in any vessel or carriage carrying passengers, under a penalty of 5,000 dollars. In case of death from a violation of the law, the parties are liable to be indicted for murder. Nitro-glycerine is not to be transported unless packed in a metallic vessel separate from all other substances, and labelled, "Nitro-glycerine—Dangerous." Violations of this clause are to be punished by a fine not exceeding 3,000 dollars.

Some interesting particulars have been communicated to the Academy of Sciences by M. Kopp, who stated that nitro-glycerine had been introduced into the sandstone quarries of Zorn, on the Lower Rhine, where it had been exclusively used for six weeks. M. Kopp is of opinion that the transport of nitro-glycerine should be entirely forbidden, and that it should be prepared on the spot; and he gives the details of the method of preparation which he thinks the best. The properties of nitro-glycerine, as given by different experimenters, appear to vary very much, scarcely any two observers agreeing on the subject. M. Kopp is a very eminent chemist and a well-known careful experimenter, and is moreover unconnected with the trade, so that his results have more value than any of which we have previously been possessed. He finds that when nitro-glycerine is exposed to the prolonged action of a moderate degree of cold, it crystallises in long needles, in which state it will explode by a sudden blow. It may now be handled easily and without much danger. When spread on the ground, it takes fire with difficulty by contact with a burning body, and only burns partially; a flask containing nitro-glycerine may be broken upon stones without explosion taking place; it may be volatilised without decom-

position by a regulated heat, but if it boils, detonation becomes imminent. If a drop be let fall on a metal plate moderately heated it evaporates quietly, but if the plate be red hot, the nitro-glycerine takes fire immediately and burns like gunpowder, but noiselessly. If, however, the plate without being red hot, is hot enough to make the drop boil immediately, it decomposes suddenly with a violent explosion. M. Kopp accounts for the recent disastrous explosions by stating that nitro-glycerine, especially when impure and acid, is liable to spontaneous decomposition, accompanied by an escape of gas and the production of oxalic and glyceric acid. When the substance is enclosed in well-corked bottles, the gases cannot escape. They exercise an enormous pressure on the nitro-glycerine, and in this state the least shock and the slightest movement will cause an explosion. M. Kopp's paper is translated entire in the *Chemical News* from the original in the *Comptes Rendus* of the French Academy for the 23rd of July.

Several methods of preventing the accidental explosion of nitro-glycerine have been proposed. The inventor has suggested to dilute it with wood naphtha, which may be removed when desired by the addition of water. The naphtha mixes with the water, and the pure nitro-glycerine sinks to the bottom. There are several objections to this. It is expensive, and probably there would be some chemical action between the two liquids. Naphtha vapour, moreover, forms an explosive mixture with air. It has also been proposed to store nitro-glycerine mixed with sand, which is to act somewhat in the same way as the silicious matter used by Mr. Gale for "protecting" gunpowder. It is not very clear how the sand is to be removed when the nitro-glycerine is required for use. The most sensible proposal seems to be that put forward by Professor Seely, of New York, who appears to have given the subject a good deal of attention. It consists in exercising more care in the original preparation of the compound, and in keeping suspended in the oil a small quantity of neutralising substance, so as to destroy the acid as it is formed, and thus check the tendency to spontaneous decomposition.

The nitro-glycerine sent out from Messrs. Nobel's manufactory at Hamburg is contained in wrought-iron bottles, about four-fifths full, and packed in iron-bound boxes, each bottle being separated from its fellow by a layer of marl, so as to avoid any chance of explosion by the accidental striking of one against the other during transit. It is stated that boxes packed in this manner have been flung about and subjected to all kinds of rough usage, with the view of testing the safety of this mode of transport. The latest novelty introduced by Messrs. Nobel is a signal-rocket, which is capable of ascending to the height of 800 to 1,000 ft., although the body is not more than $\frac{1}{4}$ in. diameter, and $2\frac{1}{2}$ in. long.

TOMB OF NOVEL DESIGN.

CONSIDERABLE difficulty has been found lately in designing the tombs of the departed. The old Pagan emblems of blazing urns and extinguished torches, and even the broken column, do not point out the hopes the Christian has for the future. On the other hand, the Mediæval styles may be incongruous with the habits and the customs of the present day. What can he more ridiculous than to see, as the memorial of a late liberal member for a metropolitan borough, a portraiture in incised brass let into the pavement armed in all points like a knight of Edward III.'s reign? One is tempted to say, in the words of George Canning, "No waiter! but a Knight Templar."

The tomb of which the enclosed woodcut is a perspective view has just been erected in the Brompton Cemetery, to the memory of a gentleman many years member for an important borough in the West of England. It has been designed by Mr. Ashpitel, in the style of those of the early Christians, as found in the catacombs at Rome. The body is of Portland stone; the frieze and plinth are of green Forest of Dean, and the pilasters of polished Peterhead granite. The most novel features of all are the statues of the four Evangelists, in bronze, by Messrs. Potts, of the Art Works, at Handsworth, near Birmingham, which are cast by their new process, and are undercut and chased up by hand in a very satisfactory manner. They were modelled by Signor Brucciani. On the top is a plain cross; on one side, the monogram of Constantine; and,

on the other, an interlaced Alpha and Omega. It seems curious that so little attention has been paid to the works of the early Christians. It is allowed on all hands, by all sects and parties, that the Christian religion was then in its purity; and, besides this, it was an age of great refinement. Of course we are no advocates for mere dry copyism, but we think some good aspirations might rise from the study of a style that clearly cannot be called Pagan.

ANCIENT SYNAGOGUES IN CENTRAL EUROPE.

ON first thoughts it may seem strange that the Jews have left us so very few Mediæval antiquities, but on further consideration one ceases to be astonished, as the persecutions which that ancient people endured from time to time, and their almost nomadic condition, allowed them little opportunity to pursue the fine arts, particularly architecture. The only remains of any importance in central Europe that can safely be ascribed to them are the synagogues at Worms, Prague, and Frankfort. All these buildings are small, and none of them can be quoted as first-rate specimens of the architecture of the date at which they were erected.

The earliest is the synagogue at Worms. This building consists of a nave about 50 ft. long by about 35 ft. wide, divided down the centre by two cylindrical columns, and a kind of transept or aisle built at right angles, opening into the nave by two sharp-pointed arches. The capitals of the columns of the nave are very remarkable, and show considerable elegance of design and skilful execution. Each cap is carved out of one solid block of stone; the shafts are also monolithic. These columns support a simple Roman vault, of very solid construction, but entirely devoid of ornament; and the contrast between the richly-sculptured capitals and the plain vaulting gives rather an Eastern appearance to the interior of this singular building.

The windows are mostly semicircular-headed, two of them, however, arched; but the splay of the head is made to take a semicircular form internally. Above some of the windows are simple round openings. The "ark," or tabernacle for keeping the sacred books, is a work of the latter part of the sixteenth century, and is in rather a barbarous Italian style; but very peculiar. In the centre of the building is what we should call the choir in a Christian church, with a stone desk; this portion of the building is raised one step above the rest of the nave, and surrounded by a low iron railing. From the roof some very fine chandeliers, of seventeenth-century work are suspended; several of them are adorned with scroll-work, and have the imperial eagle over them.

The exterior of this building is nearly as singular as the interior; one is first admitted into a court, three sides of which are occupied by buildings, and the fourth side is open to a kind of cemetery. The first side of this court consists of a sort of gatehouse, of no very early date; the next side is formed by the before-mentioned transept, which, by the way, is devoted to the use of the female portion of the congregation; a stone bench runs along this building, protected by a kind of penthouse roof. The third side is formed by a portion of the nave of the building and a small late addition called the "Raschi Chapel." The earlier portions of this synagogue are probably as early as the twelfth century. The people at Worms claim for it a much earlier date, but the peculiar style of the caps fixes the date almost beyond a doubt. It is singular that one of these caps bears a strong resemblance to one in the Church of the Nativity, at Bethlehem.

This synagogue is now being restored, and the whitewash with which it was disfigured is being scraped off. In the view, made specially for our pages, the benches are omitted, as they are quite modern, and very ugly.

The synagogue at Frankfort* is of the same general plan as that at Worms, with the exception that there is no transept or aisle. The vaulting is curious; it is arranged in an oblique form, so that a pendentive comes opposite to each arch. The date of the building may be half a century later than that of Worms.

The synagogue at Prague is exactly similar in plan to that at Frankfort; it is a building of the thirteenth century, and very pure and good

* We fear this building has been destroyed during the alterations of the last few years.

in all its details. The columns are octagonal, with capitals that form a star on plan: each ray of this supports one of the vaulting ribs, which are well moulded. The windows are simple lancets, except at the east end, which is lighted by two plate tracery quatrefoil openings, inclosed in circles. The "Ark" is very singular, and looks like a piece of Italian Gothic of the fourteenth century. It is composed of a kind of grey limestone, and has twisted columns, and a pediment adorned with regular Italian Gothic

crockets. The women's gallery looks into the synagogue only by three small segmental windows.

Near this last is a very small synagogue, probably of fifteenth century work. It is simply an oblong room, with a prettily vaulted ceiling. All the windows have been modernised, and the interior was refitted during the last century. There is a large old cemetery belonging to the Jews in Prague; but although it has been used for over ten centuries we do not think that any monu-

ment at present in existence is of an earlier date than the sixteenth century. The monuments greatly resemble those in English churchyards of the last century; simply a large head-stone, with a good deal of bad "Rococo" carving over the upper part of it.

The synagogue at Ratishon is a fifteenth century building; but we were unable to find out whether it had always been used for its present purpose.

We are not aware of the existence of any

A TOMB IN BROMPTON CEMETERY.—MR. ASHMET, ARCHITECT.

other old synagogues in Germany; nor do we know of any in France.

Spain is said to possess one or two, but we have been unable to gain any information respecting them. In England the only building of the kind is the old borough gaol at Bury St. Edmunds, which is known originally to have been a synagogue. It is a very small Early Norman building, 36 ft. long by 27 ft. wide. At one end are two well-moulded semicircular headed windows. The interior of the building has been so much mutilated that it is quite im-

possible to realize its original condition. Until a recent period this building went by the name of "Moses's Hall." The fact which most strikes an observer in all these synagogues is their great similarity to Christian buildings of the same date. And one is led to wonder how it was that a people so isolated from those who surrounded them as the Jews were, should have condescended to have adopted the style of those amongst whom they lived, particularly in their religious buildings, where it might be expected that anything like "Christian architecture"

would have been most scrupulously excluded; and this leads us to the conclusion that the synagogues we have described, although built for the Jews, must have been erected by Christian workmen. On the other hand, however, the similarity of plan to be observed in these buildings would seem to point to some traditional arrangement which the builders were unwilling to depart from for many centuries; and this would appear to indicate that these synagogues were, even if erected by Christian workmen, planned by the Jews themselves.

ANCIENT SYNAGOGUE, WORMS, GERMANY.

PHOTOGRAPHY.

M. NEPCE DE SAINT-VICTOR states that the obtaining of the black tints in chloroform is certainly more extraordinary than obtaining colours. There are four processes by which these results can be produced. The first offers most interest, because it allows pure black tints to be obtained either in the camera or by contact. These results are accomplished by the reaction of a highly alkaline liquid upon chloride of silver.

M. Silvy has sent to the Photographic Society of France some photographs obtained by the aid of the magnesium light, of the vanits of the Chapel Royal of Dreux. These vanits, without being subterranean, are excessively dark, and only receive the daylight through painted windows placed at a considerable height, and very intense in colour; so that, without artificial illumination, it was impossible to take photographs of them. The lamp he used is so arranged as to burn at the same time four ribbons of magnesium passing through two parallel tubes, and the light produced by it is exceedingly beautiful. A great portion, however, of it is lost, or rather intercepted by the part of the ribbon which, having been burned, does not detach itself fast enough, and so obstructs the brilliancy of the flame, exactly as a candle which wants snuffing. It would be very easy, however, to obviate this inconvenience if, while waiting for some better contrivance, these primitive lamps were a little improved. As, in this actual case, a great surface, that of an entire tomb, had to be lighted up, the lamp was obliged to be placed at a certain distance, and moved nearer to or farther off, according to the effect to be produced, and the time of exposure was rather long; it was never less than six or eight minutes with plates prepared with wet collodion. The lamp used was furnished by Mr. Solomon, of Red Lion-square, London. The six tombs reproduced are those of the Duchess dowager of Orleans, the Duke of Orleans, Princess Marie Duchess of Wurttemberg, the Duke of Penthièvre, Made-moiselle de Montpensier, and the Angel of Grief.

NEW CHURCHES AND RESTORATIONS ABOUT WORCESTER.

Owing to the large increase of the population in Worcester and its neighbourhood during the last few years several new churches have sprung up, and the enlarging and restoring of others is being rapidly proceeded with. From the local *Chronicle* gives an account of these, from which we quote. A new edifice has been erected near the Shrub-hill Railway Station for the parish of St. Martin, which has become too populous for a single church, and another at Barbourne. Only a few months back the new Presbyterian Church, in Castle-street, was opened; and now efforts are being made to build another church in connexion with the English establishment in this, the Tything district. The site selected for this church is nearly opposite St. Oswald's-walk, in the Tything. It is intended to re-pew St. George's Church.

St. Nicholas's, Worcester, is being generally repaired and re-seated. The roof, which was in a lamentable state, has been for the most part renewed. The old pews have been removed and open sittings substituted, by which means additional accommodation will be obtained. The high gallery front has been removed and replaced by an open one, in which wrought-iron work, executed by Skidmore & Co., of Coventry, has been introduced. The building will be warmed by means of Haden's hot-water apparatus. It will be lighted and ventilated by a central sn-light gas-burner. This edifice was always considered a dark and gloomy one, and it was rendered still more so by the erection of the new City and County Bank, but it will, owing to these alterations, be rendered much lighter, especially when the side windows have been re-glazed.

The rebuilding of Hallow Church is also being rapidly proceeded with by the contractors, Messrs. Inwood & Osborne, of Malvern, from plans provided by Mr. W. J. Hopkins, the diocesan architect. The site is central. The edifice will consist of a nave and chancel, north and south aisles, vestry, south chapel for the children, south porch, and a western tower. The tower is not included in the present estimate. The nave will be 42 ft. high from the floor to the collar-pieces of the roof, 60 ft. in length, and 20 ft. in breadth. It will be divided into four

bays, the arches to which will be supported by circular columns, having corresponding responds. Over each of the columns and responds, and spanning the whole width of the nave, will be stone arches supporting the roof-timbers, answering the purpose of ordinary wooden principals or trusses. The thrust of these arches, and those of the corresponding ones over the aisles, will be counteracted by means of external flying buttresses. The body of the church will be lighted by means of a large five-light western tower window, having rose tracery; circular clerestory windows, having alternating patterns of tracery; and the several tracery two-light windows in the north and south aisles. The chancel will be 32 ft. in length by 18 ft. in width, having a lofty open-timbered roof. It is lighted by an east window of three lights, and north and south windows of two lights. The children's chapel is placed at the east end of the south aisle, and the south window of the chapel is rendered distinctive by being gabled. The vestry and organ-chamber are placed in a corresponding position at the end of the north aisle. The tower and broach spire will be 143 ft. high, if built. The church is of the Early Decorated style. It will be built entirely of stone, given by the Earl of Dudley, and chosen by the architect from one of the best quarries on the estate. It will be fitted up with plain open deal seats, and the pavements will be laid with red and black encaustic tiles, from the manufactory of Mr. Godwin, near Hereford. A slight polychromatic effect will be produced by the introduction of grey stone with the neighbouring red stone, in the columns, arches, and other portions of the building. Earl Beauchamp intends giving a reredos.

At St. George's, Kidderminster, an improvement has been made, by the erection of a reredos, extending the whole width of the sanctuary, and formed into three compartments, by means of three horizontal bands. In the centre, over the altar-table, is a canopied recess, surmounted by an alabaster cross, enclosing a large sculptured group, the subject of which is the Ascension, by Mr. Wm. Forsyth, of this city. The floor of the sanctuary has been raised, and laid with encaustic tiles. Several other improvements have been made in the arrangement of the east end of the church, and the walls are being decorated so as to harmonise with the new reredos.

The old Chantry Chapel at Kidderminster has been restored, by Mr. Hopkins, at the expense of the Earl of Dudley. A new open-timbered roof has been substituted for the flat modern plastered ceiling. A new floor has been laid, and the whole of the building renovated. The builder was Mr. Haigh, of Kidderminster.

CIVIL ENGINEERS AND PUPILS.

CONSIDERABLE discussion has from time to time taken place at the Mersey Dock Board relative to the restrictions placed upon the engineer of the Board (Mr. Lyster) as to taking articulated pupils. Last week a proposition was made to abolish these restrictions, and letters were read from the engineer-in-chief of the London and North Western Company and other eminent engineers, stating that it was one of their privileges to take articulated pupils. It was pointed out that the Mersey Dock Board Estate offered a field unequalled in the world for young aspirants to engineering skill and fame. Ultimately the proposition was adopted, the arrangement being that the engineer should be allowed to take three pupils, which it was estimated would add about 300l. a year to Mr. Lyster's income, which is at present 3,500l.

PADDINGTON.

AMONG other improvements going on in this important parish is the erection of a bridge over the canal at Westbourne-green, commonly called the Lock Bridge. The Board of Works guaranteed to subscribe the sum of 1,500l. The work was at once commenced. A temporary bridge, built for the traffic during the construction of the new one, was opened in September last. The work, according to the contract, was to be completed in four months; but, owing to the great obstacles that had to be contended against, and the temporary bridge being found to stand well, a further grant of time is allowed to the contractors, who are Messrs. Dixey, of Abchurch-lane, City. The cost will be 5,040l., which will

principally be borne by the parish, the Board of Works paying the 1,500l. as above named. The bridge will be constructed chiefly of iron. It is being manufactured at Birmingham, and is on its way to the works. The sides will be 6 ft. high on each side, to prevent the nuisance that was so great on the old bridge to foot-passengers, through so many idlers standing about. The new bridge will be about 30 ft. wider than the old one. The work is being carried out under the superintendence of Mr. E. H. Thomson, resident engineer, on behalf of Mr. W. Kinipple, C.E., and the Vestry of Paddington; Mr. Cook being the principal on behalf of the contractor, Mr. Dixey. Messrs. Vigers have erected large wharfs on the right of the bridge; and a new road is formed, called Ambley-road, likewise a terrace, opposite the hospital; and in the coming summer there will be upwards of 400 houses commenced on the fields across to Kilburn.

INDUSTRIAL TENEMENTS, DUBLIN.

The first stone of the new model dwellings about to be erected in Meath-street by the "Industrial Tenements Company" was laid on the 20th instant by the Lord Mayor of Dublin.

The plan of the buildings represents a series of double dwelling-houses four stories in height, each floor affording two complete family tenements, comprising living-room, scullery, and bed-recess, with two extra bed-rooms, each communicating directly with landing, or inclosed at pleasure, with external door at entrance, the staircase being in the centre, upon each lobby of which an open gallery has been provided, having cinder-shaft on one side, and water supply with sink leading to drain on the other. The ground-floor fronting Meath-street has been appropriated for shops, the entrance and stairs to dwellings over them being in the centre, and the hasement being intended for storage. The ground-floors are intended to be paved with tiles on concrete, the upper stories having boarded floors. The laundry and drying-rooms, with "closets," will be provided in the airing-ground at rear of all the buildings. It has been considered desirable to give the buildings more the appearance of a number of commodious dwelling-houses than that of a public institution, as being more suited to the tastes and habits of those for whom they are intended, affording also greater safety from contagion, fire, or other casualties. The entire buildings will afford 120 rooms, with two extensive shops and stores on basement for letting. The contract has been taken by Messrs. W. & J. Beckett for 4,365l., and will be carried out with all speed under the direction of Mr. Charles Geoghegan, architect to the company.

THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held at the House, in Conduit-street, on Friday evening (the 21st ult.), Mr. E. J. Tarver in the chair.

The following gentlemen were elected members of the Association:—Messrs. Lovejoy, Drury, Colthart, Woodcock, Winks, Capes, E. Skerritt, &c.

Mr. L. W. Ridge called attention to a class which had, he said, been established to fill the place of the Voluntary Examination Class, and the object of which was to promote the knowledge of practical subjects. The mode of study would be by question and answer; and he hoped that as many members of the Association as could spare time would attend it.

Mr. G. H. Birch then read a paper "On the Conventual and Parochial Churches of the City of London and its ancient Wards." In reviewing the history and describing the more salient points of many of these buildings, he expressed his regret that there was no conservative spirit abroad to save such historic monuments from desecration and destruction. Of the 114 churches in the City of London and the wards belonging thereto, which were in existence before the Fire of London, eighty-nine were destroyed by that great disaster. The East Minster, so called to distinguish it from West Minster, and founded by Matilda, the wife of King Stephen, was removed in order to make room for St. Katharine's Dock, which might just as well have been placed a little lower down the river. Having referred to several other churches,

of which no vestige now remains. Mr. Birch concluded by entering a protest against the proposed destruction or removal of City churches. Such relics of Old London ought, he thought, to be dear not only to the antiquary and archaeologist, but also to the architect; and he hoped that no utilitarian considerations would be allowed to disturb them.

Mr. Ridge called attention to the gigantic railway station lately erected by the South-Eastern Company, in Canon-street, which, he said, completely shut out the view that used to be obtained from London Bridge of St. Paul's Cathedral, Dow Church, Christ's Church, and other buildings, and which used to form so pleasing an architectural combination. He regretted that no measures had been taken in time to prevent this, as he saw no reason why the roof should have been carried to such a height.

The Chairman suggested that it would be very desirable that the members of the Association should visit the old City churches still left.

WASTE LANDS AND WASTED RESOURCES OF IRELAND.

Of all the great questions that agitate the public mind, and which are daily growing in intensity, those relating to Ireland are the most momentous at the present crisis. It was proposed in 1852 by the party now in power, just before the ministry collapsed, to enact a law for the establishment of tenant right; in subsequent sessions various other measures of improvement were debated, such as the modification of the Church of England, and a more equitable appropriation of its revenues in that country; but no definite and pronounced plan has ever been mooted for the attainment of objects which would, beyond all others, promote the prosperity, happiness, and content of the people; and these are, first, the reclamation of waste lands; and, secondly, an extended system of education.

Seeing that one of the most fertile regions of earth, in the temperate zone, in close affinity with Great Britain, should at this epoch, with a redundant and energetic population, be cultivated in only one-fourth part of its extent; that the people, to the amount of one-third of their number, are wholly untaught and steeped in ignorance; under these circumstances, coupled with the fact that five-sixths of them differ from the established and endowed religion of the country, it can excite no surprise that disaffection should widely prevail amongst them, and that they should seek upon a remote Continent fields for cultivation and homesteads which were denied them at home.

Representing over a fourth part of the United Kingdom, the condition of Ireland is a standing reproach to the ruling authorities. Since the first invasion and subjugation of the island by Strongbow, a continued series of feudal strikes, revolts, and massacres, kept the country in a constant ferment, until Cromwell, under his lieutenantcy, in 1617, established a firm, if not a better, order of things; and from that period when, under the Act of Settlement, the greater part of lands were forfeited, a large infusion of English soldiers and settlers took possession of almost the whole extent of three out of the four provinces, locating the extruded population in the province of Connaught, vast numbers of Scottish families having previously settled in Ulster, under the reign of James I.

In the year 1672, the first recorded census returns the population as 1,820,000 souls; in 1754 it was 2,372,634; in 1792 it was 4,088,226, from which period, and subsequent to the union with Great Britain, in the year 1841 it had increased to 8,196,597. In consequence of the famine of the year 1817, caused by the disease of the potato, and the failure of that crop, a rapid decrease had set in, until the year 1861, when the census returns gave the number as 5,798,967, being a reduction, in twenty years, of 2,397,630.

Owing to the default of manufacturing enterprise and the dearth of employment in other than agricultural labour, famine effected fearful ravages; but the decrease of population was chiefly owing to emigration, which carried off to America a million and a half between the years 1851 and 1856.

The insufficiency of cultivated superficies in Ireland for a population thus redundant, and the conditions of land tenure, coupled with latent disaffection in the multitude, unable to obtain patches of ground to grow their only subsistence—the potato—lured them across the Atlantic,

where, on a less fertile soil, and in a less genial climate, they at last found scope for that industry which, when encouraged by the actuality of freehold possession and an open market for labour, soon realized so much independence as enabled them to remit to Ireland in ten years as many millions sterling, and thus they attracted their relatives to share the land of their adoption.

The whole area of Ireland, very little improved by reclamation or drainage, represented originally, as it now does, in round numbers, 21,000,000 acres.

Of this superficies, according to authoritative returns of 1864, the quantity actually under tillage was 5,705,636 acres. Of this extent the quantities are as follow:—Cereal crops, 2,257,461 acres; potatoes, 1,039,282; turnips and other green crops, 436,253; flax, 301,890; meadow and clover, 1,608,124; and fallow, 32,656. Thus it appears that of the five millions and a half acres, over one million consisted of potatoes, which was the staple food for a nomadic population.

As to the social condition of the multitude, a very fair inference may be drawn from the educational returns of the decade between 1851 and 1861. In the former year the total number of persons who could read and write were 1,938,685; of those who could read only, 1,203,046; and of those who could neither read nor write, 2,766,283; whereas, in 1861, the numbers ran, of those who could read and write, 2,105,958; of those who could read only, 1,022,787; and of the utterly ignorant, 1,973,382.

From these authoritative returns we perceive an apparent advance in the year 1861 over 1851, which might argue a great improvement in mental culture of the people; but, unhappily, the census returns also furnish an estimate of the number of ignorant persons who emigrated within the decade, and sets down the probable number as 458,901, who transferred at least their physical forces to a foreign allegiance.

Owing to the influx of English and Scottish farmers since the year 1820, and perhaps to an improved system of agriculture, the profitable lands of Ireland were let out in more extensive tenures; to effect which small farms were discontinued to a great extent; and proprietors generally became averse to granting small tenures or cottage-holdings; whilst hordes of families were evicted in favour of the new system: thus the extended population, unable to find work or wage, added to the misery of the time, and to the discontent or disaffection of the masses.

In the present condition of the country there is not room and location for its population, although reduced by something over two millions? What, then, is to be done for the unsettled portion? There is a remedy; for, independent of the unprofitable wastes, there yet remain five millions of acres capable of reclamation, and of conversion into the richest pastures.

These lands or wastes are possessed in fee by great proprietors, and, if purchased by valuation, an average, perhaps, of 11s. sterling per acre would be an ample compensation; or if taken in perpetuity at a chief rent, then 2s. per acre, or 10 per cent. on the improved value or rental, would fully compensate the owners in fee, giving them a fixed income out of sterility.

These works of arterial drainage and reclamation would be, however, too extensive and too costly for private enterprise; therefore by the interposition of Government alone could such works be carried out.

Of the whole area of wastes, peat or turf bog covers 2,850,000 acres; being nearly half as much as the portion in cultivation, and one-seventh of the whole island! This desolation, consists of 1,576,000 acres of level or flat bog, superimposed upon limestone plains; and of 1,254,000 acres of mountain bog, detached amongst the various mountain and hill ranges.

That such a condition of the island must increase the humidity of its climate is but too palpable; and it is equally clear that, by drainage of these immense morasses, a more genial temperature might be secured, whilst the health of the population would be improved, and the climate rendered more equable and attractive for perennial residence. Many parts of Lincolnshire and Yorkshire fens thus treated are wholly changed in character; and from being heavy and unwholesome, have become agreeable and populous. If this, then, be so upon a small scale, how much the greater must be the efficacy when extended throughout the entire surface of a land not now considered un-

healthy—the worst characteristic whereof is its constant rainfall and humidity.

As this drainage and reclamation would desiccate and improve the climate, so it would also yield ample returns for the outlay; producing live stock for the English markets, and bestowing greater aptitude for cereal crops upon the now existing tillages, which, owing to the humidity of the atmosphere, grow but a very small proportion of wheat.

By a maximum outlay of 5s. per acre, including the purchase of proprietary rights, the most fertile pastures might be formed upon an extensive scale, the annual rental whereof may be estimated on an average of 10s. per acre; for at such a rental small holders would regard such leases as independent possessions.

Such a system could be undertaken by Government authority only; for, no company, and therefore no individual landowner, could do it.

So long back as 1675, Sir Wm. Petty, a great authority in his day, who was Surveyor-General under the Commonwealth, Charles II. and James II., and by whom the celebrated Down Survey was completed, drew out a treatise, with this unpretending title,—“The Elements of Ireland, and of its Religion and Policy, by Sir William Petty, Fellow of the Royal Society, 1687.”

The drift and chief object of it was to convert the whole extent of Ireland into a stock farm; to withdraw a million of the inhabitants to England, leaving only 300,000—one half herdsmen, and the other 150,000, dairy-women!

The dedication to the king, being terse, is given as written, viz. :—

“To the King's most excellent Majesty.
When I find out puzzling and perplexed matters that may be brought to terms of number, weight, and measure, and consequently may be made demonstrable; and when I find things of vast and general concernment, which may be discussed in a few words, I willingly engage upon such undertakings, especially when they tend to your Majesty's glory and greatness, and the happiness of your people, being one of them myself, and
Your Majesty's most humble,
Faithful, and obedient servant,
WM. PETTY.”

After this dedication, follows a brief metrical Latin heading, selected discursively from Virgil, and not inaptly strung together.

From these short introductory specimens of the MS. essay, no one could imagine what the author was about to reveal, although he admits that he delighted “in political pastimes and paradoxes;” but the secret is fully communicated to his readers, in the following language:—

“Some have imagined, these being about 1,370,000 people in Ireland, that to bring 1,000,000 of them into England, and to leave the other 300,000 for herdsmen and dairy-women behind, and to quit all other trades in Ireland but that of cattle only, would effect the settlement, improvement, and union above propounded; but against this method there lies this gross and obvious objection, viz. that the transporting of a million of people will cost a million of pounds; that the housing and other goods in Ireland which will be lost thereby are worth two millions more; nor is it safe to estimate other damages and expenses consequent on this undertaking, at less than one million more, in all at 4,000,000l. of expense and damage.

To which objection there is a gross answer, which is, that by bringing 1,000,000 people into England, where are already, the King's Revenue of Customs, Excise, and Hearth, will rise from 7 to 8, that is, to two hundred thousand pounds per annum, which increase, at 20 years' purchase, is above 4,000,000l., and more than the loss above mentioned. Now, when the King's Revenue shall naturally and spontaneously increase, it is rationally to be supposed that the people's wealth may increase 20 times as much, the Public Revenue being, almost by a law of nature, $\frac{1}{5}$ part of the people's expense.

Wherefore, suspending any further answer to the said gross objection, we proceed to say, that the transportation, and new cattle trade above propounded, will produce the effects hereafter mentioned.”

Without quoting *in extenso* from the MS., these effects, as predicted by the theorist, may be summed up in the complete tranquillization of the country, the reclamation of its wastes, and their utilization for the sustenance of the whole kingdom.

How much more would such a national undertaking, as I have outlined, benefit the State under existing circumstances: it would give employment and wages to the whole industrial people; but, further, it would give them locations, homes, pastures and gardens, and stop the exodus before the land is depopulated, turning their disaffection to quietude, if not loyalty.

The temper of the time is manifestly to make just concessions to the demand, and necessities of the Irish people; the educational question, equalization of the churches, land tenure or tenant right, and others, which these would fall like manna upon the land, if the great reclamation scheme were at once set on foot, but without that, the bestowal of civil and religious privileges is utopian. A man must be located and

housed, and thus personated, before he can be identified as a free subject: education will then follow. The sons and daughters of the soil leave Ireland, not because they love America the more, but because they have no employment, no home, and, consequently, no protection in their native land.

It cannot be denied that there has been, within twenty years last past, an obvious improvement in the condition of the people; but still the range of pasture land is increased, whilst the area for tillage and cereal crops is being progressively reduced, and at the same time land measures under five acres are merging fast into larger farms: thus the food of the people becomes more stunted, and their cottages and homes are razed, driving them of necessity to seek new homes and occupations; for if in Ireland, there is no manufacture or industrial labour, they are forced to seek it abroad.

There are good landlords who deplore this, and who, being resident on their estates, address themselves to the physical and moral improvement of the country; but for the wide tracts held by absentee proprietors there can be little hope, unless a new field be opened under Governmental auspices. In other countries, and notably in France, national funds are applied for national improvement; the waste lands of Ireland offer an inviting field, and a sure return for such an expenditure.

T. H. HARDINGE.

ARCHITECTS' AND ENGINEERS' ASSISTANTS' BENEVOLENT SOCIETY.

SIR,—In your paper of the 15th ult., one who signs himself "Assistant" wants to know why he should not be a Benevolent Institution. If this is the desire of more gentlemen than this one let them come forward and say so.

After the revelations which there were in the same paper concerning references, I think it is most necessary that there should be some institution where our remorseless fellows can get relief; but I do not believe that architects' assistants should depend upon the references of an employer, but that they should all enter their profession in a right and honest manner. They should go as students of the Royal Academy, or of the Institute, and try for some [travelling] studentship, and afterwards, when they are real architects, there is a scholarship offered by the Royal Academy, for which I understand there has been no competition for the last two or three years; and I think that this is shameful, and should like to know more about it. If young men could take the proper means for their education they would be able to get certificates from other sources, which could enable them to snap their fingers at their late employers. For other professions a man is obliged to show special requirements. Even in a trade a man cannot get a unless he has given his whole attention to it; but it appears to be growing more apparent every day that any one who enters an architectural profession is an architect. This greatest of all professions is in great danger of us joining together and trying to save it.

As to the Benevolent Institution, I believe it would be very useful to us. I think we ought to be able to start such a society even without the aid of our friends the architects and engineers; but I am sure they would give us all the aid in their power. And finally that, if you will be so kind as to receive names, those gentlemen interested and willing to work can send theirs to you; and, perhaps, an assistant who has some spare time may be inclined to take the leadership in this matter.

J. W. A.

PROPER BUILDING FOR ARCHITECTS.

SIR,—Are there no Pugins left? Has his "green enthusiasm" died quite out? Is there not one architect left who will raise his voice against this money-mad system of architects? Not one true, real enthusiastic architect in our ranks? If such were the case, we should be most miserable; but, I believe,—though much depravity has crept into the ranks of the profession, and many of our brethren who are working hard because they love art, and wish to elevate their fellows. Should we give up all love of art, and turn our whole attention to money-grubbing, and to the miserable days of our youth, and our youth as we and all England. Oh! may the rising generation of architects keep alive their "green enthusiasm" and may the chill winds and damp fogs of winter "blow over us without taking the freshness out of us!" Amen, say we.

Let us remember that, though we can do but little towards the elevation of the present generation of architects, the formation of the rising generation lies in our power, and that upon the way in which we each perform our part depends the honour or disgrace of English architecture. Foreign countries have been allowed to get sufficiently ahead of us. Let us each determine that we will do all in us to prevent their further ascendancy. Can nothing be done to persuade the Museum authorities to build a iron building now, as was done at South Kensington, and wait until a subscription can be got in, or a company formed, to build an Architectural House? I hope we are not so infected by the current love of money that the latter part of "Scrapsitt's" letter is what we exactly believe. We have seen enough disaster and disgrace caused by a hasty haste to get rich; if there are any artists who have not in this rush, let them now turn their backs on the world, and begin a new year with an effort to the world that they love art more than money, and, therefore, will have a proper building for architects.

ADRIEL.

DESIGNS FOR THE NATIONAL GALLERY.

The competition designs have been sent in, and are about to be hung in the Royal Gallery at the Houses of Parliament. They will be open to the public on Wednesday, the 9th.

The following letter bears on this subject:—

"As my name has usually appeared in the list of those invited to compete for the New National Gallery, I think it right to state that I have found myself obliged to retire from the competition, owing to the claims upon my time of the concurrent competition for the New Law Courts. GEORGE GILBERT SCOTT."

GETTING DAYLIGHT INTO ROOMS.

It was by no means intended to suggest as a substitute for Sir David Brewster's arrangement, or for the "Patent Daylight Reflectors," a hood projecting with only a slight fall or slope. This would doubtless be open to most of his seven objections, or even to all of them if the ground side were upward. It was only mentioned to enable a reader to follow better the reasoning that leads to what I ultimately suggested as most practicable in London, a hood falling at a steep inclination, in no case less than 60°. This would not project sufficiently to affect the windows of a lower story more than cornices or eaves usually do already, nor nearly so much as our shallowest balconies or railed window-sills, or as the Patent Reflectors must, if ever used elsewhere than on the ground floor. I assumed that no practical builder would ever turn the ground side of the glass outward. If he did, the fourth objection would apply just as much to the vertical window as to my plan; and the turning it inward—as we always must, from the rain and dirt—actually involves, in the vertical window, a very slight sacrifice of light—not, indeed, worth considering; while in my plan it is optically quite indifferent which way it is turned. The outside being smooth and inclined at least more than 60°, would be no more liable to the third or fifth objections than a vertical window (to which snow will stick at times, and from the upper sheltered parts of which the rain cannot remove the dust). The sixth and seventh advantages are simply and very properly forbidden us in our chief cities by Building Acts, which require all our wood to be kept back behind a clear 4½ in. of brickwork.

Otherwise, or where no such regulations are in force, the easiest way of applying this principle would be, I think, in common domestic sub-windows, to omit the bars of the upper or outer sash, and carry out its sides and top in the manner of a box, so as to receive ground glass retained by a thin metal rim quite flush with the outer wall. This glass need not extend so low as to the meeting bar, for the bottom of our box is best made to slope inward at an angle of more than 45°; and if this and the sides and top be then all lined with reflecting material,—say tin-foil protected by varnish,—as well as the fixed soffit and linings, we have the upper half of the window completely assimilated to the philosopher's ideal; and the lower is comparatively of no importance. E. L. GARBETT.

HOMES FOR THE MIDDLE CLASSES.

SIR,—Much is now done for the benefit of the working classes. Has any one thought of the great need existing among the middle classes of small means, yet compelled by their vocations to live in London, and of the difficulty, nay, impossibility of finding moderately-rented houses in respectable situations? The only alternative for families thus situated is to brave the miseries of unfurnished apartments, fully to appreciate which, they must, perhaps, have been experienced. The many discomforts need not here be enumerated; many of our readers will, doubtless, endorse my statement. Why does not some enterprising capitalist come forward, and construct buildings, to be let out, something on the plan of the Edinburgh "flats," but with the modern improvements of the "model lodging-house," or "Familière" of M. Godin-Lemaire, at Guise? Rents of from 30l. or 40l. to 50l. or 60l., according to the number of rooms, &c., might adapt the "flats" to various pockets, and at the same time offer a good investment to the builder. These "flats" being entirely shut in, would offer the comforts of home, which can exist only in name in an ordinary house inhabited by more than one family; and where each one is sub-

jected to more or less interference, to espionage, and to causes of irritation more than enough to destroy the realisation of that popular fallacy of every Englishman's home being his castle. If my suggestion were adopted, families of small means would also be spared another source of constant torment,—I mean by the mistress being obviously more independent of "servant-galism." To combine economy and comfort, it would be an additional recommendation were a restaurant, baths, and even a laundry included in the building. In my own small circle many are ardently wishing for a movement in this direction; and practical people are of opinion that as in the case of the "model lodging-house," hundreds would rush to secure a chance of homes such as I have endeavoured to describe. W. A.

ARCHITECTURAL MEMS.

- 1. EVERY country develops by degrees its own literature, art, and architecture.
2. Architecture in its earliest stages is constructive; decorative character follows in later ages; perfection, therefore, is not in one age.
3. Architecture in early ages, though constructive, is often barbarous and crude in its decorative forms. Savages construct well, but decorate rudely.
4. When a country has developed its characteristics there is no further necessity for the introduction of foreign traits. English architecture was the result of climate, material, and race—a combination of Celtic, Norman, and Saxon elements—Aryan; but we have necessity now of new Aryan traits from hot climates like India or South of France.
5. The development of English architecture has been continuous: every successive age has given us something new,—fourteenth century, exquisite tracery forms; fifteenth century, magnificent east windows; Elizabethan and Jacobean, admirable mansions, excellent farm-houses, half-timbered, weather-tiled, mullioned according to country and material; Queen Anne town brick houses, with the most practical of all forms of window, viz., the segmental arch and white sash frame; Elizabethan and Jacobean ornament, most lovely from the certain classic element in it.
6. Old English gardens, with terraces, straight walks, clipped hedges, and fishponds, bad design, which the modern imitation of nature called landscape gardening has not.
7. All old work from 1000 to 1800 was good, and should be kept, historical; if a building is of various dates, keep each part in order accordingly.
8. Art education should lead to an appreciation of northern picturesqueness, high roofs, &c., as well as to the refined proportions of southern classic façades—each in its climate. W. S.

ROYAL ACADEMY STUDENTS.

SIR,—May I ask you to give publicity to the following, as I think it is of some public importance—certainly to art students and those who now do the work of our art capitalists and employers of art labour. President Sir Francis Grant the other evening, at the distribution of the Academy medals, expressed himself so unlike a regular and orthodox President, and so kindly as regards the Academy students, that I have felt encouraged to ask him to bring before the Council of the Royal Academy a very long standing grievance; one, indeed, dating from the very foundation of the Royal Academy. You know that any artist fortunate enough to obtain an entrance into the Academy as a student, is, or rather was, admitted for a term only of ten years; it has since been reduced to seven. After that term has expired studentship ceases, and all the helps and aids which the Academy can so well and easily give are withheld; and the student is no longer such, and the Academy doors are finally closed to him. Why this should be so it would be difficult to understand, as no art student can possibly finish his art education in so short a time as seven years, or even in twice that number of years. I must ask you to bear in mind, too, that the ranks of the Academicians and associates are mainly, nearly wholly, made up from the ranks of the student class, i.e., the Royal Academy would cease to exist were the student class to become extinct. Suppose,

therefore, at fifteen, a student enters the Academy; at twenty-two he ceases to exist in the Academy sense, but it may be at thirty or forty he may be thought worthy of the Associateship: so that through the most valuable years of his art-labour life, he is deprived of all help and aid from that institution which was expressly formed for his instruction and help. The library is closed when he most needs it; the antique is shut up from his view; the life-school is dead to him; and the lectures he can never listen to, though the lecture-room hold empty benches in abundance. Why is all this, and who is benefited by it? I have many times been in the library all day *solus*. Of what use is an institution, if those who need it, and might use it, are excluded from it?

The Academy is to be reformed, we are told, and an unlimited number of associates are to be added to its ranks. I hope they will be compelled to furnish specimens of their personal art-power—not clerks and students' work, but their own. If then the associates are thus thought of, why not the students, who need it more? I have, therefore, respectfully asked the President of the Royal Academy to take into his kindly consideration the following:—

First, that a student once fully admitted into the Royal Academy, should be a student for life, unless he becomes an associate, that he may at least have the privilege of further study within the Academy walls.

Secondly, that his name as a student should be printed, and appear in the list of the members of the Academy, of which he may form in the future,—and *must*, in some cases,—a distinguished member.

I will add but one word more. At the Academy dinner, which would your rather boast of, as president, the fact of there being 1,000 students of a great Academy, the select art-energy of the time and country, or only fifty? C. B. A.

LECTURE ON FORCE.

AN able lecture was recently delivered by Dr. Monckton, in connexion with the Literary and Mechanics' Institute at Maidstone, on "The various Forms of Force, or, Niagara the Coal Mine of the Future." The lecture was illustrated by some brilliant experiments. In commencing, Dr. Monckton said that it had long been considered by philosophers that matter, out of which natural objects are evolved, is one single thing, indivisible and unchangeable. That it was quite understood to consist of but one elementary form—a molecule or minute atom—out of which every ponderable body was manufactured, from the light gas to the ponderous metal. This foreshadowed the fact that various forms of force had something to do with each other. The lecturer then entered *seriatim* into a detailed and experimental illustration of this thesis. It was the convertibility of one force into another, and the fact that if you possessed a sufficient command of one form, others could be extracted from it, that was present to his mind, he remarked, when he spoke of the Falls of Niagara being the coal-mine of the future. It would be perfectly possible by heat and light Buckingham Palace by the agency of that great cataract; it being only necessary to convert the force of the fall into motion by wheels or turbines; that into electricity by friction; conduct this current to England by the present Atlantic cable or other wires; reproduce heat in a coil, and distribute the same by hot-water pipes or other apparatus throughout the building. Of course he was expressing no opinion as to the exhaustibility of coal, and feeling no desire to suggest, that these substitutions were at present practicable in daily life; but the principle was sound now, and the application possible hereafter. The fountain whence our supply of all these forces [attractive as well as repulsive?] was derived existed in the sun. [?] This great luminary was incessantly flooding space with waves of force-motion, that is, in the shape of ethereal undulations. It was not strictly correct to say that the sun gave off light and heat; for half-way between us and him no light and heat existed, all was pitchy darkness and eternal frost; he gave off motion, which traversed space inoperative, and only became developed into light, heat, and chemical tension, when it was received into, and transmitted by, material bodies; just as the motion of the clapper of a bell under an exhausted receiver is not converted into sound so long as the bell swings in vacuo. But if we

received this motion energy from the sun, whence does he himself derive it? In all probability, from motion too. The meteoric theory affords the most plausible explanation of the continuous re-creation of the sun's expended energy. A few weeks since the air was alive with meteors; the earth had been traversing in its orbit, the long end of the oval plane of small planetary masses which constituted the Zodiacal light: there was every reason to believe that space was filled with planetary matter sufficient, by its constant impingement with great and violent velocity on the sun's body, to extricate an amount of heat, or *converted motion*, fully equivalent to his yearly emission. At the close of his lecture, Dr. Monckton said he would venture to suggest, and as he believed for the first time, that the ignition of meteorites was partly due to the arrest of their motion, brought about by the attraction of the earth's mass. It was certain that if a meteoric body travelling forty miles per second in free space was reduced suddenly to a rate of twenty miles by the earth's attraction, violent heat would be evolved, unless the reciprocal gravitation of the meteor should itself replace the motion lost, as an equivalent form of force: and on that point, without further reflection, he would not decide.

TRADE BOOKS.

A new edition, issued by Messrs. Law & Co., of their Pattern Book, deserves a few words of commendation. They have evidently endeavoured to make it as comprehensive as possible, giving a fair selection of examples of the various branches of their manufactures, and have spared no expense in the fine-art part of the work, or its engraving. The Messrs. Leighton, too, have done justice to the designs by Messrs. Digby Wyatt, Street, Seddon, Burges, Garling, Goldie, and Owen Jones. The designs and engraving have cost, we are told, over 1,400*l.*, independently of the cost of the printing. The price book accompanying it (a very important adjunct), is arranged with special regard to easy reference. Every pattern is consecutively numbered, and a price is given in the list of every individual tile or design, saving the necessity of classification of the different descriptions of manufactures, which very few people understand: they have also kept to a single series of figures throughout the list, the paramount advantage of which few book-makers and catalogue compilers sufficiently appreciate. We take the opportunity to remark that tile-makers generally would do well to make better arrangements for London customers than at present exist. Without special reference to Messrs. A. or Messrs. B., we must complain (on the part of many) of the great difficulty with which anything at all out of the common way can be obtained, and the time that is required even when the thing needed is not out of the common way. We could tell some funny stories on the subject, but this hint may perhaps suffice.—Messrs. Peard & Jackson's new book, "Examples of Metal-work" contains a large number of good (Medieval) designs for brattishing, vanes, lamps, grilles, gas-standards, desks, and so on, with accompanying price-list to each page. The whole of the examples were drawn,—and very well drawn, too,—by Mr. W. G. Smith.—"How to Make and Fix Paper Texts or Emblems, to Decorate Churches or Rooms" (Beal, St. Paul's-churchyard), will be found useful to the considerable number of ladies and others who now take interest in such matters.

THE INSTITUTION OF CIVIL ENGINEERS.

THE report read on the 18th ult., Mr. C. H. Gregory, V.P., in the chair, referred to a memorial recently received from a number of engineering pupils and assistant engineers, soliciting the sanction and patronage of the Institution in favour of a Junior Engineering Society, proposed to be established with the avowed purpose of mutual self-improvement in professional knowledge, and more particularly in that scientific knowledge of theory, which was becoming more and more essential to the success of the young engineer. The council informed a deputation of the memorialists, that they would endeavour to devise a plan for the consideration of the members of the Institution generally, which should

substantially meet the wishes of the memorialists; but that they could not support the proposal for a subsidised and self-governed society. The members were reminded that, under the will of the late Mr. Joseph Miller, C.E., a sum of 3,000*l.* had been left in trust, to be applied in awarding premiums or prizes to the students of the Institution.

In order to show the progress of the Institution during the latter half of its existence, extending over a period of twenty-four years and a half, or from June 30, 1842, to November 30, 1866, two tables had been compiled, from which it appeared, that at the former date the total number of members of all classes was 625, as against 1,338 at the 30th November last, showing an actual increase of 514, or 155·2 per cent. The annual increase per cent. during the past six years had been 1·61, 5·84, 4·00, 5·23, 9·84, and 11·30 respectively. During the same period, the honorary members have been relatively diminished from 68 to 1·6 per cent., and the graduates from 12·9 to 0·5 per cent.; while the number of members had been increased from 345 to 494 per cent., and of associates from 45·9 to 57·6 per cent. Or, in other words, taking the honorary members and the graduates together, they had, at the first date referred to, amounted to nearly one-fifth of the whole number of members, whereas at the present time they only constituted the one-fiftieth part of that number. Nearly one-half of the members and associates were resident in London and its vicinity, one-third in other parts of the United Kingdom, and the remainder in British possessions abroad and in foreign countries.

An analysis of the statement of receipts and expenditure for the year ending the 30th of November, 1866, showed that there had been received, including in each case dividends on investments, 4,945*l.* on the general account, 994*l.* in respect of the building fund, and 300*l.* on trust funds, making together 6,239*l.* The expenditure had been 4,153*l.* on the general account, and 131*l.* for premiums under trust, while 2,974*l.* had been invested, on different accounts, in Gornels, and debenture stock of the Great Northern, the North-Eastern, and the London and North-Western Railway Companies. This showed a net increase of 2,086*l.* in the receipts of 1866, by which amount the available balance at the bankers had been reduced. The nominal value of the different funds now belonging to the corporation together, amounted to 267,000*l.* as against 24,833*l.* 1*s.* 6*d.* at the date of the last report.

CHURCH-BUILDING NEWS.

Ashby Parva (Lutterworth).—We are requested to state that Messrs. Law & Son were the builders employed in restoring the church here, and Mr. Jas. P. St. Aubyn the architect.

Ipswich.—St. Stephen's Church, Ipswich, has been re-opened for divine service, having been for some months in the builder's hands. Alterations have been effected, which give the interior a lighter appearance, and increase the number of sittings. The old pews in the nave and south aisle have been replaced with open benches of white pine, stained and polished. The gallery at the west end has been taken down, giving a clear view internally from west to east. A new window has been inserted in the tower. The chancel roof has been renovated. The columns of the arches have been cleaned, and prove to be Pinchbeck marble, and like those in the Temple Church, have never been polished. The number of sittings is somewhat more than before, notwithstanding the removal of the west gallery. The church is heated by hot water pipes, arranged by Messrs. Turner. The gas-fittings were supplied by Messrs. Archer & Gross; and the organ was put into the hands of Messrs. Goddall. The contract has been carried out by Mr. Godholt, of Harleston, from the plans of Mr. F. Barnes, architect, the cost being about 450*l.*

Gloucester.—Two new designs for the church for St. Catherine having been obtained, Mr. Gambia Parry was requested to select one, which he did, and which turned out to be that sent in by Messrs. Medland & Maberly, who were requested to prepare the necessary working plans and specifications, that tenders might be advertised for and a faculty applied for should the cost not exceed the estimate of the architects. The internal width of the church will be 28 ft., depth of the nave to the chancel arch, 68 ft., depth of the chancel, 24 ft., width, 22 ft., and transepts, 13 ft. The pulpit will be on the north side, against the chancel arch, and the reading-desk on the south side. At the north-west corner there will be a porch, 8 ft. by 9 ft. Ornamental bands of red and white bricks will be carried along the walls within and without. There will also be a bell-turret 20 ft. high.

Claydon.—The church here has been reopened. The old church of St. Andrew, Claydon, consisted of a nave, chancel, and a low tower, and was, previous to its restoration, in an exceedingly dilapidated condition; indeed it was found utterly impossible to restore the nave. The church was built in the Decorated style of architecture, and this style has been adhered to in the re-building of the nave, the shape being a simple parallelogram, which has been preserved in the restoration. There are

three windows on the south side and two on the north, and there is also a Decorated porch on the south side. The chancel has been reared, a new vestry having been added on the north side, whilst a new Decorated window has been inserted at the east end, the glass being simple cathedral glass, with a greenish tint. The old church seats, some of which were painted a character, have been refixed, and several deal seats have been added at the west end. The design for the chancel is not yet down, but the design is being executed by Messrs. Maw & Co., of Boreley. The walls of the chancel before restoration inclined outwards considerably, but now they are kept in position by two buttresses on the south side, and the vestry on the north. The old roof of the chancel has been restored. The roof of the nave is quite open, and has six pairs of principals, with carved moulded ribs supported on stone moulded corbels. They have embattled cornices, and are all stained and varnished. Almost all the stone used in the restoration was that which formed the old church. The architects of the restoration were Messrs. E. F. Law & Sons, of Northampton, and the contractor Mr. John Gee, of Coventry.

Altrincham.—St. John's church has been consecrated. The site of the new church is the plot of land between the east end of St. Margaret's schools and Ashley-road, not far from Fordon station. It is close to the large and rapidly-increasing population of New Town. The architect is Mr. J. Medland Taylor, of Manchester; and the contractor Mr. Joseph Thompson, of the same city. Accommodation is provided for about 950 persons, all of whom, except a few in a small gallery over the western porch, will be seated on the ground-floor. The plan consists of a broad nave of five bays, with north and south aisles, and north and south transepts. There is a large western porch; and adjoining it, on the north side, is the baptistry, which is marked off from the north aisle by a small triple arcade. On the south of the porch is the steeple. The chancel is of large dimensions and terminates apsidally to the east. The chancel aisles open by arches into the chancel and transepts, and these arches are filled to the height of about 7 ft. with arched wooden screens. The style is Early Decorated. The material is stone, of three or four kinds for the outside, and for the pillars and other similar features inside. The steeple rises to a height of upwards of 40 ft. The three apse windows are filled with coloured glass in grisaille patterns, by Lavers & Barrand. The vestry and baptistry windows are filled with similar glass, and have also, as part of the pattern, Scriptural inscriptions suitable for the respective places. The heating apparatus is Haden's. The builder's contract was 5,330l.

Sydenham.—Holy Trinity Church, Sydenham Park, has been consecrated by Bishop Anderson, recently of Rupert's Land, North America. The church is situated in Sydenham Park, near the road leading from the railway on the side of the sharp ascent, to which it stands at right angles. The ground on which it is built was given by Mr. Robert Harrild, of Round-hill, who subscribed liberally in addition. The exterior presents no particular pretension to any architectural display, and a tower is wanting. The principal entrance is at the west end. The roof is a lofty, and the ceiling of stained wood with wooderings. There are no galleries. On either side of the middle aisle are stone columns, fluted and capped. The seats are all open, and the edifice, we understand, will contain a congregation of 1,200 persons. Pendant from the roof are gas chandeliers, of a temporary character. The floor is composed of encaustic bricks, and the reading-desk and pulpit are east and west of the chancel. There is no reredos, and at present the communion-rails are not constructed. Between the pulpit and the vestry is the organ chamber, which contains an instrument erected by Messrs. Hill & Son. There is but one stained window at present in the church, which is placed in the west side of the chancel.

Shepperton.—St. John's mission chapel, which has just been erected here, has been opened for divine service, by licence from the Bishop of London. The chapel is a plain brick building, 50 ft. long by 20 ft. broad. It has an apsidal termination at the east end, with a small bell turret at the west. The door is on the north, and a small vestry on the south side. The site was given by Mr. John Walter Lea, of the Grange, Shepperton-green, the rector's son-in-law. The architect, Mr. R. P. Pullan, of London, had intended that there should be an entrance

porch, but owing to want of funds this has not been erected. The builder was Mr. E. G. Hoppley, of Shepperton-green. The contracted price for the building itself was 355l., which has been raised by subscription, with the exception of 50l., which was granted by the committee of the Church Association for the United Dioceses of Hampton and Staines.

Gloucester.—The plans of Messrs. Medland & Mabery have been accepted for the church to be built on the site of the old church of St. Catherine. The building will consist of nave, two transepts, and apsidal chancel. The internal width will be 28 ft., the length of nave 65 ft. The material used will be brick, of which there will be ornamental bands.

Bristol.—Emmanuel Church, which is being erected in College-road, is designed for the use of the district severed from Christ Church, Clifton; but the completion of the main building, as well as the addition of a tower, being at present delayed for want of funds, the consecration has been postponed, and the body of the building has been opened for divine service.

Birkenhead.—The foundation-stone of a new church in Cathcart-street, Park-road, has been laid by Lord Grosvenor. The new church is intended to supply the wants of a section of the large parish of Holy Trinity, which has a population of 22,000, and has hitherto had only one church; and is to provide accommodation for 700, and to cost 2,400l. The site will cost 875l., and it is also proposed to raise an endowment and repairs fund of 1,450l. The patronage will be vested in the Bishop of Chester. All the seats in the church will be free.

DISSENTING CHURCH-BUILDING NEWS.

Ezmouth (Devon).—The chief corner stone of a new Congregational Chapel has been laid here. The chapel (which stands on the site of an old building erected by Lady Glenorchy in 1777) is at the corner of the Exeter-road and Meeting-street, and consists of nave, side aisle, with tower and spire at the south-west angle, under which is the principal entrance. There are vestries arranged to be thrown into one by means of a moveable partition. The style adopted is Early Decorated, and the materials local (Borryhead) stone, in black mortar, with Bath stone dressings. The roof will be open, carried out in fir, and stained and varnished: an arcade will be formed between the nave and aisle with wood columns and diagonal struts, the spandrels being filled in with quatrefoil piercings and other devices. There will be 450 sittings, which will be open benches stained and varnished. A minister's, or chapel-keeper's house will adjoin the chapel on the south side. The contract for the chapel and house is taken by Mr. George Gibbs, of Ilfracombe, for 1,200l. Messrs. Habershon & Pite, of Bloomsbury-square, are the architects; and Mr. J. R. Manning is clerk of the works.

Rickmansworth.—The Wesleyan Chapel in this town, which was destroyed by fire a little more than a year ago, has been replaced by a new building, which has been opened for divine service. The chief subscriber to the building fund was Mr. McMurray, of Loadwater, a member of the Scottish Presbyterian Church. The new chapel is situated partly on the site of the old one, but covers a larger space. It is in the Early English style, and its chief external features are an octagonal tower and spire, rising to a height of 75 ft. The material of the building is brick, with Bath stone dressings. The tower is at the north-west angle, and contains a clock (with three faces), by Benson, and three bells, two of which strike the quarters, and one the hour. The clock and bells cost about 206l., and are the gift of Mr. McMurray. The spire is covered with tiles relieved by green bands, and is surmounted by a weathercock. A school-room adjoins the chapel, under the same roof. Internally, the chapel measures 60 ft. long, and 30 ft. wide. The available sittings number altogether about 350. Above the communion table is a stained glass window, which is the chief feature of the interior. The window is the gift of Mr. McMurray, and was executed by Messrs. Heaton, Butler, & Bayne. It is divided into three principal compartments, and represents the crucifixion of our Lord. The cost of the window is about 70l. The total cost of the erection has been about 2,500l. Mr. Thos. Pearson, of Bathworth House, was the architect; and Messrs. C. & J. Waterman, of Watford, were the contractors. The stone work was

done by Mr. Coney, of Watford; and the gas fittings were supplied by Messrs. Hart & Son of London.

Lury.—The Independent Chapel, Whiting-street, has been re-opened for Divine service, after undergoing alterations and renovation, the principal feature of which is the erection of a new Gothic front, in white brick, with Bath stone dressings, in the centre of which, above the doorway, is a traceried window of four lights, with two smaller ones on either side. The old rectangular pewing in the body of the chapel has been replaced by benches of stained deal. The windows at the side are new, and new three-light gas-burners and other fittings have been put up. The alterations have been effected under the direction of Messrs. Bacon & Bell, architects, whose designs have been carried out by Mr. Tooley, builder, and Mr. Farrow, stonemason. The open palisading in front of the chapel was wrought by Mr. Andrews, ironmonger, from the architects' design. The entire cost of the alterations is about 600l.

Liverpool.—A new Wesleyan Chapel, at Rock Ferry, has been opened. The edifice is dedicated to the Trinity, and situated in New Chester-road. It is in the Italian style. The front and sides are faced with red bricks, with dressings of Stourton stone. The main feature of the building consists of two square towers, surmounted by a mansard roof, and 65 ft. high from the level of the New Chester-road. In each tower there is a staircase leading to the galleries, and the space between them is connected by a colonnade, covering all the entrances to the chapel. The colonnade is approached from the road by a flight of York stone steps, as the level of the chapel floor is raised considerably above that of the road, in order to secure plenty of light and ventilation to a spacious school-room and two class-rooms underneath. The entrance to the school-room, which, like the chapel, is 63 ft. by 50 ft., is from the back, and two staircases leading from it communicate with the body and galleries of the chapel. The chapel has class-rooms and a minister's vestry behind the body. The body will seat 500 persons, and the gallery, which is circular, has accommodation for 350. The work has been carried out by Mr. John Hogarth, builder, of Rock Ferry, under the superintendence of Mr. Joseph Brattan, of Birkenhead, architect. The entire cost, including the price of the land, is estimated at 5,500l.

STAINED GLASS.

Gloucester Cathedral.—The public memorial of the Rev. H. Burrup has now been placed in the east walk of the cloisters of this cathedral, by Messrs. Hardman, of Birmingham. The subjects of the windows in the cloisters, as remarked by the local *Chronicle*, in giving an account of this memorial, are after a design which was settled some years ago by Bishop Jonne. The present window is the first of the series, and represents our first parents in the garden—Eve offering Adam the fruit, and the Angel driving him from Paradise. It consists of four main lights. The tracery lights and the lower lights are filled with decorated glass and designs, one of which is that of the Crown and the Palm.

All Saints, Cambridge.—Upon the death of Lady Afleck, the wife of the late Master of Trinity, her friends in the University seemed desirous to keep alive the memory of one loved by many and esteemed by all. The vicar of All Saints' made a proposal to them to fill the east window of her parish church, of which she laid the foundation-stone, with stained glass, as an appropriate and lasting memorial. A large sum of money was at once promised for the purpose. A window, according to a design generally approved, was ordered from Messrs. Morris & Co., London, and is now placed in the church. It is a five-light window. In the centre light, at the top, is represented Christ in Majesty, surrounded by angels. The rest of the window is filled up by four rows of figures. The highest contains the patriarchs Adam, Noah, and Abraham,—with Eve; the next, kings,—David in the centre, with Edward the Confessor and St. Louis, as historical kings, on either side, and Melchisedek and Judas Maccabeus at the two extremities. In the third row are Apostles and Prophets,—St. Peter in the centre, St. James and St. Stephen on either side, Elijah and John the Baptist at the two extremities. The last row represents female saints,—St. Rhadegund in the centre, as queen and abbess, patroness of Jesus

College; with four martyrs.—St. Barbars, St. Agnes, St. Dorothy, and St. Catherine. The figures are on a ground of grisaille, where flowered quarries alternate with hands on which the names are written. The cost of the window, with certain attendant expenses, was about 360*l*.

Episcopal Church, North Berwick.—A stained-glass window has been erected here by Colonel Denny, in memory of the officers, non-commissioned officers, and soldiers of the 71st Royal Highland Light Infantry who died in their country's service in Canada, the West Indies, the Crimea, and India, and who served with him from 1842 to 1857. The subject is Christ raising the widow's son, "Young Man, arise." The colours and badge of the regiment are introduced in the base panels. Messrs. Ballantine & Son, Edinburgh, were the artists.

Old West Church, Greenock.—Two additional memorial windows have been placed in this church. One in memory of John Hunter, shipmaster. The subject illustrated is Christ walking on the sea, "It is I, he not afraid." The other window is in memory of Mrs. Denniston, erected by her son. Subject, the Presentation in the Temple. The artists were Messrs. Ballantine & Son.

St. Mary's, Diss.—This church possesses some good specimens of stained glass, and the south side has been recently beautified by the addition of two memorial windows, by Mr. Hughes, of London. One is in memory of members of the rector's family.—Thomas Manning, Edward Bosworth Manning, Susan, wife of John Shearman, and Frances and Anne Manning, and represents "Joseph's Dream," "The Cup found in Benjamin's Sack," and "The meeting of Jacob and Joseph." The other is in memory of the late Samuel and Harriet Farrow, and contains "The Good Samaritan," "The Parable of the Talents," and "The Wise and Foolish Virgins."

Pewick Church.—The chancel of this church has just been further adorned by the erection of another stained-glass window. In this case the donor is Mrs. Moore, in memory of her deceased husband, the late Mr. W. Moore, of Elm Bank. The window was designed and executed by Mr. George Rogers. The subjects selected are the Bearing of the Cross and the Resurrection of our Saviour, in panels. Beneath are the symbols of the Pelican and the Cross, with the sacred monogram I.N.R.I. The quatrefoil at the top contains the Dove; a rich groundwork of the vine upon a ruby forms the background, and is surrounded with borderings of roses and foliage.

PROVINCIAL NEWS.

Ware.—The foundation-stone of the proposed corn exchange, at Ware, has been laid.

Ashtown.—The manufactory which Messrs. M. Bond & Co. are erecting at Hanging Bridge, about a mile and a half from Ashtown, has been completed, so far as putting on the roof. The building stands on the site of the New Mills, destroyed by fire a few years ago. The new building is three stories high, the material being pressed bricks, with alternate string courses of blue brick and freestone, and brick plasters. The dimensions inside are:—Length, 137½ ft.; width, 54 ft.; height of rooms, 12½ ft. There are about 170 windows, the majority of which are 7 ft. 6 in. high by 4 ft. wide. The top room has 45 such windows, besides 13 skylights. The staircase is built of Maclesfield stone. In the turret are two iron tanks, supplied by Messrs. Wright, Brothers, of Gosport Ironworks, Walsall, capable of containing 4,400 gallons of water, to be available, besides their use in the daily operations carried on, in case of fire. The building is surmounted by two angle turrets, with ornamental finials, and a clock-tower with two faces; and at one end of the main building is a counting-house, with ornamental ridge and finials. Besides the main building described, there are in course of erection—gas-house, boiler-house, and drying-room, stabling, coach-house, &c., and a dining-room for the hands. Attention has been bestowed on the ventilation of each division and room of the new mill. The building was designed by Mr. Sugden, architect, Leek; and the execution of the work by Mr. John Mathews, builder, also of Leek, who died somewhat suddenly on the 23rd ult.

Liverpool.—At a special meeting of the Mersey Docks and Harbour Board, a long discussion took place recently in reference to the new Bill

which will be presented to Parliament during the forthcoming session. The proceedings included a motion to the effect that the sum of 255,000*l*, intended for the completion of the docks at the north end of the town, he excluded from the Bill, which embraces additional borrowing powers. After a long debate the proposition relating to the exclusion of the 255,000*l* was rejected by a majority of seven, and the Bill as originally drawn out, which carries its borrowing powers to the extent of 1,100,000*l*, was adopted. This Bill will enable the Dock Board to complete the new docks, basins, and carriers' sheds now in course of erection at the Boothe end of the dock estate.—The present Southern Hospital at Liverpool being too small for the demand upon it, a movement was commenced for erecting a new building on another site. A sum of 40,000*l* is required, and at a meeting held at the townhall, subscriptions to the extent of 24,000*l* have been announced.—The New Exchange Company have entered into a contract with Messrs. Parker & Son, for the stonework of the two remaining wings of the new exchange buildings. The amount of the contract is 72,450*l*.

PATENTS CONNECTED WITH BUILDING.

MACHINE FOR PRESSING BRICKS.—H. A. Dufrene. A communication. Dated January 13, 1866.—This invention consists in an improved construction of pressing machine for the manufacture of bricks and other like articles made of brick earth or clay, by which more uniformity is obtained in the thickness of the articles than by the ordinary apparatus. This press is constructed of two parts, an upper and a lower part, acting on the middle of a frame of the form and dimensions suited to those of the articles to be pressed. The press receives a continuous motion from an eccentric worked by steam or hand power, and which, in its rotation, is made to move apart and bring together the said two parts of the press, between which the brick earth is placed and is compressed. The upper part is fixed to two rods, united by a striker or huffer fixed by four rods to a sliding-piece or block united to the collar of the eccentric, which sets it in motion. The lower part is free, and is raised by the striker or buffer during its ascent, and falls back of itself during the descent of the striker or buffer. The quantity of clay or brick earth exceeding that required is thrown back by the press itself by means of a hole, which may vary in its dimensions, made in one of the sides of the part of the press on which the pressure is exerted.

MACHINERY FOR MAKING BRICKS, TILES, &c.—C. G. Johnson. Dated January 13th, 1866.—This invention relates to that class of machinery for making bricks, tiles, and similar articles, in which a stream of clay is expressed from a pug-mill through a moulding die or dies, and afterwards cut into lengths. In constructing machinery of this description according to this invention, the patentee places the knives or blades of the pug-mill on the same axis as that which carries the screw that is employed for forcing forward the stream of clay through the moulding die or dies. The portion of the outer casing of the pug-mill in which the screw works is by preference made of smaller diameter than the part of the casing in which the blades or knives of the pug-mill work. The exit end of this contracted portion of the casing of the mill is enlarged into a bell or enlarged mouth, and the end of this bell or enlarged mouth is closed by a fixed plate, which carries a bearing to receive the end of the shaft of the pug-mill. On one side of the bearings of this shaft is placed the moulding-orifice or die through which the clay is to be expressed. By forming the exit end of the pug-mill in this manner, the stream of clay is not diverted by the bearing of the pug-mill shaft as it is when the moulding-orifice is placed opposite to the centre of the shaft, as is now the case. Above the top of the mill, where the clay is arranged into the machine, the patentee places a pair of rollers, between which the clay has to pass before entering the pug-mill; these rollers crush any stones there may be in the clay. The rollers are driven from a wheel on the pug-mill shaft.

IMPROVEMENTS APPLICABLE TO WATER-CLOSETS AND COMMODE-PANS.—H. E. Newton. A communication. Dated 15th January, 1866.—The inventor of the present improvements looks upon the closing of the direct orifices

of the pans as a secondary consideration, and effects the intended object by surrounding the seat or portion occupied by the person when sitting down with a continuous hermetic joint at the upper part of its circumference, thus enclosing the pan (and the part contiguous thereto) in the limits within which the matters, whether solid or liquid, can be projected. By this means, not only are the faecal matters arrested, but also any others which might adhere to the interior of the space above mentioned. In order to do away as much as possible with any obstacle which might stop the descent of the solid matters, the sides of the pans are made vertical instead of inclined as usual. With regard to the urine, it is arrested by the front projections set in such a manner that it prevents splashing, and forces the liquid to flow down inclines into the receptacle below.

Books Received.

The Theory of Strains in Girders and similar structures, with Observations on the Application of Theory to Practice, and Tables of the Strength and other Properties of Materials. By BINDO B. STONEY, B.A., Memb. Inst. Civ. Eng. &c. &c. London: Longmans, Green, & Co. 1866.

To every earnest student in the engineering profession Mr. Bindo Stoney's book on the theory of strains will be a welcome friend. One of the principal reasons why many English engineering students never pass beyond the grade of moderately good draughtsmen is, the difficulty of acquiring from books a proper understanding of the subject of their profession.

This is not the case with engineering students abroad. In the Polytechnical schools of Germany, the pupils are well grounded in the theory of engineering, and come over to England and heat the young English student on his own ground.

Most of the English authors of authority on engineering write in too high a style for the comprehension of young beginners; and as, in an engineering office, an individual instruction to all the pupils is altogether out of the question, a pupil, except in instances of rare perseverance and ability, after having duly served his period of apprenticeship, finds himself a draughtsman and not an engineer.

There are no gradations by which he may rise. He must encounter at the first step such an array of formulae and equations that he cannot successfully cope with them alone, and so is obliged to settle down to the drudgery of the profession.

The results following from this state of things are becoming serious enough to invite special attention. It is questionable, indeed, whether the prodigious arithmetic sometimes brought into force be necessary at all to the elucidation of numerous matters to which, by the force of habit, it is applied; and as has been lately noticed by some writers, the entire science of modern geometry is becoming so overlaid with symbols and figures that the subject of inquiry is often buried beneath them.

The portion of Mr. Stoney's work treating of transverse strain and deflection, is, we fear, still not what is required for learners; but nothing could be more admirable than the chapters on bracing, and various other portions of the book. Perhaps Bow's treatise on bracing does not include so many examples, and so ample a definition of the various kinds of bracing in use, as we find given in the first volume of Mr. Stoney's theory of strains.

The style in which the book is put together must also be commended, affording simple and unusual facilities for reference, which in no way interfere with its being read through continuously.

VARIORUM.

The Art-Journal gives some particulars of the Albert Memorial in Hyde Park, especially of the metal work. Framework, and wrought-iron is employed for the whole of the framework, and cast-iron for the structural parts that are to be built upon this framework. All the more distinguished visible portions of the work, the bases and capitals of columns, the cornices, crests, finials, and other similar details, and with them the cross that is to crown the entire edifice, are to be of a fine bronze. Mr. Skidmore has covered with lead the whole of the ironwork that otherwise

would be visible, and consequently would be exposed to atmospheric action. "Lead and bronze are the only visible, and therefore the only assailable, metals. This same lead-work is wrought into an elaborate series of exquisite surface-designs, of which the leading motive is to form settings for innumerable pieces of polished agate, onyx, jasper, cornelian, crystal, marble, granite, and other richly-coloured hard substances, together with inlays of enamels of various hues. The cross that forms the final of the memorial is a work of great dignity, executed in bronze, with inlays of stones and rich gilding. It is a Latin cross, severe in outline, and yet at its head and other extremities, and also at the intersection of its limbs, a strict simplicity of form is not maintained. It stands upon a highly enriched globe, which, in its turn, rests upon the foliated capital of a single cylindrical shaft, wreathed towards its head with spiral enrichment: and, lower down, wrought to an octagonal section, having four of its faces studded with gem-work, while a statue is placed in front of each of its other four faces. Sixteen bronze statues, of various heights, the four principal ones being 8 ft. high, are grouped about the several stages of the spire, and add greatly to the dignified beauty of the whole composition."—Hardwicke's "Science Gossip" goes on, and improves as it goes. It has evidently found a public.—A paper "On Water-Filters" by Dr. Divers, in the *Popular Science Review*, deserves attention.—The *British Workman* and *Bond of Hope Review* (the yearly part of each is just out) are specially noticeable for the excellent woodcuts, of large size, with which they are filled. One of these, in the *British Workman*, is drawn from the notice against swearing affixed by Sir Christopher Wren to the walls of the Cathedral. A capital sheet almanac, for a penny, is issued with each of these serials.—The "Financial Reform Almanac," at the same price, exhibits at a glance a large amount of financial information.—The *January Fraser* is a very entertaining number. It includes Lord Stanhope's lecture "On the Influence of Arabic Philosophy in Medieval Europe." "Among South-Western Cathedrals" is too slight to satisfy architects.—The *Gardener* (W. Blackwood & Sons) promises to be an agreeable and useful cheap monthly. The editor wants specially to make it useful, he says, to that large and increasing class of the community who, previously to the development of the railway system, lived in cities, but who now live in the country.

Miscellaneous.

THE LOCAL GOVERNMENT OF THE METROPOLIS.—The Right Hon. S. H. Walpole, the Secretary of State for the Home Department, has appointed Tuesday next, the 8th inst., at two o'clock, to receive the deputation agreed to at the recent public meeting at St. James's Hall, called by the Metropolitan Municipal Association for Promoting the Better Local Government of the Metropolis.

ATLANTIC CABLE DIVIDEND.—The Anglo-American Telegraph Company have announced that the net profits of the company have exceeded the rate of 25 per cent per annum from the date of opening the cable for public traffic on the 25th of July last, it has been resolved to distribute to the shareholders, early in February, a dividend, on account, equal to 10 per cent. on their shares, leaving the remaining 15 per cent. to be disposed of at the annual meeting to be held in July or August next.

SUPPLY OF GAS TO THE METROPOLIS.—At a meeting of the Strand District Board of Works, held on the 19th ult., resolutions were passed condemnatory of the monopoly afforded to the gas companies as highly injurious to the consumers, and directing a petition to the Board of Trade that steps may be taken during the next session of Parliament to repeal the present Gas Acts, and provide for a good supply of pure gas for the public. The subject was very fully discussed, and the resolutions passed unanimously; the general feeling throughout the discussion appeared to be that the improvement of the quality of the gas was of paramount importance, and that this would only be accomplished by the Metropolitan Board or some other municipal authorities having the whole management of the gas vested in them, as is the case in many of the municipal towns in the provinces.

DRAINAGE OF HORNCASTLE.—The recently-formed Local Board of Horncastle have resolved to proceed, at once, with drainage works for the town, and have instructed Mr. Lawson to prepare the necessary plans.

NEW UNIVERSITY COLLEGE, GLASGOW.—By direction of the Building Committee of the New University College, of which Mr. G. G. Scott, R.A., is the architect, plans were submitted by several engineers for the ventilation and warming of the building. Ultimately those of Mr. W. W. Phipson, C.E., London, were accepted. The cost of the building will be about 200,000l. Mr. Thompson, of Peterborough, is the contractor.

WORKMEN'S LODGINGS IN SPAIN.—A Madrid letter in the *Courrier de Bayonne* has the following:—"The question of workmen's lodging-houses has been discussed during the last few days by the *Epoca* of this city, and by the *Provincias*, a journal of Valencia. The inquiry into subjects intended to insure or increase the comfort of the necessitous classes seems to me more important than any others, and for that reason I insist more particularly on them. The Society of Friends of the country of Valencia has, on its side, been examining the most economical means of procuring lodgings for the poor."

IMPROVED VENTILATION OF MINES.—A plan for the ventilation of coal mines has been invented and patented by Mr. Joseph Lang, overlooker at Mr. Outram's Castle-street Mill, Moorlane, Preston. The ingress of fresh air by the descending shaft, and the expulsion of foul air by that ascending, are secured by mechanical agency. At the mouth of the ascending shaft a fan is connected with the cupola. Upon the fan being set in motion, ascending pipes act as "suckers," and remove the gases received below in junction boxes. As the bad air is thus expelled, fresh air enters the pit by the descending shaft, and thus a continuous current of fresh air is secured, proportionate to the foul air expelled, while the former forces the latter to the junction boxes, giving it no opportunity for accumulating in the several workings. The quantity of air to be admitted and expelled can be simultaneously regulated at the will of the operator; so that a hurricane of wind might be improvised, on the one hand, while on the other a gentle breeze can be had with equal facility.

SMOKE CONSUMPTION.—A new appliance for the consumption of smoke has been in operation at the works of Messrs. J. Wade & Sons and Messrs. Rouse & Co., of Bradford. The design has been for some time patented by Mr. Charles Gall, an engine tender, of Bridgenorth, Shropshire, and has, it is said, been already applied with success at various establishments in Bridgenorth, Wolverhampton, and Blackburn. The bridge is fitted with an air-valve below the level of the fire-bars, the valve being slung in the same manner as an ordinary throttle-valve. A short distance behind the main bridge is formed another of considerable height, this second bridge being fitted with a "striking plate," which deflects upwards, the air entering the air-valve. When the air-valve is opened, the air entering through it is directed upwards, and mixed with the heated gases escaping from the fire, thus supplying the oxygen necessary for their complete combustion. The simple self-regulating arrangement which forms the principal feature of the plan, is to admit the quantity of air required according to the state of the fire. This consists of a pair of vessels capable of containing water, the pair being connected by a bar which turns in a centre fixed to the boiler. The bottoms of the vessels are also connected by a small pipe furnished with a stop-cock, and another pipe of large diameter leads from the bottom of one vessel to the top of the other. The bar connecting the two vessels is furnished with a couple of tappets, these being acted upon by the pin of a small crank fixed at the upper end of the hinge-pin of the fire-door, this pin being prolonged upwards for the purpose of carrying it. To the underside of the one vessel there is attached a link, the lower end of which is coupled to a lever fixed in a slight shaft which extends along the asphalt to the bridge, this shaft carrying near its inner end another bent lever. This bent lever acts upon another lever, which is connected to the upper part of the air-valve by a short link and staple, and thus by depressing the lever the air-valve will be closed, in the manner in which the valve is hung tending to make it fall open.

SANITARY RESPONSIBILITY OF CORPORATIONS. Mr. Brumback, of Louisville (U.S.), who lost his wife and daughter by cholera, has sued his city corporation for damages in the sum of 25,000 dollars, alleging that if the streets in his vicinity had been properly graded, no deaths would have occurred.

THE LIGHTING OF DURHAM CATHEDRAL.—The system of gas-lighting adopted some time since in the cathedral having recently been found in an unsatisfactory state, the dean and chapter have lighted a portion of the nave in the manner adopted in the choir of York Minster and round the dome of St. Paul's. The mode of lighting is by pipes laid on the string-course immediately over the nave arches, each pipe having about ninety small jets projecting from it, and giving the effect of rows of brilliant beads of light. These pipes are supplied by large mains carried along in the triforium, and have each separate taps, so that the different portions can be lighted either singly or all together. The general wish seems to be in favour of its extension to the choir. The work has been carried out by Mr. G. Newby, under the direction of Mr. C. Hodgson Fowler, architect.

THANTED NEW GAS WORKS.—These works are now complete. The contractors for the buildings were Messrs. Cole, Brothers, of Thaxted. The retort-house, coal-shed, and other erections are of white brick with red piers. These are in the low part of the town. The chimney-shaft is tubular, and about 40 ft. high. The roofs are covered with Taylor's patent red tiles. There are two double pipe condensers in front outside, and three retorts, two of which will be worked in summer and all in winter; two purifiers with patent centre valve, and the gas-holder is self-acting, 31 ft. in diameter, 8 ft. deep, and calculated to hold 12,000 ft. of gas, with five extra strong columns. The grounds are inclosed with white brick walls and red brick copings. Many private lights have already been burnt; and it is expected that 180 will be commenced with, at 6s. 8d. per 1,000 cubic feet. The public lamps are twenty-four, provided for by a district rate on the inhabitants of the town at 6d. in the pound.

MISS HOSMER'S MONUMENT TO ABRAHAM LINCOLN.—A model of "The Freedmen's Monument to Abraham Lincoln" has been set up for exhibition in the Art Gallery of the Boston Athenaeum. It recently arrived from Italy, and is the last work and the masterpiece of Miss Harriet Hosmer. It will be 60 ft. in height, and the base 60 ft. square. The architectural work will be of New England granite; the figures, the ornaments, and the bas-reliefs of bronze. It will cost a quarter of a million of dollars. The idea originated with a negro woman, who volunteered a 5-dollar bill to begin with, at the time of the president's assassination. The freed people have already contributed 23,000 dollars. The salient features of the monument comprise a temple, with thirty-six female figures, hand-in-hand round the base, representing the states; the emancipation of the slave, represented by four bas-reliefs; and the preservation of the Union, by representations of four events of the war, one of these being the assassination. The temple contains a statue of Abraham Lincoln, on a sarcophagus, with four Victories mourning his death.

THE STREETS OF ROME.—The correspondent of the *Telegraph* writes,—"The filthiest streets of Rome are in the Borgo, and the Borgo is composed of the streets immediately surrounding St. Peter's. "Tu es Petrus," runs the great inscription in mosaic round the drum of the dome, in letters every one of them as tall as a Life-guardsmun,— "Tu es Petrus, et super hanc petram edificabo ecclesiam meam;" but underneath the rock of the Church priestcraft has built up a daughill. One loses patience altogether with the splendour of the Roman churches when we contrast that splendour with the squalor by which it is environed. At least, among us heretics, consigned by the Romanists to eternal torment, the church goes hand-in-hand with the trim school-house, full of clean and rosy children, with the hospital, the asylum, and the reformatory. But here there is but one step from Raffaele's pictures and Bernini's statues to Beggar's Bush and the Cadger's Arms. Bramante and Fontana's great façades only screen the nest of hovels behind; and all the loathsome losels of the Roman Alsatia wash their rags in fountains adorned with saints and angels."

SURVEYOR OF POLICE BUILDINGS.—The surveyorship of police buildings in the metropolitan district, and of county courts, held by the late Mr. Reeves, has been given to Mr. T. C. Sorby, architect.

DUNDALK.—A Louth correspondent of the *Freeman's Journal* states that the engine-drivers employed on the Belfast Junction Railway have given notice of their intention to resign their places in consequence of the frequency of attempts to upset trains on that line.

THE STATUE OF THE QUEEN FOR LIVERPOOL.—Mr. Thornycroft, with the assent of the Queen, has been selected as the sculptor for the equestrian statue of her Majesty to be erected opposite St. George's Hall, Liverpool, in a line with that of the Prince Consort. The statue is to cost 5,000.

THE STREET GAS EXPLOSION, NEAR LEATHER-LANE.—The coroner's inquest on the three persons killed by this accident has not yet been concluded. From the evidence already led it appears that the men employed in the street by the Chartered Gas Company left work on the Saturday of the accident without sufficiently securing the gas in the main, where they were at work; and some hours afterwards, the explosion took place, knocking down two houses, and killing three persons, at Nos. 4 and 5, Summer-court, Eyre-street-hill, between Little Bath-street and Back-hill.

ARCHAEOLOGICAL INVESTIGATION IN WESTMORLAND.—Investigations have lately been made in five sepulchral tumuli, situated in the mountainous country about Appley, Brongh, and Kirkby Stephen. The excavations have yielded remains of ancient Britons, both burnt and unburnt, and in two cases showed the practice of Anglo-Saxon adaption of older barrows for burials in a barrow slightly to the south of Kirkby Stephen, a British burial having there been disturbed by Anglo-Saxons to insert the rough log coffin and body of an Anglo-Saxon, as shown by the funeral accompaniments.

RE-OPENING OF SPITALFIELDS CHURCH.—This church has been re-opened for Divine worship, after having been kept closed for a period of six months, during which it has undergone extensive renovations. It was originally built by Hawkmore. The windows have been enlarged, the columns have been freed from the encumbrances by which they were defaced, and the ceiling has been thoroughly cleaned, and its decorations have been brought into relief. The architect under whose superintendence these changes have been effected is Mr. Christian. The total cost of the renovation is estimated at 6,650l.

ARCHITECTURAL PRIZES, PARIS.—At the recent public meeting of the French Academy of Fine Arts, the Deschamps prize of 1,500 francs, founded to aid young architects without fortune, who have relatives dependent on them, was divided between M. Marcel Boissert and M. Mégnier. The latter artist was, at the age of twenty-six, a workman in a factory, when his arm was broken by machinery; the limb was incompletely cured, and he was compelled to seek a new occupation. He studied architecture, while getting his living by writing, and afterwards obtained employment as conductor in the department of the Ponts-et-Chaussées, and supported his mother and sister. The *Priz Leclère* was awarded to M. Dubert, architect, for a design for a monument commemorative of the visit of the Emperor to Algeria. The subject proposed for the same prize next year is "a monumental bridge, situated in the midst of a great city, at the point of an island, magnificently decorated, and presenting an edifice consecrated as a souvenir of a universal exhibition of industry." These terms accord exactly with the position of the Pont Neuf, which touches the point of the island of the old city of Paris, where stands the equestrian statue of Henri IV., and the rebuilding of this bridge, and of the quaint old triangular Place Dauphine, once a quiet quarter of the town, has long been under consideration. The subject for the Bordin prize for 1868 is the analogies and differences which appear between Greek and Roman architecture; the authors being instructed to point out, either on the evidence of facts, or by deduction, what artists and artisans contributed to the construction and decoration of the public and private edifices either of Greece or Italy, and what was the civil and social condition of such artists and artisans.

RE-OPENING OF THE ROYAL CHAPEL AT WINDSOR.—The Royal Chapel near Cumberland Lodge, in Windsor Great Park, has been re-opened for divine service. The new edifice, the chance of which was consecrated some time back, has been erected in the Early English style of architecture by the Commissioners of Woods and Forests, from designs by Mr. Salvin and Mr. Teulon, the works having been superintended by Mr. Morris. The plan includes a nave, an aisle, chancel, and transept, while the open-pointed oak roof is carried partly by the north wall and some carved stone pillars separating the nave from the south aisle. In the chancel is a memorial window to the memory of the late Duchess of Kent. Separated from the chancel by an oak hand-rail, and on its south side, is the royal closet, which has a stone screen dividing it from the end of the aisle.

POWER OF BURIAL BOARDS OVER INSCRIPTIONS.—In the case of the Dean of Carlisle and the Carlisle Burial Board as to the right of Burial Boards to interfere with monumental inscriptions, Chancellor Burton, in the Consistory Court of the Diocese of Carlisle, has given judgment. After reviewing the Acts of Parliament relating to the subject, the Chancellor said the law directed the ground to be consecrated; and it was to be noted that every deed of consecration of burial grounds, whether under the anciently accustomed regulations, or the principle of cemeteries, saved all episcopal rights and jurisdiction. That was an invariable condition. The 33rd section of the 15th and 16th of Victoria gave Burial Boards the right of "erecting or placing any monument, gravestone, tablet, or monumental inscription" in their ground, but he considered that the Act only had the incumbent in its eye; the bishop's authority may still permit the inscription or may still refuse it, or may order its removal. He held, therefore, that while the Board may object to any particular inscription, as ministers and churchwardens have heretofore objected; on the other hand, any person hindered by the Board may appeal to the Court.

THE MANAGEMENT OF FENCES.—The subjoined is an extract from a paper read by Mr. H. W. Keary, at the quarterly meeting of the Wenlock Farmers' Club:—"Although I deprecate most strongly an unnecessary number of fences, I am convinced that true economy points to the maintenance of good, strong fences, and such as will really answer the purpose for which fences are made. And this will not be found to be a work of any difficulty, if only a little attention and method are shown in their management. If possible, only one, or at most, two men should be employed to cut the hedges on a farm, and great care should be taken to furnish them with proper tools. A few lessons, and a little firmness at first, will be quite enough to teach a handy labourer how to do his work, and I believe that the very fact of his having a particular branch of labour entrusted to him operates as a stimulus to do the work well. On my very light sand I have sometimes observed old trimmed fences become a little cankered on their lower stems. This, however, has been entirely remedied, and at a small cost, by throwing up the soil to the roots on each side; and, indeed, it is not a bad plan to treat one or two fences in this way every year. The soil is naturally washed away after a lapse of time, and I know nothing that renovates a weakly fence more. The system of pleaching fences is so generally adopted in this district that it appears necessary to say a few words respecting it. The skill of the workman is quite as important in this branch of hedge-cutting as is the one I have just considered. Great care should be taken to cut down all the large and thick pieces, and to lay or pleach only those that are likely to live under the operation. The pleachers should not be too long, and plenty of stakes should be used. On pastures I think it desirable to use binders on the top, otherwise the cattle are apt to disturb the pleachers with their horns, and materially injure the fences in early growth after cutting. At the time of pleaching, the ditch, if any, should be well cleared out, and all weeds well cleaned away from the roots of the thorns; fresh soil should then be thrown up and worked well into the face of the bank; the bank should also be reduced to its proper size, and left with a sufficient slope. Many old banks are much too large, and may be reduced with great advantage; but care and judgment are required even here, for if a bank is cut down too steep and too close, the roots of the fence are exposed, and will gradually die away."

SOUTH KENSINGTON MUSEUM.—The number of visitors during the Christmas week was 24,108.

THE RESTORATION OF GLOUCESTER CATHEDRAL. The youthful Earl of Eldon, who owns considerable property on the Cotswolds, and whose coming of age was celebrated a few weeks ago, has forwarded to the Dean of Gloucester 500l., to be applied to the restoration of the cathedral.

BUST OF THE LATE LORD MACAULAY.—A bust of Lord Macaulay has, with the permission of the Dean and Chapter, been placed in Westminster Abbey by his sister, Lady Trevelyan. It stands upon a bracket, designed by Mr. Scott, and is placed in the immediate neighbourhood of the grave and of Addison's statue, in Poet's Corner.

CARPENTERS' APPRENTICES.—In a case just tried it has been decided that a master is not justifiable in employing an apprentice in domestic or other uses unconnected with the business he is learning,—such as in heating carpets, or even in stacking boards. The judge gave a verdict against the master, with 15s. damages, the claim, however, being 50s.

COST OF LAND, LONDON.—Mr. Mechi writes: "The great city of London is comprised in an area of only 632 acres and a few poles; in fact, the size of a farm which in the country could be had for a rent of 600l. to 1,000l. per annum. My country friends will be astonished when I tell them that the last cheap thing I heard of as purchased land in Lombard-street was over two millions sterling per acre, or nearly 70l. per square foot of area."

GLASS TRADE, AMERICA.—The making of window and bottle glass at Pittsburg (U.S.) gives employment to 800 men and boys, whose annual wages amount to 1,395,516 dol. The amount of silica consumed is 242,000 tons, and it is chiefly brought from Missouri. The annual value of the manufactured glass is estimated at 2,160,000 dol. These reports are of the window and bottle glass work alone, and do not include the nineteen flint-glass factories, which are valued at 1,298,100 dol., pay weekly wages amounting to 19,000 dol., and annually consume 2,095,806 bushels of coal, employ 3,304 hands, and make 2,000,000 dol. worth of glassware.

UNPROPOSED INFIRMARY FOR WIGAN COLLIERY DISTRICT.—It has been resolved at an influential meeting of the inhabitants of Wigan and its neighbourhood that an effort be made to raise 30,000l. for the erection of a suitable building, and as a part of the endowment fund, for an infirmary, which should contain some fifty or sixty beds, and the working expenses of which would be about 3,000l. annually. A committee has been appointed, and a donation list opened. The employers of labour are advised to confer with the operatives in order to secure a donation of 1d. per week from each person. The subscriptions promised in the room amounted to 14,500l.

MEMORIAL OF THE LATE ARCHDEACON COXE.—The memorial of the late Venerable R. C. Coxe, Archdeacon of Lindisfarne and Vicar of Eglingham, has taken the shape of a porch to Eglingham Church, according to plans approved by the late archdeacon, and which were found in his library. The committee are about to record the dedication of the porch to the memory of Archdeacon Coxe by placing a brass plate therein with the following inscription:—"Unto the memory of Richard Charles Coxe, M.A., Archdeacon of Lindisfarne, Canon of Durham, and during 12 years Vicar of Eglingham, this Porch was erected by his Neighbours and Friends; whereby was followed out a plan which had been designed under his own eye to provide a worthy vestibule to the Church. He died, venerated by the clergy and beloved by his people, August 25th, 1865, in the 65th year of his age." Mr. F. R. Wilson was the architect. The total cost has been 104l. 18s. 8d.

TENDERS

For a row of four labourers' cottages at Hadlow, for Mr. Wm. Grindwell, Mr. Henry Stapley, architect:—
Hammond..... £348 10 0

For a detached villa residence, to be built in the Ridge-way road, Epsford, for Mr. H. W. Draper, Mr. T. J. Hill, architect. Quantities supplied by Mr. B. L. Curtis:—
Morland & Burton..... £2,159 0 0
Field & Sons..... 2,100 0 0
Fairhead..... 1,876 0 0
Cushing..... 1,875 0 0
Anley..... 1,850 0 0
Pattison Brothers..... 1,849 0 0
Webb & Sons..... 1,767 0 0

The Builder.

VOL. XXV.—No. 1249.

The New York National Academy of Design.

NEW YORK came forward nobly for the erection of the Academy of Design, and that, too, at a moment when engaged in civil war. In the early part of the autumn of 1825, there was formed in the City of New York, a "Drawing Association," for art study and social intercourse, which embraced, among its members the greater portion of the artists then in the City. This Association prospered in such a degree, that it soon became necessary to extend its field of operations, and the result was the foundation, on the 19th day of January, 1826, of the present National Academy of Design.

The first Annual Exhibition of the Academy was held in the year 1826, on the second story of a building at the south-west corner of Broadway and Roade-street. One room only was occupied, and that a small one, being but 50 ft. long and 25 ft. wide. It was lighted in the evening by six ordinary gas-burners, and this is said to have been the first occasion on which gas was used for an exhibition of pictures. In 1850, the Institution purchased property, and a suite of six galleries was erected on it; and was so ably managed, that, after years of patient labor, it produced the first means of any amount ever in the possession of the Academy. After five years of occupancy, this property was sold for about one hundred and twenty thousand dollars, giving the Institution a clear return of sixty-nine thousand dollars, and leaving, after the payment of all outstanding debts, a balance of nearly sixty thousand dollars.

After wandering for some time, the Academy, in 1860, purchased a site, at the cost of 50,000 dollars, and invited designs from the leading architects of the city. The design submitted by Mr. P. W. Wight was selected, and steps were taken to appeal to the sympathy of lovers of art outside to raise the funds that would be required. With this end in view a new class of members was established, with certain stipulated privileges, on the payment of 100 dollars for a life-interest, or of 500 dollars for the same interest in perpetuity, with power in the latter case to transfer or to transmit it. The citizens of means and taste responded with such liberality, that after only a few weeks the council felt fully assured of being able to realize their plans in the simplest manner. Many men, indeed, with a munificence quite unexpected, con-

tributed not merely the sums required by the terms of the fund, but in large excess of it; so as to leave no doubt of the successful completion of the new edifice and the endowment of the Academy in such a manner as to enable it to worthily achieve its important ends.

On the 21st of October, 1863, the first stone was laid, when several excellent addresses were made. One of the speakers, alluding to the mighty struggle in which they were engaged, as a tempestuous spring-time to which would follow a glorious summer of intellectual growths, said,—“May we not hope that out of the throes and convulsions of our darkened and strenuous present may be born a future of grandeur and radiance? Nay, may we not discern on the very smoke-wreaths of battle the same glorious how of promise which the Divine Benignity paints on the storm-clouds when the tempest is overpast?”

“But, to attain that lofty consummation,” the speaker continued, “our artists and our public must learn to estimate art in its true dignity and character, not as a frivolous pastime, like the antics of Harlequin; not as a minister to ostentation, like a fashionable upholsterer; not even as a better sort of schoolmaster, teaching a finer selfishness; but as, indeed, it truly is, the purest and best efforts of the purest and best minds in their purest and best hours. Art amuses us, it is true, like many lesser things, but it elevates while it amuses; it delights us, but it enables us through that delight; it instructs us, but it informs us, or forms us inwardly, while it instructs. The genuine products of a mysterious fusion, which blends the sense that sees all beauty with the wisdom that perceives all truth and the love that sympathizes with all life, it has no other function and no other sphere than to speak to the whole of man's higher nature,—to his most exquisite sensibility, his shaping imagination, his penetrative reason, and his vivifying soul.”

In 1865 the building was ready for occupation, and the 17th of April was named for opening it. On the 15th of that month the world was startled and saddened by the murder of President Lincoln, and the members of the Academy immediately passed resolutions expressive of their regard for the memory of their late chief magistrate, and postponed the inauguration till the 27th of the same month. On that day it took place, when the president delivered an address, and the venerable William Cullen Bryant, the poet, followed him with eloquence. He did not overlook the fact that the new building had an old one for a type; but saw in this “an historical congruity to the purpose it will serve, since it was for the adornment of buildings not dissimilar in style that the art of modern painting put forth its early efforts, and advanced to that stage of perfection which gave us the great colourists of the Venetian school.” “I am confident in the expectation,” he said, afterwards, “that a day of great glory for art in this country is at hand—a day of which we now behold the morning, coincident with the signal overthrow of a mighty and fearful conspiracy against our national existence, and with the near prospect of returning peace. The temperament of our people and the influence of our climate are, I think, highly favourable to the cultivation of the fine arts. Some quality in the air of our part of the world, which I do not pretend otherwise to define, promotes, unless I am greatly mistaken, the activity of those faculties which conspire to make the great painter and sculptor.”*

The new building, of which we give an engraving,† stands at the north-west corner of Fourth-avenue and Twenty-third-street. It has a front of 80 ft. on Twenty-third-street, and a front of 98 ft. 9 in. on Fourth-avenue. The principal entrance is in the middle of the narrower front, facing southward. It is on the level of the floor of, what is called there, the second story (with us it would be the “first-floor”), and is reached by a double flight of steps.

On this story, as shown on the plan, is a wide

* A Report of the proceedings on this occasion, and of those at the laying of the corner stone, has been published by Mr. G. H. Mathews, of New York, only a small number being printed. It is excellently got up, and a credit to all concerned.
† See p. 23.

hall, extending from the principal entrance nearly the whole length of the building, with stairs leading to the top story. To the right of this hall, entering the building, is a range of four large rooms, lighted by the eight windows which are shown in the engraving, and by the three windows of like design which open in the shorter façade. The first is a reception-room; the next two are used for the library of the Academy of Design; and the fourth is a meeting-room for the council or governing body of the institution. There are three similar windows to the westward of the main entrance. The first of these gives light to a treasurer's office, the others light a ladies' parlour. Behind these small rooms, is a lecture-room, intended to accommodate 300 persons; and with a private stairway, leading to the story below.

The stairs which lead to the upper story are in the centre of the building, occupying the whole width of the hall, and are an important feature of the interior. The top story is wholly occupied by exhibition galleries, conveniently arranged around the central staircase, and all communicating so as to admit of passage all round. These are lighted from the roof, and need no side windows, except in one gallery, which, being intended for sculpture, has a large north window. The circular openings, filled with tracery, shown in the engraving, are ventilators communicating with the picture-galleries.

The lowest story (called the first, on the plan) is principally devoted to the School of Design, but some rooms in it are intended for the residence of the janitor. The entrance to the School of Design is at the side. The three large double windows near it give light to three studios, which, with a large hall opening into them, are the rooms of the Antique School. Adjoining is the hall of the Life School, which is used only in the evening. This room, the lecture-room above it, and the sculpture-gallery, on the top floor, have windows opening upon a small court-yard, taken from the regular parallelogram which the plan of the building would otherwise occupy.

The interior of the building is well and expensively fitted up. The greater part of the wood-work is of oak, walnut, ash, and other hard woods, oiled and polished, so as to show the natural colour and grain. Each of the four large rooms on Fourth Avenue has an open fireplace, with a hearth of ornamental encaustic tiles, and a mantel-shelf of oak. The windows of the Library and other rooms are fitted with plate-glass in sliding sashes, and inside shutter-blinds. The rooms are connected by large arched openings, two of which are fitted with folding-doors, glazed with plate-glass. The vestibule at the main entrance is floored with an ornamental pavement of inlaid marbles of different colours; and the floor of the main hall is of walnut and maple, in ornamental patterns.

The Academy is the only Gothic building of any importance, other than a church, yet erected within the city limits, and is more richly decorated with sculpture than the exterior of any building in America. The double flight of steps leading to the main entrance—rendered necessary by the small size of the plot on which the building stands, a sufficient staircase within being an impossibility—is an ornament to the building. It is very richly carved with floral ornament, and is built almost entirely of white marble. It affords, also, a good place for the drinking fountain, which occupies a triple arcade under the platform of the stairs.

The walls of the lower story are of gray marble, from Westchester County, New York. The darker hands are of North River blue-stone, selected and smoothed pieces of the same stone as that of which the flags are made which cover our side-walks. The arches of the small windows of the janitor's rooms, in the Twenty-third-street front, are of white marble, the dark band of blue-stone passing over them. The little circles

in the white marble archivolts, just seen in the engraving, are filled with a flower each—the flowers being all different. The corbelled arches over the door and windows of this story, in the Fourth-avenue front, are constructed of alternate voussoirs of blue-stone and gray marble. The clustered columns that support these are of gray marble, but the carved capitals and bases are of white marble.

The sculptured capitals throughout are of a very ornamental character, reminding us of some of the best works of the kind in this country. The three illustrations given are selected, in Fig. 1 from the Fourth-avenue side of the building, and in Figs. 2 and 3 from the entrance in Twenty-third-street. In Fig. 1, as well as in the right-hand capital of Fig. 3, is carved the well-known Virginian creeper—*Ampelopsis hederaea*; the former apparently mingled with some species of pitcher plant, and the latter with the Iris-like "day lily." In the left-hand capital of Fig. 3 is the exotic garden-rose and the *rhododendron*; whilst in Fig. 3, it is easy to detect, on the left, the noble garden-lily, *Lilium candidum*, and a small *narcissus*; and in the right-hand capital the *azalea*, with another plant probably belonging to the same natural order.

The carving in the spandrels, and on the capitals of the drinking-fountain, is particularly good and appropriate, though too small to be seen in our view. In the spandrels are recs, lilies, and *arums* or *caladiums*, the large green leaves of which so beautifully spotted with brilliant red, so many will long remember as displayed at the Horticultural Congress in May last. In the capitals are ferns and other plants appropriate to the situation, and (as throughout the rest of the building) mostly of American origin.

The wall of the next story is of white Westchester county marble, with bands and alternate voussoirs of blue-stone. The shafts in the angles of the windows are of the same gray marble as that of which the walls of the lower story are built. The capitals of these columns are of white marble, carved with designs composed of leaves of forest trees. The tympana of these windows are of white marble, pierced with foliated openings, after the fashion of plate tracery. In the spandrels of the arches of these windows, on the Fourth-avenue side, are open circles which show the brickwork of the wall. It is intended to fill these, at some future time, with medallion portraits of white marble. The irregular spaces about these circles and the spandrels of the arches on the Twenty-third-street front are to be filled with mosaic of coloured marble or tile. There are spaces to be decorated in the same manner in the great gable over the main door. But the principal needs of the building, as it stands, are, at other points, also near the main doorway. The two great buttresses which flank the entrance and the gable are, for the present, finished with caps; but they are designed for statues whenever such may be presented, or can be bought. The tympanum under the arch of the great door is to be filled with a mosaic, if possible, representing some subject or scene in the history of art.

Of the walls of the upper story, it is only necessary to say that the materials are white and gray marble. The cornice is wholly of white marble, but under each little arch is a square of coloured tiles. The cost of the building was about 150,000 dollars.

We may add that the National Academy of Design, when it was instituted, January 18th, 1826, consisted of the following members:—Samuel F. B. Morse, Henry Inman,* Thomas Cole,* Rembrandt Peale,* William Dunlap,* A. B. Durand, Charles C. Ingham,* Thomas S. Cummings, Frederick S. Agate,* John Evers, Edward C. Potter,* Hugh Reniacle,* John L. Morton, James Coyle,* D. W. Wilson,* John V. Paradies,* Nathaniel Rogers,* J. Parisien,* John Frazee,* Mosley J. Danforth, Chas. C. Wright,* William Main,* Peter Maverick,* Martin E. Thompson, and Ishiel Town.* It was chartered April the 5th, 1828. The number of works of art exhibited in the first year, 1826, was 170; the number in 1865, 647. The Academicians appear now to be 78 in number, and there are 78 associates.

One of the local chroniclers of the inauguration meeting says at the close of his notice,—“Our hope took shape. Beauty, art, culture, shall yet be ours, shall yet love America.” We earnestly echo the aspiration, and fully coincide in the belief.

* Deceased.

“NO THOROUGHFARE.”

The Geysers of Iceland have long ranked among the wonders of the world. It is not alone as perennial fountains of hot water that they have excited the attention of the traveller. We have hot springs in this country; and the baths and gold-fish ponds of Matlock are fed from an incessant and bubbling spring, which, when an Icelandic atmosphere surrounds it, gives visible proof of its high temperature in clouds of vapour. But the peculiarity in the Geysers which strikes the imagination even more than the contrast between the boiling spring and the surrounding winter, is the intermittent nature of the flow. A jet of hot water, springing boldly from the surface of its own little crater-like pool, becomes by degrees feebler and feebler, and at last altogether ceases to rise. The orifice appears to be closed, and the communication with the hidden fires is for the time entirely cut off. After an interval, however, of longer or shorter duration, the explosive force of the subterranean steam has accumulated to a pressure that overcomes the temporary obstacle, the escape-pipe is cleared with a burst, and the full column of the Geyser again springs high into the air.

Not a few of our public affairs in England seem to be conducted on the principle of the Geyser. All the conservative elements in the national character, and we have plenty of these elements, respectable and disreputable, tend to form a deposit that chokes the channels of activity, and throttles the efforts made for improvement. Men who labour without degrees in the service of their fellows lose heat by degrees in face of the constant dead weight of obstruction with which they have to contend. Old habits become more inveterate, and more intolerant, by virtue of their very age. Official routine gradually becomes stereotyped, and red tape is triumphant. At last the block becomes so palpable and so unendurable, that the impatience of the country is raised to an overpowering tension, public indignation explodes, and the obstructive nuisance, or the obstructives who have carefully built it up, are blown suddenly away. In the Geysers, the process is one of constant repetition,—we hope that the parallel may not be absolutely true.

Not a year, we might say not a month, passes without affording an illustration of this method of conducting public affairs. We have just had an instance on a scale of imposing magnitude. On the second day of 1867, the inhabitants of London awoke in a new world. Those who are fortunate enough not to have their rising on dark mornings absolutely regulated by the clock, were surprised to find how late it was when they awoke, and how unseasonably disinclined they felt to get out of bed. Those who rose early soon had reason to consider whether it was not the part of wisdom, as well as of comfort, to return to their warm beds. It did not seem as if they would do much good elsewhere. That which so often occurs in individual streets, with a frequency that seems to mark it for an especial amusement of the authorities, had taken place all over London,—a gigantic “No thoroughfare” had been everywhere exhibited, by no less a power than that of our old friend, Jack Frost. The *impasse* was complete. Railway-trains came slowly to a standstill in some deep cutting, and steam refused to move the driving-wheels. From New-cross to London became a distance of three hours' journey. Omnibuses simply had disappeared. Cabs were not to be found, until, later in the day, they were to be discovered in the new form of tandems. The architecture of the streets assumed a novel and imposing aspect, from the massive shade given to the string-courses by heavy coverings of snow. The clocks denoted contradictory hours, or were altogether veiled in white. The statues which so remarkably adorn London had assumed robes more majestic than their usual attire, and King George III. wore the same flowing full-bottomed wig with which, Mr. Jesse tells us, his Majesty so much horrified his beholders on a great official solemnity. Sir John Franklin alone, among these ghostly denizens of the metropolis, looked in his natural element. London seemed in the course of forty-eight hours to have been shifted to the latitude of St. Petersburg.

This was all very well for a time; but the snow-fall ceased, and the obstruction to our traffic continued. Men sought to go about their business, and there were no paths by which they could do so. Business had to remain undone.

The daily papers became full of the complaints of correspondents, loud in their denunciations of those who let matters take their course, or rather made no effort to prevent the evil of there being no course to take. Day succeeded day, and nothing was done; or, in some cases, worse than nothing. And as public inconvenience gave rise to public indignation, and the vestries, who are supposed to have control over the communications of the various districts into which London is inconveniently and absurdly divided, became the objects of uncomplimentary remark. An officer and champion of one of these governing bodies came forward to assure the public that nothing would, or could, or should be done when it happened to snow. Unfortunately for the value of his opinion, this gentleman committed himself to figures. He told us that it would require 1,500 carts and 3,000 horses to remove 3,000 loads of snow from Regent-street. We can only say that if such be the estimate formed by a surveyor of the capabilities of the plant and stock of a contractor, the work of the latter under his orders must be most extensively lucrative.

We confess that we regard this great stoppage, unprecedented as it is in its magnitude, as a hopeful symptom. It cannot be called the straw that has broken the camel's back, for it has been a load ample to overpower many caravans. Its completeness, its persistency, and the manner in which it has brought into relief not only the helplessness of the local Boards, but the unblinking complacency with which they regard their helplessness, and even seek to justify it, is enough, we would fain hope, to raise the public indignation to a pitch that shall hlow away with last year's snow. No event could have occurred better calculated to strengthen the hands of Lord Ebury, and those of his fellow-labourers, who are anxious to provide a better local government for the metropolis. Men who are unfit to deal with an emergency that is rather in accordance with, than an exception to, the ordinary laws of climatology, should not be allowed to middle away the time, the convenience, and the money of their fellow-citizens. Worse alarms at times occur than those caused by a snow-storm, and where should we be then? We have been content to regard the Great Fire of 1666 as the last great fire possible in London. Is it so? Although our roofs are no longer thatched, how much is there of combustible matter stored in the materials and furniture of our houses? If, as we have but too unfortunately seen, our principal waterworks are allowed to catch fire; if the reservoirs of the great fountains of the Crystal Palace were allowed to be unavailable on the only occasion on which there has been a real necessity for their use, who shall sleep secure in a city which for a week has been left impervious to the engines of the fire brigade? What would be our condition if an earthquake, such as has just devastated Algeria, and of the possible visitation of which we have not been without significant hints, should suddenly shake St. Paul's. It is the part of wise citizens to read the lesson set us by the blockade of the 2nd of January as one of timely and salutary warning; and, if we fail to do so, we may be sure that worse will come of it.

It ought to be a rule with all great public, and even great private, establishments, to have an alarm given at periods of sufficiently frequent recurrence, to ensure sufficient action in the hour of real need. How such an obvious precaution could have been neglected at the Crystal Palace is matter of wonder—or rather would be matter of wonder if precaution were not with us the exception rather than the rule. By the employment of this slight touch of the quarter-deck, plants and animals, sparkling Alhambra all the rich tribe-ferns, gorgeous parrots, and which have been accumulating for more than ten years at Sydenham, would now have been unharmed. We beg to urge most emphatically on the authorities at our great mansions the necessity of this rule. There are buckets visible enough at South Kensington. Is there any water to fill them?—any one who knows the way to the supply?—any one to give orders?—any practical, efficient, organized system to be adopted, and that on the instant, in case of an alarm of fire being given at that storehouse of such rich treasures? We hope to hear that an alarm of fire is given there within a week. It is the only way to be secure against what often gives us alarm, till too late,—the actual outbreak of fire.

What, too, are the precautions adopted at the National Gallery?

The subject is one for the attention of the insurance companies. It ought to be insisted on in the policies of all heavy insurances. It is universal for the owners of valuable and combustible property to insure for its amount, and then to leave all but the very simplest precautions at the risk of the under-writers. No office ought to insure such a building as the Kensington Museum or the Crystal Palace, either wholly or in part, without providing for the instant applicability of the resources of the establishment in case of the outbreak of fire.

Twice within the week have we had a warning. What shall we deserve if we pay no heed? The waste of available power, the absence of the right thing at the right time, the helpless blaze of the Crystal Palace, around the very bases of the great water-towers, might have been warning enough. But there are men too busy to read the newspapers—men whose golden minutes are too profitably occupied, or whose precious eyesight is too severely taxed, to allow of the relaxation,—men whose daily thoughts are limited by the walls of their place of business. So the hint has come to them, so loud that they could not fail to hear, so unpleasant that they can not readily forget. There is not a single inhabitant of London to whom the first week of 1867 has not brought positive proof that things are not so ordered as they should be in the great city in which he dwells. If, after such a warning, we fail to set our houses in order, it is in accordance with all that we know of human history to expect that we shall have cause bitterly to rue our neglect.*

THE DESIGNS FOR THE NEW NATIONAL GALLERY.

For thirty years nearly, or ever since its completion in 1838, the building that has occupied what we have become tired of hearing described, in Sir Robert Peel's words, as "the finest site in Europe," has been the best abused building in Europe. Getting somehow, at once, and even more from causes now undeterminable, than from those which are obvious, a bad name,—that "worst of woes that wait" on the reputation of a building as on that of a man,—it soon became the favourite example for quotation by the ardent critics of the newspapers; who are never so happy as when they are demonstrating the utter inferiority of architectural work that is accomplished, to the standard which the reader is to suppose them acquainted with. Generally, we think, in no subject handled by what is called the public press is such inferiority of treatment shown as in the subject of architecture; and the worst part of the matter is that neither is the ignorance confessed, nor are the pains taken which might speedily produce qualifications for effecting some amount of good: on the contrary, condemnation is taken as the tone, because of the unlearned or unthinking writers' incapacity for such pleasurable appreciation as it has been lately said, and not ill said, is the proper office of criticism. Simple blame is more easy of expression than judicious estimation of the right and the relative wrong; and the former has this advantage to the ordinary self-constituted judge, that it gains him with the public to whom he addresses himself, the reputation of superior knowledge. Observations similar to these which we have just made, may have been made before; but we offer them here because they are immediately suggested by the recollection of what has appeared in connexion with the subject of the building in Trafalgar-square, and by what is at present appearing with reference to the designs for the new or modified building.

These designs, sent in competition by ten architects, are now on view, or on the last four days of each week, in the Royal Gallery of the Palace at Westminster, and have already been noticed in the daily papers, and we might say, adjudicated upon, with a facility and a conclusiveness which we are unable to emulate. It is essential to recollect what the problem set before the competitors really is, or was. The solution of such problem is not necessarily started in the production of even the most carefully-executed set of drawings; and the particular problem includes not alone the doing justice to the "finest site," &c., but also the

provision of amiable quarters for the national pictures. It is a problem, too, that is by no means free from difficulty as to the site; and is one that, as presented to the competitors, was not exactly definite: since there are two, or even three, problems, rather than one, of which the collateral solution was asked by the late Government.

We could not be satisfied to give this week much more than a general notice of the competition and drawings. We must defer particulars of the majority of the designs; although the rapidity with which non-professional judges, and even professional, got through their work, may make us in arrears.

The architect who have sent designs are Messrs. Owen Jones, C. Brodrick, G. E. Street, F. P. Cockerell, J. Murray, E. M. Barry, F. G. Penrose, G. S. Clarke, M. D. Wyatt, and Banks & Barry. Of these ten, each one has sent in two designs as required by the instructions; and the greater number of the ten have sent, in addition, one or more variations of their main design. Consequently there may be about thirty designs, in fact, for the consideration of the judges. The drawings altogether not being numerous, it has been possible to arrange them in the Royal Gallery much better than competition-drawings are arranged usually. Besides the walls at the sides of the Gallery, for a portion of the length, and similar space at one end, there is a screen down the middle of the Gallery: thus there has been no necessity to place drawings so much above the eye as to preclude examination of them,—excepting with the help of steps or ladders,—contrivances such as were required on the last occasion, but were not made use of. The Royal Gallery is however an unsuitable place, at this time of the year, for exhibition of any number of architectural drawings. At two o'clock in the afternoon, this week, the light has been quite inadequate. Amongst the sets of drawings, remarkable for number of the drawings, as well the execution of them, are those contributed by Messrs. Cockerell, Murray, Clarke, and Wyatt. Mr. Murray's drawings are on twenty-seven straining-frames: Mr. Wyatt's are on twenty-four; Mr. Cockerell's on twenty-two; and Mr. Clarke's on twenty-one. Mr. Cockerell's drawings are perhaps the most skillfully executed; though several others, as Mr. Wyatt's, are almost equally good, whilst very different in general appearance. Our non-professional readers are requested to bear in mind that good drawing may or may not be associated with good design. Architects should not require to be reminded of the distinction that there is: though, we are obliged to say, they are more impressionable by good drawing, even than the public. As regards the uses of the building, nearly all the designs seem to be the result of careful study of the requirements; albeit the gallery of the Sheepshanks Collection, at South Kensington, having been mentioned to the competitors in a letter from the Office of the Works, when a description of it was furnished, the usual consequences of such references in instructions may have accrued, in many of the designs, in the omission of a certain exercise of judgment.

The original "Circular to Competing Architects," with the "Instructions to Architects," was sent from the Office of Works on the 15th of February, 1866. It will be recollected that, before this, the question of site had been for many years under discussion. Different quarters of the metropolis, including one or other of the parks, and Kensington Gardens, and most recently the Burlington House site, had been named. Also under discussion had been the South Kensington estate, or part of it, that is to say, the locality in which the pictures of the Sheepshanks collection were; and where the whole of the modern pictures, including what were in Trafalgar-square, are at present, as well as the cartoons removed from Hampton Court. Some where about 1851, there was a proposal to appropriate Buckingham Palace to the purposes of the National Gallery. In that case, the present building in Trafalgar-square would have been given up to the Royal Academy; and a Royal Palace would have been placed in Kensington Gardens. The project in connexion with the Burlington House site was at one time so far advanced, that a design had been made by Messrs. Banks & Barry. In this design, the limitation of the galleries, or exhibition-space, in fact the building generally, to one story, combined with appropriation of the whole ground, or without courts, was the characteristic. It was considered that taking into account both light and wall-

surface, more was obtainable by the arrangement here referred to than by that of galleries in two stories. We may mention that Messrs. Banks & Barry's present design, or for the Trafalgar-square site, much resembles the previous one for the different site. Our allusion to the question of multiplication of stories versus appropriation of the ground that would have been given to courts, may help the public to the reasons of differences between the ground-plans of designs, as to space left for lighting; which differences, certainly, are at first very remarkable.

The decision in favour of the Trafalgar-square site, with additions, being considered final, it only remained that the boundaries of the ground to be taken, should be settled, along with the question as to the existing building, of which the eastern portion is to be vacated by the Royal Academy. The new ground, since acquired or about to be, is bounded on the east by St. Martin's-place, on the north by Hemming's-row, and on the west by Castle-street, or rather by the wall of the barrack-yard. This area is now occupied by the workhouse, by different premises at the east (which include one house occupied by several literary and scientific societies, a savings-bank, a house let as offices, and a shop), and by Archbishop Tenison's Library at the west. The present passage along the back of the National Gallery, or Royal Academy, would be absorbed. Besides the immediate appropriation of the area described, the competitors were to be at liberty to contemplate the western extension of the buildings in the rear, as a measure for the future, that is utilizing in some way ground now belonging to the barracks. The "Instructions" say: buildings "hereafter erected over the barrack-yard." Nearly all the competitors have understood this as involving, or allowing of, the entire removal of the barracks; and some of them show a street from Pall Mall East, in which there would be a western frontage to the building as they propose that it should be eventually. Much was said at one time about building a portion of the addition to the Gallery on iron columns over the barrack-yard; but whatever may have been intended by those who framed the "Instructions," the competitors are right as to the thing desirable: any arrangement of a building on columns would be most objectionable; whilst the new street at the west is much wanted. The new ground is by no means rectangular; and the eastern end of the entire site is very irregular. Hemming's-row, with its prolongation, and the line of frontage of the present building, are not parallel: the line of the new street, of some of the competitors, at the west, would be considerably longer than the distance is of the east end of Hemming's-row from Trafalgar-square. As regards the eastern boundary, it will be recollected that the houses in St. Martin's-place, up to Hemming's-row, are considerably in advance of the end of the present building of the National Gallery. None of the competitors have thought fit to sacrifice the eastward projecting piece, or to give it up to the street: though for the latter course there might have been arguments. Most of the competitors place here an apsidal projection from the main block.

The "Instructions" required designs under two alternatives, preparatory to a decision on the best mode of laying out the new site, and on the question of "retaining the existing building," or "reconstructing or remodeling it." By the first alternative, buildings would be erected on the site already described; and these would communicate with the existing building; wherein no costly alterations would be made. By the second alternative, the work would include the demolition and construction, or the remodelling, of the existing building. The Trafalgar-square front was "to be arranged so as not to obscure the view of the portico of St. Martin's Church from Pall-mall East, or from any part of Trafalgar-square." This stipulation, as worded, seems to have occasioned difficulty to some of the competitors. It will be recollected that the similar injunction laid upon Wilkins, was the cause of that setting-back of the ends of the building, which has been attended by a reduction of the accommodation, whilst it has contributed to architectural effect,—as it certainly has even in the National Gallery building itself. But Wilkins made the portico projecting considerably: on the other hand, he sacrificed one of the finest features of a portico, steps in front,—so well displayed in his other work, the London University College. The entrance to the building the "Instructions" said, was to be as at present.

* The destruction of Croydon Church, consumed while the fire-engines were delayed by the snow, forms an emphatic comment on our warning.

but there were to be exits into St. Martin's place and Hemming's-row. There was to be a residence for the keeper, and one for the porter. The largest possible extent of wall-space for hanging pictures was to be obtained, so far as "consistent with grand architectural effects." Top-lighting was preferred; but side-lighting was made admissible for cabinet-pictures and original drawings. A width of 50 ft. was prescribed for the largest galleries, because, as the "Instructions" said, ample floor-space was needed for the accommodation of the multitude thronging the galleries. Thorough and easy ventilation, warming by hot-water pipes, "fireproof construction," and tanks of water on the roof were also mentioned. Each architect was to be paid 2000*l.* for his drawings and statements; which were to become the property of the Commissioners of Works. The First Commissioner did not engage to adopt any of the designs; but if one of the designs were adopted, the author of it would be employed to carry it into effect, being paid "the usual commission of 5 per cent. on the outlay," inclusive of all expenses of measuring.

Several of the competitors had gone to work when, on the 29th June, the competitors received a copy of a reply by Mr. Wornum to a letter addressed to him from the Office of Works, requiring information as to the accommodation that should be provided for receiving, storing, and cleaning pictures. The reply gives, under twenty-seven heads, the designations of rooms and particulars of accommodation that would be required in connexion with the business of the establishment. The plain judicious course would have been to apply to Mr. Wornum before the issue of the original instructions.

In the letter of the 29th June, it is stated that "the committee of judges" to "be appointed to decide upon the plans" would "include within its members not less than two professional architects." The time originally named for sending in the plans was three months from the 15th February, 1866; but the 31st October was afterwards named, and afterwards the 1st January of this year.

There are merits in the present building of the National Gallery; although there has been general agreement amongst the public as to certain defects. The lowness, the central dome, and the terminations stigmatized as "pepper-boxes," have had no defenders; and they should not have. Features of the building also defective, but less frequently mentioned, are the blank-looking podium-wall carrying the columns, the somewhat too low pitch of the pediment, and the side-porticoes without semblance of utility. In addition to these features of the building itself, those of Trafalgar-square, as designed and carried into effect by Sir Charles Barry, have often been objected to. In nearly all the designs retaining the present front, each of the features of the building itself, which have been named, is got rid of; and in several of them the retaining-wall and balustrade of the terrace-road is either omitted, or greatly modified. The Square was indeed not one of Barry's best works. A flight of steps in the centre has sometimes been referred to as what should have been provided. Some of the competitors have introduced this feature; and at least one design, Mr. Brodric's, does away with the wall and balustrade entirely, and substitutes a flight of steps occupying the whole width between the pedestal of the statue of George IV., and the corresponding pedestal. The dome and "pepper-boxes" of the building are got rid of in the designs generally; and a larger dome, or other more commanding feature than the present one, in the centre, is substituted: the building is heightened, as by the addition of an attic; the podium-wall is rusticated, or otherwise decorated; or the portico is entirely altered, so as to admit of steps; and the wings are improved, as by the connexion of the side-porticoes, by columns, with the central portico. The staircase-hall, adapted in size to a larger building than the present one, is made to revert to the arrangement that it had as left by Wilkins, with the opposite flights of stairs, but with inserted columns in the ground-story.

In the plan of the upper floor, the present rooms of the western half of the building, and the exhibition-rooms of the Academy, considered by Mr. Wornum to be very good rooms for their purpose, are generally retained: this is the case even in designs that modify the building considerably. Where new galleries are designed for the larger pictures, the prescribed width, 50 ft., has been adhered to: but this width is greater than necessary; and such is the view taken by many of the competitors, and by Mr. Wornum

also. Wall-space is the first consideration. The galleries for cabinet-pictures, generally side-lighted, are of course narrower than 50 ft.; and some designs provide two stories of these galleries in the height of one story of the principal galleries. One disadvantage of great width is that it requires corresponding, that is unnecessary, height. It used to be objected to the present rooms of the National Gallery, that pictures of the largest dimensions, like some of those of the Venetian School, could not be hung in them; but the truth is that such pictures would so seldom be obtainable, that it could not be desirable to arrange every room as in preparation for them: one room would be quite sufficient. Mr. Street's design is Gothic; and so is one of the designs submitted by Mr. Somers Clarke. Mr. Wyatt's design is remarkable for both elaboration and novelty in the decorative design, including details. But we will at present express no judgment on comparative merits of the designs, and suitability for selection. Previously to judgment, facts of designs must have been got at from the drawings; and some of these data we have yet to collect. But, next week, we will give further particulars of the designs.

The judges appointed to adjudicate on the designs are,—Viscount Hardinge; Lord Elcho, M.P.; Mr. A. J. B. Beresford-Hope, M.P., president of the Royal Institute of British Architects; Mr. W. Tite, M.P.; Mr. W. Russell, trustee of the National Gallery; Mr. W. Boxall, R.A., director of the National Gallery; Mr. David Brandon, architect; Mr. T. Gambier Parry; and Mr. R. Redgrave, R.A., inspector-general, Science and Art Department.

THE COST OF LONDON MUD.

THE city of Turin deservedly attracts the admiration of the tourist. We rejoice that the steady progress of the great Mont Cenis Tunnel bids fair to remove, within a reasonable time, the chief obstacle to visiting the sub-Alpine capital. Our architects and engineers, and all those interested in the improvement and in the comfort of London, might draw from the example of a city which might, for its size, be lost in one of the great outlying districts of the English metropolis, unseen and unknown to many who pass three hundred days out of the year in the City precincts, a lesson to which we now take leave to refer.

We are not about to describe the broad streets and steady honeysucks of the gallant little city, or to dwell on the noble panoramic view that rewards the ascent of the hill which commands the full current of the Po. With the exception of a very small portion, the most ancient part of the town, the perfect symmetry and regularity of the plan gives a high idea of the organizing habits of the builders. The palace of the Dukes of Savoy, now a royal Italian residence, looks straight through the rival structure of the railway station, as if the geni of the past and of the present, the ghosts of *Tête de Fer* and of Robert Stephenson, the embodied expressions of feudalism and of steam power, were resting on their arms in presence of each other. We are not about to dwell on the efficient and unpretending military defences of the place, on the revetted moat that protects the City from a *coup de main*, and on the manner in which the communications of the place are so contrived as to be free, open, and convenient, and yet capable of immediate closing in case of need. But the point to which we now wish to call attention is this. People can walk about in Turin all the year round without ruining their boots or their skirts. Violent thunder-storms from the Alps hurst at times over the city with a force that converts every street, for a few minutes, into a stream, and covers the pavement with an inch or two of water. But half an hour after the rainfall has ceased its traces have disappeared, and patent leather boots or satin shoes can trip from the Station to the Palace, and from the Palace to the bridge over the Po, with less damage than would attend the passage of a single crossing in Regent-street, or of ten yards' distance from any of our metropolitan termini on half the days in the year.

It is obvious that it is more easy to clear the

ways of a city that includes a population intermediate between that of Bristol and that of Leeds than of one sixteen times its size. But the very reference to the names of those smaller English cities that occur as illustrative of the size of Turin will convince us that the question is not one of size alone. The three quarters of a million passengers who daily enter the City of London constitute a traffic marked by peculiar features, and neither chemistry nor chance has produced elsewhere a substance that could be mistaken for London mud when the streets are what is appropriately called "greasy." But the neglect and the filth of the London streets are not wholly due to the magnitude of the traffic. Pimlico is as dirty as the Strand; Bayswater is little or no better than Newgate-street. Without disrespect to Bristol or to Leeds, without even asserting a had pre-eminence over those towns, we may well call London signally and abominably dirty, neglected, and uncared for, as regards the comfort of the pedestrian.

Who and how many are the pedestrians who tread the streets of London we have recently seen. What a wet day costs them (and we have 157 wet days per annum in London), it is not so easy to reckon. If we say that three millions sterling are spent every year in shoeing the London population, we shall probably be far within the mark. If we estimate that to plunge daily through muddy streets, especially for those pedestrians who have not a sufficient number of pairs of walking-shoes to allow the wet ones to be slowly and thoroughly dried, will shorten the duration of two-thirds of these articles by 25 per cent., we shall, no doubt, have the assent of unfortunate experience. That would give us a waste in shoe-leather alone of half a million sterling a year, in consequence of muddy streets. The tailors of London amount to only two-thirds of the number of the shoemakers. The outlay incurred in clothing men's legs in trousers, will be only a fourth or a fifth of our tailors' bills. But then comes the question, of skirts. A hundred and twenty thousand women enter the City daily, of whom ninety thousand walk. That is for the City alone. Over the whole metropolis we cannot reckon that less than three-fourths of a million of skirts daily perform, inefficiently, it is true, but still at a ruinous expense, the duties of the scavenger. With the exception of the comparatively few ladies who drive in their own carriages—and even they can hardly be at all times altogether exempt—the whole female population of London is subjected to a tax of which we will not venture to estimate the amount, by the neglect of the streets. Who would contract to make good the unnecessary destruction of garments of all kinds by the mud of London for a million sterling per annum? If we add the cost of additional washing, of the hire of vehicles, of the wear and tear of vehicles and of horses, and of medical services rendered necessary in consequence of colds and worse disorders caught from wet feet, we shall find that a very large annual sum, not easily calculated, but amounting, at all events, to seven places of figures, is annually wasted by the residents of London in consequence of the neglected state of the streets.

If such be the cost of our London mud, the question naturally suggests itself, why should not the mud be removed or prevented? Would the cost of an efficient system of street-cleaning approach that incurred by street-neglect, to say nothing of the contributions exacted by the volunteer corps of crossing-sweepers?

Why should English people, who are wont to pride themselves on their personal cleanliness, suffer their streets to remain in a state that would be found intolerable in continental cities? Why should London, and Bristol, and Leeds be worse for the pedestrian than Paris, or Turin, or lazzarone-haunted Naples?

The question is not one to be answered by a simple recommendation to sweep the streets more frequently. We must consider the difference in the arrangements for the sewage, as well as for the scavenging, of English and of Continental towns; and we must inquire how our roads are made and maintained, before we can reply to the inquiry how they are to be cleaned.

The first difference to be considered is that which relates to sewage. In London, the main object of the large cost incurred in the construction of the sewers is the self-acting purification of the dwellings. The cesspools common in Paris are, very properly, not permitted in London. The rainfall, it is true, makes the best of its way into the subterranean channels; but it is

considered important to prevent it from sweeping the mud of the streets in its course, as it does in Continental cities, and the attention that is given to secure the health and comfort of private dwellings forms an obstacle to the most natural mode of cleansing the streets.

On the other hand, we must hear in mind that the streets of most Continental cities afford to the inhabitants an accommodation rigidly denied to the Londoners, that, namely, of a dust-heap and dung-hill,—that great part of the refuse of the houses is systematically thrown into the streets, and, after passing under the inspection of the members of the vagrant profession of *chiffonniers*, who live upon this humble prey, is carted away by scavengers paid for the purpose. If, then, more facility exists for removing purely liquid mud in Paris than in London, it must be borne in mind that in the latter city we have only to deal with the mud created by the wheels of vehicles and the feet of horses, and with the natural consequences of a large vehicular traffic.

Prevention is better than cure. Before we inquire how best to get rid of our mud, it is well to ask whether we cannot avoid making so much. For it is a costly product. The water that goes to form it, indeed, we get for nothing; but the solid mineral constituent has been brought to our roads at a considerable expense, broken by hand labour, and comminuted by a more costly machinery than we have yet constructed for crushing Californian quartz. Before our mud is removed from our streets it has cost us pretty nearly as much per ton as the coal which we burn in our grates.

The selection of the material for pitching as well as for metalling the streets of London appears to have been made on mechanical grounds alone, without reference to the no less important question of chemical constitution. The granite which floors so much of the carriage-way has a structure that resists attrition in a considerable degree, and that is also capable of being worked by the pick into regular form. For curb-stones to keep the foot-paving in place, and to ward off the occasional inroad of a carriage-wheel, granite is well adapted. But when the constant friction of heavy traffic grinds the surface into powder, whether in pitched or in macadamised roads, the felspar which forms a main constituent of the rock, is decomposed, and the mineral which, geologically speaking, is the mother of clay, gives forth an aluminous mud. Our roads may almost as well be coated with London clay itself as with powdered granite, and this, mingled with horse-dung and with soot, forms our peculiar mud. The flinty pebbles used in the formation of some of our quieter streets, may be more readily powdered than the granite or limestone; but the difference in cleanliness and in facility of drying between a felspathic or a calcareous and a flint road may be any day observed by passing from the inner to the outer circle of the Regent's Park, or from the Portisdown-road to the Edgeware-road. The mere substitution of a siliceous stone for that at present used in the macadamised streets, would be a most important gain to the cleanliness of London.

Two thousand years ago cities were founded; now they spring up unawares. In old times they were designed, now they seem to agglomerate by chance. The *Cloaca Maxima* of Rome dates from the 150th year of the city; the main drainage system of London was constructed eight centuries after the Norman Conqueror gave a charter to the capital of his new dominions. From Rome to her great Neapolitan port, the *Via Appia*, yet to be traced, was solidly constructed of blocks of lava 18 inches square. From London to Westminster, to Kensington, to Highgate, no record exists to show that any road was ever constructed at all. Bit by bit the original cattle-paths and foot-tracks have been gravelled, widened, occasionally straightened, partially paved, inconveniently macadamised, and so on; but at no time in our history has the question of metropolitan road-making been thoroughly investigated and resolutely grappled with. It was the chance observation of a country magistrate that led to the adoption, within the memory of man, of that great improvement of our former country-roads that is known by the name of Macadam. Without more ado, the macadamised turnpike-road has been adopted for the greater part of the street-communication of our cities, and inconveniences that are tolerable for long lines of rural highway, where traffic is sparse and where it is a question of the cost per yard of maintenance whether you can have any road at all, have been accepted as un-

avoidable under the very opposite conditions of our city streets. A shilling per yard, 88 $\frac{1}{2}$ per mile, from London to Holyhead, was a matter of great importance. As referring to the paving of Oxford-street, such an item has only an infinitesimal value. Can we do no better than transplant a fair make-shift country-road into the heart of our great city? It is strange that the question should need putting at this time.

Not, absolutely, for the first time, for private enterprise has brought forward several attempts at patented improvements, without a larger success, however, than might have been predicted for the effort. We have been fated to slip and slide over wood, and to grind over iron, always coming back to our mud. One point we must for the present take as settled, and that is that setts, or small solid blocks of stone, when laid on a carefully-prepared bed, afford the most convenient support to the enormous traffic of these main highways with which we are as yet acquainted. A pavement of this kind has many defects: it is noisy and liable to displacement, but it forms less mud than other roads, and it can readily be repaired and kept clean. It affords foothold to horses, and it supports heavy weights. The extension of solid paving along more of the main lines of traffic is highly to be desired.

For streets of the second order, streets which, while forming no part of the main through-system of east and west or north and south communication, yet accommodate a large traffic, we should most strongly advise the adoption, at least experimentally, of one of two systems common in Italy. Large square blocks, like those of the *Via Appia*, and those with which Naples is paved, might be adopted with equal advantage in London; or long, broad paving blocks for the wheels, with the intermediate spaces pitched with setts, would not be less available in London than in Turin. The successful application of either of these methods to streets of a secondary traffic would be an immense improvement.

For streets of the third class, where the traffic is light and rare, a solid stone pavement is not absolutely requisite. But none the less carefully should such streets be guarded from becoming fountains of mud. The duty of pulverising and rolling the road metal should no longer be performed by the most expensive and the least efficient instruments, namely, the wheels of carriages built on springs. The roadway should be carefully laid with properly-broken stone of a purely siliceous nature, the interstices filled in with a sharp grit, cemented by the use of hydraulic lime, and consolidated by a steam roller, before any vehicles are allowed to pass. Thus constructed the durability and cleanliness of the quieter streets would be great, and the entire metropolitan system of roads would be in a condition to form the minimum quantity of mud, and thus to present the most favourable area for the operations of the scavenger.

We may add, that the best roads in England are some in the neighbourhood of Bromsgrove, which are formed from the primitive siliceous rocks of the Lickey Hill. Whether this rock is capable of being quarried in blocks fit for paving we are uninformed; if so, no stone could equal it for the purpose. For the concrete or macadamised surface of unpaved roads we have never seen any material, in any part of the world, to compare with that laid on the roads round the Lickey, and the employment of this stone for our London streets, if once tried, would never be abandoned.

We cannot just now examine the question of cleansing. We can only add, that in the effort that is being made to secure a rational system of municipal government for the home of a sixth part of the population of England, we see a hope and a promise that it will not be always a pure waste of time to offer such observations as the above, but that we may hereafter meet with a set of men who will not only take an enlightened interest in the physical welfare of their fellow citizens, but be able to give effect to that interest—a governing body who first will be anxious to ascertain what is best to be done, apart from fear and from favour, and who, having arrived at the conclusion, will then Go AND Do It.

THE SHROPSHIRE COUNTY SURVEYORSHIP.—At the general quarter sessions of Shropshire, Mr. Thomas Groves, jun., has been appointed to the office of surveyor for the county, in the room of Mr. Edward Haycock, resigned.

CROYDON CHURCH.

LAST week's calamitous and always-to-be-regretted fire at the fine old, almost archiepiscopal, parish church of Croydon, in Surrey, will give satisfaction alone to one person—the lucky architect who is likely to get the task, not of restoring, but of replacing it. Two facts connected with English art deserve special note: one is not mentioned by those who have written about the church in this century, and the other has been overlooked in the *Life* of one of the very ablest of our Anglo-American artists.

The Croydon half-recumbent effigy-tomb of the famous Archbishop Sheldon, to whom Oxford, and all who speak the English language, owe Sir Christopher Wren's Sheldonian Theatre (still a wonder in a wood-roof ceiling), has been destroyed. It was of Italian marble, not of the purest, but good of its kind, and was the work of Latham, the City architect (temp. Charles II.) and Bonne, as Walpole tells us in his "Anecdotes of Art." What we have to add is very far indeed from being generally known.

The capital engraving of this statue to be found in the first volume of the Messrs. Lysons's "Engravers of London" (see "Croydon"), was made, they tell us (vol. i., p. 183, ed. 4to, 1795), from "a beautiful drawing by Mr. Lawrence." This "Mr. Lawrence," we have to point out, was the future Sir Thomas, president of the Royal Academy of Arts in London, and something more. The drawing must have been exquisitely just and delicate.

John Singleton Copley, R.A., is the capital painter of two fine English historical pictures,— "The Death of the Great Lord Chatham," and "The Death of Major Pelisson," bought (1864) at his son Lord Chancellor Lyndhurst's sale, for the nation, price 1,600 $\frac{1}{2}$. Sir Charles Eastlake was the purchaser.

This unhappy fire at Croydon Church has told us where Copley lies buried. The fire revealed his grave,—an inscribed stone, and nothing more. This fact is not to be found even in that useful work, Britton & Brayley's "Surrey."

Many who visit the Church of St. John the Baptist, Croydon, will take special care to stand by the charred gravestone of a great historical painter, and the father—as well—of Lord Chancellor Lyndhurst.

Fire! that has been too much a master-witness the Houses of Parliament—the Tower of London—Doncaster Church—the Austin Friars' Church—the Savoy Church—the Crystal Palace—and, now—Archiepiscopal Croydon Church. Which of our national treasures will fall next?

PRESERVATION OF WOOD IN DAMP AND WET SITUATIONS.*

No introductory apology for the theme of this paper is judged necessary. A few plain statements will show that the subject is one of vast though unheeded importance.

The annual drain which is exhausting our forests is startling when we remember the large areas of our country utterly destitute of timber—when we learn, for instance, that "upon the 55,000 square miles of Illinois, there grows not a single pine large enough from which to fashion a board.† Statistics show that, in 1855, above 5,000,000,000 feet of lumber, 2,000,000,000 of shingles, and 900,000,000 pieces of lath were sold in Chicago alone.‡ Michigan and Wisconsin almost entirely supply that market. 6,000 feet of pine lumber per acre is an average yield.§ No formal calculation is necessary to show us that, with the present demand, a single generation will exhaust the supply which those states can afford.

But the consumption increases in a rapid ratio. It has already raised the prices. Clear lumber sold for 18 dols. per thousand in 1855, for 24 dols. per thousand in 1860, and for 45 dols.

* The following paper, written by Mr. H. W. Lewis, University of Michigan, for the *Journal of the Franklin Institute*, gives useful references to information on an important subject scattered over the pages of the *Builder* and other journals.—Ed.

† *Hunt's Merchant's Mag.*, Feb., 1866, page 105.

‡ Lumber, 5,080,023,033 ft.; shingles, 3,650,038,212; lath pieces, 938,297,743.—*Hunt's Merchant's Mag.*

§ "An average estimate of the product of lumber of all the pine lands in the State is 6,000 ft. to the acre. Some sections will overrun, some fall short, of this amount." * * * "seven years will exhaust all the pine lumber within five miles of any of the navigable rivers."—*The Pine Lands and Lumber Trade of Michigan*, page 4.

per thousand in 1865.* And following close on Chicago, in this trade, are Albany and Pittsburg.†

Improvements will soon, we fear, make us as dependent on foreign supplies of timber as is England, who has already granted numerous patents for processes promoting the durability of the lumber every enlightened nation must have.

Shall we employ those processes whose utility experience has demonstrated? Self-interest returns but one answer. But in American railway management, self-interest seems to be disregarded. While the average life of English railway sleepers is fifteen years, that of American sleepers is only seven years.‡ Allowing 2,112 sleepers per mile, at 50 cents each, § 1,056 dols. per mile of American railroad decays every seven years. Thoroughly impregnate those sleepers with sulphate of copper, at a cost of 5 cents each, and they would last twice as long. Thus would be effected a saving of 880 dols. per mile in the seven years, on sleepers alone. ¶ In the United States are 33,908.6 miles of railroad. ¶¶ The whole saving on these lines would be 29,839,568 dols., or upwards of £2,627,795 dols. per annum.

Again, English engineers deride American wooden railway bridges. Eight years is their average duration.* Crescote them and they are good for double or treble that time.† For ordinary railroad purposes they cost 40 dols. per linear foot.‡‡ The use of Bethell's process would effect a great saving on such a line as the Grand Trunk railway, whose wooden bridges measure 9,355 feet upon the Montreal and Portland division alone.§§ Further illustrations of the importance of preserving timber from decay seem unnecessary. Let us proceed to the discussion of this desirable object.

In situations so free from moisture that we may practically call them dry, the durability of timber is almost unlimited. The roof of Westminster Hall is more than 450 years old. In Stirling Castle are carvings in oak, well preserved, over 300 years of age. Scotch fir has been found in good condition after a known use of 300 years, || and the trusses of the roof of the basilica of St. Paul, Rome, were sound and good after 1,000 years of service. ¶¶ After these well-attested examples of preservation, the further consideration of wood in this state seems unnecessary.

Wood constantly wet in fresh water is quite as durable. Piles were dug from the foundations of old Savoy Palace, in a perfectly sound state, after having been down 650 years. The piles of old London Bridge were found sound and perfect 800 years after they were driven.***

While the acidity of hog-water retards decay, it seems to us that part of the preservative property attributed to the stagnant liquid ††† should be ascribed to the salts of metals or alkaline earths held in solution, and deposited among the woody fibres.

In the above situations, the action of natural agents cannot be improved; but in certain other conditions, man must resort to preservative processes to secure permanence of structure. For convenience of discussion we have introduced the following classification:—

- 1. When wood is damp we have to guard against dry-rot.
- 2. When wood is alternately wet and dry we have to guard against wet-rot.
- 3. When wood is constantly wet in sea-water we have to guard against *Teredo navalis* and *Limnoria terebrans*.

1. **Wood in Damp Situations.**—When unseasoned wood is surrounded by dead air, it very rapidly decays, fine fungous growths extending

through every part. After the rot has begun, the mere contact of decayed and sound wood seems sufficient to ensure, by a catalytic action, its spread through the latter. This has probably led some observers to their conclusions, that the accompanying parasitic plants, *Merulius lachrymans* (or *L. vastator*) and *Polyporus hydrinus*, cause the decay. But the highest authorities now regard these growths as accessory, and beginning only after a suitable habitat has been prepared for them.* Thus the fungus acts the part of a scavenger and converts corrupt matter into new forms of life. The presence in the timber of the fungi spores is easily explained. The researches of Pasteur show that atmospheric dust is filled with minute germs of various species of animals and plants, ready to develop as soon as they fall into a congenial locality. He concludes that all fermentation is caused by the germination of such infinitesimal spores.† That they elude observation does not seem strange, when we consider that some infusoria are only $\frac{1}{10000}$ of an inch in length.‡ Admitting that they are only ten times the linear dimensions of their germs, the latter will be $\frac{1}{100000}$ of an inch long. But with the best microscopes we cannot perceive objects measuring less than $\frac{1}{100000}$ of an inch. These germs might find their way into the growing plant through both roots and leaves. The whole tree is thus filled with the seeds of decay, awaiting suitable conditions to spring into growing organisms. The prolonged vitality of spores, in a serious objection, when we remember the vigour of the "minny wheat," and the unknown plants which start from the earth raised from deep excavations. Indeed, time, even when measured by centuries, seems hardly to affect the vitality of vegetable germs.

But what prepares timber for the germination of the fungi spores? Probably fermentation of the juices and semi-solids of the moist wood. For fermentation, five conditions are necessary, § viz.—1. Presence of water. 2. Temperature from 40° to 110° Fahr. 3. Presence of a fermentable body. 4. Presence of a fermentable body. 5. Exposure to the atmosphere.

Three of these conditions almost always prevail. Very rarely, if ever, can we maintain the temperature of any timber construction below 40° Fahr., or above 110° Fahr. Probably countless numbers of ferment spores are annually absorbed into the fluids of the smallest sapling. Completely excluding any construction above earth and water, from the atmosphere, is practically impossible. The two remaining conditions we can generally prevent.

1. We can remove the water by thorough seasoning, and in damp situations we can practically prevent its return by ventilation or resinous coatings.

Examples of remarkable durability of wood have been cited. With equal care in selecting and preparing the lumber, modern constructions might last as long. But while the wood of those old edifices was drying through years of preparation, the timber of modern constructions is translated from the primitive forest into a painted and varnished city dwelling in less than a single year's time. No wonder that in a very few decades, the whole structure is unsafe, || and that an odour of decay makes the mouldering rooms untenable.

Thorough ventilation is indispensable to the preservation of even well-seasoned naked wood in damp localities. The rapid decomposition of

* There is no reason to believe that fungi can make use of organic compounds in any other than a state of decomposition.—Carpenter's *Comp. Physiology*, page 165. (See also *Encyclopædia Britannica* on this subject.)

† "Powders suspended in an air are the extreme origin, the first and necessary condition of life in infusions, in putrescible bodies, and in liquids capable of undergoing fermentation."—In translation of Pasteur's experiments in vol. xxxii., page 6, of *American Journal of Science*.

** Some infusoria are not more than $\frac{1}{10000}$ of an inch in diameter, and if we suppose the spores to be only $\frac{1}{10}$ of the parent's linear dimensions, there must be an incalculable amount of germs no larger than $\frac{1}{100000}$ of an inch in diameter. Since, according to Sullivan and Wormley, with the most powerful microscopes, is limited to objects of $\frac{1}{10000}$ of an inch, we need not be surprised that we do not always see the floating germs of animals and plants.—Note by the translator of Pasteur's researches, *American Journal of Science*, vol. xxxii., page 9.

‡ Notes on Prof. A. B. Prescott's "Lectures on Organic Chemistry," in the University.

§ For an account of the rapid destruction of the floors and joints of the Church of the Holy Trinity, Cork, Ireland, by dry rot, see *Civil Engineer's Journal*, vol. xii., page 303.

¶ For an account of the decay of floors, studs, &c., in a dwelling, see the *Builder*, vol. xi., page 54.

¶¶ In some of the mines in France the props seldom last more than fifteen months.—*Annales des Mines*.

sills, sleepers, and lower floors is not surprising where neither wall-gratings nor ventilating flues carry off the moisture rising from the earth, or foul gases evolved in the decay of the surface-mould. In the close air of cellars, and beneath buildings, the experiments of Pasteur detected the largest per-centage of fungi spores. Remove the earth to the foot of the foundation, and fill in the cavity with dry sand, plaster-rubbish, &c., or lay down a thick stratum of cement to exclude the water, and provide for a complete circulation of air, and lower floors will last nearly as long as upper ones.*

Various expedients have been resorted to in order to hasten the seasoning process. Mr. P. W. Barlow's patent † provided for exhaling the air from one end of the log while one or more atmospheres press upon the other end. This artificial aerial circulation through the wood is prolonged at pleasure. However excellent in theory, this process is not practicable. By another method, the smoke and hot gases of a coal fire are conveyed among the lumber, placed in a strong draft. Some writers recommend the removal of the bark one season before felling the tree. All good authorities agree that the cutting should take place in the winter season.‡

An impervious covering upon undried timber is very detrimental, for by it all the elements of decay are retained and compelled to do their destroying work. The folly of oiling, painting, or charring the surface of unseasoned wood is therefore evident. Owing to this blunder alone, it is no unusual thing to find the painted wood-work of older buildings completely rotted away, while the contiguous naked parts are perfectly sound.

In concluding this part of the subject we may say, thoroughly season your lumber, afterwards cover it with varnish, paint, or pitch, or maintain around it a constant and thorough circulation of air.

2. We can remove the fermentable body, or chemically change its nature.

Woody fibre consists chiefly of cellulose and lignine. The former is very durable, but the latter moulders away but slowly, when exposed to air and moisture. But permeating through these, and increasing from the heart to the alburnum, are nitrogenous substances of the sap and immature wood, mostly vegetable albumen. These are the fermentable bodies we desire to remove or change. A patented process has been proposed to wash out the albumen by water flowing in at one end of the log while a vacuum was produced at the other. Theoretically satisfactory, this method does not seem to have been adopted. Boiling and steaming partly remove the ferment spores, but may not destroy the vitality of those remaining. For, according to Milne-Edwards, he has seen tardigrades resist the prolonged action of a temperature of 248° Fahr., and has known them to survive a temperature of 254° Fahr. § That low forms of vegetation are fully as tenacious of life cannot be doubted.

Boiling and steaming also coagulate the albumen at 140° Fahr. Although coagulated albumen is insoluble in water, the water of solution is, by this heating process, sealed up in the wood, and the cohesion of the latter is said to be diminished.

Albumen is also coagulated by sulphate of copper, pyrolignite of iron, chloride of mercury, chloride of zinc, &c. Some of the compounds thus formed are albuminates of the metallic oxides. Probably this is the reason why some of those salts are such excellent preservatives. But the researches of Kœnig || show that, when basic vitriol is employed, a certain portion of basic sulphate of copper remains combined in the pores of the wood so that water will not wash it out. The most resinous woods retain the most of the basic salt. Impregnated woods also contained, he found, less nitrogen than

§ Oak trees felled in the winter make the best timber.—*The Builder*, 1859, page 138.

¶ Although, in ordinary cases, the death of animals takes place when the temperature is sufficiently high to coagulate the hydrated albumen in their tissues, we know that this is not always so in the case of those previously dried. I have seen tardigrades resist the very prolonged action of a stove whose temperature stood at 120° C., and in the researches of Mr. Dojère, the heat was carried to 140° C. (254° F.) without death ensuing from the heat.—*Am. Jour. Science*, vol. xxxi., page 405.

natural. It is even possible, he states, to remove all the azotized compounds by long immersion in the sulphate solution. The aluminous substances first precipitated by the solution, are re-dissolved by excess, as in case of concentrated sulphuric and muriatic acids.* The operation of such solutions should, therefore, be one of lixivation. Kœnig hopes, similarly, to explain the action of the chlorides. A recent experiment on animal albumen by Professor Prescott shows that its precipitate by the chloride of mercury, is also soluble in excess of the chloride solution. From this we may conclude that the antiseptic qualities of the chlorides depend, at least partly, on their dissolving out the albumen.

But could all the nitrogenous substances be removed, thereby preventing fermentation, the cellulose and lignine of unprotected wood would slowly decompose. Hence the salt used should act on those substances also. According to good authority, sulphate of copper has this action. M. Wetzl maintains that, after a time, the sulphuric acid leaves the base, and acting upon the timber, carbonizes it. He has seen the props in a mine, opened 1800 years ago, charred by the free acid thus eliminated, and in a perfect state of preservation, while their surfaces were covered with metallic copper in regulus. †

The use of corrosive sublimate was patented by Mr. Kyan in 1832; that of chloride of zinc by Burnett in 1838. M. Boncherie has used solutions of blue vitriol and pyrolignite of iron. Easy impregnation of the wood is the great merit of his method.

Each process has in turn excited the most extravagant hopes, and neither has justified a title of the expectations formed. While "kyanizing," "burnetizing," or the use of any salt whatever, has not prevented the ravages of *Teredo navalis* or *Limnoria teredrans*, each of the processes named improves the durability of wood exposed to dampness. Each is, therefore, worthy of explanation here.

Kyan's specified solution ‡ was one pound of chloride of mercury to four gallons of water. Long immersion in the liquid in open vats, or great pressure upon both solution and wood, in large wrought-iron tanks, is necessary for the complete injection of the liquid. The durability of well-kyanized timber has been proved, but the expensiveness of the operation will long forbid its extensive adoption.

For "burnetizing," § a solution of chloride of zinc, one pound of salt to ten gallons of water, is forced into the wood under a pressure of 150 lb. per square inch.

Boncherie employs a solution || of sulphate of copper one pound to water twelve gallons and a half, or pyrolignite of iron one gallon to water six gallons. It encloses one end of the green stick in a close-fitting collar, to which is attached an impervious bag communicating through a flexible tube with an elevated reservoir containing the salt liquid. Hydrostatic pressure soon expels the sap at the opposite end of the log. When the solution makes its appearance also, the process is completed.

He finds the fluid will pass along the grain—a distance of 12 ft.—under a lower pressure than is required to force it across the grain, three-fourths of an inch. The operation ¶ is performed upon green timber with the greatest facility.**

THE REMAINS OF THE ROMANS IN CARLISLE.

At the last meeting of the Cumberland and Westmoreland Antiquarian Society, Mr. J. A. Cory read a paper on Carlisle Cathedral. Subsequently, Dr. Bruce gave an account of the Roman remains recently found in Carlisle. As Englishmen, Dr. Bruce said, we must be interested in the past history of our country. Unhappily a large part of the earliest history of Britain is mainly dependent upon the researches of the antiquary: it must be dug out of the ground by the spade and the pickaxe. Even in cases where the historian does come to our aid, the researches of the antiquary are often necessary, in order to correct his chronology and

rectify many of his statements. For example, the statements of Gildas, the first British historian, as he is called, can only receive full credence when they have been sifted and rectified by the Roman inscriptions and the hoards of coins which are turned up from time to time. Even in cases where we have to deal with historians of undoubted credit, the researches of the antiquary lend additional interest to the pictures of the analyst. Tacitus, for example, tells us that Agricola commenced the battle of the Crampians by ordering forward some Tungrian and Batavian cohorts. How interesting it is to find hurried in some of the wildest parts of the North of England, where they must have lain undisturbed since the days of Roman occupation, slabs and altars carved by Roman hands, which mention both Batavian and Tungrian cohorts. The stone gives vitality to the lettered page. In Cumberland a vast field opens itself to the labours of an archaeological society. The ancient roads of this part of the country are yet to be accurately traced. In Northumberland much has been done in this matter, and that almost entirely through the agency of one honored individual—the late Duke of Northumberland. At his request Mr. Lauchlan not only surveyed the Roman Wall, but the Watling-street from the Scottish border to the Tees, the Devil's Causeway, and the various branch roads communicating with these. He also surveyed the ancient British and the Saxon and Danish encampments in large districts of that county. He is now laying down the combined results of all his investigations in a map of ancient Northumberland. It is, perhaps, not too late to undertake a similar work for Cumberland. It may be that some large-hearted nobleman with ample means will resolve that it shall be done. But if it be thought too great a task for individual enterprise, the combined efforts of a society like this might accomplish much. The facilities for doing it are greater now than they ever were.

The sheet plans of the ordnance survey form an excellent groundwork for such a map. No doubt, where the ancient roads are still to be seen, they will be laid down by the ordnance surveyors; but, in the majority of instances, these roads have been ploughed up, and their former existence can only be ascertained from the testimony of old men and the records of the local historians of the last century. There is no time to be lost; each winter makes sad havoc amongst those who were plough-hoys in 1801. I am the more anxious upon this subject, for I feel sure that important results would appear. It seems to me that the Romans took a firmer grasp of Cumberland than of any other part of the north of England. Besides, the stations on the wall, including Birdswald and Bowness, and all between, a chain of forts, the chief of which was Maryport, has extended all along the coast. These have evidently been intended to prevent the enemy, whether from Scotland or Ireland, landing within the wall. A road has connected these coast defences. Besides all this, several stations some miles removed from the wall and the seacoast, have been planted in the interior, with the view of sustaining the garrisons that would have to hear the first brunt of hostile aggression. Such were Old Carlisle, Plumpton, Papcastle, and others. A network of roads has evidently connected all these camps together. How desirable it is that all these stations, and fortlets, and roads should be clearly set down in a map of ancient Cumberland. And besides, every ancient British barrow and camp, every Danish camp, every Border tower and Peel house, ought to be carefully marked. There is another matter connected with Roman antiquities that some members of this society might undertake. I refer to the formation of accurate catalogues of Roman coins that have been found in any particular locality. Such catalogues would be of historic importance. Coins give us an approximate idea of the time during which any station has been occupied by Roman troops. [Having given some examples in illustration of this, Dr. Bruce proceeded:—] On examining a list of coins you can form some idea of the degree of activity which has prevailed at different times in the station in which they were found. I had the advantage of examining last week the coins at Nether Hall, which had been found in the neighbouring station of Maryport. They have been carefully arranged by the Mr. Senhouse of the last generation. I am disposed to think that the station was first occupied by Hadrian, the personal friend of his father, Marcus Menius Agrippa, whose name occurs on some of the altars found. There was

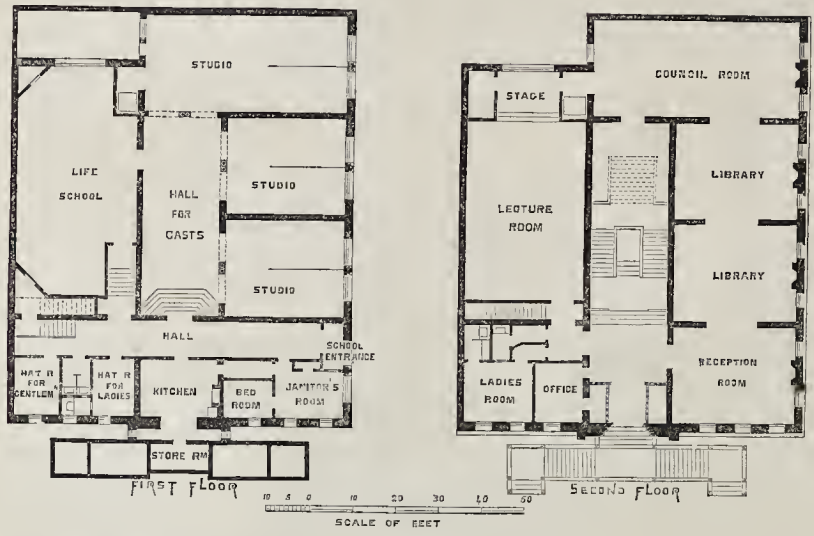

possibly an engineer employed in its construction. At the time Hadrian visited England, A.D. 120, the coins of his predecessors Trajan would constitute the larger part of the currency of the empire. It would be mingled also with some of the coins of previous reigns and a few pieces of the republican era. After the time of Antoninus the coins diminish in number. It is remarkable that the only coins of the time of Severus are one of his wife and one of his youngest son. From evidence akin to this I am disposed to think that Severus chiefly expended his energies in the central part of the line—the path that he chose in his advance into Scotland, and by which he probably retreated. At all events, a carefully constructed catalogue of all the coins found in the various localities occupied by the Romans in Northumberland and Cumberland would throw light upon this subject. To revert once more to the collection of coins at Netherhall, I notice that the number increases during the reigns of what are called the "thirty tyrants," several of them being supposed to have assumed the purple in Britain and Gaul. The number belonging to Constantine the Great is considerable, 13. The usurpation of Carausius and Allectus had been put down, and Britain, in common with the rest of the world, enjoyed peace. The intercourse with Rome must have been considerable. The station must have been in a state of poverty towards the close of the series. Of Valentinian I., who died in 375, there is only one coin; of Theodorus, who died in 395, there is only one; and the same is the case with the last reign of which there is an example, that of Honorius. The date of this last coin I take to be A.D. 417. In a year or two after that time the station was probably abandoned. Objections will, I know, be brought against any conclusions derived from a single collection of coins. Accidental circumstances may influence it. That is true, but if we have a numerous body of catalogues to reason upon, we may build our conclusions with safety, for in this case the law of averages comes to our aid. Amongst the coins at Netherhall are several newer denarii. As they were dug out of the camp, there is no doubt that they are ancient forgeries. As early as the period of Claudius false coins were imported into Britain. I have been speaking of Roman coins. A collection of English coins has a corresponding value. If all the coins of the fourteenth century that have been found in Cumberland had been carefully catalogued, we should have been able to trace with greater accuracy the marches of the three first Edwards to and from Scotland. One thing I wish much that this society would undertake, and that is the preparation of an accurate history of Roman Carlisle. I am persuaded that Carlisle has been a place of great importance in the Roman period. It was the seat of comfort and luxury, and hence, also, probably of commerce. The ornaments and vessels found in it are much superior to those found in the stations of the Wall. If all that are still in existence could be collected in one place it would be found to what an extent the elegances and luxuries of life were enjoyed in it. A map might surely be prepared marking the course of the wall which probably surrounded it,—its gates, its principal streets, the spots where the most important remains have been found, its wells, its burying-ground, and other details. A memoir of Roman Carlisle, after the model of Mr. C. Roach Smith's Roman London, would be an effort worthy of this society. Another point of great importance which may be accomplished by this society is the preservation of the sculptured and inscribed stones in which this neighbourhood abounds. In the south of England there is an almost total absence of these memorials of an era long past. We are rich in them. On us devolves the responsibility of taking care of them and rendering them easily accessible to all who wish to study them. An individual dig up an altar, he is pleased with it at first, but when the novelty is worn off he ceases to care about it and gives it away. It is soon lost sight of, and then is destroyed. And then again great labour and expense is imposed upon those who study Roman antiquities by the wide diffusion of the remains of even a single station. In the course of my own investigation of the antiquities of the Wall, I have often had to undertake a whole day to travel to see a single altar; and to save myself a journey and voyage to the Isle of Man I had to have sent me the cast of an altar which had been taken from Maryport to Gaskellton. It is important that the antiquities found in this neighbourhood should as much as possible be

 ¶ As a modification of this method he also cut a channel in the wood throughout the circumference of the tree, fitted a reservoir thereto, and poured in the liquid. The vital forces speedily dissipated the solution throughout the tree.

Carved Capitals.

concentrated together. If a museum could be formed in Carlisle upon a permanent basis much good might result—if it cannot be formed I would recommend that the inscriptions that are at present scattered about should be sent to museums that are already established, and of whose permanence there can be no doubt. I have to apologize for my boldness in making these suggestions. I pray you give them only so much attention as they are found worth. My interest in the subject and my desire for your prosperity have influenced me in saying thus much. Having read so far, Dr. Bruce said that circumstances had prevented him writing more, and he proceeded to describe *ex tempore* a number of Roman altars recently discovered in Cumberland, illustrations of which were placed in the hands of the visitors. When he was recently examining some antiquities at Netherby an intelligent farmer had expressed his surprise that “the Romans had copied so famously our English letters.” Children at school were little

aware from what source they derived the very first elements of knowledge—the Romans were their first schoolmasters. Among the altars which Dr. Bruce proceeded to describe were some found during the excavations in Carlisle for the sewerage works, and for the offices of the *Carlisle Journal*, one found at Maryport (now in the possession of Lord Lonsdale) and one discovered the other day at Silloth. With respect to the altar found at Silloth, Dr. Bruce said it was about 10 in. high. At Skinburness there had been an ancient harbour or creek before the year 1301, and there was a thriving borough or port; but a great eruption of the sea carried away the harbour and greatly damaged the town. The making of a harbour at Silloth recently had changed the sweep of the sea, which had exposed a quantity of boulder stones upon the shore, and this altar had been found. The conclusion he drew from it was that the Romans had had a little fortress at Skinburness. The altar bore the inscription “Matribus Parcis.” Dr. Bruce

also described a Roman coin of which there was an illustration upon the sheet in the hands of the members. These Roman coins, he remarked, were wonderful productions, and it was important to have contemporary portraits of the rulers of the earth in those days. They could be perfectly certain as to their accurateness. Unlike the portraits of the Queen upon our coins—which were always the same—we frequently found their growth from youth to age. Nero he had found on many of the coins as a chubby-cheeked innocent-looking youth, and at last as a bloated sensualist. Commenting upon the names found upon some of the altars, Dr. Bruce said they showed that Spaniards, people from Languedoc or elsewhere, had been among us, and they proved how vigorous were the efforts made by the Romans to subdue England and to keep it in their possession. He had no doubt that the discipline the people of this country underwent in those times had been of the greatest service in forming the English character.

THE NATIONAL ACADEMY OF DESIGN, NEW YORK, U.S.—Mr. F. B. WOOD, Architect.

[See p. 21, ante.]

THE SANITARY ACT OF 1866.

The regulations under this Act relating to lodging-houses, and for which we long fought, are now coming into operation. Rules approved by the Home Secretary have been issued by several of the districts in the metropolis. Those issued by the Board of Works for the Poplar district we have already spoken of. The rules for the St. Giles's district are also very stringent. Among the most important it is specified that no person shall let any house, or part of a house, in lodgings, or to be occupied in lodgings, by members of more than one family, and in which more than two persons shall sleep in one room, until such house, and the person proposing to let the same, are registered in the office of the Board of Works. In no case will an accommodation of less than 400 cubic feet of space be allowed to each person. Persons letting such house, or part of a house, must have the walls and ceilings of every room, &c., thoroughly cleaned and limewashed at least four times every year. Cellars are to be cleaned out once a week, and limewashed as often as needed. The rooms are to be ventilated, &c., to the satisfaction of the medical health officer. Proper accommodation must also be provided for washing, and such a supply of water for the use of lodgers, with proper covered cisterns, as shall be satisfactory to the health officer. The cistern must afford at least fifteen gallons a day to each inmate. The dustbin must be emptied once a week, and for every twenty persons a separate water-closet is to be provided. Every house is to be properly drained. Every owner not resident in or near the registered house must appoint, as agent, some person who is resident in or near to the house to see that the regulations are carried out. Every house and room shall be open to the medical health officer for inspection between the hours of eight o'clock a.m. and ten o'clock p.m. Any persons violating the regulations will be liable to a penalty not exceeding 40s. for any one offence, with an additional penalty, not exceeding 20s., for every day during which a default in obeying such regulations shall continue.

As we have already said, great discretion will be requisite in the carrying out of the powers of the new Act. There is otherwise a risk not only of inflicting much suffering as well as inconvenience on the struggling poor, especially those with large families, but of rendering the Act utterly inoperative, useless, and impracticable, from attempting too much at the outset.

One of the most annoying results of sanitary pioneering has been the ridiculous lengths to which the desired change of public opinion is apt to go, and the false teaching of quasi-reformers under such circumstances. Take the metropolitan omnibuses as an example. They used to be close and stuffy, and utterly devoid of ventilation, as indeed a portion of them still are. Since the public, however, have been better taught as to the importance of ventilation, the wisecracks who construct many of our omnibuses have them (on the principle apparently that there cannot be too much of a good thing), stuck all over with "ventilators," and especially in front, *behind the horses and drivers*; so that, while the omnibus is thus turned into a complete funnel with draughts, the passengers, at the same time, have the benefit of breathing the cast-off steam and gases from the horses and the sitters on the front outside; and it is a fact that not unfrequently the most nauseous smells enter through these funnel-holes, which for the better "ventilashin" of the "bus, are actually now made for winter no less than summer use on the open and fixed venetian-blind principle appropriate to stables and cow-sheds!

We are sure that our strictures and warnings will not be misunderstood when it is remembered that the conductor of the *Builder* himself was the first public suggester and advocate of the new sanitary powers with reference to lodging-houses, which have recently been adopted by the Legislature. All that is requisite is to bring these powers to bear upon the present state of things by degrees and gently, even in cases where there is glaring need for amendment. Let *Festina lente* be the motto of the authorities, and all will be well.

There is one point on which we may say a word for taste and art in a humble sphere where we conclude. Hundreds of the lodging-houses with which the new Act is empowered to deal have their walls papered with cheap but cheerful and pretty paperhangings, in which, often, both lodger and landlord take a pride. Are all the

walls of such lodging-houses to be henceforth stripped entirely of their ornamental coverings, in order that they may be "limewashed at least four times a year?" We are quite aware that there are evils connected with old and had papering of room walls, but surely these might be regulated and remedied without so harsh an interference with the tastes and comforts of the poor. The papers usually put on (often by the lodgers or landlords themselves) are extremely cheap,—from 5d. for twelve yards:—could it not be ordered that such papers shall be removed, say once a year, and the walls scraped and cleaned before new paper is put on?

SANITARY.

Proceedings of the Chelsea Sanitary Committee.—When cholera threatened the parish, a committee of nine members was appointed by the vestry to watch its progress, and to take all proper preventive and other measures for its diminution. The committee appointed five medical visitors, with salaries of 10 guineas a week, and ten assistants with salaries of 34 guineas, and other active measures were adopted, all of which are now detailed in a full Report of the Proceedings of the Committee, printed by authority for private circulation among the members of the vestry. These proceedings, no doubt, greatly checked the progress of the epidemic, and facilitated its final removal from the parish.

St. Marylebone Parish.—The medical officer of health for this parish has just issued his report for the year 1865. The annual rate of mortality for the entire parish was 24.95 per 1,000 population, being nearly 1 per 1,000 below that of the previous year. The mortality was highest in Christchurch sub-district, small-pox, fever, measles, being most prevalent and fatal. The annual death-rate in that sub-district was 28 per 1,000 living. In Cavendish-square sub-district the proportional number was only 18 per 1,000. Some striking instances have occurred of the apparent efficacy of sanitary measures in arresting the progress of cholera, and it is suggested whether these measures might not be adopted with similar success during the prevalence of smallpox, which has broken out with frightful activity in the vicinity of Lisson Grove. It is mentioned that the progress of sanitary works has been satisfactory, 1,240 ft. of new sewers were constructed, 7,688 ft. of new pipe-drain laid down, 83 cesspools have been abolished, and water laid on to 326 closets. The water is supplied to the parish by the West Middlesex Company, whose source of supply is the river Thames at Hampton, Middlesex.

SCHOOLS OF ART.

The Keighley School.—The annual meeting of this School has been held in the ball of the Mechanics' Institute, at Keighley. There was only a small gathering. Mr. T. H. Ingham, of Marton Hall, occupied the chair; and, in course of his address, said, in reference to general education, that after all there were schools sufficient, and the difficulty was to overcome the inertia of parents in getting them to send their children to schools; and he believed they would never overcome the difficulty until they adopted a system which had an ugly name, and that was, compulsory education. National interests—for the wealth of the nation depended on its manufactures—were involved in Schools of Art. As an institution, they were quite new in the country. They only began, as it were, after the Exhibition of 1851, when our deficiency in artistic manufacture was very manifest; but when the Exhibition of 1862 was held it was shown what advantage had been derived from the Schools of Art; for, instead of being outstripped in design, we were outstripping our neighbours. National interests, therefore, were involved; and the question was one for all classes; and the working men had shown what they could do if they only received encouragement. They would remember the story of Benjamin West, the painter. When a boy, he was left at home by his mother to rock the cradle, and while alone he made a drawing for which he received a kiss when his mother returned. That kiss, he said, made him a painter; and, said the speaker, what that kiss was to West, let their smiles and encouragement be to the Keighley School of Art. The report

stated that during the past year 71 students had attended the male classes, with an average attendance of forty for each term. The ladies' class, which had been formed this year, had been attended by seven young ladies, and the work they had executed was considered very creditable. The classes are still under the superintendence of Mr. Walter Smith, head master of the Leeds School of Art, and are regularly taught by Mr. Andrew Stevenson, assisted by Mr. W. H. Jackson, late a successful student in the school. The prizes were ultimately distributed.

THE MODELS IN THE CRYSTAL PALACE.

THE KIEFF BRIDGE.

AMONG the many works of art consumed by the late fire at the Crystal Palace, were the extensive and valuable collections of naval and engineering models, placed in the galleries of the Tropical Department. Conspicuous among these was the model of the great suspension-bridge, half a mile in length, over the river Dnieper, at Kieff, in Russia, erected about fifteen years ago, by Mr. Vignoles, F.R.S., for the then emperor, at a cost of nearly half a million sterling.

This model was first shown in London at the Exhibition of 1851, and was subsequently placed, on loan, in the Crystal Palace, where it had remained many years. It was considered a remarkable work of mechanical skill, and was constructed at an expense of several thousand pounds. The loss to Mr. Vignoles is irreparable, though a duplicate model remains in the Engineering Gallery at St. Petersburg, placed there by the Emperor Nicholas I., to whom it had been presented, with the Imperial permission. A few notes of the bridge will not be out of place with reference to the beautiful and singular work, destroyed, with so many other most interesting objects of nature and of science, exhibited in the Crystal Palace.

The architecture of the river piers is rather novel, and of a striking character, harmonising with that used in the extensive range of first-class fortresses which crown the heights of Kieff. The portals through the piers have a clear breadth of 28 ft., and a height of 35 ft. to the soffit of the semi-circular arches. The platform has nearly 53 ft. of extreme breadth, of which nearly 35 ft. is for carriage-way. The platform is suspended from four chains, all on the same horizontal plane, two on each side of the road; the footpaths project beyond the chains, and are carried by cantilevers round the piers exteriorly; so that the foot-passengers are completely separated from the horsemen and carriages.

The chains are composed of links, 12 ft. long, each link weighing about 4½ cwt. Eight links form the breadth of each chain; the total length measured along their curves being nearly two English miles.

For the swivel bridge the iron employed therein is almost exclusively malleable. The bridge is moved horizontally (on the same principle that locomotive engines are sent round on the large turn-tables at a railway station), and by the efforts of a few men only, acting on a very simple apparatus. The construction of the platform of the bridge presents several novel combinations of wood and iron, and is of most remarkable stiffness, to resist the violent action of the eddies of air in violent winds, which have so often injured and even destroyed the ordinary platforms of suspension-bridges in other places.

The total weight of iron used in the construction of the bridge was about 3,500 tons, including the machinery used in the various stages of its construction.

A whole village of warehouses, offices, shops, sheds, dwelling-houses for the superintendents, and comfortable cottages for the numerous workmen, was erected on the left bank of the river, on ground expressly raised for the purpose above the flood-level; a regular commissariat was attached to the establishment; and the whole organization of service made very complete.

Not the least remarkable part of the establishment was that for the manufacture of the hydraulic cement required for the foundations and masonry. It is, in fact, an "artificial puzzolana," made from a peculiar clay found in the Kieff hills, and prepared on the principles laid down by the celebrated French engineer, Vicat, in his recent publication on puzzolanas. The buildings for this purpose were very extensive, being gigantic laboratories, where the operations

were carried on day and night. Eight large roasting ovens, besides numerous grinding mills, in constant action, manufactured upwards of 300 bushels (or about 500 cubic feet) in every twenty-four hours.

This bridge is, perhaps, the largest in Europe, the length being nearly half an English mile, and covering an area of 140,000 square feet,—considerably more than 3 acres.

The bridge was opened with great ceremony on the 10th of October, 1853, by the Grand Duke Nicholas of Russia, the third son of the Emperor Nicholas, attended by all the ecclesiastical, military, and civil authorities, and almost the whole population of Kieff. It has since been constantly travelled over, particularly by artillery, cavalry, and troops entering and leaving the fortress, which is the great central military depot and arsenal of the South of Russia. The total cost was about 432,000 sterling.

THE LOCAL GOVERNMENT OF THE METROPOLIS.

On Tuesday last, a numerous and influential deputation from the Metropolitan Municipal Association for Promoting the better Local Government of the Metropolis, waited upon the Secretary of State for the Home Department, in accordance with the terms of a resolution passed at a recent public meeting at St. James's Hall, with the view of inducing the Government to initiate immediate legislation on the subject. The deputation was introduced by Lord Elnor, the president of the association. Mr. Buckmaster, hon. sec., Mr. J. Beal, Mr. C. Buxton, M.P., Mr. T. Hughes, M.P., Mr. Reardon, M.P., Mr. J. M. Ludlow, Mr. Godwin, the Hon. F. Lyng, Mr. Begg, Mr. Dresser Rogers, Mr. Peter Graham, and others having addressed the Home Secretary.

Mr. Walpole said, it would be premature for me to give any opinion at present as to the details of the measure to be submitted to Parliament, but I may say that I hold the opinion that the government of the metropolis might be greatly improved, and that one of these improvements would be the establishment of larger areas with smaller authority; but having said that I hope you will excuse me from expressing any further opinion. I will only say in addition, that I will give the subject my best attention, and will take care to communicate to her Majesty's ministers what has passed, but I hope you will not ask me to give any further pledge.

We shall return to the object the Association has in view.

A HINT TO PATENTEES.

The Commissioners of Patents have just issued a new order which is of importance to all intending patentees. The order runs as follows:—

"After the 31st day of December, 1866, every applicant for Letters Patent shall deliver at the Office of the Commissioners, with his provisional specification, or (when a complete specification is filed with the petition and declaration) with his complete specification, an abridgment, in duplicate, of such provisional or complete specification. The abridgment must describe, in as short a manner as possible, the features of novelty which constitute the invention. The abridgment and the copy thereof must be written upon sheets of foolscap paper, and upon one side only of each page, leaving a margin of one inch and a half on the left-hand side of the page.

Dated the 17th day of December, 1866.

(Signed) CHAMBERS, F. C.
FOMLEY, M. R.
JOHN ROLZ,
JOHN B. KARSLAKE."

We do not quite understand the object in view, but it is apparently intended to make use of this document as "copy" for the series of abridgments published by the commissioners, and thus to save the money now paid to the gentlemen who are engaged on the work. We have already expressed our opinion of the value of these abridgments,* but we do not think that this is the way to increase their usefulness, and inventors will not thank the commissioners for adding to their burdens. The inventor has already to deposit duplicate copies of his provisional and final specifications, which are used as printers' copy. An extra copy of the drawings has also to be deposited, which is only of use during the few days that the original is in the hands of the lithographers. In some cases, these extra copies are very costly, and now the inventor will be put to a further expense in preparing this

abridgment. There is also another question of some importance, viz. the exact legal value of the new document. Supposing a discrepancy to exist between the specification and the inventor's "abridgment," will it be possible to make this want of agreement a foundation for setting aside the patent in a court of law, as is now done, in case the provisional and final specifications do not agree? The commissioners, we believe, will have no power to refuse an inspection of these documents; and will also, if we understand 16 & 17 Vict. c. 115, sec. 4, be bound to grant office copies, which could hardly be denied as evidence by a judge. In case these abbreviated descriptions are printed intact, the abridgments will have an official character which they do not possess at the present time, inasmuch as they will contain the inventor's own description of his invention. But we do not consider this to be of any advantage, inasmuch as the commissioners' abridgments were never intended to "supersede the necessity for consulting the specifications," to use the words of the notice prefixed to each volume. No two patentees, moreover, will form exactly the same idea of the commissioners' requirements as regards the nature and length of the abstract required, and as a natural consequence, there will be a want of uniformity—some will be too long, others too short. Supposing however, that these documents be found to require examination by a skilled person to see if they really do give a concise and intelligible account of the essence of the invention, then we are at a loss to understand what advantage will be gained. The person who is able to judge whether the abstract comes up to the standard, would also be capable of abridging the specification; and the time occupied in the two processes would, in most cases, be about the same, so that there would be no saving of expense under this head. We shall be curious to see how the system works, and to know the legal value of the new document. In the mean time, we would advise inventors to be very careful in drawing up their "abridgments," and suggest that they should, where possible, use the exact words of their "provisional," or of their claim in the "final" specification.

FROM IRELAND.

Leighmeay.—St. Mary's Church here has been consecrated. The edifice is built from a design furnished by Mr. William Atkins, of Cork, architect. It stands close by the bank of the Innoshannon river, near the bank of the unbraided woods of Shippool, having in its front the castellated and ivy-clad ruin of that name. In form it consists of nave and chancel, with semi-circular termination; tower, spire, porch, and ringing-room. The spire is supported by eight marble shafts resting on the upper part of the tower. The porch also rests on marble pillars. The masonry is enriched with hands of red brick and vousoirs in the arches. Internally the walls are lined with red, yellow, and black brick and tiles, arranged in patterns. The steep-pitched roofs are of stained deal, the principals carried by stone corbels. The passages of the church and chancel are paved with different coloured tiles. The sittings, which can accommodate about 80 persons, are all open, and of deal stained like the internal roofing. The site of the church was granted free of rent by Mr. T. B. Herrick, of Shippool.

THE ANCIENT LOUVRE, PARIS.

The excavations in the court of the Louvre to discover the site and boundaries of the Philip-Augustus tower are nearly all filled in and levelled. Some openings are to be left leading to the underground story, for the purpose of gaining access to it if necessary. The vaults which were filled with earth have been completely cleared.

The great tower of the chateau of Philip Augustus and of Charles V., which has been laid bare by the excavations in the court-yard of the Louvre, and known by the names of Tour Neuve, Philippine, and Ferrand, stood fronting the entrance opposite to the Pont des Arts. The foundations are of considerable depth, and commenced at the ancient level of the bank of the river. This building was 96 ft. high, with walls 12 ft. thick, and was surrounded by a deep

ditch. The precise date of its foundation is unknown; but it is known that in 1204 this tower had been but recently built, since in that year Philip Augustus declared that he owed 30 sols to the prior and brethren of St. Denis-de-la-Châtre on account of the tower of the Louvre, which he had built on their land. At this period, the edge of the river which bathed the Louvre was called the Rivage de St. Denis. The new tower being, moreover, in the seigneurie of the bishop and chapter of Notre Dame de Paris, they were entitled to compensation, and the King charged the provost of Paris to make the Parisians pay the indemnity. Celebrated in the feudal annals, the terror of vassals and the King charged the provost of the Louvre was also employed as a place of deposit of the royal treasures. Access was gained to the upper portions by a winding staircase. The entrance was defended by an iron door with numerous locks and bolts.

This donjon was also the centre of royal authority, and the great functionaries of state came there humbly to take the oaths of allegiance and homage. After about three centuries and a half of existence, the tower and buildings forming the *ensemble* of the parallelogram of the castle were demolished, and Francis I. laid the foundation of a new palace, after the designs of Pierre Lescot. Among the materials brought to light by the excavations in the court of the Louvre some evidently belong to a period anterior to the epoch of Philip Augustus. There exists a diploma, reported in the history of the University, which affirms that in the seventh century a royal mansion was built on this site, in the reign of Dagobert; and that in the twelfth century a chateau was built. The fortress of Philip Augustus succeeded this last construction.

REPORT OF METROPOLITAN BOARD OF WORKS.

The Metropolitan Board's report for 1865-6 has been published.

Amongst the various important subjects treated of are the claims in respect of the Thames Northern Embankment, which were, for freeholds, leaseholds, &c., 311,257 l. 11s. 1d., which were settled for 211,374 l. 10s. The claims for the new street to the Mansion House were—freeholds, leaseholds, &c., and yearly tenancies, 1,184,723 l. 7s. 5d., which were settled for 1,059,234 l. 6s. The claims in respect of the Thames Embankment (South) were—freeholds, leaseholds, &c., 142,742 l. 14s. 5d., which were settled for 109,975 l. The whole of the building plots in Carriek-street (which was opened to the public in March, 1861) have been let on leases for eighty years, with one exception, where the term is fifty years. The aggregate rental reserved for these plots is 2,454 l. per annum. The Board would have proceeded to sell these ground-rents, but they deemed it inexpedient, owing to the state of the money market, to do so as yet. The cost of the properties required for the formation of this street was 102,831 l. 6s. 8d., which, with other expenses, including professional and law charges, gave a total of 121,353 l. 13s. 11d. In Southwark-street, which has been open for nearly three years, out of 206 plots, into which the surplus land in the line of the street had been divided, 177 have been let on lease, and the income derived from the ground-rents, including the rent of some warehouses purchased by the Board, but not pulled down, is 6,904 l. per annum. The cost of the properties and interests purchased by the Board was 476,222 l. 11s. 2d., and the professional and other charges swelled the total to 582,630 l. 11s. 4d. The cost of the removal of Middle-row, Holborn, is estimated at 61,152 l. The compensation claims for freeholds and leaseholds amount to 17,566 l. 10s., and the settlements thereof to 15,950 l. The net cost of the Whitechapel improvement is estimated at 115,361 l., and the Board have been engaged in purchasing the properties required up to March 31. The Board agreed to settle claims for three freeholds and four copyholds, &c. The sum claimed was 47,708 l. 1 s. 4d., settled for 42,818 l. The quantity of land purchased for Fishery Park was 120 acres, which cost 56,550 l., or about 472 l. per acre.

The report states that the experience of last year fulfils the anticipations of the benefit to be derived from the increased purification of the river. These benefits are evidenced by the fact of the return of fish in large numbers to those

* *Builder*, vol. xxiv., p. 663.

parts of the river which had before been in a polluted state; and further improvements are anticipated as arrangements for purifying the upper waters become matured, and a more efficient system of water-supply is organized.

On the subject of the Metropolitan Gas Acts, the report expresses the belief of the Board that these Acts "have been evaded by meter-makers, gas companies, and others."

A considerable portion of the report is devoted to the embankment and drainage works, with the progress of both of which we have already occasionally made our readers acquainted. It also contains an important communication by Mr. Bazalgette on the Ventilation of Sewers.

THE THAMES EMBANKMENT AND THE SEWERAGE.

Mr. BAZALGETTE presented, at last meeting of the Metropolitan Board of Works, a report, the substance of which is as follows:—

On the Northern Embankment (contract No. 1, between Westminster and Waterloo Bridges), about 3,730 ft. in length of iron caisson and timber coffer-dams have been constructed or are in various stages of progress: 2,637 ft. of the Low Level Sewer, 2,123 ft. of the subway, 2,925 ft. of the 4 ft. by 2 ft. 8 in. sewer hitherto discharging on the foreshore of the river, and 284 ft. of the flushing-sewer have been completed. About 3½ ft. above Trinity high-water mark of the Westminster steam-boat pier for a length of 320 ft. have been completed; 45 ft. in length of the Charing-Cross steam-boat pier, and 306 ft. of the river-wall have been brought to heights varying 1 ft. to ½ ft. below Trinity mark. The Adelphi landing-stairs are progressing favourably; filling to the extent of from 400,000 to 500,000 cubic yards has been carried out behind the walls and works of the Embankment. The works that are dependent upon the operations of the Waterloo and Whitehall Railway are still in the same condition as at the date of the engineer's last report. The upper parts of the Embankment works to the westward of this point are waiting generally for stone to complete them. 8,269l. worth of work has been done during the last month. Between Waterloo Bridge and Temple Gardens (contract No. 2)

about 60 ft. of river-wall, sewer, and subway are completed to within 4 ft. of Trinity high-water mark. Beyond this the only remaining portions of the work to be executed to complete the contract are the parapet and the upper part of the Temple steam-boat pier, the stone for which is arriving on the ground. The approximate value of the work done, and of the materials and plant upon the ground, is 206,616l. Of the total amount, the proportionate sum of 195,319l. is for works, 8,297l. for materials, and 3,000l. for plant. But little progress has been made during the past month with the Isle of Dogs branch of the Low-level Sewer, in consequence of the contemplated alterations in the line of sewer near the East and West India Dock entrances. The value of the work completed is 59,558l., of which sum 3,213l. represent the progress of the past month. Fair progress has been made at the Abbey-mills Pumping-station. The value of the work completed is 93,230l., 5,230l. being for the progress during the last month. On the Southern Embankment a length of 2,370 ft. of dam and staging has been driven to a depth averaging 15½ ft. Within the dam about 1,600 ft. in length of the river-wall have been brought up to levels varying from 17 ft. 4 in. to 6 in. below Trinity high-water mark, and about 300 ft. of the wall have been brought to a level of 3 ft. 9 in. above that mark.

THE TRADES MOVEMENT.

Manchester.—With a view to offer the more effectual resistance to the combinations of employers, and the action of locks-out, a movement originated in Sheffield, last July, for the formation of a national alliance of associations of the employed. The scheme has proceeded so far that the first conference of the alliance has been opened in Manchester, with fifty-six delegates accredited from fifty-four different trades in various parts of the country, including Scotland, and representing, it is said, an aggregate of 50,830 members of workmen's associations!

North.—The masons employed by Mr. Joseph C. Rees, contractor for the Wesleyan chapel, have

struck work "in consequence of a disagreement with the clerk of the works, whom they consider not a practical man." Other masons employed by the same contractor threaten to strike unless Mr. Rees gives those already on strike other work not connected with the chapel; and every mason resuming work at the chapel while the clerk is employed on it will be held liable to a fine of 2l. until the strike be settled.

Sunderland.—Nearly 100 carpenters employed by Messrs. Taylor & Scouler, Sunderland, have struck work, in consequence of their employers not complying with their request to give them beer at three o'clock in the afternoon. It appears that in order to make the most use of the short days, Messrs. Taylor & Scouler caused their men to cease work 20 minutes to half an hour before time, and then gave them the beer. Their own men did not complain, but the union interfered, and the men are ordered to cease work until their employers agree to their request.

Hertford.—A convivial meeting took place at the Dicker Oil Mill, at Hertford, on Monday last week. The men in the employ of Messrs. Inskip & Manser are in the habit of entertaining their employers to supper on Christmas Eve; and on this occasion the annual gathering was made the occasion of giving permanent expression to the feeling of confidence and good will between the firm and their working men.

EVICTED TENANTS' AID ASSOCIATION.

A NUMEROUS deputation from the Evicted Tenants' Aid Association waited upon the Earl of Derby, on Wednesday last, for the purpose of bringing under the notice of the Government the evils and miseries entailed upon the poor of the metropolis by over-crowding in their dwellings. The deputation urged that Parliament should be asked to pass measures compelling railway companies to provide dwellings for the poor evicted by their works; and, further, that Mr. Torrens's Bill of last session, for the rebuilding of dilapidated houses, and for otherwise providing houses for the poor, should be passed. Lord Derby replied,—"I can only say there is not one of you feels a greater interest in this question than I do. It is a most difficult and painful subject to deal with; and I may say, on the part of my colleagues, it is one that has commanded our very anxious attention. If we can see the moment for introducing a measure at all satisfactory, we shall be most happy to carry it through, and to receive the co-operation and assistance of those who have studied the subject, and can render us valuable and efficient co-operation and assistance. It is not a question of party in any sense. It is a question of humanity, and it is also a question with respect to which we must bear in mind the maxims of economy. We cannot, on the part of the Government, make it a question of mere charity and philanthropy. If any mode can be shown by which we can mitigate the evils which are most excessive and painful, nothing will give us greater pleasure than to carry a measure which shall effect that through Parliament."

RAFFAELLE AND HIS WORKS.

UNDER this title Mr. Bevington Atkinson gave an interesting lecture at the Royal Institution, Bristol, on the 7th inst. After elucidating the first and second styles of Raffaello by alluding to the Madonnas and holy families, of which he painted no less than fifty—the best known were especially commended for the simplicity and purity of their Christian sentiments—Mr. Atkinson remarked with reverence that Christian art, if true and positive and of any worth, must follow in the footsteps of Him who was at once human and divine. He then proceeded to discuss the questions of genius, and inspiration, and beauty in art, remarking that the Christian art into which Raffaello threw himself was the embodiment of Christian truth and beauty. Raffaello joined physical and spiritual beauty, and so made that enduring and ideal humanity which reconciled as it represented two natures. Thus laying aside all pretension to inspiration (the lecturer remarked) in any sense, he had endeavoured to show how from merely natural powers and materials Raffaello matured Christian art. The genius he had ascribed to him infused into the manner of the period vigour, heauty,—in short, nature. Of the painter's third, or Roman period, it was remarked that it

brought with it a vast development; and to it belonged the greatest pictures the world contained. When at the age of twenty-six Raffaello travelled to Rome, he did not get rid of his Florentine manner; the two periods overlapped each other; there was no break in continuity, no sudden revolution, but merely progress through development. Directing attention to the Roman school generally, of which Raffaello was the founder and chief ornament, the lecturer, the better to illustrate his observations, glanced at the intellectual and religious condition of Rome at the time, and then went on to show what compensations and advantages came to the Roman school of paintings under the changes he had just traced. He denied the charge that Raffaello owed the greatness of his Roman style to Michelangelo, partly because, with the exception of one or two figures, such as Isaiah, there was nothing in common between the works of the two contemporaries, and also because there were other causes amply sufficient to effect the change from the Florentine to the Roman manner. Raffaello had in style and mind grown into the man, and in Rome he entered a great and busy world which called forth his power. The support of patrons and the rivalry of the greatest artists of the age stimulated to utmost effort. He was also accustomed to take counsel of the learned men and leading intellects of the time, and thus they could in some measure understand how Raffaello was called to the highest arguments, and as a painter representative of the times. Raffaello, so far as he was not self-made, was fashioned by his age; in part he founded the Roman school, but that school had never been known had the city of Rome not existed. That city demanded a school; and it was not from Michelangelo, but from sculptors of a prior age that the school found patronage, whose works were then exhumed from the *débris* of the Roman empire. Indeed, no artist was removed from this world-wide influence. In the Roman style of Raffaello this painting of many generations obtained its consummation. Raffaello made the old art live and move; he saw nature through the classical, and from the classical he drew that which was eternally true. He made no dead transcripts from the Greek, but worked as the Greek artists would had they received from Julius and Leo commissions. They recognised in his lines the same grace, in his forms the same beauty, in his compositions the balance and the symmetry, in his humanity the ideal and transcendent types which brought Greek art so near perfection. This was the Roman school of which Raffaello was the founder, or rather the reviver. The stern grandeur of the Greek was in his hands softened; it was in this blending of two schools, the Christian and spiritual of Florence with the grandeur and simple nature of the Greek, that the perfection of Raffaello's Roman manner was reached.

PROVINCIAL NEWS.

Walsall.—The completion of the Town- or Guild-hall has been celebrated by a banquet given by the Mayor. The new building covers the same area as its predecessor, but is made to afford a greater amount of accommodation. The style is Italian. The chief façade towards High-street is a composition based upon a story of the Doric and Ionic orders of architecture. The inferior order which forms the lower part of the façade is Doric, upon a rusticated and vermiculated plinth, and presents a centre recessed with two corresponding wings. The centre is flanked with three-quarter columns, and the wings with tripled pilasters of the same order, supporting an entablature. The peculiarity of the site enabled the architects to introduce a Mezzanine story, which, although it to a certain extent destroys the harmony of the façade, has been artistically treated. The three windows, the magistrates' private entrance, and the three windows of the court room, form the centre, and are deeply recessed—each window having detached columns raised on pedestals, and carrying a denticulated entablature forming an impost, the walling throughout being rusticated. The keystone to the principal entrance, and also the keystones to the court windows, are enriched with carved heads, representing the four seasons, or rather four stages in life from childhood to old age. The superior order is Ionic, forming an arch in connexion with the wings of five arcades, the walling being executed in red brick-work, the main columns and pilasters having

enriched capitals with swags of fruit and flowers from the volutes and columns supporting the arcades. In the apertures between the columns are the windows of the council-chamber and ante-rooms on the same floor. Part of the façade is slightly broken up by the introduction of a niche, in which is placed the statue of Justice, from the entrance of the old guildhall. Three of the compartments, forming one arcade of the Goodall-street front, are in character with those composing the High-street front. The other part of the Goodall-street façade corresponds with the Free Library, which at some future day will no doubt be connected with it. The ground-floor comprises the court-room, the magistrates' private room, witness-room, and the Inland Revenue Office. From the day-room to the prison, which is underneath the court, a stair communicates with the dock, so that the prisoner passes direct from one to the other. On the Mezzanine floor is the grand jury room. The upper floor comprises the council chamber, mayor's private room, and the town clerk's room. The ventilation is effected by the introduction from the exterior of the building of cool fresh air, which is warmed, and passed through a series of flues to its destination. Fifty cubic feet of pure air per minute can be poured into the cells. The foul and vitiated air is drawn by means of a series of flues and channels into an extracting shaft, and so carried away. The building has been erected by Mr. Charles Burcott, of Wolverhampton, the amount of whose contract price was 5,083*l.*; and the warming and ventilating part of the work has been carried out by Messrs. Hacon, of Trowbridge. The erection has been superintended by the architect, Mr. G. B. Nichol, of West Bromwich and London. Mr. Burton acted as clerk of the works.

COMPETITIONS.

Sheffield.—A new chapel is to be erected in Sutherland-road for the Primitive Methodists. The trustees invited designs for a chapel to seat 1,200, vestries, and schools, &c., from four gentlemen in a limited competition; and, after meeting several times, adopted the design submitted by Messrs. C. J. Innocent & Brown, of Sheffield, and appointed them the architects.

JERUSALEM.

SIR MOSES MONTEFIORE, Bart., has determined, since his return last spring from the Holy Land, to erect another hospice at Jerusalem for the residence of several poor Israelitish families. This building will be on a large scale, and built near to that which was erected in the year 1859, under the superintendence of Mr. William Edward Smith, architect, of Upper Bedford-place. The contemplated new building is entrusted to the same architect.

THE "OVER-HEATED FLUE" MISERY.

SIR.—How soon, I am hold to ask, are likely to cease irreparable destruction of fine old churches, or injuries to grand modern erections, (*vide* Croydon Church and the Crystal Palace), through the actually sickening recurrence, for some time, of "overheated flues?" And, pray, where might not be the next effect of the ill-omened flue?—St. Paul's, Westminster Abbey, or St. George's Chapel, Windsor?

The supposition is irresistible, that there must be often some great unskillfulness or inattention in those who manage them. But if they do not know their business, others should be employed who do. One can easily guess now, instantly, the cause of fires in public buildings. Really, sooner than this, we had better revert to the old "open-air registered stoves" (I think that is the title), with ascending pipe.

Reasonable comfort to persons in church is one thing; danger to the buildings from somewhat "Sybaritic" luxury in exotic heating (which, if "cleanliness" be, is hardly also "next to godliness") is another. I dare say good St. James would not have discouraged the moderate warming of churches; but I am sure, if present in a London winter, he would have bid us remember the densely cold dwellings of the poor before luxurious seats in the temple.

Of the monuments sacrificed, Oxford should mourn Sheldon's, who so liberally ornamented it.

The organ, I remember to have read, was pronounced by Avery his best and favourite work. Ho was, I believe, the first "great man" in pedal pipes, and put in those at Trinity College, Cambridge (the previous builders being Schmidt & Green), the finest organ in that university. On the whole, and such catastrophes—a "murain on your pestilent flues"—is the rough thought of

JONATHAN OLDBUCK.

INJURY BY NEIGHBOUR.

SIR,—Will some of your readers kindly inform me if I have any redress, and what, for a very serious grievance, viz., I am the landlord of a house let to a highly respectable widow with invalid daughters, and the next-door neighbour has just raised his house two additional stories; in consequence of which all the chimneys in my house smoke to that extent that the windows are obliged to be set open day and evening while the fires are alight. I have received notice from my tenant, who pays eighty guineas per annum, that she is going to leave in consequence of this annoyance.

Both houses are detached though only about 5 ft. apart. Z. Z.

CELLINGS IN IRON HOUSES.

SIR,—I have a two-storied building at the Cape of Good Hope, with an iron roof, the upper story of which is unbearable in the summer months, on account of the heat. Can any of your subscribers inform me of the best and cheapest material of which to form a ceiling that will act as a non-conductor to the intense heat?

I may state, that the height of the ceiling is 70 ft. long by 94 ft. wide. Planking or matchboard lined with felt is generally recommended, but the land carriage (being 300 miles from the sea) makes such expensive.

I have a notion that some sort of coarse flannel or blanket, lined on the upperside with brown paper and just stretched from wall to wall, would answer every purpose; but not having a practical hint, I hesitate to incur the expense without first asking for the experience of those well versed in such matters.

I may add, that should any inexpensive and effective ceiling be offered, a very large demand would immediately spring up.

G. P.

THE GREAT BELL OF YORK.

SIR,—It is seriously urged that the great bell of York Minster should be re-cast, "reducing the size to harmonize with the other bells, and attaching it to the clock, so that in future the quarters would be struck upon four bells, instead of two as at present; and the amount of the bell, distinct, yet ponderous bell, heard without difficulty in every part of the city." Now, I would remark upon this plan, that to re-cast the great bell would spoil one of the finest and largest bells in Europe. In the late Mr. Aspinall, of the Minster Gate, York, got up the subscription for this bell; and he had a list of subscribers' names, at the head of which was the Archbishop of York, for procuring the machinery for the striking of the hammer to mark the hours on the bell, which subscription unfortunately was not carried out owing to his death. I heard the great bell of York Minster rung shortly after it was hung; the old foreman of Mears, of Whitechapel, London, where the bell was cast, refusing to leave York till it was rung, which was done by having sixty strands of rope attached to the main rope, and sixty men pulled it. Now, the machinery was estimated to have cost 30*l.* for striking the hours, which Mr. Aspinall was getting the subscription for. Let such a sum be raised for that purpose, and a far further sum, the interest of which may pay the men for ringing on the great festival of Christmas Day and Good Friday, and the old tower of York Minster will be used for what it was intended by our ancestors.

The late Dr. Canage, of York, took great pains to have the great bell of York Minster cast to the tone of the great bell of Notre Dame, at Paris, which is the finest toned bell in the world. I may mention that the great bell would be heard twenty-three miles round York if the hammer struck it with the machinery as a propelling power proposed by the late Mr. Aspinall.

When I heard it rung it was the most magnificent tone I ever heard of the kind; it sounded not like a bell, but the roar of a loud ocean.

YORKIST.

HOT-WATER PIPES AND THE BUILDING ACT.

THE Superintending Architect of the Metropolitan Board of Works writes to us as follows:—

"I enclose copy of a correspondence between Mr. Berry and myself respecting the heating apparatus lately put up by him for this Board under my superintendence, which was referred to by Mr. Berry in an inquiry before Mr. Traill, when a case was heard with respect to another apparatus supplied by Mr. Berry, all of which was reported in your paper, and several others. I am sure you will say the correspondence is very conclusive, and in justice to myself I must ask you to insert as much of it as you may deem necessary in the *Builder*, in order to place me right as a public officer before the public."

GEORGE VULLIAMY."

It is, indeed, quite conclusive. After a hugging attempt to evade the real question, Mr. Z. D. Berry (*Fimlico*), writes:—

"In no part of your building are the pipes within the distance, and the coils in your case stand upon bricks, 9 in. by 4 in. by 3 in."

Mr. Traill was led, therefore, to give an illegal decision by an altogether incorrect statement.

* See vol. xiv., p. 961.

ILLUMINATED MSS. BY ENGLISHMEN OF THE TIME OF KING CHARLES I.

In the last number (the New Year's number) of a small quarto weekly (nay, healthy) favourite with all scholars, "Notes and Queries," there is a notelet, full from the beginning to the "postscript" (that essential appendage to a lady's letter) of new matter about the last—to my thinking—of illuminating heralds attached to the venerable and valuable office of the Earl Marshal of England—rich in its names with "the blood of all the Howards." The writer of the article is Mr. John Bruce, a ripe scholar in English history and biography. How can, in his humorous, roughish way, and with his riches of reading and remembering, puzzle by "Queries" they cannot answer and he can't—but I am not in your columns for "panegyric praise," only to relate something new and about the last of our Herald's College, Herald's encouraged by the Earl Marshal of England and the nobility of England.

Mr. John Bruce asks for "You and Yours," "Pray what was a chain organ?" The answer to that "query" I leave to our friends Mr. William Chappell and Dr. Rimhult, long well-known correspondents. What I have to tell is who Edward Norgate was.

When a clerk under the Commissioners of Audit in Somerset House, many a Saturday afternoon hour (attendance closed) I have spent in the Archbishop of Canterbury's Official Will Office in Heraldic and Prerogative Doctors' Commons. Those were hard-riding separate shilling Calendar searchings in those days, and my dinner was often reduced in quantity by this longing for learning. There was no access such as now (Sir Herbert Jenner Fust then reigned), and I have—without bragging—often reduced two ovals to one, for this, to me, pleasant and unprinted information.

Well, I found this information out to-nobing Edward Norgate, and it is what in part Mr. Bruce asks to receive. There is an additional pleasure in being able to oblige a friend and a scholar—who rarely needs information but he knows where to find it for himself.

Edward Norgate, Clerk of the Signet to King Charles I., and Windsor Herald, made his last will and testament in 1649. It was proved in 1651. Our skilled illuminator and herald desires to be buried in the churchyard of St. Bene's, Paul's Wharf, in London, or in the churchyard of the Cathedral Church of St. Paul. He appoints his wife, Ursula Norgate (what was her maiden name?) his executrix; and attributes his leaving so little to the many disorders of the times. His unfinished picture drawings, engravings, and books, he bequeaths to that son who had caused him "the greatest trouble." Why? There are odd, unaccountable legacies to strangers, or omissions of the names of sons and daughters in thousands of wills, commencing "In the name of God, Amen."

PETER CUNNINGHAM.

CHURCH-BUILDING NEWS.

Treeton.—The chancel of Treeton Church has been restored, according to the *Sheffield Independent*, and the edifice re-opened. In the restorations the original design of the chancel has been so preserved that no old stone has been removed from the building. The interior was previously plastered and whitewashed, presenting a very misguiding aspect. Both plaster and whitewash have been removed, and the old stonework has been cleaned and pointed afresh. The chancel is of the twelfth and thirteenth century style of architecture. The restoration to its ancient form has been superintended by Messrs. Hadfield & Son, of Sheffield. Mr. Joseph Rodley, of Sheffield, has executed all the stonework, and Mr. Arthur Hayball, of Sheffield, all the woodwork. The four paintings of evangelistic symbols in the reredos were done by Mr. Westlake. Outside the church the mullions and tracery of the window at the east, and the other three windows, have been restored to their original form. Two pinnacles at the east end and a cross bave had to be replaced. Ere long the church will be further beautified by a stained-glass window, a gentleman having promised to provide one for the chancel.

Kidderminster.—The alterations to St. George's Church have been brought to a conclusion, the whole of the east end having been re-modelled, altered, and improved, since the removal of the

... and reading-desk from their former position. The first alteration comprised removing screens, and throwing the additional space obtained within the communion-rails. One of the pulpits was also lowered. On the wall of east end a carved reredos of Caen stone has been erected, the centre portion containing a grouped carving of the Ascension. The decoration of the wall above the reredos has been done by Mr. Preedy, of London. Within the communion-rails encanestic tiling in a warm tone has been laid, supplied by Mr. Godwin, of Weymouth. Around the front of the communion table a metal railing, with suitable standards of ashed brass, has been fitted by Mr. Skidmore, Coventry.

Southsea.—The district church of St. Simon has been opened for divine service. The cost has been 4,000l. The church has been erected in the designs of Mr. Thos. Hellyer, of Ryde, architect, by Mr. Lawrence, of Southampton. It is chiefly built with white bricks, relieved with red brick bands, with moulded bricks in the interior, the nave arcades and chancel arches, Bath Portland stone being used for the windows, capitals, caps, and bases. The style is Early Gothic, and the whole treatment is based on the brick architecture of the Continent. The peculiarity of the church is its wide and airy nave, its width being 44 ft. from centre to centre of the columns supporting the nave and clerestory, whilst the ridge reaches a height of 70 ft., with a length of 92 ft. in the nave. There are north and south aisles, each 18 ft. by 14 ft.; chancel, with apsidal end, 33 ft. by 18 ft.; chancel aisles, 21 ft. by 9 ft.; also a story of future tower at the south-east, and the vestry at the north-east angle of the chancel, making a total length from west to east of 136 ft., including west porch, and a total width of 82 ft. from north to south. In addition to the west porch there are four other entrances, north-west, south-west, and south-east chancel, and entrance through vestry. There is a west gallery, in which at present is placed an organ, by Messrs. Gray & Davidson. The church will accommodate 1,000 on the ground-floor, and eighty more in the west gallery. The pews are open and stained throughout, that of the chancel being groined in wood, with moulded tracery. The nave is lighted by a clerestory, containing twenty-four two-light windows, with decorated heads, and three large west windows, each with the five arched windows, are all glazed with tinted rolled cathedral glass; the apse in addition contains five large quatrefoils, filled in with stained glass, by Mr. Wallis, of Newcastle. *The Hampshire Independent* gives the following somewhat curious account of the progress, if we may so call it, of the works:—

It was originally intended to build only the nave and chancel with its aisles, and to add the other portions as funds were obtained. With this view the work was commenced in 1865. The architect, Mr. Lawrence, laid the foundation stone in September of that year, and the work proceeded as funds were collected until the 22nd of November, 1865, when the roof being partly on, a heavy squall bore down upon the temporary bracing, and swept the whole off the site, except one pair of principals, which turned completely over, describing a semicircle of 70 ft. diameter, in which position they remained stationary, thereby saving the clerestory walls and nave arcade, which at that time stood without any support from the aisles subsequently added; the timbers destroying in their fall the chancel arch, and damaging a triforium in the chancel walls. The work was recommenced again immediately, and hoarded in the 11th of February of the present year, when the terrific gale of that day moved the whole of the roof 5 in. from south to north, thrusting the north wall of the perpendicular to that extent, and dragging in the south wall to the same amount; the Portland stone piers of the nave arcades were by this means thrown out of their vertical position, and two of them split from top to bottom. Means were immediately taken by the builder to secure the building by fixing chains to the feet of the principals on the north side, and securing them to the foundations on the outside of the foundations of the south aisle; and after anxious deliberations by the building committee, it was decided to build the north and south aisles, the contractor undertaking, in consideration of the sum of 200l. being paid him towards the expense, to get the roof back to its normal position, to pull down and rebuild the clerestory walls, also the west wall to the extent of 50 ft., and to further strengthen it by additional bracing, and also to cut out the broken columns and replace them with new. All this with the additional work now been accomplished successfully, the mode resorted to being the erection of a strong timber stage 30 ft. from the ground, loading it with 30 tons of materials, and setting it sufficiently firm to sustain a fulcrum for timber wedges, by which the roof was thrust back in its place, and is now firmly kept there by additional braces and walls secured to the roofs of the aisles.

Livesey.—The chief stone of a church, to be dedicated to St. Andrew, has been laid at Livesey, near Blackburn. The building will be in the designs by Mr. E. G. Paley, of Lancaster and Meriton, and after the taste of ecclesiastical structures erected in England during the twelfth century. The ground plan is in the form of a

cross, having an apsidal termination at the east end, and consists of a nave 53 ft. in length, transepts (north and south), 25 ft. 6 in. in width, and 64 ft. across. The seats will be open benches, having moulded ends and division framing. The north transept is devoted to children's benches. The church will be built of Darwen pier points, with quoins at the angles, the spire being built of ashlar.

Books Received.

Papers on Subjects connected with the Duties of the Corps of Royal Engineers, contributed by Officers of the Royal Engineers. New Series. Vol. xv. Printed by Jackson & Son, Woolwich. 1866.

This volume of professional papers contains, amongst others of a more strictly or exclusively military character, a useful paper on Representation of Ground, &c., in Sketching, by Captain Webber, R.E., and another on "Foundations on Treacherous Soil," by Captain Mitchell, R.E., the inventor of the screw pile. Of course, on the principle of "nothing like leather," Capt. Mitchell, ignoring concrete, recommends screw piles in such cases. The use of concrete in other circumstances is treated of by Lieut. Ardagh, R.E., in a "Report upon Concrete Revetments built at Newhaven Fort." There are other papers of some value on proposed substitutes for gunpowder, by Professor Abel, F.R.S., V.P.C.S.; on demolition with gun-cotton charges, by Major Miller, R.A., V.C.; and on the Fire-Alarm Telegraph at Montreal (with map), by Lieutenant Grover, R.E. The first paper consists of "Brief Notes on the Career of the late Captain Powke, R.E.," by Mr. Henry Cole, C.B.

Miscellaneous.

WORKSHOPS FOR THE BLIND.—In August last the Association for the Establishment of Workshops and Class-rooms for the Blind opened their first workshops in a three-storied warehouse in Commercial-street, Spitalfields, near Spitalfields Church; and last week the members of the committee invited the workmen and their friends to a substantial dinner in one of the rooms, which was decorated for the occasion. The committee has at its head the Archbishop of Canterbury, and includes such names as the Earl of Shaftesbury, the Bishop of London, Lord Ehury, Mr. G. Moore, Mr. Samuel Morley, Mr. R. C. Hanbury, M.P., and many others, who were moved to undertake this work from the knowledge that there are 3,000 blind persons in London, and that the greater part are in destitute circumstances.

THE DRY-EARTH CLOSET SYSTEM PROPOSED FOR NORWICH.—A communication has been addressed to the Sanitary Committee of the Norwich Board of Health, by an inhabitant of the city, recommending the dry-earth closet system for Norwich, instead of the proposed system of sewerage, which is to cost 60,000l. It is to be hoped the local authorities will not listen for a moment to the adoption of a system which, however well it may look in theory, is certainly impracticable with the mass of our town populations. Were they all sanitary reformers, or all blessed with intelligent discretion, such a system might be tried; but the case is notoriously otherwise, and the system in question would in reality become no system at all, but an abominable and general nuisance.

PRIVATE BILLS IN PARLIAMENT.—SESSION 1867.—According to the "General List" published by the Private Bill office of the House of Commons, there are 317 bills in Parliament this year, 152 of which are railway ones; but of the 152 very few are for new railways. The others are for gasworks, waterworks, enclosures, improvements, and other miscellaneous works. The most important and, no doubt, the greatest fighting bill of the session will be the Metropolitan Gas Bill, by which it is proposed to put all the gas companies within the metropolitan area (of which there are twenty-two), under the control of the Metropolitan Board of Works, and to supply to the public gas of pure quality at uniform rates in all the districts, the rate proposed being 3s. 6d. per 1,000 cubic feet. The Metropolitan Gas Bill will, no doubt, receive great support from the public, and unanimous opposition from the various gas companies.

YORKSHIRE ARCHITECTURAL SOCIETY.—The annual meeting of this society has been held in the School of Art, Manster-yard, York. The attendance was but small. The twenty-fifth annual report was read and adopted. It stated that the society maintained its ground, and was steadily advancing in position and working power. The Rev. Canon Raine read a paper, titled "A Survey of the Abbatial House of Howden," with several extracts from the original survey; and the Rev. J. R. Lunn, of Marton-cum-Grafton, read a paper on "The Ecclesiology of the Rural Deanery of Aldborough, Ripon."

KITCHEN BOILER EXPLOSION IN HULL.—The liability to explosion of kitchen boilers in the North of England is a remarkable circumstance, of which we have before taken note. An explosion has just occurred in Hull, from frost, it is believed, having arrested the flow of water into the boiler till it became red hot. One person was killed and another injured, while two windows were blown out by the explosion. Whether it be that many more boilers are fitted up with pipes in the north than in the south of England, or that there is some defect in the arrangement, is a question worth inquiring into. In the present instance, the pipes communicated with a cistern which was more exposed to the action of frost than it ought to have been.

ST. GEORGE'S, KIDDERMINSTER.—The east end and part of the side walls of this church have been beautified by the addition of a reredos, from the design of Mr. Jeffrey Hopkins, of Worcester. It is of alabaster and inlaid marbles, with the Ascension, carved by Mr. Forsyth, of Worcester. An altar-rail and encaustic tile pavement have also been added. The upper part of the wall and first bay of the roof have been painted, from the designs and under the supervision of Mr. F. Preedy. The large surface of the wall is covered with a delicate diaper, on a parchment-coloured ground, and rich borders. There are eight medallions containing angels, on blue grounds, the larger and lower being the four archangels, Uriel, Michael, Gabriel, and Raphael; the other angels have instruments of praise. The roof is blue, with an ornamental centre, and powdered with stars, the bosses being gilt.

THE WINCHESTER DRAINAGE PLANS.—At a meeting of the town council acting as the local Board of Health, the committee reported that, in answer to advertisements offering premiums of 150l., 100l., and 50l. respectively for the best, second, and third plans for the main drainage of the city and suburbs, including schemes for disposal of the sewage, twelve plans had been sent in, and three other engineers had applied for an extension of time, which could not be granted. In answer to an inquiry from the committee, Mr. H. Newman, the surveyor to the Board, admitted that he was the author of one of the plans sent in, but he said he would withdraw it as a plan competing for a premium; but there it was for the use of the Board hereafter, if they chose to make use of it in any way. The report was adopted, on the understanding that the plans would be open to the members, but not to the public.

TRAFFIC RECEIPTS.—It appears from a Parliamentary return just issued that the total receipts on railways in the United Kingdom for the year 1865 amounted, on 13,289 miles, to 35,890,113l.; and for the year 1864, to 12,789 miles, to 34,015,564l.; showing an increase in the mileage of 500 miles, and in the receipts of 1,874,549l. The total receipts for passengers, mails, &c., in the year 1865, amounted to 16,572,051l., against 15,684,040l. in 1864; showing an increase of 888,011l. The total receipts for merchandise, minerals, and live stock amounted, in the year 1865, to 19,318,062l.; and for the year 1864, to 18,331,524l.; showing an increase of 986,538l. The total working expenses amounted, for the year 1865, to 187,149,073l., or 48 per cent. of the receipts, against 16,000,904l., or 47 per cent. in 1864; showing an increase of 1,148,765l. The total number of passengers (exclusive of holders of season and periodical tickets) conveyed in the year 1865 on railways in the United Kingdom was 251,862,715, against 229,272,165 in the year 1864, showing an increase of 22,590,550. Of the 251,862,715 passengers 151,416,269 were third-class and Parliamentary, 70,783,241 second-class, and 29,663,205 first-class; against 136,301,581, 65,269,169, and 27,701,415, respectively, in the year 1864; showing an increase of 15,114,688 third-class, 15,614,072 second-class, and 1,961,790 first-class.

THE DUDLEY SURVEYORSHIP.—The Borough Surveyor (Mr. Bateman) has resigned his office, stating that he finds it impossible to conduct his private business and that of the Council without the interests clashing. There is said to be a strong feeling in the town with reference to the surveyor devoting the whole of his time to the duties of his office. The matter has been referred to the Public Works Committee.

CONGREGATIONAL MEMORIAL HALL.—The Congregational denomination of Dissenters are about to erect a memorial hall in London with the two-fold object of commemorating the ejection of the 2,000 Nonconformist ministers from the Church of England in 1662, and of providing suitable offices for the various societies in connexion with the Congregational or Independent Union of England and Wales, and also a large hall for public meetings. An eligible freehold has been purchased in the neighbourhood of the Mansion House. The works will be immediately commenced, and the estimated cost is about 70,000l. Towards this sum 50,000l. has been already raised. Mr. Tilt's Salt has just added his name to the subscription for 5,000l.

CO-OPERATIVE SOCIETIES IN SWITZERLAND.—A communication from Berne, in the *Moniteur*, publishes information as to the Swiss co-operative societies. These for consumption, of which the mechanism is the most simple, have also taken a large development as yet in Switzerland. That of Lausanne confines itself to procuring for its members articles of food of primary necessity at as low a rate as possible. The financial statement for 1864 shows a sale of butcher's meat to the amount of 143,566 fr.; bread, 23,510 fr.; and sundries, 8,939 fr.; with a total profit of 8,572 fr. In 1865 the amounts declined,—for meat, to 140,948 fr.; and for bread, to 21,657 fr.; with a profit of 6,718 fr. One which supplies every one, and acts as a kind of savings-bank for its members, producing results much more considerable, is that of Zurich, the amount of its transactions being 1,078,644 fr., with a net profit of 26,864 fr. After that come those of Vevey, Nenchatel, &c. A considerable number are now in existence in Switzerland, and fresh ones are being daily established.

THE LIVERPOOL SANITARY ASSOCIATION.—At a meeting of the members, held at the Common Hall, Hickins-hey, a report of the proceedings of the executive "with regard to the signatures and presentation of the memorial to the mayor and corporation on the water-supply of the town," was received and adopted. The memorial set forth that the comfort of the inhabitants necessitated a very large and constant supply of pure water, and that the sanitary changes which it was proposed to introduce would render such a provision absolutely indispensable. The memorialists, therefore, respectfully requested that the authorities would, with all convenient speed, determine upon such a large and comprehensive scheme as would effectually meet this difficulty for a long series of years. Mr. Samuelson said the fact had been elicited that whilst it only cost the town 2l. per million gallons for water from Rivington, it cost 8l. per million gallons from the wells. Manufacturers were charged 9d. per 1,000 gallons, which was something like 36l. per million gallons. He was of opinion that a report should be prepared showing how far salt water could be utilised.

ST. MARY MAGDALENE'S, WALKERINGHAM.—A scheme for placing a stained-glass window in St. Mary Magdalene's church at Walkeringham, near Gainsborough (diocese of Lincoln), was set on foot three years since. This Advent has witnessed the consummation of the efforts made by the vicar's wife and her "Mary" friends. The stonework having been restored from the designs of Mr. Drury, of Lincoln, at a cost of 25l., the stained glass has been added at an outlay of 75l. more. There remain, however, about 10l. to be made up by Marys (or in devout memory of Marys) not yet enrolled. The subjects, designed and executed by Mr. Freedy, of London, are the Epiphany, Purification, Flight into Egypt, Doctors in the Temple, Marriage at Cana, Nativity, and exorcism of the patron Saint (introducing the Mary of Scripture, and illustrating the rites of churching, catechizing, wedding, burial, and absolution), with legend, &c. "The west window was restored A.D. mdcclxvi, the stained glass thereof being given to this church of St. Mary Magdalene by more than 700 namesakes of the Blessed Virgin and the Penitent Saint who loved much." ✠

ANOTHER VICTIM TO A BAD DRAIN.—We are informed by one who ought to know that last autumn a medical man of station drew the attention of the local police to a foul drain passing close by the house of Mr. Alexander Smith, and assured them that cholera, diphtheria, or typhoid fever would prevail if it were not cleaned. It was, we believe, by one of these discreditable disorders that Mr. Alexander Smith has been carried off.

MR. SPURGEON'S ALMSHOUSES AND ORPHANAGE.—The Rev. C. H. Spurgeon has just concluded the purchase of 2½ acres of land, adjacent to Clapham Common, upon which the buildings for the purposes of a new orphanage, under his auspices, will be erected. It is, however, not intended to commence the whole structure at once. In the centre of the site, the schools, chapel, and other necessary buildings, will be first proceeded with; after which small houses will be reared, in which the children can live, to the number of ten or twenty to each. It is true, as stated some time since, that a benevolent lady has placed a sum of 20,000l. at his command for the purposes of the orphanage; but it is accompanied by a condition that only 8,000l. out of it shall be spent, the remaining 12,000l. to go to capital account for the permanent benefit of the institution. The first batch of orphans will number fifty. The almshouses and day schools, which will stand next to the Metropolitan Tabernacle, at Walworth, are now sufficiently advanced to admit of the laying of the foundation stone.

SAW TEETH.—A patent has been recently allowed in the United States to Mr. W. P. Miller, of San Francisco, for saw-teeth constructed upon an improved plan, which are claimed by the inventor to possess the following advantages over all others, as reported in the *American Gaslight Journal*.—"The teeth being nearly encompassed in the plate, are rendered immeasurably stronger than even solid teeth formed on the plate. For the reason of their great stiffness laterally, these saws may be fully one-fourth less in thickness than solid teeth, and one third less than other insertable teeth-saws. The teeth are self-attaching and adjustable in their sockets, thereby differing from any other saw-teeth. Should the point of one or more of them become broken, by simply turning them forward in their sockets they will attain the necessary projection; then file them, and the damage is repaired. These saws remain exactly the same size, and never can get out of round or balance. They cannot by any means be thrown out of their sockets, and hence the operatives are secure from injury. The teeth remaining in order need not be reduced to accommodate those that may be dull or broken. They are alike applicable to circular saws of every size and for all purposes, and are peculiarly adapted for cutting-off saws, as well as for splitting."

TENANT'S RIGHTS IN MINERALS.—A case of some public interest, as affecting the right of tenants for life under settlements to work minerals, was decided by Vice-Chancellor Wood on the 19th ult. Tenants for life may work mines already opened; but if not empowered to commit waste, may not open new mines for their own benefit, and the question has been often raised,—what amount of previous working renders a mine open, so that tenants for life may work it for themselves? The plaintiffs in this case were Colonel Stepany and his two sons, who are the present owners of the Stepany estate, in South Wales; and the defendant was Mr. William Chambers, who is the executor of a late tenant for life of the estate, who was not by the terms of the will of the settlor authorised to commit waste. On coming into possession of the estate, however, he granted a lease of all the coal under certain farms forming part of the estate, and the suit in question was instituted for the purpose of recovering the amount of the royalties received under this lease. The defendant contended that the mines were open ones at the date of the settlement, and that it was consequently not waste in a tenant for life to work them; and in support of his view he proved the existence on the farms of an old trial pit, and a considerable amount of superficial working at the outcrop of the various seams of coal on the side of the mountain. The Vice-Chancellor, however, held that workings of this description did not amount to an opening of the mine, and gave the plaintiffs a decree with costs.

ENGLISH ENTERPRISE IN RUSSIA.—A telegram informs us that on Tuesday evening last, the works of the Moscow Gas Company were opened, that the city was lighted, and the whole a great success. Mr. Frederick Leslie is the company's engineer. Allowing for the difference of time between the places, the news came from Moscow to Focadilly in five hours.

THE SUPPLY OF WATER.—Her Majesty's Commissioners for the purpose of ascertaining what supply of unpolluted and wholesome water can be obtained by collecting and storing water in the high grounds of England and Wales, either by the aid of natural lakes or by artificial reservoirs, at a sufficient elevation for the supply of the large towns (the Duke of Richmond; Sir John Thwaites; Colonel Harries, R.E.; Sir B. S. Phillips, one of the aldermen of the City of London; Mr. T. Elliot Harrison; and Mr. Joseph Prestwich), are to report—1. Which of such sources are best suited for the supply of the metropolis and its suburbs; and, 2. How the supply from the remaining sources may be most beneficially distributed among the principal towns.

VOL. XXV.—No. 1250.

Government and the Evicted Poor.

ONE of the fathers of natural history, when a student at a northern university, was accustomed to enliven his lonely rambles on the seashore by collecting specimens of the *algæ* thrown up by the tide. When the collection had attained some respectable magnitude, and the strange and graceful forms of the then unclassified marine plants had attracted the admiration of the fellow students of the self-taught naturalist, he was encouraged to submit it to the notice of the professor who was the official teacher of natural history. The great man glanced superciliously at the carefully-gathered specimens, and pushed them contemptuously away

with the remark, "Pooh, sir, a lot of weeds!" The name of the professor would now only be remembered by virtue of the light reflected from that of the student whom he snubbed, while the "lot of weeds," scientifically arranged, are the subject of many elaborate botanic works, and are favourite objects for the herbarium of the amateur or the tyro botanist.

An anecdote of this nature is of value, not only as enabling us to bring clearly before the imagination the giant strides which the science of natural history has made since the time, and in consequence of the initiative, of Linnæus, but also as serving to show the very different manner in which we are becoming accustomed to regard facts, when compared to the habits of thought common in previous centuries. Inductive knowledge is especially grateful to the practical English mind, and it is a hopeful and striking feature of the present times that we are endeavouring, confusedly perhaps and feebly, but still with a definite purpose, to render the same sort of service which Linnæus performed for the organic, and Cavendish and Dalton for the inorganic, kingdoms to that more recondite and more important branch of science which Aristotle calls politics, and which Comte termed sociology. The proper object of all labour, whether of the brain or of the arm, is to increase the welfare of the human race. The highest, therefore, of all sciences, is necessarily that which unfolds the working of the laws which regulate social life. As all other sciences are subordinate to this master-knowledge, so is this, of necessity the last that we can hope to perfect; but it by no means follows that its foundations cannot be laid broad and deep long before we have a clear perception of the symmetry of its future structure. It is, therefore, a sign of progress when we find the great questions that lie at the root of the national welfare to be removed from the arena of party contest, when we have to record the fact, and to admire the tone of such a discussion as took place the other day between representatives of the Legislature, the philanthropists, and the first minister of the Queen.

Imperfect scientific knowledge is for the most part dogmatic and intolerant in proportion to the narrowness of its range. In science, as in religion, a man must not only have learned much, but must have acquired the habit of regarding a subject from different points of view, before he attains the large and wise tolerance of a truly Catholic spirit. It is therefore in accordance with the whole history of human thought, that when a clear and vigorous thinker attacked that master-science which had made little or no progress since the great Alexandrine era of intelligence, set himself to collect the facts that contemporary knowledge offered, and to reason on the laws that affect the Wealth of Nations, theories that are incontrovertible while confined to their proper object should be stretched by less original minds to an undue extent, so that moneyed riches were confounded with wealth or well-being, and men were led to believe the affairs of the mart to be those of the commonwealth. Those who regard, as so many do, the science of political economy as more than a constant and minor part of the science of politics are thus in the constant habit of drawing false inferences from true principles, and of confounding skill in buying and selling, in manufacturing and in transmitting, with statesmanlike ability in the government of mankind.

In this confusion of thought among many of the writers and speakers of the day, a confusion not accidental but essential, and which is thus liable to vitiate the whole structure of their argument, we trace one cause of the extreme difficulty which all admit to attend the solution of the question of housing the homeless poor. Questions of very varied nature have to be solved, as it were, by the same operation, and in the absence of that clear scientific grasp that should at once strike out the limits of the subject, deciding how much falls within the province of philanthropy, how much within that of commercial action, how much within that of the duties of the State, there is no room to wonder that we have remained so long paralysed in face of a great and admitted evil, and, what is more, of a great and crying injustice.

The state of things—we do not say which the deputation laid before the Premier, for the Society, to our minds, started on somewhat wrong grounds, and on the occasion in question were not very clear as to what they wanted, but which originated the necessity for both the interviews of the association so respectably represented—is briefly this. Our London poor, the very poor, are homeless, houseless, almost altogether shelterless. Daily their numbers are augmenting; daily the numbers of such poor and unfit shodds as are within their reach is diminishing. While the metropolitan population is doubling itself within forty years, it is stated that public and private enterprise has had the effect, within the last four or five years, of demolishing so many of the poorer dwellings as to thrust some fifty thousand of their former inmates into the scanty room already overcrowded by some four hundred and fifty thousand of their companions. The cases of personal hardship, of injury to health, and to morality, of irresistible and therefore of unjust and wicked stress put upon so large a number of those of our fellow citizens who are just the least able to withstand it, are such as to raise the alarm of all who know them, and that not for the injured half million alone, but for the whole three millions of Londoners. It is not necessary in these pages to dwell on the frightful magnitude of the evil.

The sole question is as to the nature of the remedy or remedies best to be employed. It is of course in this, the therapeutic part of the subject, that the difficulties make their appearance. How is the accommodation so urgently required to be provided? By organised private charity, is one reply. Very noble have already been the efforts of private charity. Very munifi-

cent the charity of one honoured name, as to which, though we ought not to regret that it is American, we are at liberty to lament that its princely philanthropy has inspired so little emulation in our own country. But private charity can do little more for the great destitution than the collection of Peter's pence can effect for the chronic and fatal impecuniosity of the Roman revenue. It is a drop in the bucket. "Philanthropic and enterprising persons and associations have succeeded in providing improved dwellings" for how many of the evicted? For ten thousand out of the fifty; that is to say, a number equal to the average increase of the actually evicted poor during eight years! for less than the average natural increase of the half-million ill-lodged poor during a single year. Say that the demolitions now complained of have occupied a term of five years. During that time fifty thousand have been evicted, sixty thousand have been born or have come to the metropolis. A hundred and ten thousand souls have sought for shelter, and philanthropy and enterprise together—generous Englishmen, a noble American, shrewd minor capitalists, and builders anxious for work,—have among them altogether provided shelter for ten thousand. Nor is it beside the mark to inquire how many of these ten thousand lodgings have been appropriated by members of a less needy class.

If we now turn to the political economist for aid, we shall be told that the demand has only to attain a certain urgency to ensure supply; but the rule, golden as it is when wisely applied, here altogether breaks down. The demand=110—the supply=10. The equation will not work out. An important element has been left out in stating the sum, and usually is left out in similar arguments. Demand ensures supply when demand and supply are congruous—not otherwise. Take a well-to-do, rent-paying demand, an 8 per cent. return on investment demand, and supply will follow sure enough,—although in this matter of house-building the quality of the supply is not altogether to the taste of the intending tenants. But take a demand which, as in the present case, may represent a 4 or 5 per cent. return for capital, and even that uncertain, and requiring special exertion for its collection, and the supply is not likely to increase. The philanthropist does something; but he does it alone. The commercial man would do all; but it must be made worth his while. Attempt to fuse the two, and you break down altogether. Ensure by wise arrangements an ample return for the capitalist, not exorbitant, but ample, and what do you do then? You provide comfortable dwellings, into which small tradespeople and others, now ill and expensively housed, but forming no part of the half-million, will readily gravitate, and your houseless poor are houseless still.

Again comes the question, what is to be done? and that in a tone too urgent to be considered in our usual English manner,—that is to say, by being left to answer itself. Lord Derby remarked, "The Government could not be looked to to find lodgings for the poor." We will not impugn the general statement, although it is familiar to one so versed in English history as the noble premier, and is tolerably evident to the most casual traveller through our country, that, since the time of Elizabeth, the Government has been, to a certain extent, both expected and accustomed to find lodgings for the very poor, and that the same authority that provided the stocks for "masterful heggars" has provided through our country parishes a last refuge for the otherwise homeless.

There is, however, a peculiar feature in the case before us to which we think that attention has not been sufficiently, if at all, directed, and that is the question of direct responsibility. In the happy anomaly of our institutions, we often find much that is clear to the instincts of

Englishmen without being altogether capable of presentation in an acceptable form to an intelligent foreigner. The glorious uncertainty of the law, as typified in what used to be called the palladium of our liberty, trial by jury, is a case in point. Another is to be found in the curious and often highly complex compromise by which legislation and administration are to some extent amalgamated and shared between Parliament and the Cabinet. The invariable tendency of representative assemblies to gather all possible power within their grasp has not been in fact in the House of Commons. Thus more and more of what is properly the judicial function has been assumed by the two Houses; and when the occasion for a new branch of administration has sprung up, as in the instance of railways, Parliament has readily occupied itself with details into which it was naturally incompetent to enter, instead of deciding on principles, and handing over details to a competent tribunal. Thus our railway system, as we have recently pointed out, has emerged in such a patched and crippled form from the scrambles of Parliamentary committees, as to have cost us two hundred millions sterling in excess—a tax of 10l. a head on every soul in England and Wales, if we leave out Scotland and Ireland,—a wasteful and useless expenditure, equal to adding a fourth to our National Debt.

This, accordingly, is a not unnatural result of a mode of legislation which is just like deputing the appeal duties of the House of Lords to any casual sub-committee of half-a-dozen lay peers, or of debating all the clauses of all the evidence of a divorce Bill after a whip in the House of Commons. It is, therefore, hard, perhaps impossible, to lay the blame on the due shoulders,—to say the Cabinet did this, the House did that; this is due to the Government, this to the voice of the country.

Into questions of this nature neither the 50,000 homeless poor, nor the 450,000 quasi homeless poor, nor the 2,500,000 of Londoners pained, perilled, and damaged by the existence in their midst of a daily-increasing nomadic population, can be invited or expected to enter; but there is one broad fact patent to them all,—Cabinet, Senate, House of Commons, it is all one to them,—their governors, as a body, have done them this great injustice. Their governors, as a body, have passed, one by one, special laws, empowering other persons for their own, and may be for the public advantage, to turn them out of doors. It is by direct *ad hoc* legislation that officers of the legion whose name is Railway have been armed with artillery powerful enough to destroy, not only their poor dwellings, but even their native constitutional right to hold their English homes as their castles. Who does not remember the glorious burst of oratory with which a great statesman declared that, wind-swept and rainwashed as might be the poor man's home, the King of England dared not enter it if forbidden. That which the majesty of the law respected for so many centuries, public expedience has set aside. The legislators of the country have, by new legislation, unhoused 50,000 Londoners,—poor, ragged, very likely dirty, naked, destitute, but still Englishmen;—they have turned their adrift, *pro bono publico*, by the strong hand: they are bound in right and in conscience to shelter them.

If public attention, in and out of Parliament, be once fixed on the aspect of the case which we now present, a first and a most important step will have been taken towards the removal of the evil. We are at a loss to imagine what arguments can be urged against the truth of our view. As matter of special pleading, indeed, it is easy to produce arguments on either side of any similar question; but the doubt and hesitation which so often will arise in the breast of the conscientious man as to which is really the right side of a case are here, we think, quite excluded. It is a case like that of a trustee, who, with no bad intentions, has neglected his duty, and allowed the funds of his trust to be tampered with. Perhaps he knew nothing about it, and only signed some paper, of the contents of which he was ignorant, and which he was told was a mere formality. Nevertheless, the Law says he must pay; and Justice, in this case, accords with Law. Thus when the Legislature has given power to private companies to unhouse 50,000 helpless poor,—poor who must live, if they live at all, God help them, within a certain area,—and has neglected to insist on due provision being made to supply the want thus created, the Legislature, the careless trustee in this instance, must pay. It has

allowed the companies to go scot-free—it must stand in their shoes.

If this be once admitted,—regarded as a national and not as a party question,—as the noble premier most justly puts it, the way out of the difficulty is, to a great extent cleared. We can, in this case, at once provide for the evicted; and, by the time that we have succeeded in so doing, we may have collected information and experience enough to enable us fairly to deal with the whole great question of housing the City poor. What is immediately requisite is, to do for the poorest class at once, somewhat less than private enterprise now annually effects for the enlargement of London. We might, indeed, say very much less, if we regard the nature of the accommodation required, the number of cubic feet per tenant that should be allotted in the new streets and terraces that must replace much of the crumbling, wasteful, ruinous back yards laid open in so many instances by the course of railway demolition. Private enterprise accommodates 75,000 new inhabitants of London, of all classes, per annum; the restitution now demanded by the evicted is that of dwelling accommodation for 50,000 of the very poorest. The cubic space to be occupied by the requisite buildings cannot be the half of that which is annually roofed in by the London builders.

The mode of providing this accommodation will readily suggest itself to those accustomed to deal with public works, so soon as Government or Parliament admits its fair responsibility. Nothing can be simpler. We speak without the authority of any of those beneficent and active friends of the poor who have been, and who will be, at the front when required, but we feel that we can speak in their names with little hesitation. Let Parliament guarantee five per cent. per annum on a certain maximum sum to be expended in providing decent and frugal accommodation for the evicted metropolitan poor, of course with proper stipulations to obtain the right sort of dwelling. Power must also be given to obtain the removal of positively uninhabitable dwellings, and sites for the new ones, by means of such a bill as that brought in by Mr. Torrens, amended as may be needed, and philanthropy will do the rest. Men will gladly come forward to consecrate their time and their talents to the task, as well as to advance their money, with this one assurance, that they are not to lose it. The organisation familiar to Englishmen for the execution of great works can be at once commenced. The names of an efficient and a trust-worthy board of directors can almost be decided on by acclamation. Responsible architects and engineers must be properly engaged. Over the whole expenditure of the association, in purchase of sites, and in building, as well as over the rate and mode of collecting rental, the Government will be bound, in virtue of their contingent responsibility, to exercise just that species of control which will be most useful, so that there shall be no chance of any misappropriation or any sentimental extravagance. The *Poor Man's Home Association*, to which all who would assist the poor man will gladly contribute all the aid they can afford, commanding an adequate capital, expecting no profit, but secured by Government guarantee from losing the ordinary interest on their advances, bringing all that science can effect and that philanthropy can wisely suggest to bear on the removal of that which, if longer neglected, will be a national crime, would raise its head with honest pride among the munificent associated Institutions of London.

THE NEW TOWN OF EDINBURGH: ITS DRAINAGE AND WATER SUPPLY.

We promised to return to the questions of the drainage and water supply of the New Town of Edinburgh, as affecting its sanitary condition. Before doing so, however, it may be as well to glance,—and we shall do so very shortly,—at its situation, the variations of climate and temperature, the prevailing winds, and the annual rainfall. It stands, as we have seen, in close proximity to the Frith of Forth, at a considerable elevation. The valley of the Princes-street Gardens is 169 ft. above the level of the sea; George-street is 226 ft. above it, and from this the New Town descends gradually down about 180 ft. to Inverleith-row, where it is about 45 ft. above the sea. It is situated in 55° 57 north

latitude, and 3° 14' west longitude from Greenwich. The average temperature is 47° Fahrenheit; but the alterations of temperature are very great, having been observed in the same day to vary from 30° to 40°. The annual mean of atmospheric pressure, as indicated by the barometer, is 29.52 in.; and the annual rainfall is 24.33 in. The coldest months are January, February, and March. The mortality is, however, greatest in the months of November and December, when, although the barometric cold is not so great, the city is blown over by piercing east and north-east winds.

With regard to the supply of water, both the old and the new towns are fortunate. Private wells are unknown in the New Town, as indeed they are in the old; and thus the inhabitants are exempted from the evil of the sewage escaping from defective cesspools into them, and so polluting the drinking supply. There are but two public wells in the New Town,—one in the Upper Water of Leith district, and the other in the Calton and Greenside district. There is a number of drinking-fountains chiefly erected by the late Miss Catherine Sinclair, of Ulhater, to whom, by the way, the city is indebted for the numerous wooden benches which are to be seen placed alongside of the various gardens under the grateful shade of trees.* These fountains are of simple action. By pressing a valve stud the water is made to flow into the metal cup, attached to the fountain by a chain, while an ample waste-hasin prevents the water from wetting the pavement. Most of these fountains are made of iron, but there are others of granite, a species of well-case with self-acting tap fixed to a wall front; but they are too few in number; nor is it creditable to the town to leave their erection to the generosity of private individuals. Edinburgh appears to be amply supplied with good water from the Crawley and other springs on the Pentland Hills by the Edinburgh Water Company, which was formed in the year 1819. At various times, as the population increased, the company have had to make application to Parliament for powers to acquire new springs. The Crawley springs discharge their waters into a covered cistern, which is 45 ft. long, 15 ft. wide, and 6 ft. deep. Thence they are conveyed to town, a distance of nine miles, by a chain of pipes varying from 20 in. to 15 in. in bore. Towards the town termination of the line the pipe is carried through a tunnel 2,160 ft. in length, and about 80 ft. under the surface of Heriot's Green. Then, as it crosses the Grassmarket, it bifurcates by one branch to a large reservoir on the Castle-hill, and by another 120 ft. beneath the reservoir, right through a tunnel 740 ft. long out through the rock, of which the ridge leading to the Castle is composed. Branches are laid through all the principal streets. The pipes, the joints of which are spigot and faucet, were tested before being laid down by a pressure equal to a vertical column of 800 ft. of water. The branch leading to the reservoir can deliver into it 253.56 cubic feet of water per minute. In 1843 the company obtained power to bring in the Black Springs and those of Listonshields and Bavelaw, situated respectively nine, ten, and twelve miles and a half from Edinburgh. In 1847 the Bavelaw and Listonshields springs, about forty in number, were made available by being conveyed in clay pipes into a stone cistern at Westrigg, distant twelve miles from town. They are thence conveyed for nearly five miles through an aqueduct to Torphin

* It is intended at once to proceed with the erection of a memorial of the lady. The monument, which is to be placed at the junction of North Charlotte-street and St. Colme-street, will resemble in design some of the old English market crosses, such as those of Winchester and Leighton Buzzard, or those erected by the memory of Queen Eleanor. The structure, which will be placed above a flight of three steps, will consist of a basement and two superincumbent stories, and will attain a height of about 60 ft. The basement, which is octagonal in plan, and 25 ft. in diameter, will have its eight compartments separated from one another by buttresses, which, divided into stages by shafts and ornaments, will be protected by the shape of grotesque animals, will terminate in pinnacles enriched by crockets and finials. Each compartment will contain a semicircular canopied niche, surmounted by a high triangular pediment with crockets and finials. The niches will be occupied by statues, placed on pedestals resting on elaborately carved brackets or corbels, which in their turn will be supported by shafts. A gallery, protected by a parapet pierced by flamboyant tracery, runs round the top of the basement, and is broken by the heads of the buttresses and of the pediments. Within this parapet the first story will be carried up octagonal, and will resemble the basement, except that there will be no buttresses, and that the niches will be empty. The second story, diminishing in size, will be carried up octagonal, and will be terminated by a massed buttress, surmounted by a finial and the figure of an angel with outspread wings. The architect is Mr. David Bryce.

Hill, and from that to Edinburgh by an iron pipe with an internal diameter of 16 in. These works were designed by Messrs. Rendel & Beardmore, of London, and carried out under the superintendence of Mr. Leslie, C.E., of Edinburgh. The total storage of water in the company's reservoirs at Lognraen, Cluthie-dian, Torduff, Glenrose, and Bonally is 109,619,756 cubic feet. These reservoirs alone can supply 350 cubic feet of water per minute for a period of four months without rain.

In 1863 the total sum expended by the company amounted to 485,937l. 5s. 1d., and the daily supply of water amounted to 31-12 gallons for each inhabitant. By their Amendment Act, passed in the same year, they obtained powers to raise 46,000l. for the purchase of new springs, &c., and it has been calculated that when these have been added the daily supply will reach 89 gallons.

The Lord Provost, magistrates, and council of the burgh and city have adopted various clauses of "The General Police and Improvement (Scotland) Act, 1862," by one of which it is made compulsory on all proprietors of houses to introduce water into them, and the writer believes that this provision has been generally enforced. The water-rates are 10d. per pound on four-fifths of the actual rent or value of houses above ten pounds; 4s. on houses under five pounds; and 3d. per pound on four-fifths of the rental on shops.

The supply of water has contributed much to the comfort and health of the population by enabling them to have baths and other conveniences easily and cheaply.

It is believed that, situated as it is on high ground, and at no great distance from the sea, Edinburgh may be readily relieved of its surface waters and the washings of its streets, as well as of its sullage (by which is to be understood its cloacal matter and washing and kitchen waste) by a single system of sewers, and such is the system there in use. Each street is provided with a main sewer, into which the sullage is carried by a branch drain leading from each tenement, while the surface-waters and washings of the streets are conveyed into it by guttersways lying between the foot-pavement and the causeway. The main sewers, which drain the western portion of the New Town, have hitherto discharged their contents into the Water of Leith, converting into a great festering open sewer what many persons remember as a pure, unpolluted stream, abounding in speckled trout. The horrors of this crying nuisance have been so often exposed in the pages of the *Builder* that it is unnecessary here to make more than this passing allusion to the subject, the more so as the Water of Leith Drainage Works, which are expected to remedy the existing state of matters, will, in all probability, be completed in a very few months. These works consist of a main conduit and ten branches, and extend from Colt Bridge to the Black Rocks in the Frith of Forth, a distance of about five miles and a quarter. They commence at Colt Bridge with a brick culvert or tunnel 4 ft. high and 2 ft. 8 in. wide, which is carried through below the Colt Bridge-road to the Colt Bridge dam. From that point to the Caledonian Railway viaduct, the sewer consists of a 2 feet cast-iron pipe, placed in the bed of the river. From the viaduct to opposite Donaldson's Hospital, it is again a culvert of the same dimensions as above. From the hospital down to Canonmills Bridge, for the most part the great sewer, which is placed in the bed of the river consists of cast-iron pipes, varying in diameter from 2 ft. to 2 ft. 9 inches. Between Stockbridge and Malta Green Ford, there is a pipe on either side of the river, the one on the north side, a 12-inch pipe, being intended to intercept the Deanhaugh drain, and the other drains on that side of the stream. From Canonmills Bridge to below Bonnington dam, a brick culvert, 4 1/2 ft. high by 3 ft. wide, is substituted for the iron pipe. Down to this point the great sewer is entirely finished, as are nearly all the lateral drains connected with it. Between the dam and the new Sugar-house at Bonnington, the works are in active progress, and from the Sugar-house down to the Old Town, at the shore of Leith, they are completed. Along the shore the sewer is constructed of iron pipes, 3 ft. 6 in. in bore, while above that there is a culvert, 5 ft. 3 in. in height, and 3 ft. 6 in. wide. The great sewer crosses Leith sands, and up to Tower-street consists of iron pipes of the same dimensions as those along the shore. The pipes, which cross the sands, lie upon a framework of green-hearted

timber. The culverts, so far as they have been completed, are already in use at the Water of Leith village, Stockbridge, Canonmills, and the shore, and the sewage at these places is no longer discharged into the channel of the river. The works for the drainage of the mill-lade, at present a highly dangerous nuisance, have not been commenced as yet. They will be of a very light description, and will not occupy any length of time. They will commence near St. Bernard's Bridge, and terminate at the old ford below Warriston Cemetery. The Messrs. Stevenson are the engineers, and Mr. T. C. Hunter, the contractor.

The works will supply drainage for a population of 80,000. The expenses will be defrayed by an assessment of 2s. 6d. per pound imposed upon the proprietors of the Water of Leith district. The Act of Parliament also allows a charge ultimately to be imposed for their maintenance.

While it is to be regretted that so much valuable sewage should be thus thrown into the sea instead of being turned to account, we must congratulate the citizens of Edinburgh upon

der malaria, nor act in any appreciably hurtful manner on the health of the human beings inhabiting their neighbourhood." It may be so, and Dr. Strang's opinion is entitled to much weight; but we confess to being very sceptical on the subject, especially when we reflect on the two following facts. In 1849, the village of Restalrig, which is situated in the midst of the celebrated Craigentiny meadows, was more than decimated by cholera. The returns gave the large proportion of one attacked out of every five, and one death out of every nine of the population! And within the last twelve months the Army and Medical Commission have condemned Piershill Barracks as the most unhealthy in Scotland; in consequence of which the headquarters of the cavalry will be removed to Hamilton.

In connexion with the branch drain which leads from each house to the street sewer, there is generally a cesspool placed in the front sunk area. The superintendent of streets and buildings, in a recent report, stated that it might be taken for granted that all the houses in the New Town erected before the year 1854, as well as

PLAN

SECTION. X.Y.

their riddance of the Water of Leith nuisance. We cannot doubt that the medical officer of health's report for next year, should other necessary ameliorations take place, will show a great diminution in disease and mortality in the upper and lower districts of Water of Leith, of Canonmills, Bonnington, and the shore at Leith.

The north-eastern portion of the New Town is drained by a sewer, which, terminating at London-street in a canal, flows past Gayfield-square, and finally falls into the Water of Leith above the harbour. The sewage of the houses on the Calton Hall and vicinity is carried to Leith in ditches between the London-road and Leith-walk, chiefly covered in. The contents of all these sewers, except those falling directly into the Water of Leith, are used in irrigation. Nearly 1,000 acres of land in all are so irrigated in the vicinity of the city, the grass raised on them letting annually for from 25l. to 50l. an acre. It has been confidently asserted that this sewage irrigation of meadows is not prejudicial to the health of the city. "One conclusion then alone admits of being drawn from the facts collected," says Dr. Strang,* and that is that the irrigation of meadows with the sewer-water from a town does not appear in this climate to engen-

many built since that time, have each a cesspool. These cesspools have proved a prolific cause of discomfort and disease. Here it is necessary to observe that an Edinburgh cesspool is a very different thing from what goes under the same name in England, which is either a covered receptacle for sewage, unconnected with any drain, or an uncovered receptacle for ashes, in connexion with a privy. The accompanying plan and section will enable the reader to understand the construction of one of these Edinburgh cesspools, which, we may mention, cost from 3l. 10s. to 5l. 10s. A pit, B C, 7 ft. 4 in. long by 5 ft. wide and 5 ft. deep, is dug in the course of the branch-drain or house-sewer, D E, which runs along the ground-floor of the house, and joins the street-sewer. The cesspool is laid with pavement, and its walls are made with rough masonry, often of the "shivers" or chips struck off by the mason in shaping his stones. Across the cesspool, and resting on its side-walls, a tongue, A, descends about midway, somewhat beneath the lower edge of the house-sewer D. An opening is carried up at C, covered with a square flag, with a ring attached. This admits of the cesspool being inspected and cleaned. The cesspool, of course, fills up to the level of the drain B, by which the overflow is discharged into the street-sewer. The tongue A thus separates the air on the side of the street from

* "Inquiry into some Points of the Sanitary State of Edinburgh." By James Stark, M.D.

that on the side of the house. It further serves the purpose of preventing rats from finding their way into the house from the street-sewer.

Into these cesspools are discharged the ejecta from the waterclosets and the kitchen and washing waste. As we have said, they are a constant source of discomfort and disease. The first evil attending them is a very apparent one. The solid matter of the sullage carried from the house into the cesspool is of course deposited, and each time that water passes into it the whole of the seething putrescent mass in the division C is disturbed, evolving sulphuretted hydrogen and other noxious gases, which find their way into the house by the drain D. If we consider that the compartment C has an evaporating surface of nearly 7 square feet, we may form some idea of the extent of these fetid emanations. Although there is a very simple and cheap remedy for this state of matters, it has been only very sparingly employed as yet. A syphon pipe, like that shown in the woodcut,

and which only costs a few shillings, possesses these advantages. It is water-tight; it effectually prevents the entrance of rats; and by allowing the water to flow for a few minutes, it prevents the sullage from being arrested long enough either to deposit sediment or to throw off noxious gases. The water gradually fills up the space A, until it reaches the level of the outlet at C, which is usually about 2 in. or 3 in. lower than the inlet B. The quantity of water retained, although somewhat less than 3 cubic feet, instead of 37, as in the present cesspool, is sufficient to form a trap.

Further, cesspools are seldom water-tight, in which case the basement story is invariably found damp. The green moss and fungi which are so often found on the area walls and round the edges of the flagstones, are in nine cases out of ten caused by the leakage of the cesspool. Stringent as are the regulations of the Edinburgh Police Acts, to which we shall advert by-and-by, regarding the removal of ashes and solid refuse from the houses, it is to be regretted that there is none requiring the periodical cleaning out of those receptacles of all abominations. Will it be credited that in many parts, even of the New Town, such a cesspool common to the six or eight flats of a tenement, and receiving the discharges from the soil-pipes of as many or more families, frequently remains uncleaned for several years? Yet that such is the case is attested both by the medical officer of health for the city, and by the superintendent of streets and buildings. In self-contained houses this happens comparatively seldom, but in a tenement of flats, where the expense of cleaning the cesspool, which is considerable, is distributed among the different proprietors or tenants, the latter of whom are continually changing their place of abode, it is difficult to obtain the necessary consent of all the parties. Before this has been done and a thorough cleansing effected, "each house," we quote Dr. Littlejohn, "has been filled with emanations from the sewers. The windows have been kept open in order to dilute the noxious smell; and although the object is partially effected, the sewage gases are sucked into the house in greater volume, on account of the draught which has been occasioned. It is not to be wondered at, if, under such circumstances, ill-health, in varying degrees of intensity, should be the result, requiring, it may be, little medical attendance, but causing great discomfort. Should epidemic disease of any kind affect the inmates, the illness is intensified, and the ailment may assume a character of malignancy, which can only be accounted for by the faulty sanitary state of the house. But it must be remembered, that the air in the street also becomes tainted. A cesspool filled to overflowing, and leaking, can be recognised in the street by its odour. It is placed in the area, and of course the emanations escape in all directions. It is urged as an amelioration of the nuisance, that a survey should be made of all the cesspools in the city, that a register be kept of them, and that the city engineer be instructed to have them inspected from time to time; and enforce the regulation that every cesspool within the

municipal boundary be cleaned out at least once a year.*

The remedy proposed would abate the evil, but there would still remain the nuisance of the intolerable stench, which is caused by the existing method of emptying cesspools. Cases have occurred where the men employed in doing so have been afflicted with temporary blindness by the ammoniacal vapours given off. If they must be retained, the plan adopted in the City of New York might be considered. Attached to an air-tight cylinder, which has its air exhausted, is a large leathern hose. The hose is lowered down into the cesspool, when, on opening a valve, the whole sullage, solid and liquid, is quickly forced into the cylinder by the atmospheric pressure. The hose is then drawn up and coiled into its barrel, which is filled with disinfecting fluid. The New York cesspools are provided with a lid or cover, which is tightly keyed down, and which is removed at night when the cylinder is brought round at stated periods. The only proper remedy is to get rid of the cesspools altogether.

Still further mischief arises from the imperfect construction of the house sewer or drain. Made in most cases of shivers, it allows the drainage to escape through its crevices in all directions, and the fetid exhalations find their way into the house. The form, too, of the house-drain is radically faulty. It is a large square drain, commonly called a box-drain, and permits a greater or less quantity of black putrescent filth to accumulate in its interior with such deleterious results as might naturally be expected. It is impossible in any private house to command a stream of water sufficient to carry away the deposit which collects in this manner. These box-drains should therefore be at once got rid of, and smooth tubular pipes should be substituted.

The evils attendant upon defective cesspools and house-drains are clamant for a remedy; but so long as the authorities have not the power to enforce it,—so long as landlords are apathetic, selfish, and money-grasping, and so long as the general public is ignorant of the real and serious extent of the evil, little will be done. The Local Police Act, 11 & 12 Vict., cap. 113, sec. 190, does indeed provide that any person, who "shall suffer any cesspool to become stagnant," shall be liable to a penalty not exceeding forty shillings; but the enactment is practically a dead letter.

In too many instances the main drains of the streets have been constructed on the same faulty principles as the house-drains, being built of rough fragments of stone roughly cemented together. The consequence is, that the sewage is arrested in its onward flow by the ragged and uneven surface over which it has to pass, and oozes out on all sides, soaking the ground and polluting the atmosphere, while admittance is given to rats. From all this it frequently results that the street gives way and falls in.†

THE DESIGNS FOR THE NEW NATIONAL GALLERY.‡

HAVING last week made our readers acquainted with the conditions,—or so far as by the Government they were set forth,—of the problem comprised in the alternative projects for the National Gallery reconstruction or rebuilding, we are now in a position to invite attention to detailed particulars of some of the designs. To such particulars we must mainly confine ourselves at present; for examination should precede judgment; and such examination, if the judgment is to be of value, must necessarily be of a deliberate and painstaking sort. The ten or other number of competing designs, in any case, are like the same number of books on a given subject; which, to be critically estimated, must have been read. It may not require so much time to read a design as to read a book; but, there is this difficulty for the untrained observer, that nothing is completely represented on any single sheet; or, so to speak, the nouns are on one page, the verbs on another, and the adjectives on a third. Thus, there are impediments to examination of architectural drawings in an exhibition; which the general public, who cannot be said to attempt the examination, and who would be incompetent for

it, bare no idea of; and which even the competent men, professional architects, habitually disregard, ignore, or forget. An opinion expressed merely from the examination of a perspective-view, cannot be conclusive, even as to the decorative part of an architectural production; and, of course, it leaves entirely untouched the question of the suitability of the design to the uses of the building, that question which must be responded to before the effect shown in the drawing can be deemed possible of execution,—unless by a negation of the special art, architecture.

As it is, opinions are freely pronounced condemnatory of the whole number of the designs in their decorative character; and so much so is this the case, that "Wilkins's design" is said to be the best. We alluded in our last article to the fact that there were merits in the present structure. But any conclusions formed without examination of the geometrical drawings,—those which really, and alone entirely, have in themselves the materials for the formation of a judgment of the appearance of the building when erected, must be worthless, and should especially be steered clear of by architects, whose art and profession both are so much misunderstood through the erroneous manner, on the part of the public, of looking at drawings.

It may be that this competition repeats the experience of previous cases, in merely affording hints, without supplying the exact design that should be adopted in building. There is certainly (we say so, after much careful examination), less evidence of art in the designs, than the profession should have presented; and even the questions of arrangement and lighting are not conclusively solved in conjunction with the production of good decorative character. Of one or two of the competitors it may be said that they have expended a liberal sum out of the 200l. of each, on the mounting and getting-up of drawings; whilst money would have been better earned by a devotion of their personal study of the subject and their origination thought.

We must, however, refer to what we said in our last, as to the "Instructions." Architects call out for instructions; whilst the need is at most suggestions. In the present case, arrangement and lighting of the pictures should have been mentioned along with whatever might be the views of such men as Mr. Wornum and Mr. Redgrave. Instead of this, we are constrained to believe that the "Instructions" have in one way or another run counter to both those authorities, without leaving the competitors room to choose or think. We differ from the conclusions to which Mr. Thos. Fairbairn arrived in his letter this week in the newspapers, as to the essential superiority, for pictures of every size, of the wide, lofty galleries of the 1862 Exhibition and the Manchester Art-Treasures Exhibition; though, also, we by no means agree with him that there was superabundance of light in 1862 on the frequent rainy days, whether of the summer of that year, or of the approaching winter. Extent of wall-surface, which may be somewhat increased by lessening dimensions of width to 42 ft. at most, is one consideration for a National Gallery; whilst another, not mentioned, and tending, it might be said, the other way, or against small rooms in public galleries and museums, is that such rooms would not permit required supervision of certain classes of visitors to the Gallery. But as to side-lighting, set down in the "Instructions" as admissible for cabinet-pictures and drawings, there is much to be said in deduction from the advantages which it might give for planning the building generally. The wall in which the window is, is worthless for hanging pictures upon, and had best be given to the largest area of opening. The wall opposite the window is a bad place, for small pictures more than any others; because the spectator's head will be apt to cast a shadow upon the pictures. On the sides of the rooms, or recesses, the pictures are not lighted as they should be; and the shadows of the frames have to be considered; whilst there is a necessary deduction for the doors of entrance and exit. These disadvantages were very clearly exemplified at South Kensington on the recent occasion of the Exhibition of Portraits. The conclusion is obvious, that no one of these points of planning and arrangement of the galleries, should have been named either dictatingly, or as though it would be a thing likely to meet with approval. An architect desirous to be selected to compete, and to be paid 200l., should have been credited with power of selection and judgment as to data that might have been offered him.

* Report on the Sanitary Condition of the City of Edinburgh. By Henry D. Littlejohn, M.D., Medical Officer of Health for the City, p. 163.
† To be continued.
‡ See p. 23, ante.

Whatever the results of this competition, however, we would by no means revert to the system of unlimited competitions. The public will not readily learn that these latter competitions defeat their object: but no one with an architect's experience could often advise them.

With all the improvement as to arrangement of the drawings, and space provided for them, that the exhibition of the National Gallery designs affords, there is one capital omission in it. It is, indeed, generally made in such exhibitions. The plan of the ground, documents, and "Instructions," which were the basis for the competitors' labours, are not to be seen.

In noticing the designs, we shall not place them with reference in any way to merit. Accident in this case seems to have determined the order in which they are disposed, and are generally examined by visitors.

Mr. Owen Jones's design made in response to the demand for a project involving "no costly alterations" in the "existing building," and which he distinguishes as Design B, contemplates no change in the present building, but of course appropriates the new ground, or what is occupied by the workhouse and the premises east of it, and by the passage at the back of the Royal Academy. In planning the additional buildings he has observed the same distribution as in his design A, to which then it may be sufficient to confine description. Mr. Jones believes that it will be impossible to add to, or improve, the present building, so as to produce a satisfactory result; and he makes this remark:—"It is as difficult for one architect to alter the work of another as to forge handwriting; and if the building is to remain, it had better, he thinks, remain as it is—a record of the state of the art of architecture at the time of its erection,"—an excellent remark,—though there has been an architect, Sir Charles Barry, who was particularly successful in altering the work of others, and yet leaving the mark of his own hand distinctly.

Mr. Jones's chief design (A) deals with the whole of the ground, inclusive of the site of the barracks as well as of the workhouse and present National Gallery; which last he would remove, and erect a new frontage of buildings of entirely different character, and set back considerably. Viewing the complete plan, it is distinguished for its extreme rectangularity. In several of the designs, the eastward projection of the new ground, in St. Martin's-place, has led to an obliquity of the line, on that side, with the line of present frontage, and to angles which are more or less acute, unless where the angle is rounded off. Again, Hemming's-row and its continuation, Orange-street, not being parallel with the frontage, but tending somewhat northward, and a line of frontage being carried along that side, the north-west angle of the plan as intended when the barracks are removed, is made acute. But Mr. Jones has no frontage taking the line of Hemming's-row: his rearward line would be parallel with that of the main front and of the Square. The two lines would be intersected by three others, leaving ground for two large internal courts. The southern ends of these lines of the plan become centre- and end-pavilions of the Trafalgar-square front; whilst the northern ends differ from one another in projection, according to the rake of the ground. The only deviation from this rectangularity, is as regards a portion of this rectangle which occupies part of the eastward projection next St. Martin's-place. This portion is semicircular on plan, and incloses its own court. Thus, in the building, there would be that simplicity of distribution of the galleries which would be important for the easy circulation of crowds. The entrance would be as required by the "Instructions," namely as at present; and there also would be a way of exit. Visitors would enter a grand circular hall, from a wide porch or projecting loggia of arches, ascended by steps, and would have in face of them the staircase, and, right and left, galleries of the ground-floor. This circular hall has a balcony round it, carried by columns, and has a vault after the manner of that of the Pantheon, at Rome, as regards the lighting, but with the coffered ornamentation disposed on diagonal lines, somewhat after the method adopted by Mr. Jones in several of his recent works. From this hall, or rotunda, the visitors, having turned to the left, would make the entire circuit of the building: from the hall again, they would ascend the stairs: from the top-landing of these they would pass south to the gallery round the

hall: thence they would pass westward, to make the circuit as before. The principal gallery would be 300 ft. in length by 51 ft. 6 in. in width; and an arched ceiling is shown, with a light in the centre, and effective ornamentation. The longest projecting block, on the north, 95 ft. by 51 ft. 6 in., would be devoted to purposes other than the exhibition of pictures. In the central projection towards Hemming's-row, would be the keeper's residence. It may be well to mention, referring to what was said some time since respecting the provision of a residence in the present structure, that the keeper is required to reside in the building. As to the amount of provision in the designs now at Westminster, it varies considerably. We do not quite make out that in the design before us, the provision is adequate. Near to the residence in this design, is the unpacking yard; and it is considered that the keeper would command the galleries, as well as supervise the matters of business requiring his attention. The re-entrancing angles of the two chief courts are filled with little blocks of building, containing rooms for police, attendants, and the service generally. Side-lighting is of course the principle, in this design, for the entire ground-floor: it also obtains in the second story or first floor, for the south and east fronts of the building, or for drawings and cabinet-pictures, to be placed on screens at right angles to the windows." Mr. Jones says, "as they were in the National Portrait Gallery at South Kensington." He adds that this method "admits of increasing the hanging-space as the collection may require it." If the increase be meant as contrasted with what might be got in top-lighted galleries, we think we should hardly admit the force of the observation. The piers of the building are narrow, and the openings wide: the former are 15 ft. from centre to centre; which, therefore would be the distance of the screens. The side-lighting allowed by the "Instructions" has furnished "the key-note" of the design. Mr. Jones expresses as his opinion, that "a facade without windows would be like the human face without eyes, and be void of all expression." We think this the wrong way of reasoning in matters architectural, and a way that Mr. Jones, judging from what he has written, would not have followed excepting by an inadvertent subjection of himself to the ever-troubling "Instructions." The first question for the competitor's decision was, or ought to have been,—what is the best, or the efficient, mode of lighting? It might be that Mr. Jones would have replied, as he seems disposed to do, side-lighting, considering what are other conditions of the planning; but, had he felt obliged to say with some others, top-lighting, we hardly think that he would have therefore made a bad building. Surely, a building may be without windows, and yet not void of expression. Indeed, are there not old styles in which the window plays hardly any part,—the Greek, for instance? Though, we should not deduce from that, that a picture-gallery must necessarily be columnar. Mr. Jones knows how many ways there are of decorating a wall: even Soane's attempts, dispensing with windows, at the Bank of England, would show that something may be done without them. Or if top-lights there would be, might they not be made to contribute to the external decorative character? The character as it is in Mr. Jones's design, may be called a variation of Italian; but, as usual in productions possessing originality and art-character, the decorative expression and details of this design cannot easily be stated in words. There are seven major divisions in the length of the front, including the ends. These are pavilions: each of these, with each of the two recesses next the centre, has its own roof hipped at the ends,—the central pavilion, however, having the roof covering of the rotunda, circular on plan. The centre, in the highest part, is made just the same as the loftiest feature in the present building. All these roofs being about the same height, there is defective grouping; which was never the result from their prototypes, the French roofs. The character of the front is mainly resultant from the details; but general features not described, of the designs, are a podium-base, two stories of modified orders,—the lower order being of panelled pilasters, and the upper one of columns clustered with pilasters, and the group having somewhat elongated shafts,—and an attic filled in with large panels for sculpture, whilst the piers between are terminated by anthemions. In the

interpilasters of the lower story, the windows are square-headed, and have moulded and enriched splay, and sills which are carried by a peculiar feature including two brackets-forms placed parallel with the wall-line, instead of projecting from it. The windows of the upper story have sub-arches, carried by an elongated baluster-mullion in the centre. There is much good ornament in the panels of the pilasters, and in the friezes of both orders, especially where anthemions are introduced. It is right to say that the different intimations from the Office of Works as regards the drawings, such as that none of the perspective-views should be in colour, that no drawings to a larger scale than 16 ft. to an inch would be received, and that the elevations were to be in line only, or etched with Indian ink, but not tinted,—disregarded, one or more of them, by some of the competitors,—have all been attended to in the design that we are examining. Mr. Jones's particulars, however, state that he would use terracotta, of varied colour, and some coloured marble, in the south and east fronts. One journal has stated that the upper windows in this design were blanks. It will be understood that this was an error. Mr. Jones's approximate estimate for design B, is 95,500*l.* That for design A, taking in the ground of the barracks, is 375,000*l.*

Mr. C. Brodriok's drawings, which come next, comprise three designs, Nos. 1, 2, and 3. They display considerable ingenuity in planning; and for the chief design a somewhat imposing effect of columnar architecture. Design No. 1 would preserve the present building, only making the staircases with the opposite flights. The buildings would form three sides of a courtyard, of over 150 ft. each way, the south side being formed by the half of the building now in the occupation of the Royal Academy. In this yard there seems to be lost space. The eastern range of building, transverse, is not at right angles, but askew with the main front. From this eastward range there is a large semicircular projection; that is to say, it is similar in position to the semicircular projection on plan in the design last described. But there is here no court. The semicircle, and that part of the line to which it is attached, are arranged somewhat ingeniously, for side-lighting. The divisions, or screens, in the semicircle, radiate from the centre, or rather from a small semicircle about the centre. This latter curve, on the inner side, is filled in with niches, and being enriched with columns, it would, properly treated, form a very pleasing feature in the plan; whilst as to the divisions of the larger space, the radiating arrangement would mitigate greatly the short-comings of side-lighting. The space not in the semicircle or apsis is divided in the ordinary way. The north gallery, following the line of Hemming's-row, would be 280 ft. in length and 50 ft. in breadth. As designed, the internal effect of this gallery would be highly satisfactory. The divisions of the length are formed by arches and side-openings, the arches carried by columns, and the spandrels enriched. These features carry an entablature, continued from that of the room. From this latter rises an arched ceiling; which has an opening for light in the centre. Both the general features and the ornamentation resemble, in some measure, what may be seen at the Louvre and Versailles.

The design No. 2 includes the site of the barracks; whilst as to the ground, bounded by Hemming's-row and St. Martin's-place, the plan corresponds with what we have described: in effect, there are two large courtyards, instead of one,—the western one, of course, being the larger. But as regards the site of the present building, or rather building itself, the treatment is important, both as regards what would be built and what would be left; for, in the latter category there is much. Thus, whilst the decorative character of the building would be entirely changed, though still kept columnar,—or rather, made markedly so, by a profusion of added columns,—the present exhibition-rooms, which we have taken care to inform our readers are liked by Mr. Wornum, (or, at any rate, three of them at each end of the building) would remain unaltered. A new staircase-hall, of large dimensions, would be added in the centre; and in advance of it, there would be a recessed portico, of fourteen columns between ante, in the front, and of eight internal columns, placed two together, or dividing the length into five spaces of three intercolumns each. This portico has a flight of steps in front. The order, Corinthian, is continued, or with six columns

on each side, to the ends of the building, where there are quadrants, each formed with two columns in the space. The centre-porcho has no pediment; but ten of its columns, in the front, carry the same number of columns of the front of a temple-formed attic-building, which has eleven columns on each side, and of which what we may call the *naos* or *cella* is the upper part of the staircase-hall. This attic-building has a pediment, of which the tympanum is charged with sculpture. There is an attic, or balustrade, to the order of the wings; and the piers, corresponding with antae, are terminated by groups of figures. Where the attic would be interrupted by the porcho of ten columns, the cornice-lines of the attic-pedestals are carried across, or partly round the shafts. This device is no doubt intended for tying the different parts together; but the aim is not reached; and the shafts of the upper order look stunted. The larger order runs along the east end of the building, and round the semicircle or apse, where there are two stories of niches. In the rear-walls of the porches are sculptured elabs. The staircase-hall would be highly effective, judging from the plan and section. There is a centre flight of steps up, opposite the entrance; and there are two parallel flights at the sides, down. Round the hall are columns, twelve on each side: the entablature of these forms the base for a passage-way and arcade,—the archivolts of the latter being carried by Persians or Caryatides, which are set in the reveals. Behind the arches are windows in the intercolumns of the attic-building. The front for Hemming's-row and Orange-street presents an effectively decorated wall, with a pavilion for the centre. Mr. Brodrick's design is set off by two large and effective views: indeed the drawings are complete, and the design matured, as compared with his design on the last occasion of a competition of which the drawings were exhibited in the Royal Gallery; when he was so fortunate as to get the third premium for what could not have been executed in the way that the drawing showed the work. Mr. Brodrick proposes to alter the arrangement of the Square by taking away the terrace-wall, and substituting steps for the whole length between the two large pedestals, of which one bears the statue of George IV. It has been suggested to us that Sir Charles Barry's choice of the balustraded wall in preference to steps, must have been governed by the design of the National Gallery, and made different from what it would have been had a flight of steps been a feature of the porcho. The courts in Mr. Brodrick's design are characterized by extreme plainness. The principal galleries are 50 ft. in width.

Design No. 3, by the same author, is explained in a mere plan, which shows the spaces of the courts of the other design, nearly filled by parallel galleries, each 30 ft. in width.

We must sometimes reverse the order in which the two chief projects are taken up by the competitor. We adhere to the order in which they were originally stated by the Office of Works. Thus we arrive at Mr. Street's design for the "Enlargement of the Existing National Gallery." Of the drawings in this case, he says it is not necessary to say much in explanation. He has prepared them because "desired to do so; not because it will even be possible to enlarge the present Gallery with satisfactory results, unless, indeed, the existing building is so much altered as to make the work nearly as expensive as a reconstruction." He notes that the ground-floor is useless for exhibition-purposes; but, if side-lighting be admissible, we imagine that the main objections to the ground-floor now are as to the two ways through the building, and the steps down from the entrance-hall. He also notes the universal condemnation of the chief front; and he points out that the front to the rear would require treatment—apparently forgetting to note that there must be a new rear-front in any case, at least to Hemming's-row. His design consists of an addition, in the Gothic style, to the present Greco-Italian front. Retaining the present entrances, the staircase would be formed out of the large room lately added. The 50-ft. galleries would run north from this, and would have side-lighted cabinets at the side. With other galleries, these would form a quadrangle, — much as he has the arrangement of his other design. The floors would be raised considerably above the levels of the floors of the present building, "so as to render the ground-floor rooms really available as exhibition-rooms." The area of galleries and rooms for

pictures would then be as here given, stating, however, the floor-space:—

The Gallery-floor:—		
Existing Galleries	14,300 ft.	
Additional Galleries	20,650	35,250 ft.
Cabinets		7,175
Total		42,425 ft.
The Ground-floor:—		
Existing building (space of an inferior kind), Turner Gallery and drawings of old masters, ..	6,339	
New Building:—		
1. Gallery and Rooms for drawings and prints in East Wing ..	6,450	
2. National Portrait Gallery on north side	9,145	
3. Rooms on west side of quadrangle, suitable for water-colour drawings or original drawings ..	10,188	25,813
		32,152 ft.
Total Exhibition-space		74,577 ft.

We have modified the form of statement; but the figures of course are the competitor's. Mr. Street points out that a great portion of the 74,577 ft. would not be so valuable as in the other design. He has certainly succeeded in designing an addition as incongruous as possible with the present structure, decoratively regarded.

In his design "for rebuilding the whole Gallery," he has been in his due position; and he has expounded his views, and given particulars of his intentions, in an elaborate pamphlet. Whatever be our estimate of the result of Mr. Street's work, in his drawings, we must say that his written statement, however we may sometimes differ from what is said in it, cannot be read without advantage. He says that the invitation to compete was one that he felt it was his duty to accept, as it had long seemed to him that the public mind was unjustly biased towards a particular style of architecture "for our great institutions." After an expression (which, from him, we were gratified to read) of his distress and surprise at any disparagement of the Houses of Parliament, he says there has been a return, with bad results, to the old course wherein it seems to be assumed that some adaptation of Classical or Renaissance architecture is the only style allowable for museums, picture-galleries, and other such buildings. He mentions the fact that when his name was first uttered in connexion with the proposed competition, objection was immediately taken to him in the House of Commons on the ground that he would be sure to design a Gothic gallery, and that such gallery must needs be a failure. Now it seems to us, without expressing any approval of the decorative part of his present design, that Mr. Street is just as much in the wrong in his way of answering these remarks in the House, as were those who made the remarks. Is it not clear that the moment any architect allows the decorative character, chosen or imparted, of his design, to influence disadvantageously the serviceableness of the building, his production departs so much from good architecture? The operation of designing the gallery, in fact, should make the style, or help to do so: the gallery must not be adapted to a style. If our architects, whether Classicists or Gothicists, as designated, are unable to produce a well-lighted and otherwise suitable building for a National Gallery, the cause must be that they are alike moving in courses which are nearer to those of copyism and anjection to precedent, than to those which are the proper ones for the architect, and artist-architect, of his day. Mr. Street himself gives evidence in the mere matter of the writing to his drawings, of this subjection. When an architect prints "National Gallery" in such a guise that the greater number of people will read "Paciopal," or perhaps "Episcopal," Gallery,—and when for "Pictures" he writes what looks like the French for "Cigars," he not merely cuts off from himself his object,—if he does not even offend,—but he also helps to narrow his own mind. We could also believe that the seemingly-stagnant had drawing of the porcho of St. Martin's Church, in one of the views, had some similar explanation.

In Mr. Street's chosen arrangement of the galleries and rooms, as in much of his statement of principles of the planning of galleries, there is, as we have intimated, matter that deserves attention. He however overstates, we think, the element of the problem, comprised in the ground and site for the National Gallery.

He says that when a gallery for pictures occupies one of the most costly sites in London, it is "criminal" on the part of the artist to waste land. Of course, he points here, and rightly enough, to the uneconomic planning of the present building, as regards its ground-floor, and its means of access to the porcho. But he proceeds to say that "a Gothic building does not involve any of these difficulties,"—as though the defects of Wilkins's building had necessary connexion with present possible use of the style or models that Wilkins used. He has the truth of the matter lurking in his mind, where he says afterwards that he has "never seen a gallery yet, which was specially adapted for displaying pictures well, which had much architectural style of any kind in the planning or detail of the rooms,"—that what there is, "consists usually of decoration and nothing else," and that he "cannot conceive" why the "sort of work should present the slightest difficulty." He then states essentials of a gallery for pictures, very clearly; but he winds up by saying, he maintains that "these can be more easily obtained in a Gothic than in a Classical building." We cannot however go into all the points of the argument upon which Mr. Street has entered, or do justice to our own position, which is that in a right condition of our art, such questions would not be raised. It remains only to say with reference to the matter, that the Gothic influence has helped to satisfy Mr. Street of the advantage of covering the entire ground. His front to the Square is as symmetrical as that of any classic structure; but the eastern end of the building follows as nearly as possible the irregularities of the ground. He has not recollected that there would be some reason for giving up ground to the street.

We have yet more to say of Mr. Street's design, but must leave it for our next article.

PRIZES TO ART-WORKMEN, SOCIETY OF ARTS.

THE works sent in on the present occasion are 107 in number, and, though fewer than might have been anticipated, considering the numerous prizes offered, include works of greater merit than were found in the previous competition. The ironwork is much more satisfactory, and a piece of repoussé work in metal deserves especial commendation. The prizes have been awarded by Mr. Redgrave, R.A., and Mr. M. D. Wyatt, with the secretary, Mr. Le Neve Foster.

INCREASE THE SCHOOLS.

THE principal changes sought by the deputation from the Social Science Association who attended the Lord President of the Council on Tuesday last, were that a "certificated" teacher be not necessarily required "in town schools in which the fees in the aggregate do not amount to more than one-ninth of the total annual expenses," in order to obtain the Government grant; that the grant for average attendance be raised, except in infant schools, from 4s. to 5s., and the grant after examination from 8s. to 9s.; further, that whenever additional expense is incurred for industrial teaching a grant in aid be given. The Hon. A. Kinaird, M.P., introduced the deputation. Mr. G. W. Hastings read the memorial setting forth what was asked; and the Rev. W. Clay further set forth the various points in it. It was shown that it is vain to expect that schools for this class of children aimed at can be permanently maintained by benevolent persons, for the burden is too heavy. In other elementary schools, the subscribers have to provide only about one-third of the annual income, the children's fees and the Government grants furnishing the rest; but in these the fees range from nothing to about one-ninth of the total cost, while experience has shown that schools frequented by the children of poverty-stricken parents, even if the conditions of the Revised Code were complied with, must always fall below the average standard, and consequently obtain, on the present terms, very small assistance from Government. That as to a certificated teacher, the existing requirement places poor schools at a great disadvantage, because the more efficient certificate-holders will not take charge of a school for destitute children in a squalid neighbourhood, unless induced to do so by a high salary. And with reference to

the asked-for grant in aid of industrial teaching, that however desirable industrial teaching may be in other elementary schools, in those for "neglected and destitute children" it is almost a necessity; partly because from their habits they are unfit to bear long mental exertion, and partly because they have to be taught in school to earn their livelihood.

The Rev. G. H. McGill supported the views set forth with illustrations from his own labours in the East of London. Mr. Charles Ratcliff (Birmingham) showed how the changes were needed in his town. From Manchester, evidence was given by one member of the deputation that masses of children were growing up without going to any school whatever. Mr. Godwin set forth, from his own experience, the condition of thousands of children in the metropolis whose only education was downwards, and who served to keep up the ranks of the criminal classes at that rate to the country. Mr. R. C. Hanbury, M.P., Mr. James Heywood, F.R.S., and others, also made confirmatory statements. The Duke of Buckingham and the Hon. Mr. Corry, who was with him, entered fully into the matter, and promised it should be considered by her Majesty's ministers.

In asking for exceptional treatment in favour of poor town schools, two dangers have to be avoided. In the first place, no inducement should be held out to any schools to lower their fees and their standard in the hope of obtaining larger grants; and, in the second place, parents able to pay the usual fees should not be tempted to send their children to free or very cheap schools. The first danger is guarded against by the moderation of the petition now forwarded. There are not many town schools in receipt of Government aid where the charge is so low as 2d. a week, and almost none where it is less. The demand is so moderate that, if granted, it will not be worth the while of any school now charging 2d. to lower the charge to 1d. Against the second danger it will be for the Education Department to guard. But as it has been found quite practicable to exclude from the existing schools a higher class than that for which they were intended, so it will not be difficult to confine the humbler description of schools which we wish to help to the use of the really poor. For our part, we go much further than the Association, and would insist upon education to good for every child. We assert, as we have often asserted before, that if this were done, even at the country's expense, the country would be the gainer, as well in a pecuniary point of view as in others more important still.

PARIS EXHIBITION AND ENGLAND.

At the last meeting of the Commissioners, presided over by H.R.H. the Prince of Wales, it was determined to appoint a committee to promote a proper representation of Indian architecture. The Prince, on the same day (January 11), presided at a meeting of the Associate Commissioners, when deficiencies in certain classes were made known. We find that Terra-cotta, Bronze Castings, Plans and Models of Farm Buildings, and Plans of Cheap Dwellings, as matters at present stand, will be very inadequately represented in the Exhibition. Something should be done to remedy these deficiencies.

PARIS EXHIBITION OF 1867.

The concession of the International Theatre has been granted to M. J. Reynier by the Commission, who has decided also that the internal decorations may be regarded as objects exhibited, after having been received by the Commission. Consequently they will be inscribed in the catalogue, and can compete for the prizes.

Russian peasants have been for some time in Paris: they are occupied during the day in constructing, in the park surrounding the building, huts after the model of their country. According to the French papers, they are anything but happy in their new life. They seem to be plunged in an incurable melancholy state. The snow enlivened them a bit, and gave them reason to exclaim that there was at least one good thing in Paris.

As to the Russian section, it occupies 1,000 square metres (square metre equal to 10½ square feet nearly) in the rectangular part of the park,

situated between the Exhibition building and the Avenue de Suffrein. We remark there:—

1. A large outhouse, two stories high, the lower portion being for exhibiting agricultural machines, and the upper story containing an inquiry office, lodgings for six *moujiks*, and the forage store.

2. Opposite, the office of the Russian commissioners,—a wooden pavilion, very ornamental, in the style of the boyards of Northern Russia. All the mechanism of construction is apparent. The chimney of terra-cotta, is, as is the custom, capped with an iron pot turned upside down, and the bottom knocked out.

3. A great *isbah*, or peasant's cottage, composed of three buildings grouped together. There is, first, a building of red deal, forming a complete habitation. The walls are composed of round trees, barked and squared with an axe. The lower end of each piece is mortised, to receive a tenon on the top end of the lower piece, and the joints are made tight with tow.

The ground floor is laid out in stables and cow-houses. The upper story, divided into two rooms, comprises the habitation of the peasant and his children. In the angle is placed an immense stove, serving the double purpose of warming and baking. The staircase is outside. Adjoining the building is a covered courtyard, serving specially for sheltering the farm-carts which the Russians construct rather tastily.

Next follows a small habitation without stables, in white deal, put together as in a great house. It is a sort of guard pavilion, preceded by a portico.

In these different constructions there is neither nail nor peg. The whole of the *isbah* is a special article exhibited by the Domain, under the direction of M. Gromoff, one of the greatest wood-merchants in St. Petersburg.

4. A vast construction, 249 ft. 4 in. by 23 ft., with pavilions at each side, and projecting main body in the centre, is intended for stabling the horses sent by Russia. These types of Russian breed will be arranged longways parallel to the wall, so that a visitor can see them to advantage; provided, of course, that one side of a horse is the same as the other side, and we think that it is. On the upper story there are lodgings for ten *moujiks*.

This building is well ornamented; the style being an application of the Russian *hospodar* art of the centre of the country to modern usage.

5. A *yovets*, or tent, 19 ft. 6 in. in diameter, in the form of a beehive, of felt sewn together. Above is an aperture for letting in light and air, and giving an exit to the smoke. How the air can go both ways we will not stop now to explain; suffice it to say that it is the national habitation of the Cossacks and the nomade Tartars.

Among the curiosities of nations to be presented to the public at the Exhibition we may cite the Chinese portable kitchen.

One man carries it on his shoulders and serves out his culinary produce to customers. It is a structure of wonderful lightness; especially so by the employment of bamboo cane, to which it is suspended. The contrivance is 2 metres high and 3 metres wide. One hand of the carrier steadies the machine while the other minds the cooking, tends the fire, and serves the public; in the front compartment, on the first shelf, are plates and dishes well arranged; on the second shelf, wood and matches; on the "ground-floor" is arranged the cooking apparatus. The back compartment contains all that can comfort man, in a raw state. Meat, poultry, fish, vegetables and herbs, peppers, spices, &c. For an extremely small sum a workman, in China, can have a comfortable repast without quitting his place of work; all he has to do is to beckon to the *restaurant*-man, and up comes the dinner.

Another ambulatory occupation is that of barber. This Chinese "shaver" has a boiler of hot-water on his head. On his shoulder is a hambo, carrying at one end the provision of cold water, at the other end the traditional shaving-dish, a razor, and towel. He not only takes off the beard, but the hair of the head also, leaving a small tuft, enjoined by the Mandchou under penalty of death.

A bull-fight circus, to accommodate 15,000 persons, is to be erected. The horns of the bulls in action will be balled, so as to render them innocuous, and the sword blunted; so that, instead of blood, the only vital element spent will be money in the shape of costumes, which are to be represented in the most sumptuous manner.

A lecture-building is being constructed in the

park, in the form of a theatre, by a company of whom M. Pierre Petit, the photographer (photographic concessionist for the Exhibition), is director. It will hold 500 persons seated. Several lecturers have been engaged to explain the progress of science, arts, manufactures, the machines exhibited, &c. These lectures, given in French, English, Italian, Spanish, and German, promise to be extremely interesting.

PROPOSED ART EXHIBITION IN LEEDS.

THE prospects of the proposed "National Exhibition of Works of Art," to be held in Leeds, in 1868, appear very promising. The guarantee fund amounts to 110,000*l.*, or some 35,000*l.* more than the Manchester people raised for the Art Treasurers Exhibition in 1857.

The Right Hon. the Earl Fitzwilliam is the president of the general committee, and Mr. W. Beckett Denison, chairman of the executive committee.

Castle Howard and Chatsworth are placed at the disposal of the committee, and the Exhibition bids fair to be one of truly national importance; we hope even surpassing that of Manchester in 1857. Mr. J. B. Waring is the general manager or chief commissioner.

SANITARY MATTERS.

Chorlton.—The monthly report of Mr. G. Greaves, the consulting medical officer of the Chorlton workhouse, states that, on November 30, there were 13 fever cases in the hospital, nearly all of which were convalescent, 15 more were admitted to December 31; during that month one patient died, 11 were discharged cured; and on the 31st of December, 16 remained in the hospital. Mr. Greaves wrote, under date January 1, that the only unsatisfactory feature in the returns was the increase of typhus in some parts of the union, which some months ago had almost disappeared from the wards. Fifteen fresh cases had been admitted, most of them within the last fortnight. Two entire families had been admitted, and, having visited the house from which one of them came, he thought it right to lay before the guardians the result of his inspection. The house was in Riga-street, Hulme, a low and crowded neighbourhood, and very near the river Medlock. The back windows overlooked Riga-court, which was closed at one end, and at the closed end, under the windows of the house, were some filthy and dilapidated public conveniences. The drainage of the surface and the ashpits appeared to be imperfect. No attempt had been made to purify or disinfect it. The floor and walls were very dirty. He was informed that the furniture had been seized for arrears of rent after the fever had broken out, and, after passing through the broker's hands, had most probably been distributed over the city, carrying with it the infection, which was of a most malignant type.

Newcastle-upon-Tyne.—Another of the local medical men has been cut off by fever. Mr. Gilchrist, surgeon, after attending to fever patients located in some of the most filthy places in the town, there caught the fever of which he died. Newcastle is notorious for fevers and a high rate of mortality.

Winchester.—Eleven competition plans have been sent in for the sewerage of the city. There is a surmise that the estimates for the main drainage works will range from 13,000*l.* to 20,000*l.*, but nothing certain was known of the result. In connection with the utilization of the Winchester sewage, the *Hampshire Independent* gives the following extract from a letter in a daily paper—"I do not know what difference there may be as regards productive capabilities between sand recently removed from the sea-side and the sand of those immense plains in which Berlin is situated, and which, extending to the Baltic, are, I presume, of marine origin; but this I can state with absolute certainty, that of all descriptions of manure, sewage is here in the greatest request, and that very abundant crops are produced by its application to the sand soils of this district, which have not any surface vegetable soil, and are certainly 10 or 20, or more, feet in depth."

Carnarvon.—Dr. Seaton, who was sent down to Carnarvon by the Privy Council, has just made his report on the cholera in that town. Dr. Seaton found that, out of a population of 9,000

persons, there had been during the five weeks preceding his visit not less than sixty deaths from cholera. The disease has not been confined to any particular portion of the town, nor has it by any means been limited to the very poorest people. One-third of the deaths have, however, occurred in a single street; and in the county gaol, which is situated in a narrow street, in a low part of the town facing the Menai Straits, there have been, in a population of thirty prisoners, six cases of cholera (four of which have proved fatal), and three or four of diarrhoea. Of the sanitary state of the town Dr. Seaton speaks thus:—"In Carnarvon there exists everything to invite and give intensity to an outbreak of cholera, or any other infectious or epidemic disease—great overcrowding and bad house construction, bad water-supply, bad drainage, absence of privy accommodation, and accumulation of surface nuisances." The overcrowding he describes as being of the worst kind. Not merely are the people crowded into houses numerically incapable of holding them, but the houses themselves are huddled together on a wholly insufficient space of ground.

OLD HOUSE AT COLOCNE.

NOTWITHSTANDING the ravages of time and the worse destruction caused by the requirements of modern times, the ancient city of Cologne still possesses many fine specimens of mediæval domestic work.

The houses are of two distinct classes; first the ordinary gabled half-wood buildings common in all old towns; and, secondly, large stone fortified houses of very superior architecture and construction. Of these latter, perhaps, the "Cürzenich-haus" is the finest example.

Our illustration, drawn on the spot, represents the angle of one of these fortified houses near the Rath-haus.

GREENOCK COURT HOUSE, SCOTLAND.

The principal front toward Nelson-street, of the new Court-house, for Greenock, presents a façade 100 ft. in length, and three stories in height, with a massive tower in the centre. The tower is finished above, at the angles, with corbelled turrets, and is surmounted by a spire, which rises to the height of 113 ft. from the ground. The door, which penetrates the base of the tower, is flanked with columns, and buttresses on either side supporting the lower part of the tower. A boldly moulded segmental arch springs from the capitals of the columns. Above the level of the street floor, and extending up to a level with the ridge of the roof, the tower is square, having no projection or break; but each angle of the front is recessed, the recess containing a shaft carved in a spiral form. Above the door is a window, with label and panel over it, and opening upon a stone balcony, carried out above the doorway, and having a parapet of cusped tracery. This window is on a level with the first floor of the building. Above it, and level with the second-floor, there are two windows with plain segmental arched heads, having above and between a large circular carved panel, with a shield on which will be engraved the arms of the town. On the level of the ridge of the roof, and at a height of 57 ft., the upper portion of the tower is carried out, and flanked with circular turrets, finished with conical roofs. From the corbelling rises a parapet, and behind and between the corbels the front of the tower is finished with a high gable, filled with a semicircular-headed window of two lights, the gable being crocketed, and surmounted with a lion *sejant rampant*. The roof of the tower beginning in a square form, becomes octagonal, as it tapers upwards to a height of 30 ft., from which altitude rises an octagonal lantern, with a conical roof, the lantern having columns at each of the eight angles, with bold bases and capitals. The façade on each side of the tower shows a row of three windows in each story. Those on the ground-floor have segmental arched heads, with label mouldings over them. Those on the first-floor are simple square-headed windows. Above the first-floor is a parapet carried on corbelling, from which rises the upper tier of windows, projecting from the roof, and finished with gables furnished with crockets and finials. This portion of the

ANCIENT DOMESTIC ARCHITECTURE, COLOGNE, GERMANY.

building presents at each end a double gable. Between the gables there rises a high ornamental chimney-stalk; and flanking the gables on the outside are circular turrets, somewhat similar to those on the tower, between which the corbelled-out parapet is continued on the same level as that described in front. The turrets are supported on shafts spirally cut, like those in front, and resting on the top of the buttresses, which extend up through the ground-story of the building. On the north gable the principal feature is the great window of the staircase, extending through two stories, and divided into a large centre division of two lights, and two side divisions of one light, each moulded and finished with label mouldings. In general style, the building may be said to belong to the Scottish Baronial.

The building is divided into two portions, the front portion, which extends back about 50 ft., being three stories in height, and containing offices for the sheriff, the sheriff's clerk, the procurator fiscal, &c., with a dwelling-house for the keeper. The entrance-hall is lighted, when the door is shut, by narrow windows on each side of the doorway. This hall is 16 ft. wide, 22 ft. in length, and runs into a corridor 17 ft. wide, and about 60 ft. in length, having at one end of it the public staircase, giving access to the upper portions of the building. Opposite the door, at the further end of the corridor, is the Court-room, forming the back part of the edifice.

This apartment is 47 ft. long by 38 ft. in width and the roof is placed at a height of 31 ft. On either side of the Court-house there are narrow corridors leading at right angles from the large corridor, and giving access to the different portions of the floor appropriated to the accommodation of the jury, witnesses, &c. The back building is only of one story, but it rises to the height of the second story of the front part of the building. There is a smaller Court-house, situated for the sake of convenience in the front building. This apartment is on the right-hand side on passing through the door into the entrance-hall, and has rooms for the sheriff attached to it.

The architects are Messrs. Peattie & Kinnear.

The foundations of the building have been laid, and the works are being proceeded with as speedily as the present state of the weather will allow.*

JOHN W. & SONS

NEW COURT-HOUSE, GREENOCK, SCOTLAND.—Messrs PIDDIE & KINNEAR, ARCHITECTS.

ART IN ROME.

We have seen the groups executed by the Danish sculptor, Jerichau, for the Princess of Wales, as already mentioned in the English papers. His "Adam and Eve," at the moment the former awakes to find his newly-created spouse at his side, is impressive and original, admirable for the expression of astonishment and delight, tempered with tenderness, in Adam (whose head is nobly beautiful), and for the modest, timid sweetness of Eve, who kneels beside his half-reclining figure. The group of "Girls Bathing," or rather leaving the bath in alarm at some stranger's approach, represents a younger and elder sister, the former taking refuge in alarm on the bosom of the latter,—the situation presented with much grace of movement and outline. This artist's statue of a hunter taking away the cull from a panther, and defending himself from the enraged dam, ordered by Sir Francis Goldsmid, is the reproduction of a work first executed several years ago, and hitherto the most popular of all he has done during a residence of many seasons in Rome.

Among other novelties that we have seen in Roman studios within the last few weeks, we may mention with praise such fine examples of portrait-sculpture as the bust and statue of Mr. Gladstone, and the bust of Lord Brougham (stat. 89) by Mr. Adams, alike admirable for the expression of calm power and for strongly-marked individuality. If, as that aged statesman declared to him, no other artist is to be honoured by sittings from Lord Brougham in his future life, Mr. Adams's likeness will indeed acquire additional and extrinsic interest for posterity.

THE PRESERVATION OF WOOD IN DAMP AND WET SITUATIONS.*

In 1846, eighty thousand sleepers of the most perishable woods, impregnated, by Boucherie's process, with sulphate of copper, were laid down on French railways. After nine years' exposure, they were found as perfect as when laid.† This experiment was so satisfactory that most of the railways that extend at once adopted the system. We would suggest washing out the sap with water, which would not coagulate its albumen. The solution would appropriately follow.

Both of the last-named processes are comparatively cheap. The manufacturing companies of Lowell, Mass., have an establishment for "burnetizing" timber,‡ in which they prepare sticks 50 ft. in length. Under a pressure of 125 pounds per square inch, they inject from two to eight ounces of the salt into each cubic foot of wood. The cost, in 1861, was from 5 dols. to 6 dols. per 1,000 ft. board-measure; § Boucherie's method must be still cheaper. It costs less than creosoting by one shilling per sleeper.¶

An American engineer, Mr. Hewson, for injecting railroad sleepers, proposes a vat deep enough for the timbers to stand upright in. The pressure of the surrounding solution upon the lower ends of the sticks will, he thinks, force the air out at their upper extremities, kept just above the surface of the solution, after which the latter will rise and impregnate the wood. In 1859, he estimated chlorido of zinc at 9 cents per pound, sulphate of copper at 14 cents per pound, and pyrolignite of iron at 23 cents per gallon. He found the cost of impregnating a railway tie with sufficient of those salts to prevent decay, to be—for the chloride of zinc 28 cents, for blue vitriol 3-24 cents, for pyrolignite of iron 75 cents.¶

Among the numerous other preservative compounds, may be mentioned, Le Gras's mixture** of double salt of manganese and lime (or zinc) with creosote, Payne's solution†† of sulphate of iron and muriate of lime, forming by double decomposition an insoluble sulphate of lime among the wood fibres; Margery's solution of

acetate of copper, and Ransom's liquid silicate of potassa.¶¶ Payne's process met with some favour, but neither of the last is of appreciable value.

Vessel-owners had long ago observed that those ships which have early sailed with cargoes of salt are not attacked by dry-rot; indeed, several instances are well attested of vessels whose interiors were lined with fungi, having all traces of the plant destroyed by accidental or intentional sinking in the sea. Acting on such hints, a trader of Boston salted his ships with 500 bushels of the chloride, disposed as an interior lining, adding 100 bushels at the end of two years.†‡ Such an addition of dead weight (35,000 pounds in this case) is sufficient objection to a procedure which has other great disadvantages.

The unpleasant odour of creosote is greatly against its use upon lumber for dwellings, and Bethell's process, therefore, is not described here, although the most satisfactory known. Pyrolignite of iron is offensive, and also highly inflammable. The affinity of the chlorides for water keeps the structure into which they are introduced wet; besides, they corrode the iron-work. Sulphate of copper is free from these objections, and is at present cheaper than the chlorides; therefore, for protecting wooden structures against dry-rot, in damp situations, like mines, vaults, and the basements of buildings, sulphate of copper seems preferable, and Hewson's or Boucherie's method of injecting it cheaper and more expedient, according as the timber is short or long.

II. Wood alternately wet and dry.—The surface of all timber exposed to alternations of wetness and dryness gradually wastes away, becoming dark-coloured or black. This is really a slow combustion, but is commonly called wet rot, or simply rot. Other conditions being the same, the most dense and resinous woods longest resist decomposition. Hence the superior durability of the heart-wood, in which the pores have been partly filled with lignine, over the open sap-wood, and of dense oak and lignum-vite over light poplar and willow. Hence, too, the longer preservation of the pitch-pine and resinous "jarrah" of the East, as compared with non-resinous beech and ash.

Density and resinousness exclude water; therefore our preservatives should increase those qualities in the timber. Fixed oils fill up the pores and increase the density. Staves from oil barrels and timbers from whaling-ships are very durable. The essential oils resinify, and furnish an impervious coating. But pitch or dead oil possesses advantages over all known substances for the protection of wood against changes of humidity. According to Professor Letheby,‡‡ dead oil, 1st, coagulates albuminous substances; 2nd, absorbs and appropriates the oxygen in the pores, and so protects from eromacansis; 3rd, resinifies in the pores of the wood, and thus shuts out both air and moisture; and, 4th, acts as a poison to lower forms of animal and vegetable life, and so protects the wood from all parasites. All these properties specially fit it for impregnating timber exposed to alternations of wet and dry states, as, indeed, some of them do, for situations damp and situations constantly wet. Dead oil is distilled from coal-tar, of which it constitutes about 30, and boils between 390° and 470° Fahr. Its antiseptic quality resides in the creosote it contains. One of the components of the latter, carbolic acid (phenic acid, phenol) C₆H₅O₂, § the most powerful antiseptic known, is able at once to arrest the decay of every kind of organic matter.¶¶ Prof. Letheby estimates this acid at

‡ to 6 per cent. of the oil. Chrysalic acid C₁₂H₅O₂, the homologue of carbolic acid, and the other component of creosote, is not known to possess preservative properties.

Bethell's process* subjects the timber and dead oil, enclosed in huge iron tanks, to a pressure varying between 100 and 200 pounds per square inch, about twelve hours. From eight to twelve pounds of oil are thus injected into each cubic foot of wood. Lumber thus prepared is not affected by exposure to air and water, and requires no painting.† A large number of English railway companies have already adopted the system.‡ Eight pounds of oil per cubic foot is sufficient for railway sleepers.§

The cost of "creosoting," as this process is sometimes called, was given in 1855, by Ronald and Richardson, at somewhat less than 4d. per cubic foot,|| in England. At 1s. per gallon,¶ the price at which dead oil was obtainable in England in 1863, 4d. per cubic foot would, we presume, be sufficient.

A process recently patented, and described in the *Scientific American*, February 17, 1866, proposes to introduce highly heated oleaginous vapours among the timber, confined in an iron tank. The patentee** hopes that as fast as the moisture is expelled from the wood, the vapour will take its place. Whether this substitution would not soon arrest itself, should it even commence, is in our mind a debatable question.

While an external application of coal-tar promotes the preservation of dry timber, nothing can more rapidly hasten decay than such a coating upon the surface of green wood. But this mistake is often made, and dry rot, instead of wet rot, does the work of destruction.†† The reason must appear from what has been said on dry rot. Carbonizing the surface also increases the durability of dry, but promotes the decay of wet, timber. Farmers very often resort to one of the latter methods for the preservation of their fence-posts. Unless they discriminate between green and seasoned timber, these operations will prove injurious instead of beneficial.

In this connexion, we remark, that inverting a post from the position in which it grew, is by some supposed to retard decay. According to the president of the "Northern Architects' Association," England, "the values" close against moisture ascending through the ducts from the earth into the post.‡‡ But, according to Gray, thin plates only separate contiguous ducts. Fluids can pass through them in one direction as well as in the other. When age obliterates these thin mediums, nothing opposes the flow upward or downward. Furthermore, the passage of fluids through wood is not confined to ducts; it takes place on all sides of them as well. In face of these facts, very careful experiments will be requisite to convince us that a post is more durable in the inverted than in the normal position.

III. Timber constantly Wet in Salt Water.—We have not to guard against decay when timber is in this situation. *Teredo navalis*, a mollusk of the family *Tubicolitaria*, Lam., soon reduces to ruins any unprotected submarine construction of common woods. I quote from a paper read here for the "Institute of Civil Engineers," England, illustrating the ravages of this animal:—

"The sheeting at Southend pier extended from the mud to 8 ft. above low-water mark. The worm destroyed the timber from 2 ft. below the surface of the mud to 8 ft. above low-water mark, spring-tide; and out of thirty-eight fir-timber piles and various oak-timber piles, not one remained perfect after being up only three years."§§ Specimens of wood, taken from a vessel that had made a voyage to Africa, are in the

* Fifty pounds of carbonate of potassa are dissolved in water, and a little lime is added to neutralize any free acid; 100 pounds of flints are added, and the whole exposed ten or twelve hours to a temperature of 300° F. This solution is evaporated to 1-500 at 60°.—*Civil Engineer's Journal*, vol. ix.

† *American Journal of Science*, vol. xxii., p. 17.

‡ *Civil Engineer's Journal*, vol. xxiii., p. 216.

§ Creosote from coal undoubtedly contains two homologous bodies, C₁₂H₅O₂, and C₁₀H₃O₂, the first being carbolic acid, the second chrysalic acid.—*Ure's Dict. of Arts, Manufactures, and Mines*, vol. ii., p. 623.

¶ I have ascertained that adding one part of carbolic acid to five thousand parts of a strong solution of glue will keep it perfectly sweet for at least two years.

‡‡ Hides and skins, immersed in a solution of one part of carbolic acid to fifty parts of water, for twenty-four hours, dry in air and remain quite sweet.—*Prof. Crace Calvert, Ann. Sc. Assoc.*, 1855, p. 95.

¶¶ Carbolic acid is sufficiently soluble in water for the solution to possess the power of arresting or preventing spontaneous fermentation. Saturated solutions set on animal and vegetable plants a violent poison, though containing only 5 per cent. of the acid.—*Civil Engineer's Journal*, vol. xxii., p. 216.

¶¶ Parasitic and other worms are instantly killed by a

solution containing only 1 per cent. of acid, or by exposure to the air containing a small portion of the acid.

§ By examining the action of a leaf, we find the albumen is coagulated. All animals with a naked skin, and those that live in water, die sooner than those that live in air and have a solid envelope.—*Dr. L. Leimaire, Ann. Sc. Assoc.*, 1855, p. 238.

musem, and show how this rapid destruction is effected.

None of our native timbers are exempt from these inroads. Robert Stephenson, at Bell Rock, between 1814 and 1813,* found that greenheart oak, beef-wood, and bullet-tree were not perforated, and teak but slightly so. Later experiments show that the "jarrah" of the East, also, is not attacked.† The cost of these woods obliges us to resort to artificial protection.

The teredo never perforates below the surface of the sea-bottom, and probably does little injury above low-water mark. Its minute orifice, bored across the grain of the timber, enlarges inwards to the size of the finger, and soon becomes parallel to the fibre. The smooth circular perforation is lined throughout with a thin shell which is sometimes the only material separating the adjacent cells. The borings undoubtedly constitute the animal's food, portions of woody fibre having been found in its body.§ While upon the surface only the projecting siphuncles indicate the presence of the teredo, the wood within may be absolutely honey-combed with tubes from 1 in. to 4 in. in length.

It was naturally supposed that poisoning the timber would poison or drive away the teredo; but Kyan's, and all other processes employing solutions of the salts of metals or alkaline earths, signally failed. This, however, is not surprising. The constant motion of sea-water soon dilutes and washes away the small quantity of soluble poison with which the wood has been injected. If any albuminate of a metallic base still remains in the wood, the poisonous properties of the injection have been destroyed by the combination. Moreover, the lower vertebrates are unaffected by poisons which kill the mammals. Indeed, it is now known that certain of the lower forms of animal life live and even fatten on such deadly agents as arsenic.||

Coatings of paint or pitch are too rapidly worn away by marine action to be of much use; but timber, thoroughly creosoted with ten pounds of dead oil per cubic foot, is perfectly protected against teredo navalis. All recent authorities agree upon this point. In one instance, well authenticated, the mollusk reached the impregnated heart-wood by a hole carelessly made through the injected exterior. The animal pierced the heart-wood in several directions, but turned aside from the creosoted zone.¶ The process and cost of "creosoting" have already been discussed.

A second destroyer of submarine wooden constructions is *Limnoria terebrans* (or *L. perforata*, Leach), a mollusk of the family *Ascolloles*, (Leach), resembling the sow-bag. It pierces the hardest woods with cylindrical, perfectly smooth, winding holes, 1-20th to 1-15th of an inch in diameter, and about two inches deep.** From ligneous matter having been found in its viscera some have concluded that the *Limnoria* feeds on the wood, but since other mollusks of the same genus, *Pholas*, bore and destroy stone-work, the perforation may serve only for the animal's dwelling. The *Limnoria* seems to prefer tender woods, but the hardest do not escape. Greenheart oak is the only known wood which is not speedily destroyed.†† At the harbour of Lowestoft, England, square 14-inch piles were, in three years, eaten down to 4 in. square.‡‡

While all agree that no preparation, if we except dead oil, has repelled the *Limnoria*, an eminent English engineer has cited three cases in which that agent afforded no protection.§§

We do not find that timber impregnated with water-glass has been tested against this enshle foe. The experiment is certainly worthy of a trial.

A mechanical protection is found in thickly studding the surface of the timber with broad-headed iron nails. This method has proved successful.|||| Oxidation rapidly fills the interstices between the heads, and the outside of the timber becomes coated with an impenetrable crust, so that the presence of the nails is hardly necessary.

In conclusion, we cannot but express surprise that so little is known in this country (America)

concerning preservative processes. Their employment seems to excite very little interest, and the very few works where they are being tested attract hardly any attention. Those railroads which have expended their use assign no reasons, and those upon which the timber is injected publish no reports concerning the advantages of their particular methods. Even the National Works, upon which Kyan's process was formerly employed, have laid it aside, and now subject lumber to dampness and alterations of wetness and dryness, without any preparation beyond seasoning. When sleepers cost fifty cents and creosoting thirty cents each, it is cheaper to hire money at 7 per cent., compound interest, than to lay new sleepers at the end of seven years. Allowing any ordinary price for the removal of the old and laying down the new ties, the advantage of using Bethell's process seems evident. If some cheaper method will produce the same effects, the folly of neglecting all means seeking to increase the durability of the material is still more palpable.

H. W. LEWIS.

THE DESIGNS FOR THE LAW COURTS.

The designs have been sent in, and will be hung forthwith. To admit of certain preliminary arrangements they will not be open to view till next month; probably on Friday and Saturday, the 8th and 9th of February, for private view by members of the Government, peers, members of the House of Commons, judges of the Superior Courts, foreign ambassadors, and other distinguished persons. After the first two days the exhibition will be open for four weeks, i.e., as at present arranged, till Saturday, the 9th of March. On Mondays, Tuesdays, and Wednesdays, the Commissioners and their officers, the legal and architectural professions, and to artists. On Thursdays, to the public—by cards obtainable at the office of the Commission. Fridays will be reserved for the special work of the Commission; and Saturdays for members of the Government and members of both Houses of Parliament.

We understand that the cost of the shed in New-square for the exhibition of the designs has been exaggerated. Including furniture and matting, it amounts to about 1,120.

Previously to any decision on the designs, the Architectural Clerks to examine them and report as to how far the instructions have been attended to, and on the comparative merits of the plans with reference to other matters ascertainable by calculation. In this, we believe, Mr. Geo. Pownall and Mr. John Shaw, architects, will assist.

We have received letters from the provinces begging that efforts may be made to keep open the Exhibition of the National Gallery designs till those for the Law Courts can be seen, or, at any rate, till nearer this time than the 26th inst., now spoken of for closing it; so that architects and others from the country may be able to see both without sacrificing nearly three weeks.

DUBLIN.

A CONSIDERABLE addition has been made at 74, Grafton-street, Dublin, enclosing with the front house a court in the centre, like several of the dwellings in Paris. The arches of the windows are varied on each story, and are surmounted by hood mouldings and fascias which are continued on the front. A tank has been built of brick and cement, to hold a large quantity of water, to flush and cleanse the drains; and care has been taken to prevent damp in the foundation-walls. Mr. Oliver Healy, of Dublin, was the architect; and Mr. Peter Casserly, the contractor.

BUILDING OPERATIONS, DURHAM.

At the Quarter Sessions, held on the 2nd instant, the magistrates agreed to expend the sum of 5,000l. in remodelling the Assize Courts, from plans prepared by the county architect, Mr. William Crozier, assimilating the internal arrangements and ventilation of the courts to the Manchester Assize Courts. The county architect has the following works in course of construction, viz.—a new men's wing, containing 126 cells, &c., at the county prison, Durham; Mr. D. S. Appleby, contractor; cost, 7,000l. At

Darlington the same contractor is building a new county police station and courts; amount of contract, 3,000l. At Castle Eden is also being built a new police station and courts, at a cost of 1,200l.; and at Ryhope and Washington villages, second-class police stations and cells, at a cost of 450l. each. Plans are also in course of preparation for two new wings to the Sedgfield Lunatic Asylum, for 320 patients, at an estimated cost of 10,000l. Mr. Crozier has charge of all these works, and has designed and carried out during the last seven years for the county upwards of 50,000l. worth of work, consisting of additions to the gaol, lunatic asylum, police stations and courts, and three large militia barracks at Hartlepool, Barnard Castle, and Durham respectively. The magistrates at their last meeting increased his salary 100l. per annum, besides presenting him with 400l. for past extra services.

THE TRADES MOVEMENT.

A SOCIETY, we hear, is in course of formation, having for its object the succour and protection of those members of the working classes who disagree with the tenets held by the trades unions. The society has already received large promises of support, and several eminent manufacturers have consented to sit upon the committee.

Leamington.—A meeting of the Master Builders' Association has been held to further consider the application of the operatives for an increase of 3s. per week in their wages, raising the amount to 30s. It was decided that the present condition of the building trade in Leamington would not justify a compliance with their request.

Liverpool.—Half the shipjoiners on board the *Great Eastern*, those employed by Messrs. Jones, Quiggin, & Co., have struck for an advance of wages from 5s. 6d. per day and 1s. a day river money, to 6s. a day and 1s. river money, as paid to the other half of the men by Messrs. W. H. Potter & Co. The men on strike are paid full wages by the society of joiners while they remain idle.

Carlisle.—The strike among the stonemasons which has been going on for so many months is nominally continued; but virtually it may be said to be at an end. The builders, while persistently refusing to accede to the regulations which the society sought to impose, as to the apprentices and other matters, have conceded the advance of wages 2s., and the local *Journal* states that all the masters have now as many men as they require. The new bank at the top of Bothenigate is making much more rapid progress, there being now about a dozen masons employed upon the work, in addition to the apprentices. After they decided to give the masons an advance of 2s. a week, the masters sent word to the bricklayers that in the summer the same advance would be given to them. With this, however, the bricklayers are not, it is said, content, and they have asked for an increase of 4s. instead of the 2s. offered.—The master joiners of this city dined together at the Lion and Lamb Hotel on Wednesday evening before last.

Lancashire.—The strike of operatives in Lancashire has come to an abrupt termination, and the men, 5,000 in number at Darwen alone, who refused to proceed to work on the reduced terms, have intimated their intention to return to their employment. Similar decisions have been arrived at by the operatives in other towns where a dispute was anticipated.

DISTRIBUTION OF THE PRIZES OF THE ISLINGTON EXHIBITION.

On Saturday afternoon the ceremony of distributing the prizes won at the Metropolitan and Provincial Working Classes' Industrial Exhibition, at the Agricultural Hall, Islington, took place at Exeter Hall. Mr. G. J. Goschen, M.P., presided. A pretty pamphlet, forming a record of the exhibition from its opening to its closing, was presented to every person who attended the ceremony. The awards numbered altogether 461, of which 55 were silver medals, 187 bronze medals, and 189 certificates of honourable mention. In addition to these, which were one and all got up with taste and appropriateness, a framed view of the late Exhibition had been prepared for presentation to every one of the 1,500 exhibitors. There

were, besides, the special prizes, which amounted to 57.

In addition to the silver medal, the highest of the prizes, which was the sum of 100, the gift of the directors of the Agricultural Hall Company, was carried off by Mr. H. A. Major, a letter-carrier, for the best painting in oil in the exhibition. Mr. Dockree, of the civil service, was the successful competitor for the second best oil painting, the gift of Mr. C. Comfort, director of the Agricultural Hall. Miss Alice Haselden, aged 17, in addition to the silver medal, received a prize of 50, the gift of Mr. J. Harris, for the best water-colour drawing in the exhibition. In addition to silver medals two silver cups were awarded to A. M. Franklin, smith, of Bedford, for his model plough, this prize being given by the Messrs. Howard, the agricultural steam-engine manufacturers, of Bedford. A cup to Mr. W. H. Myers, printer, was for an invention in railway signals. Two bronze medals were awarded to Mr. E. J. Broughton, printer's reader of the *Bell's Life and Observer* office, for a bouquet of flowers made of wafers, and a carving in limewood. At the conclusion of the prize presentation, which occupied upwards of an hour, the framed and glazed representations of the opening ceremony were presented to the rest of the exhibitors,—1,200 or 1,400 in number, by the chairman. At the conclusion of this lengthy and trying proceeding,

Mr. Beresford Hope addressed the assembly on the intimate connexion of labour with art. A table, he said, was in a certain sense as much connected with art as the painting of a picture. For a handicraftsman to despise art was to despise the means of making the most of the labour of his hands. There had been too much of the idea that workmanship was one thing and art another—that the workshop was the solid, practical thing, and that art was merely something pretty and beautiful—that the workmanship was the week-day clothes and that art was the Sunday. This was all a mistake—a fallacy. He contended that art meant good work, and that all good work was art.

THE ACCIDENT ON THE METROPOLITAN RAILWAY.

SIR,—In the transit and removal of heavy loads, every precaution suggested by an intelligent foresight, and tending to diminish the risk of accidents, should undoubtedly be adopted. It is deeply to be deplored that in this painful case no such foresight was exercised, and, consequently, no such precautions taken as might have averted the untoward disaster which resulted from so unfortunate a combination of circumstances. But it sometimes so falls out, that accidents and casualties will happen, in spite of all the studied plans and skilful arrangements which the mature experience of able men may devise. Unfortunately, in the case before us, even this plea cannot be urged in favour of those to whom the work of removal was intrusted, as not even the most ordinary care was taken to ward off and prevent the catastrophe which ensued, in consequence of such egregious neglect. At the same time, however, I am firmly convinced that it is quite within the range of possibility for the accident to have arisen in such a manner as, if proved, would go far to exonerate these men from the most serious charge of deliberate carelessness, and resolve it into one of want of judgment.

In your last week's impression may be found the following passage:—"It appears that no arrangement whatever existed for staying proceedings while a train was passing below, although the steam of the engine prevented the workmen from even seeing what they were about at the moment."

It is upon a careful perusal of this sentence that my opinion is based, the which I will endeavour to demonstrate as intelligibly as possible.

It appears from the evidence that it was found necessary to haul the girder one or two feet in order to bring it to its intended destination, and which might in the ordinary course of things have been done without any serious risk. Whilst this operation satisfactorily progressed the approach of a train was announced. According to superior orders signals were immediately transmitted to stop the engine. This was at once accomplished, but the immense tension on the connecting rope, generated by the traction of the engine and resistance of the load, un-

avoidably remained. Now, from this it occurs to me that the steam from the passing locomotive coming in contact with the rope, already strained to a very great degree, caused its contraction, thereby still more increasing its attractive tendency upon the girder. At the same time, the vapour of water impinging upon the latter acted as a lubricant, consequently diminishing the friction developed by the insistent pressure of the girder in question. It resulted from this aggregation of contingencies, in conjunction with the vibration caused by the moving vehicles, that the increased tension of the rope, and the decreased resistance of the girder, allured it beyond the insufficient margin allowed for safety, and caused it to cant over and topple into the cutting below, where the ill-fated train at that moment happened to be. The consideration of the fact that the girder descended after the primary portion of the train had passed, still strongly imbues my mind with the truth of the theory above enunciated; as, according to the doctrine of probabilities, there is more reason to conclude that it would have fallen either just previous to the arrival or subsequent to the departure of the line of carriages.

All the refused argument and cunning ratiocination in the world will not, however, extenuate censure of the executive for the lack of caution displayed in not employing some means to check the girder in case its progress should become too rapid, as actually occurred.

In conclusion, sir, I think you must concur with me that overhead work of this description ought not to be attempted during the regular traffic, unless, indeed, the intervals of time between the trains are rather considerable; so that no work should take place within, at least, a quarter of an hour of the arrival of each, in order that there might be ample time to give warning to the guard of the expected train in case of accident.

S. W. WORSSAM, JUN.

WATER-PIPES IN HOSPITALS.

SIR,—I wish to draw the attention of builders and architects to the condition of the lead-piping in hospitals during the late cold weather.

I have just visited Yorkshire and Lancashire, where I saw some very fine recently constructed buildings. There were hardly any of them where the supply of water had not been partly interrupted. Lavatories and water-closets were in a lamentable condition for a day or two, the water being frozen up in the piping. I know quite well that the piping can and ought to be protected against the cold by covering or wrapping it up with hemp, flannel, or cloth; but could not greater care be taken of the pipes when the hospitals are constructed? The mischief done in private houses is bad enough, but in hospitals matters are worse. In those hospitals which are now in course of construction I hope better care will be taken to prevent freezing and leakage of the water-piping in cold weather. It must be simple enough to provide for it by properly placing and casing the pipes.

F. OPPERT, M.D.

THE REMOVAL OF SNOW.

As a heavy fall of snow in London streets causes not only considerable inconvenience, but serious expense and loss to the inhabitants, it is necessary that means should be provided for clearing the streets of the snow as it falls, or as soon after it has done falling as possible. This, it should be, the duty of the local Boards and vestries, in whose care the streets are placed. The plan of carting away the snow to the Thames, or elsewhere, is far too slow and too expensive; I would, therefore, with your permission, propose a different scheme, as follows:—

Let snow-shafts be formed by the sides of the main sewers, from 200 ft. to 400 ft. apart, with water-tight tanks at bottom, and overflow doors discharging into the sewers. Let also moveable horizontal gratings be placed in the shafts, and strong roughed iron covers fixed flush with the streets. And near each shaft let a stand-pipe be set up, with screw nozzle, in which a length of hose, with a fan-spreader, may be screwed.

Immediately a heavy fall of snow occurs, let the officers of the Local Board and vestries collect a sufficient number of men, dust, slop, and rubbish carts, trucks and barrows, shovels and scrapers, and other appliances, and set them to

work in the chief thoroughfares; some to open the snow-scaff covers and screw on the hose; some to scraft the snow into heaps; some to shovel it into the carts, or trucks, or barrows; some to tip and shovel it down the shafts, and direct streams of water on it by means of the hose, and some to assist the discharge into and along the sewers. The snow, if only partly melted, as washed into the sewers, would soon melt there, as the temperature of the sewage and the sewer air ranges from 70 deg. to 80 deg.; and the strong currents of water in the sewers would carry it away.

It is evident that, by this method, the chief streets of traffic could be not only quickly, but economically, cleared of the snow; and, in conclusion, I would observe, that at many places the gullies themselves might be used as snow-shafts, the snow being washed down them by the hose.

JOHN PHILLIPS.

SINCE the above was in type we have received a communication from Mr. George Jennings (Stangate) suggesting that for the future any snow that may impede thoroughfares should be melted in chambers formed in accessible places, and warmed by hot-water pipes or melted over gullies in central situations by jets of steam from portable engines hired for the occasion.

HABITATIONS FOR THE METROPOLITAN POOR.

SIR,—I have read with great interest a report of the deputation to Lord Derby on this subject. It appears to me that some of the difficulties of legislating on the subject would be obviated if the Bill contained a preliminary clause providing "that upon any dwelling being judicially condemned, the owner should be compelled to pull it down, and then have liberty to rebuild it, conformably to the 'Act,' or failing that, then that he should be compelled to sell the land to the local authorities, who should be authorised and compelled to buy the site, the value to be fixed by mutual agreement, or by arbitration;"—the distinction being, between buying what the landlord calls a dwelling-house, and what the judicial condemnors of it consider a vacant plot of ground,—a much more (as I conceive) equitable view of the matter.

JUSTINA.

RECORDS OF OUR BUILDINGS.

SIR,—Can there be anything more absurd and eccentric than the usual practice of hermetically sealing up written documents and coins of the realm under the foundation or corner stone of our buildings? secreting invaluable information for centuries, perhaps for ever, from the anxious inquirers that shall come after us, when a grand pile erected in this and subsequent periods, from age, may become a tottering ruin, with its walls here and there supported against the storm by the turning ivy, similar to many once noble buildings which have now almost vanished from us, and from the remains of which writers assume their date.

It seems to be very desirable and important that records should be carefully written, preserved, and handed down to the rising generation. Let them be written with an iron tool on polished granite, built on the inside of the edifice during the progress of the work, with its plan, section, and elevation laid down to scale engraved thereon, so that its history shall be read at a glance; and let those engaged in executing a noble work, in an age of advancement like the present, be it a cathedral, town-hall, mansion, or cottage, like the Assyrians of old, delineate on stone their handy works, which shall be read by all people and for all time.

ONWARDS.

AN ARCHITECT'S STUDIES.

SIR,—At the last meeting of the Architectural Association, something was said of the course of study which students should pursue; several books were mentioned, the names of which I did not catch.

Many of us students have not parents who can afford to give them that long and expensive education which we should like,—and perhaps ought,—to have; and we should be most thank-

ful if you, and any other member of the profession who has fought through his freshmanhip, would give us some advice as to what looks to read, and in what order; what style to begin with, and how to progress; what places in England and abroad to visit, and how to go to work in the cheapest and most profitable manner; what courses of lectures they think necessary and best; and so on.

To study with system is the best—the only way to succeed in anything; and in a profession demanding so much and such varied study as ours a system is most necessary if we ever mean to get on. That we read the right books, that we study the right subjects and in their right order, is very necessary, and therefore we shall be much obliged by suggestions. We all have our own masters, whose advice we shall always be anxious to receive; but I venture to believe that “in the multitude of counsellors there is safety,” and therefore hope that many architects will come forward to aid the rising generation.

BEGINNER.

THE DATE OF THE DEATH OF EDWARD NORGATE, THE ILLUMINATOR AND HERALD.

ALLOW me to thank my kind friend, Mr. Peter Cunningham, for his information respecting the will of Edward Norgate, the Clerk of the Signet, Herald, Illuminator of Royal Letters, and Manager of Royal Organs, in the time of Charles I.

Norgate is accused of having written a Tractate on Limning, which remains in manuscript at Oxford, after he was dead,—an unusual offence, the evidence of which lies of course in the proof of two facts; first, when he died; and, secondly, when the Tractate was written. Mr. Cunningham has established that Norgate was alive in 1649, and that he was dead in 1651. I make no doubt, therefore, that the date which Noble has given to his burial,—the 23rd of December, 1650,—will turn out to be correct. But nobody believes Noble, and therefore it was that I wished that the date given by him should be verified. Mr. Cunningham has partly done this in his very interesting letter; and if inquiries which I am making at Oxford should prove that the Tractate on Limning really was written by an Edward Norgate, and several years after the entry of the herald's will at Doctors' Commons, as given by Mr. Cunningham, all we can then say is, either that Norgate was guilty of the offence I have alluded to, or that the Tractate was written by some other person of that name, of whom hitherto we have known nothing,—perhaps by that very son of the herald whom Mr. Cunningham has brought to light, and who was his father's “greatest trouble.”

An enrolment of the warrant which I communicated to *Notes and Queries*, proves that “*chaîne organ*” should have been “*chaire*,” that is, “*choir organ*.” JOHN BRUCE.

MASTERS AND MEN.

A CORRESPONDENT writes,—On the evening of Friday, the 11th inst., a trades-union meeting, interesting in comparison with the general attitude assumed between masters and men, took place at Crown Works, South Lambeth, the new premises of Mr. William Higgs, builder. About 600 men, wives, and children were entertained, and a testimonial, in shape of a timepiece, was presented to Mr. Higgs, as a mark of respect and esteem, from his clerks and foremen, and a few of his oldest hands. Various speeches were made, and the Rev. C. H. Spurgeon afterwards gave his lecture, entitled “*Sermons in Candles*.”

LOCAL BOARDS AND SURVEYORS.

Sir,—The conduct of the Local Board of Health at Kingston-on-Thames, with regard to the election of their surveyor, will certainly, when made known, be a caution to gentlemen who seek such appointments as that of corporation engineer or surveyor. Some short time since the corporation of Kingston advertised for a “gentleman” of proper qualification, to fill the office of surveyor, and the result was no less than 127 applications. These applications and testimonials the Board went through the bore of referring to a committee for examination, and their conclusion was to invite the personal attendance of ten of, as the committee supposed, the best qualified gentlemen. What actually transpired relative to these gentlemen I know not, but at the last meeting of the Local Board, it was proposed and passed without any substantial dissent, that the person holding the office of collector should receive the extra amount of 20*l.* per annum for undertaking, in addition to his other duties, the functions of town surveyor.

Now, no one can doubt that out of so many applicants, at least one could have been found eligible for the appointment, and the treatable conclusion is that there was no intention whatever to elect the best qualified of the candidates. ONE OF THE “GENTLEMEN.”

TENANTS' COMPENSATION.

A CORRESPONDENT of the *Star* calls attention to the manner in which the Metropolitan Board of Works are endeavouring to obtain possession of the various properties required under their Parliamentary powers. Being extensively engaged in conducting claims for compensations, he states his attention has been directed to this subject, owing to some clients—yearly tenants—on the line of the proposed new street to the Mansion House having been served with a six months' notice to quit by the Board of Works, who have purchased the landlords' interest. The case of one of them is a very hard one. He is a man who for many years has been labouring to establish a business, and has been at a considerable expense in adapting the premises, and his removal will entirely destroy his prospects. Yet the only answer received to an application requesting an appointment to consider his claim is “that the notice was given in due course, and vacant possession will be required when such notice has run out.”

This is a question affecting some thousands of tradesmen and others who are subject to compulsory removal for the various railways and other public works in and around the metropolis, and it is to be hoped that some of our popular representatives will ventilate the subject on the re-opening of Parliament.

LIGHTING OF CHURCHES.

Sir,—I should like to see this subject treated in your journal. The mode of lighting one large room (whatever be its size), is simple enough, viz.—by a series of candles, symmetrically placed; but where the building consists of several compartments, if they may be called so,—as, for example, in the case of a church with chancel, nave, aisles, and west tower,—the question is not so easily solved: at any rate, architects propose plans which are open to obvious objections. J. E.

DEFECTIVE SLATING.

Sir,—Can any of your correspondents advise as to any mode of treating slates from the outside to prevent the snow from drifting under the courses where it is impracticable to get at the underside to “torch” them, the rafters being ceiled on the inside? A VICTIM.

THE NATIONAL GALLERY.

Sir,—There are merits in the present building of the National Gallery. These words in your last number cannot be too well remembered, nor too largely insisted upon. It is most gratifying to see a man where they stand. Wilkins could not have designed a bad building, or one inappropriate to its situation. Whatever the present architectural shortcomings was not due to any want of capacity in the architect, but to a failure of the funds for finishing it as intended. The National Gallery has never yet received its proper completion. If I mistake not, when first we got it to the public, say nothing of the profession, were pleased with it; and, on one occasion, at least, the word *splendid* was applied to it. The nation did not discover that it was undervaluing of its position and purpose, though the brick which lay upon the facade, that it was utterly unworthy of a National Gallery. There was a trick devised by the enemy for a special purpose. There was nothing then said of pulling it down, but that was foreign to the intent, and would have defeated the object in view, which was that the Royal Academy might obtain the whole of it. Subsequently, however, the cry of “Down with it! down with it!” was set up by those who were convinced, like John Kuer in the olden time, that the only way to get rid of the rocks was to pull down their nests. It is devoutly to be hoped that the gentlemen rooks will go away quietly, without bringing the whole building about their ears. It would be a wicked folly to demolish the National Gallery for being somewhat unfinished, and before we have given it a trial, simply because an interested party has decided it down, and foolish multitude has followed them.

Besides the serious objections to such a vandalism, which must suggest themselves to every one who considers the subject, there are positive reasons for letting it remain, some few alterations and additions being made to the frontage, and extra galleries provided as circumstances may require.

The building, though still in its juvenile days, has already become historical; we like to see its less familiar face, and most of us have invested more or less of our affections in it. It suits the situation admirably, and is in harmony with its surroundings. There are points of view in which it is seen to much advantage. In effect, looking from Pall-mall East, with Gibb's church beyond, forms an architectural vista scarcely surpassed by any edifice in London. The merits of a building, deduced by the new designs now on view, tends greatly to confirm the desirability of retaining what we have got.

These new designs, no doubt, display a vast amount of talent, taste, and imagination. The merits of some may justly be described as *stupendous*: at the same time they must be confessed, that however some may be suited to the situation, others are decidedly not. There is such a requirement in architects as propriety, which may be termed, not essentially architectural, help to make up. A due deference should be shown to the *dilecti*. A dream of St. Mark's, with its companion campanile, is not exactly

the sort of thing to set down in the *grande place*, the capital, so to speak, of our British metropolis. Neither do we desire, in these days of progress, to be carried even in imagination, back to Mediaeval London, with all its associations. In looking at these new designs, it is not difficult, methinks, to point out some of their sources of inspiration. The unimpaired public can find out, well enough, likenesses to St. Paul's and the Bank. The Baptistery at Pisa, certain buildings at Bologna, the Lombard architecture of Northern Italy, and the new gallery at Dresden, would seem to have suggested various features; while other inspirations appear to have been derived from nearer home, from Paris, with its Pantheon, its Luxembourg, its Louvre, and Le Val de Grace. Admirable as all these may be, showing what may be done, at least upon paper, there are other designs which we shall get just what we want,—an elegant and the best building in London might easily be restored to favour made one of the greatest ornaments to our metropolis. A tenth part, or less, of the decorations bestowed on some of these new designs would make it *splendid*, after all. We have only to remove the “pepper-boxes,” and replace them with such ornamental structure as heartily, the domes in the centre, as suggested by another set of designs. With these, and a generous, though not extravagant, distribution of figures, bassi-reliefs, and urns, with our own most, had been raised in the previous one; and we shall then have made the laughing-stock of Europe, as if we were little children, who never knew what we wanted. H. C. BARLOW, M.D.

MORE KITCHEN-BOILER ACCIDENTS IN THE NORTH.

AN inquest has been recently held at Preston on the body of a woman named Shaw. The deceased lived in Back Sydney-street, and on the previous day she went to clean the cellar kitchen of an unoccupied house in Stanley-place. She set a fire in the grate, and some time afterwards the kitchen boiler exploded with a loud noise. She was badly scalded, and had one of her legs broken. A police officer and others conveyed her to the House of Recovery, where she died in a few hours. The boiler which exploded was constructed on the self-feeding principle, and it is supposed that the pipes had got closed up through the frost. A verdict of “Accidental death” was returned.—A sad accident has also occurred at Alton Albany mansion-house, Ayr. In consequence of the intense frost, the water froze in the pipe leading up to a cistern connected with a kitchen boiler, and hot water could not be got. In ignorance of the danger the fire was lighted, steam was generated in the boiler, and a sudden explosion took place. A boy was blown against the opposite wall, and killed on the spot; two other children who were in the kitchen were severely scalded; and the mother of the children (a coachman's wife) was also much injured. Part of the boiler was projected, as from a cannon, through the retaining wall, about 30 ft. into the library.—We must again warn our readers of the risk attendant on the careless use of kitchen boilers at this season.

METROPOLITAN BOARD OF WORKS.

At the last weekly meeting, eleven tenders were received and opened for the construction of works required for the diversion of the Limekiln Dock, and Blackwall sewers, High-street, &c. A committee of the whole Board, after examination of the tenders, recommended that the tender of Mr. Webster for 20,000*l.* should be accepted, subject to the usual inquiries.

On the motion for the adoption of the report being made, an amendment was moved that the tender of Mr. Ritson for 18,500*l.* should be accepted.

For the amendment.....	5
Against.....	22
Majority against the amendment....	17

The report was adopted, and the tender of Mr. Webster accordingly accepted on the usual terms.

SKATERS' FOLLIES.—Something must be done to “pat down” suicide by skating. Persons should not be allowed to distress their friends and otherwise derange the relationships of society, sometimes paperizing their families and throwing the burden of them on the public, by their own destruction through an insane and unreasoning love of sliding along. It should be made a criminal offence to go on to public ice certified to be unsafe. The fear of three months with hard labour might deter many who would not be kept off by the chance of losing their life.

THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held on Friday evening, the 4th inst., at the House, in Conduit-street, the president, Mr. R. W. Edis, in the chair.*

Mr. Lucy W. Ridge read a paper "On the Influence which the Architecture of the Past should have at the Present Time." Having remarked upon the persistent manner in which we constantly recur to the past for copies until, in the nineteenth century, a heathen temple (the Parthenon), no bigger than the church of St. Martin's-in-the-Fields, was still regarded as the model of art, and glanced at the works of Inigo Jones, Sir Christopher Wren, Chambers, and others, Mr. Ridge commented upon the marvellous change which the genius of Pugin had wrought in the public taste, and the impetus which he had given to Gothic art; and observed that, in his opinion, one of the great evils of the present day was, that architects looked too much to the examples of the past without reference to the materials with which they had to deal. He recommended the students of architecture to endeavour to rise above the level of mere copyists of ancient works; and, instead of going back to the remote antiquity of Greece and Rome, to study the architecture of the North-west of Europe from the eleventh to the thirteenth century. The propositions which he ventured to submit as a solution of the problem involved in the question which he had raised, were—first, that the architecture of the past ought not to influence the plan and arrangement of our buildings; secondly, that the architecture of the past ought not to influence the construction of our buildings, when inconsistent with the materials of the present; thirdly, that the architecture of the past ought not to influence the mode of executing architectural details so as to interfere with their usefulness; fourthly, that the architecture of all good styles should have great influence in educating the mind of the architect in outline proportion, and all the principles of design; and, fifthly, that the details of our buildings should be in accordance with the style in which the architect works, although the general inspiration be drawn from another style.

Mr. Blashill having expressed approval of much that had fallen from Mr. Ridge, remarked that he did not think blame could fairly attach to architects who might have two important works in totally different styles going on at the same time; because, although an architect might have a speciality for Classic as against Gothic, or for Gothic as against Classic, he would not be justified in refusing a commission for that one which might happen not to be his favourite study. The success of the great monuments of art bequeathed to us by our ancestors of monastic times, was, no doubt, to be attributed to two causes. The first, that the monks thoroughly understood good architecture; and the second, that they were not controlled in the matter of time and expenditure by clients. The only way, in his opinion, to get a new style, would be to avoid servile copies of the past, and to take a thoroughly practical view of the work which they were actually engaged to carry out.

Mr. Phené Spiers thought that the great evils of the present day were that students of architecture did not study from old works, but from those of their masters, or of professors; that they were more inclined to design than to obtain a thorough knowledge of construction; and that they looked out too soon for remuneration for their work before they gave themselves time to study. He would be glad to see a system introduced into England similar to that which prevailed on the Continent, namely, that the student should begin by a careful examination of the best examples of the old masters. He would commence with the study of Classic architecture, so as to ascertain the principles upon which the old masters worked. After that he would begin Gothic, and take for his special study the Early English style, than which no better examples could be found than in our magnificent cathedrals. After this he would begin to design, always bearing in mind that he would have to adapt his designs to the requirements of the present day. One of the great difficulties with which the architects of the present day had to combat was the improvement which time and progress might develop. Now, however, no matter what might be the magnitude of the work, the architect was bound down by irrevocable contracts, which shut him out from those advantages which his predecessors in older times were enabled to enjoy. As an illustration, he might state that he believed Mr. Woodward had scarcely got his new building at Oxford 2 ft. above the ground, before he wished heartily to be able to remodel the whole of it.

* The following gentlemen were elected members of the Association: Mr. Chas. Moran, Mr. Williams, Mr. H. Sedall, Mr. Trenchard, Mr. Bainbridge, Mr. H. Jackson, Mr. Sear, and Mr. Parkon.

After some discussion, in which Mr. Potter, Mr. Tarver, and other gentlemen took part, The Chairman, in putting a vote of thanks to Mr. Ridge, observed that he thought too much had been said and written about the absolute necessity of copying old examples. He saw no more reason why we should do so in respect to architecture than that we should go back to the very primitive attire of the earliest period, and take to fig-leaves and bear-skins as items of apparel. The study of the works of ancient times was valuable, no doubt, in an educational sense, but he deprecated that sort of professional instruction which led to servile copies instead of original ideas. Neither could he agree with those who held that "Gothic men" were higher in the scale of fame than "Classic men." The object of education and travel was to enlarge the mind and expand the intellect, to imbibe original inspiration, and not to copy, but to emulate the greatness of those who had gone before us. With regard to the paper read by Mr. Ridge, he considered that gentleman was entitled to credit for having grappled with a subject which other members of the Association had hesitated to undertake, even for a prize.

Books Received.

VARIORUM.

"The Prince of the Fair Family," by Mrs. S. C. Hall, published by Chapman & Hall, is a charming quaint story, told with all the author's usual grace and purity of feeling. It will interest and delight others besides the little people to whom it is more especially addressed. The greater number of the illustrations are by the veteran Kenny Meadows, whose hand (we might say, literally, for that important member is a favourite object of illustration with him), appears throughout the book, and Mr. Walter Allen. Mr. and Mrs. E. M. Ward, and Mr. Noel Paton also cooperate effectively; and the result is a book that may be most safely recommended.—The "Emblems" of Francis Quarles gives pleasure to only a certain number of persons, but no one can dip into it without profit, and few books of its class have been more often reprinted or imitated. None of his imitators have equalled him, much less surpassed him. The new edition, published by Tegg, "Emblems Divino and Moral," is well got up, and soundly bound, and will doubtless command the same steady sale that has followed other issues of the Hieroglyphics of the Life of Man.

Miscellaneous.

RIVER STEAMERS CUTTING THROUGH SANDBANKS.—It is said that a Prussian engineer has made an invention by which steamers on rivers can cut through or cast aside sandbanks. The invention is not described; but if it does what is said, it will be very useful in many countries, especially on the Continent, where rivers navigated by steamers are frequently obstructed with sandbanks. Might not a machine for deepening rivers be constructed upon some such principle?

"THE PARLOUR STEAM-ENGINE."—The toy issued under this title by the Stereoscopic Company is calculated to be very serviceable to boys and girls, and may be made the means of conveying to them knowledge as to the rarefaction of air by heat, the pressure of air, centrifugal force, and other scientific phenomena. Moreover, it pleases while it instructs. Although from its name some may expect to find the little machine in a different shape from what it has, it is in truth a reproduction of the first known engine in which motion was produced by steam, that of Hero, invented, if we remember rightly, some 400 years before the Christian era. We do not observe that this has elsewhere been pointed out.

THE NEW OIL TRADE OF NORTH STAFFORDSHIRE.—A new and very extensive field of industry has recently been opened up in North Staffordshire, under Young's process for extracting oil from canal coal, the common shale of North Staffordshire possessing similar properties. This shale abounds in millions of tons near the North Staffordshire ironstone seams, and has hitherto been considered as worthless refuse, a premium having been frequently paid by colliery proprietors for its removal. Young's patent has expired, and nearly 100 tons of crude oil are now being produced every week within a short distance from Burslem and Tunstall, though, as compared with its future magnitude, the trade can scarcely be said to have begun. Refining works have been opened. They have been built at a cost of 12,000l., midway between the Burslem and Tunstall stations.

EFFECT OF COLD.—The Registrar General's return says,—The effects of the cold are now visible in the returns, for instead of 1,436, and 1,437 deaths, as in the two preceding weeks, there appear on the registers of last week 1,891 deaths. The change of temperature has killed about 455 people in London. Few were directly frozen to death; the majority having vital force enough to struggle against the freezing cold, but not enough to prevent them from succumbing under bronchitis and other affections.

MAKING AND TAKING.—Recently, commenting on an assertion that the iron-trade was leaving us, the *Examiner* quoted, against such a belief, a statement of facts as from the *Mining Journal*. Thereupon the *Birmingham Daily Post* remarked,—The quotation here given as from the *Mining Journal* was taken by that paper from our own leading columns, word for word, without acknowledgment." On which, down comes the *Iron Trade Circular* with,—The editor of the *Birmingham Daily Post* has omitted to mention that he took his facts and figures from us, and we may as well say that ours were supplied to us by the *Economist*. Something of the same kind has happened with a paragraph of our own, as to the importation of joiners' work from abroad, with which paragraph, quoted by the way, as "from a London paper," the walls of two or three provincial towns, we are told, are now plastered.

VICTORIA STATION AND PIMLICO RAILWAY COMPANY.—The report read at the ordinary half-yearly meeting of this company stated that the revenue account for the six months ending December 31, admits of the payment of the same dividend as that of last half-year—namely, 3½ per cent., or at the rate of 7½ per cent. per annum; and that the very large outlay recently incurred by the Brighton, Great Western, and London, Chatham, and Dover Companies, in making the new approaches to the Victoria Station, both north and south of the Thames, and in widening the bridge, and the approaching connexion of the Victoria Station with a station of the Metropolitan District Railway, are calculated to place the maximum aggregate rental of 33,125l. (which commences on and from the 1st of April next) in the highest class of freehold ground-rents. The report was adopted, and a dividend of 3½ per cent. for the half-year declared.

A ROMANCE OF THE NEW YORK SEWERS.—A strange story of "untold treasures" having been found by a young girl and two companions in the New York sewers, is related by a correspondent of an American paper. The result of a week's search is roughly estimated at 1,500,000 dollars, in realizable value, of jewelry and other treasures. "A bushel" of jewelry contained diamond rings worth some thousands of dollars each. One plain gold ring was inscribed in Dutch,—Peter Shnyvesant to his Wife." Altogether, however, the story has an air of improbability about it; and if it were true, the New York sewers must be managed in a totally different way from those of London. "Miss Walker (who took the hint from an old newspaper) and her brother, who find themselves thus lifted suddenly from penury to great wealth, intend to proceed to England, where they have relatives," and where they will no doubt visit the London sewers, and report wonderful progress in the New York papers!

THE ART STUDIO OF MESSRS. RANDEL, JEWELLERS, BIRMINGHAM.—Nearly a year ago we recorded the praise-worthy example set by Messrs. Randel, goldsmiths and jewellers, Victoria-street, Birmingham, in erecting a spacious and well-appointed studio for the promotion of gratuitous art-education amongst their workmen and apprentices. The result, it appears, is a decided success. The whole scheme has been organized and superintended by Mr. J. J. Allen, sculptor, who is the designer and superintendent of art-works to the firm. Prizes, consisting of books (given by the editor of the *Art-Journal*), colour boxes, and other appropriate articles, were lately distributed to the most deserving of the pupils, whose art-works were exhibited at a meeting for the purpose, attended by a considerable number of workpeople and other invited guests, who partook of a cold collation in the studio. Mr. Randel presided, and the mayor and various other gentlemen interested in art were present. The average attendance at the school is about forty-five nightly for two nights weekly. The firm compel every apprentice to learn drawing on the work

STEAM IN VENICE.—It is proposed to organize a service of steam gondolas on the canals of Venice. The lovers of the picturesque think this a desecration, and the gondoliers are equally indignant, from less disinterested motives.

MUSEUM OF PRACTICAL GEOLOGY.—This museum has been lighted up at night, and the Lords of the Committee of Council on Education have ordered that in future the museum shall be open to the public on the evenings of Monday and Saturday in every week. The throwing open for the inspection of the working people of the metropolis of an interesting and instructive museum such as this, at the only time at their disposal, is a boon which, when properly known, will, no doubt, be extensively availed of.

COAL IN SHROPSHIRE.—The works in connexion with the sinking of a pair of shafts in the reputed dead ground at Prior's Lee, the successful issue of which has opened up a new coal-field, are now complete, the miners having reached the "clod coal," the ultimate stratum of the bed. The original estimate of the yield from this mine is fully confirmed by the working, and it is computed to contain upwards of 10,000,000 tons of coal. The shafts have been named the Granville Pits, in compliment to Earl Granville, one of the principal partners in the Lilleshall Company, who are working the mine.

DISCUSSIONS AT THE SOCIETY OF ARTS.—The council have decided to set apart the first Wednesday in each month, during the present session, for the discussion of various questions connected with Arts, Manufactures, and Commerce: these discussions may commence either with or without the reading of a paper. On the evening of Wednesday, the 6th of February, Mr. Henry Cole, C.B., will introduce the following subject:—

"On the existing legal regulations in reference to the Cab Fares in the Metropolis, and their effect in rendering the Vehicles inferior to those provided in other European Capitals and the large Municipal Towns of this Country."

THE RAILING ROUND ST. PAUL'S.—The Commissioners of Sewers have recently appointed a deputation to wait on the Dean of St. Paul's, for the purpose of endeavouring to have the railing of the churchyard set back, so as to widen the thoroughfare surrounding the cathedral, and a correspondent thinks the present a favourable time to suggest the removal of the railing altogether. He does not seem to be aware that this is a subject which has been repeatedly mooted in the *Builder* already. We would not wish the railing altogether removed, or at least the space thrown altogether open, but at least, as we have all along done, that a rearrangement should be made, and a portion of the space thrown into the roadway, where it is most needed.

GROWING COLOURED WOODS.—We hear of an invention by Mr. Hyett to make trees imhale colour while growing. The results were exhibited lately at the *conversations* of the Cirencester Royal Agricultural College, in the form of sections and plannchets of wood, stained with various hues. Metallic salts are introduced into the substance of the growing tree, apparently carried up by the sap, and forced into the fibre and cells of the stem. It is not said what metallic salts are used as dyes. The idea reminds us of some curious experiments recorded, though not the same, in the *Builder* many years since, in which dahlias were varied in colour by means of substances such as charcoal imbedded with the hulbs in the soil. We think, too, we have heard of colours being infused into dead woods under exhausted receivers.

LONDON ASSOCIATION OF FOREMEN ENGINEERS. The fourteenth annual meeting of the members of this society took place on the evening of the 5th instant, at their rooms in Doctors' Commons, City. The assembly-room, notwithstanding the exceptional inclemency of the weather on the occasion, was crowded. The sitting was devoted to the election of six or seven new members, the reception of the previous half-year's audit of accounts, the annual address of the president (Mr. Joseph Newton), the election of officers for 1867, and the completion of arrangements for the anniversary festival of the institution, appointed for the 16th of February. Mr. Newton was re-elected with acclamation. Mr. Keyte was chosen vice-president; and Messrs. Danson, Edmonds, and Irvine, jun., committee-men. We understand that this society now numbers 160 members, and that it has a balance of £2,000. at its banker's.

"CENTRAL COTTAGE IMPROVEMENT SOCIETY."—Competitors are complaining that the results of the competition have never been properly made known, and that they cannot get back their designs.

BRIDLINGTON HARBOUR.—A considerable improvement by the extension of the north pier has been effected in this harbour, which until recently was very inquisit in gales of wind from certain quarters of the compass. The new works have been executed from the design of Mr. John Coole, C.E.; the contractors being Messrs. Simon & Thomas Crawshaw, of Ashham Bryan, near York. In addition to the quieting effect of the new pier extension, there are 4½ ft. more water at the entrance than previously. The additional depth has been gained without any expenditure in dredging.

NORTHERN ARCHITECTURAL ASSOCIATION.—The eighth annual meeting of the Northern Architectural Association was held on Tuesday, the 5th inst., in the Old Castle, Newcastle, Mr. J. Johnston, vice-president, in the chair. Mr. M. Dunn, in the absence of the secretary, read the annual report of the committee, which stated that there had been an increase of members and associates during the year. After meeting all expenses there remained a balance in hand. The vice-president read a paper, in which he reviewed the past history of the association, its present position, and its prospects for the future.

EXPLORATIONS IN THE NORTH.—The late Mr. Rhind bequeathed 400*l.* to the Society of Antiquaries of Scotland, for the archaeological exploration of a rich field of antiquities in the *upland districts* of the counties of Caithness, Sutherland, and Ross. The secretary of the society, Mr. Stuart, has lately examined the districts, and he finds that around Wick especially there is an accumulation of important remains not to be found elsewhere. The objects referred to comprehend,—1. Pictic's castles, variously called round towers or brochs; 2. Earde-houses, or weems, which at times are double; 3. Circular hut foundations, with and without an underground chamber; 4. Groups of small cairns, frequently in connexion with the hut-foundations; 5. Large cairns, long, circular, oval, and "horned," with one or more central chambers or galleries; 6. Standing-stones, single and in circle; 7. Rows of standing-stones radiating from cairns; 8. Rows of standing-stones without any apparent connexion with cairns; 9. Hill-forts of stone ramparts; 10. Hill-forts of vitrified stones; 11. Stones and holders with cup and ring (or concentric circle?) markings. Mr. Stuart recommends a certain course to be followed in the investigation, and it is probable the Society will forthwith authorise the thorough exploration of these interesting remains.

COMMUNICATIONS BETWEEN PASSENGERS AND GUARDS.—Notwithstanding the multiplicity of plans and the fact that it is not from want of such plans that railway authorities are slow to adopt means of communication between passengers and guards, still invention is at work in devising plans; but perhaps one of the oddest is that now under notice. A number of railway directors and gentlemen connected with mechanical sciences have just been attending a series of experiments with it made on trains running between Victoria Station and the Crystal Palace. The apparatus is applied to a carriage, or any number of carriages, by simply drilling a hole in the roof. A tube, having a slight slit in it is then in reach of the passenger. In the slit is a pair of jans or jaws, covered with a chemical composition of an ignitable character, but which can only be ignited by the touch of another composition having affinity to it. This second composition is to be supplied by touching the passengers' tickets with it, and the insertion of a ticket will at once explode a rocket! which can be heard from end to end of the train, and ignites coloured fire, which will flare up for several minutes on the roof of the carriage, so pointing out where the explosion came from. The passenger's ticket will show who caused the explosion. The exploded rocket, one would think, or its vacant place, rather, would also speak for itself. Of this lucifer ticket, might we suggest, that since that is the ticket for safety (?) it might contain also a life assurance security, so that should the passenger fail in securing his life, it would at least be insured for behoof of his heirs, should the rocket explosions lead to fatal accident, such as by delay of the train or otherwise.

THE ROADS.—In Kensington and Brompton, during the frosty weather, the roads have been, and are being, well sprinkled with sand early in the morning, by means of which much inconvenience and suffering have been avoided. We give credit alike to Mr. Broadbridge, the parish surveyor, and the vestry under whom he acts.

MEMORIAL OF LORD PALMERSTON.—It has been decided by the committee that the memorial of Lord Palmerston shall be the putting in of a stained-glass window at the west end of Romsey Church, and if the funds are sufficient, the east window also; and that a statue shall be erected in the Market-place of the town. The latter is to be placed entirely in the hands of the Hon. Wm. Cowper to carry out.

THE CROYDON FIRE.—It has been resolved to call a public vestry of the parishioners, in order to consult them as to what is to be done as to Croydon Church. The general opinion is, that the remaining walls and tower are so calcined by the intense heat that it will be better to clear the ground, and have an entirely new church. There can now it seems, be no doubt that the fire was occasioned by the over-heating of the Gurney stove at the south-west corner of the church.

TENDERS

For the erection of canal wards, at St. Marylebone Workhouse. Mr. H. Saxon Snell, architect. Quantities supplied.

Ebb & Sons	£1,347 0 0
Brown	1,316 0 0
Nightingale	1,263 0 0
Hall	6,560 0 0
Kelly	1,243 0 0
Rigby	1,193 0 0
Stewart	1,176 0 0
Potter	1,140 0 0
Shaw	1,117 0 0
Crabb & Vaughan	1,083 0 0

For building St. Matthe's Church, New Kent-road. Mr. Henry Jarvis, architect:—

Church	Spire
Patman & Fotheringham	£7,376 0 0
Thompson	£2,880 0 0
Patman & Fotheringham	6,560 0 0
Gannon	6,370 0 0
Dove, Brothers	6,335 0 0
Henshaw	6,184 0 0
Myers & Son	6,075 0 0
Higgs	5,265 0 0
Mr. Higgs having made a mistake, Messrs. Myers & Son's tender being the next lowest, was accepted.	618 0 0

For villa residence in the Seven Sisters-road, for Mr. H. Taylor. Mr. William Smith, architect:—

Mariand	£1,680 0 0
East	1,665 0 0
Grover	1,648 0 0
King	1,640 0 0
Johnson	1,623 0 0
Crabb & Vaughan (accepted)	1,600 0 0
Dimdale	1,540 0 0
Blanch	1,123 0 0

For alterations to 164, Fenchurch-street. Messrs. John Young & Son, architects:—

Chester	£1,955 0 0
Ashby & Horn	1,450 0 0
Henshaw	1,293 0 0
Webb & Sons	1,245 0 0

For the erection of two warehouses in Aldermanbury, for Mr. Meyerstein. Mr. T. C. Clarke, architect. Quantities by Messrs. Hovenden & Heath:—

Hill & Sons	£7,183 0 0
Macey	7,167 0 0
Patman & Fotheringham	7,159 0 0
Newman & Mann	6,371 0 0
Kilby	6,310 0 0
Henshaw	6,196 0 0
Corder	6,117 0 0
King & Sons	6,098 0 0
Browne & Robinson	5,974 0 0

For alterations and additions to premises, 85, City-road. Mr. Thomas J. Hill, architect:—

Bishop	£390 0 0
Perry	312 0 0
Ashby	303 0 0
Sabey	291 0 0

For alterations and additions to No. 231, Upper-street, Islington, for Miss Tubbs. Mr. William Smith, architect. No quantities supplied:—

Waters	£755 0 0
Sabey	476 0 0
Masterton	350 0 0
Hunt	360 0 0
Cubitt	232 0 0

For alterations at No. 29, Kensington Park-terrace, Baywater. Messrs. Bird & Walters, architects:—

Huggett & Hussey	£501 15 0
Newman & Mann	429 0 0
Brown	350 0 0
Williams & Son	347 0 0
Kelly, Brothers	337 0 0

For alterations to the Sun Tavern, Baneflagh-street, Finslow. Messrs. Bird & Walters, architects:—

Henshaw	£647 0 0
Ebb & Sons	656 0 0
Williams & Son	567 0 0
Brown	549 0 0
Newman & Mann	539 0 0
McLachlan	510 0 0

The Builder.

VOL. XXV.—No. 1251.

Life and Death at Sea.

WE lately have been the losses at sea. In a maritime country like ours there are few persons who are not at some time or other anxious for one who has business in the great waters, and to whom the voice of the storm, as heard in the driving rain and moaning wind, does not now and then bring a message of anxiety, if not of fear. The dangers of the deep are continually being brought home to us, and no one of a reflective disposition can hear the raging of the storm without bestowing a thought of pity upon those who go down to the sea in ships. Such being the case, the annual publication issued by the Board of Trade, and

known briefly as the *Wreck Register*, must, or at least, ought to, possess very general and widespread interest. We may remark that these returns refer solely to "wrecks and casualties which occurred on and near the coasts of the United Kingdom." The volume for 1865 has been recently published. Let us see what story it tells.

The number of wrecks and casualties from all causes on the coasts of the United Kingdom, and in the surrounding seas, amounted to 1,656, against 1,390 in 1864. The annual average number of casualties during the five years ending 1859 was 1,204, and during the five years ending 1864, 1,483. Referring to this alarming increase in the number of accidents, the report says, "As has been before observed, the general average number of casualties reported will probably increase from year to year, owing to the increase in the number of ships frequenting our coasts and narrow adjoining seas." This passage requires a little closer consideration. It is well known that the authorities at Whitehall issue certain rules and regulations respecting the lights, chain cables, boats, &c., to be carried by vessels; and in the case of steamers, the boilers must be inspected and passed by an officer of the Board. The Board of Trade have, of course, no authority over foreign vessels,* but nearly 1,700 of the 2,012 ships to which casualties happened were British ships, and therefore subject to Government regulations. On the present occasion we have nothing whatever to say as to the value of these rules and regula-

tions, and we shall not inquire whether they were ever really instrumental in saving a single life or preventing a single "inevitable" accident. Assuming, however, that the system is a good one, it appears to follow, as a matter of course, that it must always be capable of improvement. New inventions ought to furnish new means of preventing accidents, and the experience of one year should yield some hints for the improvement and extension of the system during the next. Improvements are constantly taking place in the construction and fitting of vessels, and there appears to be no reason why the requirements of the Board should not be made stricter as science provides us with ready and simple methods of fulfilling those requirements. It is quite evident, however, from the sentence we have quoted above, that the Board is now, in its own estimation, perfect, so far as the enforcing of precautionary measures is concerned. "We can do no more," the officers seem to say; "we are quite satisfied with the results; and, as the shipping trade increases, so will the number of casualties. We cannot do any more good, and we promise not to do any less harm." Having protested against the implied opinion of the Board of Trade, that they may now fold their arms in mute admiration of the perfect machine which they have invented and set going, we return to the immediate subject of our article.

Although the number of casualties reported in the year under consideration amounts to 1,656, the number of ships lost or damaged reached 2,012, representing a registered tonnage of upwards of 377,000 tons. The number of ships exceeds the number of casualties, because in cases of collision two or more ships are involved in one casualty. The number of ships in 1865 is in excess of the number in 1864 by 271, and is larger than any number yet reported.

Passing now to a more important part of our subject, we find that no less than 698 human beings were swallowed up by the pitiless sea during the year 1865. This is in excess of the number lost in any year, excepting 1859, when the loss of the *Royal Charter* brought the return up to 884. It is very interesting to notice that the whole of the lives lost in 1865 were lost in 164 ships. Out of the 2,012 to which casualties happened, 124 were laden vessels, thirty-three were vessels in ballast, and in seven cases it is not known whether the vessels were laden or light; 131 of these ships were entirely lost, and thirty-three sustained partial damage. Of the 698 lives lost the very great number of 275 were lost in vessels that foundered, fifty-three lives were lost on board vessels in collision, and 335 in vessels stranded or cast ashore. The remaining thirty-five were lost from various causes, such as by being washed overboard in heavy seas, by explosions, &c.

We find then that the fury of the storm was only appeased by the sacrifice of 698 human beings. How far has this enormous sacrifice been necessary? Let us see to what extent the loss of the 275 lives in vessels that foundered was due to causes altogether beyond human control. We find, on reference to the return, that they were lost in forty-three vessels, but it does not state how many of these vessels were unseaworthy. It appears, however, that of the eighty-five vessels which foundered in 1865, thirty, or about one-third, are returned as unseaworthy. We may, therefore, say that one-third of the lives lost in foundered vessels are due to causes which human foresight might have avoided. It is melancholy to think of the number of lives which are annually sacrificed by the cupidity of owners, who, rather than go to the expense of keeping a vessel in proper repair, will risk the lives of the crew in a craft which is scarcely fit to make a voyage from London to Gravesend. What says the report? "In 1865 there were ninety-eight casualties to smacks and other fishing vessels. Excluding these ninety-

eight fishing vessels, it will be seen that the number of vessels employed in the regular carrying trade that have suffered from wreck or casualty during the year is 1,914. If this number be again sub-divided, it will be found that about half of it is represented by the unseaworthy, overlaid, or ill-found vessels of the collier class, chiefly employed in the coasting trade. For the three years ending 1865 the number is more than half." There is another point which is brought out in the report, viz., the great age of some of the ships to which casualties have happened. During the last year 1 of the vessels wrecked was more than a century old; between the ages of 91 and 100 there was 1; between 81 and 90, there were 5; between 71 and 80, 9; between 61 and 70, 20; between 51 and 60, 51; between 41 and 50, 84; and between 31 and 40, 145. "The state of rottenness and want of repair of some of the ships above 20 years old often calls for remark. Even at the age of 25 to 30, it sometimes happens that a ship is so rotten as to fall to pieces immediately on touching the ground, without giving the crew the slightest chance of getting out their boats." What, then, are we to expect in the case of ships 40, 50, 60, 70, and even 100 years old? We wonder whether the owners of rotten craft like these, which ought to have been sent to the ship-breaker's yard long ago, ever think that they are in some degree responsible for the deaths of the often notoriously insufficient crews who work these vessels. If they ever think of the matter at all they probably say, "Well, we know that these vessels are rotten, we know that the crew is insufficient, but the voyage is short, and should the vessel meet with a misfortune the cargo will be covered by the insurance: as, and to the crew, they will in all probability be picked up by some life-boat or passing ship;" and the conscientious shipowner sends his guinea subscription to the National Lifeboat Institution, and thinks no more about the matter. It may be that the multiplication of lifeboat stations has a tendency to make owners more careless, in the same way that founding hospitals are found to encourage immorality. Be this, however, as it may, it is most gratifying to learn, that during the year 1865, no less than 4,162 persons were rescued from a watery grave, some by life-boats, some by rocket apparatus, some by the ships' own boats, and some by passing vessels. It is not our intention to speak here of the lifeboat crews, whose bravery is, as a rule, beyond all praise. The number of lifeboats in the United Kingdom, now amounts to 192. In 1855 it was 127.

There is some difficulty in dealing with the 53 lives lost on board vessels in collision. The number of fatal collisions was 20, whilst the total number of collisions amounted to 354. Of this number 86 are put down as being caused by bad look-out, 18 by neglecting to show proper lights, 22 by want of seamanship, 27 by general negligence and want of caution, 30 by inevitable accident, and 31 by error of judgment. We may fairly attribute the casualties classed under the first four heads to causes entirely under human control. The total amounts to 153, or about two-fifths of the whole number of collisions. We may conclude, then, that 20, or two-fifths of the 53 lives lost by collision have been needlessly sacrificed. It is to be noted that the number of lives lost in collision is, with one exception, less than the number lost from the same cause in any year since 1858.

We now come to consider the 335 lives lost in vessels stranded or cast ashore. The return does not furnish us with the materials necessary for determining with much exactness how far the loss of these lives was due to negligence. The number of casualties other than collisions and cases of foundering for the year amounts to 1,245; of which 236 were due to "inattention,

* In January, 1863, certain regulations were agreed upon by this country and France for the purpose of preventing collisions at sea. Since that date thirty-one other governments have adopted the same regulations, which are now almost universal. It does not appear, however, to have had the slightest effect either upon the absolute, or relative number of collisions which take place annually. The proportion between the number of collisions and the number of casualties other than collisions was the same within a small fraction in 1865 as in 1863 and 1861, and differed but little from the proportion in 1862. The absolute number of collisions has been steadily increasing since 1863.

carelessness, or neglect," and fifty-six arose from "defects in ships or equipments,"—292 in all, or about one-fourth of the total number of casualties other than collisions and foundering. Thus upwards of eighty lives, or one-fourth of the number lost by strandings and foundering, might have been saved. The neglect of the lead in cases of doubt, as revealed in the course of the official investigations, is nothing less than scandalous. The stranding of the *Louisa* on the old Head of Kinsale is a case in point. This vessel, with a crew of eighty-one hands and 500 passengers, left Queenstown on the 12th of April, 1865, and in little more than two hours afterwards she was ashore. "In commenting upon this casualty," says the return, "which took place within two hours after leaving port, the Court were much struck with the want of common prudence on the part of the master in hauling the ship to the westward when the fog came on, as he had the whole Irish Channel open to him; nor had he any reason whatever for approaching the land, having left port so recently; and although the fog was very dense and the position of the ship uncertain, the important and necessary precaution of using the lead was entirely neglected." Fortunately no lives were lost, but the Board suspended the captain's certificate. So long as Board of Trade certificates are granted to men capable of committing such fatal errors, "the general average number of casualties will probably increase." To use the Board's self-styled nomenclature, the *Byzantium*, which was stranded on the Gunfleet Sands in February, 1865, with loss of fourteen lives, might have been saved had the lead been used. The *Leopold*, stranded near Hartland Quay on the 5th of April, was lost "by the gross neglect of the lead."

We must omit the consideration of the thirty-five lives which were lost from "various causes," from want of the necessary details, and we will admit, for argument's sake, that they were all purely accidental. We have, however, clearly shown that of 698 lives lost last year on our coasts, at least 200 have been literally thrown away and wasted. The most enthusiastic special pleader would, we think, hardly venture to argue that a ship is lost "accidentally" when the captain neglects the ordinary rules of navigation; that a collision is "inevitable" when, as in the case of the steamer *Alpena*, the officer keeps in his course, without slackening speed, because "he supposed the schooner was taking the same course as the steamer" or that it is a matter of surprise that ships built about the time of the battle of Trafalgar should founder by the dozen whenever a sudden storm overtakes them a few miles from land.

With reference to the geographical distribution of shipwrecks, it appears that by far the largest number of casualties happen on the east coast. Last year the numbers were: east coast, 565; west coast, 356; south coast, 187; Irish coast, 146; other localities, 69. The number of lives lost is, however, greater on the west coast. During the past year the lives lost from the Fern Islands to the North Foreland amounted to 113, whilst the Irish Sea (between St. David's Head and Carnore Point in the south, to the Mull of Cantire and Fair Head on the north) swallowed up 139. The disproportion is more striking if we take the totals for the last seven years, which give 825 and 1,736 respectively. The most fatal wind is that from the south-west, and the least so that from the north. Westerly gales are far more fatal than easterly gales.

Much has been said and written lately about the advantages and disadvantages of extending Government inspection to ships' compasses, and the subject has occupied the attention of the Royal Society. It may be well to see how far the casualties of 1865 were due to compass errors. We find accordingly that six casualties, none of which, however, were attended by total loss of the vessel, were caused by "local attraction and defects of compasses," but the return does not show what loss of life took place in consequence of these accidents. Referring to the *profits* of special inquiries ordered by the Board during the year, we find that the *Dorset*, which was stranded on a sunken rock off the island of South Uist on the 19th of June, was lost from this cause. Before leaving port, the vessel had undergone extensive repairs, which had altered her permanent magnetism. The compensating magnets of the steering compass had been removed, and not replaced. The court acquitted the master of blame. In the case of the *Hector*, which was stranded off Wicklow Head on the 9th of November, the

master was acquitted. "Either the compasses were inaccurate, or the evidence of the witnesses as to the courses steered was false; and the Court being reluctant to come to the latter conclusion, and finding the evidence as to the state of the compasses conflicting, gave the master the benefit of the doubt, and returned him his certificate." The master had only joined the ship a few days, and before leaving Liverpool he wished to have her re-swung, as he had heard that the compasses were inaccurate; but on the assurance of the former master, he proceeded to sea on the assumption that they were correct. Amongst the vessels lost abroad we find that the *Eastern Province*, which was stranded eighteen miles west of L'Agullas, on the 26th of June, 1865, was lost in consequence of a defect in the compasses. "It appears there always had been a great difference between the vessel's compasses, for which the master made allowance, but for which he could not account. The Court were of opinion that up to the time of reaching L'Agullas the deflection of the compass was constant, and that the vessel was kept on her right course, but that after passing L'Agullas some change unaccounted for occurred in the performance of the needles of the compasses, which put the master out of his reckoning. The present state of our knowledge of the variation of the compass on iron ships is most unsatisfactory, and it is doubtful whether Government control would be attended with any good results. It may be laid down as a general rule that any attempt to maintain by legal enactment a higher state of efficiency than has already been proved to be practicable is bad.

Before quitting the subject, we take the opportunity of protesting for the hundredth time against the reckless waste of precious human life which takes place every day, and which is either justified by the "pressing demands of a high state of civilization," as if civilization were a Moloch only to be appeased by the annual sacrifice of a certain number of human beings, or is put to the account of "inevitable accident." Human nature always was and always will be infirm, and wood and iron are sometimes as ineffectual as a broken reed in resisting the fury of the storm. But until we give human nature a chance, for instance, by not allowing the lookout man to remain at his post some hours after he should have been relieved, we can hardly plead negligence, and we refuse to recognise an accident when a vessel fails to ride out a gale with a cable notoriously weak and in bad condition. Viewed even in the abstract, the preservation of human life is a sacred duty with all. It is not that the life of a particular individual is of apparently little or no value either to himself, to his own circle, or to the community at large that it is not precious. It is not that the life of a man who is poor, insignificant, and wretched is of any less value in the abstract than that of one who is rich, famous, and happy. It is still a life—something which ingenuity cannot create and wealth cannot buy. Property may as a rule be replaced—not so human life. The waste of material possessions is reprehensible, but who shall estimate the sin of needlessly sacrificing human life?

DORÉ'S PARADISE LOST.*

"ANS LONGA," said the alchemist, "VITA BREVIS." Yet, wide as is the domain of art, it has its definite and natural limits, and no artist can attain the highest degree of excellence who is not aware, either by theory or by instinct, both of the nature of those lines of demarcation, and of their relation to his own genius, his own skill, and his own material and method of expression. With his skill, indeed, the true artist is never wholly content. Let his progress be as rapid as has been that of any great master before him, the outward expression will never adequately convey the full force of the inspiring idea. At times we may recognise the intellectual presence of an artistic spirit in one to whom deficient education or even niggard nature has almost entirely denied the faculty of expression. It is impossible to look at the works of Haydon without a saddening impression of this kind, an impression, moreover, that must have been but too keenly experienced by that unfortunate limner himself. At the other extreme of the scale may be ranked such a master of expression

as Titian, in a comparison between whose earlier and later productions we may trace the mode in which minute and conscientious attention to detail has educated the hand until it seemed able to counterfeit life almost without the mechanical intervention of drawing—to throw on canvas the thoughts of the artist, or the likeness of his subject, by means that can neither be copied nor altogether comprehended. In some of the later sketches of Gainsborough this marvellous power is fully evinced. One may be particularized as an example in which a donkey seems all but alive, although, on a close inspection, you can define neither the eye nor the ear. In the gradual change of the style of Turner, after the culmination of his powers we trace something more than the carelessness of conscious power, we detect the growing imperfection of the artist's eyesight. Some of these latest of his productions, which look at first mere unintelligible puzzles, become actual outstanding nature if gazed at through nearly closed eyes.

Of the three chief forms under which art appeals to the imagination, that which forms the province of the sculptor is by far the most narrow. The aesthetic limit of delicacy of detail in marble is almost as confined as is the mechanical limit. The architect may fret his tracery into lace work, and the only check upon the exuberance of his fancy, or the delicacy of his detail, is to be found in the texture of the stone which he employs; but if the sculptor force his work to smell of the chisel and the file, if he obtrude upon the sense any *tour de force*, the impression produced is rather that of wonder than of admiration. Take, for instance, that highly elaborate statue in the San Severino chapel, at Naples,—the man in the net,—or its equally finished relief companion. No fault can be found in the detail. The anatomy is perfect. The net might have been taken from a fishing-boat in the bay, and only petrified after being entwined around the limbs of a finished statue, or of a man turned to stone. And yet the impression produced on the mind, if compared to that left by the bronze Mercury in the Museo Borbonico, is like the recollection of a visit to Madame Tussaud's museum, rather than of one to the Elgin marbles. Again, the subjects fit for sculpture in relief may be limited for statuary. Few figures are more admirable than the "Evening" of Thorwaldsen, but that great artist was instinctively aware that his art could embody that poetic idea only *in relief*. The great anatomical difficulty of adding a third pair of limbs to that vertebrate skeleton of which alone we know the homology, can only be evaded—it cannot be mastered, and the hint which is given by the prophet who saw in vision winged intelligences, and which seems to be consonant with that singular osteological provision which has given a double shaft to the extremity of each vertebrate limb, has never yet been taken by the artist.

Again, the sculptor, more than any one, suffers from the restriction and from the changes of Greece dared represent the nude form, and the habits and temper of a people who dwell in a climate where clothing is at times an incumbrance, and whose chief national solemnities included the contests of the Palastra, had to be duly respected by the sculptors, no less than by the philosophers of Athens. The nude, when once arrived at, might be thought to be beyond the pale of the caprices of fashion. Yet it seems, even to us, incongruous to find Roman emperors represented by pure heroic statues. It would be intolerable to see our own kings or captains so represented. The sculptor, then, is driven either to an adoption of the costume of his time which in a couple of generations seems to be grotesque, or, as we call it, old-fashioned, or he is forced to adopt a sort of conventionalized drapery that is destitute alike of truth and of meaning, that is a sacrifice to a confused idea of decency and of expedience, and that would have been well avoided even by the earlier contrivances of terminal figures, or of partially wrought forms. In the first instance, were, from a longer lapse of time, the costume ceases to be old-fashioned by becoming antique, the work of the artist who is true to the costume of the day will regain or exceed its original value—the work of the conventionalizer will be despised.

No more illustrious instance can be cited of the struggle of genius with this great difficulty in a branch of art that forbids the use of what is vague and undefined, than is presented in the works of Ronbiliau, the artist whom Lord Chesterfield called a sculptor among stone-cutters.

* Milton's "Paradise Lost," illustrated by Gustave Doré. Edited, with Notes and a Life of Milton, by Robt. Vaughan, D.D. London: Cassell, Petter, & Galpin, 1858.

No sculptor, of any age, appears to have exercised more perfect, if so perfect, command over marble. Of the life-like expression that he could communicate to countenance and to form, as in the head of Sir Isaac Newton in the ante-chapel of Trinity; the hand and arm of Mrs. Nightingale; the attitude of the Argyll "Eloquence," the statue which Canova pronounced to be the finest in England, there has never been but one opinion expressed by any competent critic. In the drapery of his figures there is equal command of the chisel—equal truth to nature,—patience without any parallel; but the very truth to the nature of the last century is unfavourable to a full appreciation of many works of this sculptor in our own. It has been the fashion for some persons, admirers of a meagre quasi-classic elegance, or of a servile portraiture that could be equalled or excelled by mere mechanical means, to speak of the works of Ronbilio as being inconsistent with their own more excellent taste, because of their allegorical nature. A sneer at the terrible "Death" of Ronbilio is consistent with the taste of an age in which the progress of sculpture is represented by that of the Nelson Column, and its purity and dignity by the forms of Wellington on the archway, and of George IV. in Trafalgar-square. It is true that in the groups that adorn the nave and transepts of Westminster we see the same habit of thought and motive of taste that gave us the stately verso of Pope or the nervous vigour of Johnson; but the word "allegorie" may be used as a reproach to Phidias as truly as to Ronbilio. The Minerva of the Parthenon is as allegoric a subject as the Minerva of the Argyll monument. The "Eloquence" that stands beside her is as ideal as the antique and not more beautiful pleading figure in the Louvre. The moment she departs from pure portraiture, Sculpture can only produce symbolic figures, and in the choice between those afforded by the Parthenon, and those to be copied from the Missal, the real artist will feel that he has but little room to hesitate. Fame, Love, Death, from the chisel and burin of the sculptors and gem-cutters of the age of Praxiteles and of Pyrgoteles are members of the same Homeric, Dantesque, or Miltonic families that contain the Death, the Time, the Fates of the great Frenchman. The Apollo Belvidere is as true to the heroic costume of the Olympic games as is the Newton of Cambridge to that of the fellow students of the great philosopher.

The artist who covers plain surface with his productions, whether of brush, of chalk, or of pencil, has a far wider field and more unlimited range than the sculptor. He can, if a master of his craft, leave that which he dares not too minutely define in almost as much uncertainty as can the poet. But the limit of the painter lies in another direction. The artist who represents form by the chisel appeals to the same sense of beauty in whatever age he labours. He is impeded only by that which conceals his outlines, and he will ever be admired by those in whom the same blood and race produce the same appreciation of beauty. The Greek Venus will always stir the pulse of the European. The Egyptian kings and gods shed a solemn awe into the minds of men of like blood with themselves. But in the wide field over which the draughtsman revels we find the too opposite and contemporary principles of Gothic and of Latin art. There is a marked opposition between the schools—an inability of mutual comprehension. The Italian artists, of whom, in this respect, Raffaello may be taken as the loftiest type, worship beauty and idealise nature in the effort to render human beauty more divine. The imagination of the Gothic artist, when once he departs from exactitude, turns to the grotesque and the diabolic. Beauty with him is realistic, the portraiture of modest and true maiden, of comely youth, or stalwart man; he does not elongate the limbs, and diminish the head, contract the mouth, and lower the brow. When he is anything but truthful, he becomes either unmeaning or quaint and grim. In the Dutch painters and Flemish artists we find the realism of the Gothic school most fully displayed; in the portly beauties of Rubens, in the clumsy forms that are invested with the marvellous light and shade of Rembrandt. The imaginative element, which peopled the black forests and giant mountains with gnomes, and trolls, and elves, we find in such men as Albrecht Durer or Retzsch. It may be true that the Virgin Mother of Bethlehem, if we recall her blood, her country, and her age, is not more truthfully represented by the Sistine Madonna than by the hard-

featured brows of Durer. But the poetic, super-human purity of the most prominent object of Italian worship is embodied in the divine conception of the Italian painter. The Gothic artist, son of the race who in the time of Tacitus owned *simulacra nulla*, can only converse with the grotesque when he leaves the region of the real. Let the Italian attempt the grotesque and he produces only the disgusting. The political caricatures attempted by the new-born press of Italy since 1860 have proved most contemptible failures.

Of the two great opposing schools of art there can be no question as to which has the right to claim the gifted illustrator of the *Contes Drolatiques*. There is, no doubt, a classical school in France, of which it is not here needful to speak, and that the less so since neither in poetry nor in painting, neither in the tragedies of Racine nor in the pictures of David, does it commend itself to our insular taste. But there is also a widely different class of art, which is characterized by all the pointed wit, and by much of that dramatic action which we uncivilly call the grimace, of our politer neighbours. Its object is to excite a smile, and very often the smile is of that bitter kind that we term sardonic. A great master of this pictorial form of satire has just laid down his pencil; a satirist who was to Paris what our own lamented Leech was to London, save that where *Punch* chastised with whips, Gavarni chastised with scorpions. The field of an artist of this nature is very closely limited, and perhaps the more perfect is his command of his peculiar class of subject the more restricted is the range of his powers. The "*Enfants terribles*" of Paul Chevalier would have been impossible of depiction to Leech; the Frenchmen of the latter were not the *gamins* of the Boulevards, nor the hearded lions of the *Pays Latin*, but the vagrant Gaul, sea-sick, *égaré*, and uncomfortable, as we meet him in steamers or see him wander forth in search of "Lester-squarr,"—the foreigner who eats cold crumpets at the pastry-cook's,—the Parisian as he is *not* at home. Gavarni, on the other hand, when that artist visited London, not only failed to catch the idea of the Englishman, but is said to have been actually spoiled by our gloomy climate for the use of his native pencil. With all the fire, and with more than the power of Gavarni, Gustave Doré has inscribed his name in the admirable illustrations of the *Contes Drolatiques*, as a realist rather than an idealist, a Gothic rather than a Latin artist,—a lover of force, of truth, and of humour, rather than a worshipper of beauty, if we except the beauty of landscape.

In the whole range of literature, it would be hard to produce a work more incongruous to the genius of such a designer than the "Paradise Lost." A great artist,—and Doré is a great artist,—unrivalled in fecundity, unsurpassed in power and truthfulness of drawing, mastering the difficulties of torsion and foreshortening with a touch that recalls that of the great Florentine, massing light and shade with a brush dipped in the gloom and glow of Rembrandt, depicting animal life, up to a certain point, as faithfully as Landseer or Rosa Bonheur, and possessing an acquaintance with the manner in which the direction and massing of lines give at will, either height, or breadth, or distance, which seems to be peculiarly his own,—such an artist may say, *Nihil humanum a me alienum puto*. Who shall forbid such a one to enter into Eden, the garden of God? The attempt we cannot lament; of the success we must speak with high, if not with unrestricted admiration. Doré has achieved much, but he has not achieved a miracle. It is not for the artist who could paint the very knight that Cervantes drew to limn the chaste matronhood of Eve, or the proud though fallen majesty of Satan.

To realise the scenery of the "Paradise Lost," we must remember who and what was its author. An English puritan, with the education of a classical scholar, whose slowly maturing genius had been ripened by the bright skies and lovely scenery of Italy, and whose bardic talent was so fired by his religious sentiment that he failed to distinguish, in his verse at least, between the poetic and the prophetic inspiration. A puritan who would love to linger in the dim religious light of the cathedrals huilt by his Catholic ancestors. An Englishman who read and who wrote, Greek, Latin, Italian, both in prose and in poetry, to whom Homer, Dante, Virgil, were familiar friends, a man of earnest thought and ardent action, of personal beauty as remarkable as his personal purity was unblemished; and

who, looking forth from the early darkness which he shared with "blind Thamyris and blind Meonides, and Tiresias and Phineus, prophets old," saw an Eden peopled by such glorious forms as have appeared to no mortal vision since the ladder was beheld by the Syrian patriarch that reached from earth to heaven. Such was the man to whom the English people are indebted, if we may not say for their theology, yet at all events for that organised and detailed interpretation with which they have been unconsciously to overlay the simple grandeur of the Hebrew Scriptures. That the Paradise of Milton is not the Eden of the Pentateuch, is admitted by those admirers of our great poet who tell us that he drew his ideas from the whole of the Bible, or, in other words, that wherever a beautiful idea could be culled from the language of sacred allegory, or of prophecy, or of comfort, he repeated it in his melodious diction, and applied it to the scenery of his divine drama. Nor has the price been light that our days have seen paid for yielding to the seduction of Milton. As science has decyphered the stony records of the past,—as we have slowly learned that many of the things long most surely believed among us, are inconsistent with the certain record that God has left of his works,—the creed which rested mainly upon imagination has been rudely shocked, and the pupil has echoed the accusation that Geology contradicted Moses,—when it only contradicted Milton.

Between the genius of such a poet as Milton, and the genius of such an artist as Doré, no very lively sympathy can exist. That M. Doré should have attempted the illustration of "Paradise Lost" speaks much for his courage. It speaks yet more for his genius that we should have to speak of the work as a qualified success, and not as an unqualified failure. The splendid volume which has been published simultaneously in London and in New York is one of the noblest that has issued from the press. A picturesque life of Milton, from the veteran pen of Dr. R. Vaughan, is followed by a brief introduction to the poem, written in a fair and moderate spirit. The only fault to be found with the letter-press is the frequent deforming of the page by notes, as to which it is difficult to conceive what class of readers they are intended to benefit. It irritates the eye to be attracted from the even flow of the metre of Milton to receive the intelligence that "grand parents" means "first or great parents;" that "witnessed" means "expressed;" that to "suffice" means to "satisfy." Such comments are rendered the more inexcusable by the great beauty of the page, and the injury which it suffers from the small type of the impertinent and idle comments. There is no list of plates,—an omission the more to be lamented as the order of their insertion is not that of the numbering engraved on their margins; so that it is only by counting them one by one, and by assuming that the copy consulted contains all, that we arrive at the number of fifty. Of these fifty plates we have a few words to say, regarding them as naturally consisting of six several groups.

The drama of "Paradise Lost" is mainly divided into the two distinct series of human and superhuman action. To the latter class of scenes M. Doré has devoted more than half of his designs, no less than twenty plates giving the fall, the struggles, and the councils of the evil angels, and five being devoted to the denizens of Heaven. A difficulty of great magnitude awaits the artist at the very threshold of his task. We can present to the imagination flying anthropoid forms under one of three possible suppositions. We may conceive the human body to be raised by the direct exertion of some occult spiritual power, such as is attributed by the Roman Church to the ecstasies of her saints, and is represented by the great Italian masters in the Apotheosis of the Virgin, or the rapture of St. Paul. Such, too, were the classic representations of the gods, whether arriving, like Iris, with a message from Olympus, or fading from view like the Venus of Virgil from the side of *Æneas*. The classic artists never gave pinions as instruments by means of which celestial beings passed from earth to heaven. Wings with Phidias and his contemporaries were symbols alone, given to Victory and to Love, indicating in Psycho the resurrection of the soul by the allusion to the hutterly, bound on the talaria, the caduceus, and the petasus of Mercury, and shading the madness of Medusa; but in none of these instances are they presented to the eye as the mechanical instruments of flight. Christian art, improving after its fashion

on the men in white garments seen by the apostles, and on the earlier messengers from heaven, whose nature was recognised only on their departure, peopled the sky with repetitions of the classic victory. The artist who follows in this fantastic course has to contend with the impossible. The more profound his knowledge of anatomy, and his sense of weight and of poise, the more impossible is it for him to satisfy himself with the delineation of figures supported and moving in the air by the mechanical agency of wings. His angels writhe, and flap, and flounder,—but fly they do not. The wings are inadequate to the weight of the figures, the positions assumed are not those which are consistent with their flight; and yet the simple idea of the ancients, the wingless volitional flight of which we are most of us conscious in dreams, is forbidden by the introduction of these unmanageable pinions. It is true that a third method may be drawn by fancy from the analogy of nature. If we suppose the angelic forms to be destitute of gravity, or, rather, to possess the specific gravity of the surrounding atmosphere, we may consistently regard them as hovering around, and we may then imagine the wing to be employed, not as that of a bird to sustain weight, but as the fin of a fish to give impulse, and the difficulties of proportion and of position will then no longer exist. But in this case the artist must be able at the same time to present to the mind the ethereal nature of his celestial subjects, whether delineated by such lines of light as Doré has occasionally and very beautifully employed, or indicated by some effect of transparency or of pervious and aerial structure which destroys the sense of weight. Such an effect, to some extent, has been attained in the outlines of Retzsch. But the very accuracy of the drawing of Doré is opposed to this mode of eluding the difficulty, and the eye accustomed to the requirements of physiology and to the observance of the laws of dynamics will, for the most part, wander ill content through the winged hosts that soar or that struggle on his pages. The happiest exception to this criticism is to be found in the group of angels circling in chorus of praise. In this plate the aerial poise of the figures is most masterly, and yet it will be observed that the most perfectly floating figure is one without wings. The effect is no doubt heightened by the absence of any ground-line. There is not, however, a single beautiful face in the group, and the two magnified figures in the centre will not find favour with many English readers of Milton. Again, in the flight of Ithuriel and Zephon round the Garden, we have eagerly-moving, well-poised figures, the sense of mechanical weight being relieved by a delicacy in the treatment of form and of drapery that suggests an ethereal nature in harmony with the posture of the angelic guards. The direction of the main lines of the figures in this plate is signally skilful and happy. We cannot say as much for that which has been selected by the publishers as the sample to adorn the prospectus, the Descent of Satan towards our world. The body of the fiend is palpable and material; indeed it seems as if the artist had purposely sacrificed the aerial lightness of the figure for the better intimation of his moral character. For the same reason, we presume, his attributes are gradually changed; the feathered pinions degenerate into bat-like wings, the feet turn into hoofs, horns appear in the later scenes, and the armour and clothing of the Archangel is gradually laid aside, so that in the most carefully-drawn of the representations of Satan, in which he sits contemplating the Serpent asleep, the highly-finished figure is perfectly nude. In the flight towards earth, the apparent weight of the body is such as altogether to overpower the fore-shortened wings, and the effect of the figure, carefully and accurately drawn, is that of a tumbler, the backward movement of the foot rendering the unpleasant conclusion irresistible. In this plate, moreover, is to be noticed an oversight most rare in the works of Doré. The small size of the globe of earth is, of course, intended to denote its distance from the fiend, and the effort which the observer has to make, is to realise its position as a planetary body, delineated as we sometimes see the dark side of the new moon by earth shine. But this illusion is dispelled by the shadow which a cloud, so near to the eye that we detect its structure, casts on the very body of the planet, thus entirely destroying the sense of distance.

More imaginative, but, we think, less successful than the angels, are the marine monsters evoked from the abyss by the wand of the artist.

The revelations of paleontology might be studied with profit by M. Doré, with benefit to his own future works, and with great benefit to the geologist, who might hope for a better rendering of the forms of those extinct monsters, of the anatomy of which so much more is becoming known than is at present to be learned from any attempted restorations. In the work before us, the Leviathan, though wonderful in its rendering of the idea of length, is neither a dragon nor a fish, but a gigantic Proteus or Syren. Its head is decidedly that of one of this hutchinian family, and the position of the second claw renders the exceeding length of tail homologically impossible. Of the dragons that fill the hall of Pandemonium, we can only say that they are diabolic, as no doubt they were intended to be.

In the third group of plates, those presenting single figures, or groups of two or three carefully elaborated forms, we must note the draped sworded figure in the group of Sin and Death, as meriting the appellation of sublime. Death, we cannot doubt, is the subject; but if so, the companion figure by no means will answer for the representative of Sin. The first plate, where the fallen archangel appears himself from the gulf, gives one of the finest single figures in the book; but here, again, the recumbent figure hears so close a resemblance to the succeeding representations of Satan, that we are in doubt as to the meaning of the artist. In the clamour of the fiend over the wild and fearful rocks of another plate, we again are made to feel that a figure armed with such wings could not have been so painfully dependent on his hands and feet. The most carefully finished of all this series of plates is the one to which we have before referred, of Satan seated and contemplating the Serpent. The figure is superb; but the head, though a fair representation of the monkish Satan, falls far below the dignity of the Archangel of Milton.

Apart, in their idea and composition, from the other groups of designs are the three episodic plates of the building of the Ark, the Deluge, and the Descent of Moses from Sinai. The first of these gives one of the striking contrasts of light and of shade so characteristic of this remarkable master; although the size of the vessel, of which the ribs stand out black against the sky, is but that of an ordinary bark. The patriarchal figure with the frame-saw is evidently unaccustomed to the use of that implement. The Deluge recalls the plague of darkness in Egypt. The figure of Moses, though small, is fine and dignified.

In approaching that division of the designs in which the chief human interest of the work centres, we desire to keep as free as possible from any disposition to carp or to cavil at the works of a great artist, the feeblest of which possess much to excite respect and admiration. Yet it is impossible not to feel that the very truth and accuracy with which M. Doré represents nature as he sees it, has excluded him from the Eden of Milton. In almost every instance in which he has drawn the inhabitants of the fairy scenes which he conjures up, we feel that their eyes have been opened. There is a sense of something slightly uncomfortable or improper clinging to the figures—they are not unclothed, but stripped. The feet, too, of Eve, have evidently not only been shod, but seen never to have been otherwise than well and luxuriously shod,—they are not the feet of a woman who walks barefoot. The attitudes of Adam, true as is the drawing, are those of a model. There is one perfectly unconscious Eve,—the one asleep; but the figure, though an admirable representation of a sleeping woman, is not that of a beautiful woman, nor of one whose attitudes are instinctively graceful. The face never is beautiful. In the scene in which the pair are listening to the recital of the angel, that of Eve is from a fourth to a fifth larger than that of Adam. Had M. Doré filled his memory with glimpses of the unclothed tribes of Africa, with the dances and the bathing, not of negroes, but of the well-formed races that resemble animated bronze; and that regard clothing as an impertinence; had he even lingered by the side of the Mediterranean during those hot months that drive strangers to the north, and natives to the sea, his truthful pencil would have limned noble, free, unconscious forms, clothed only in their native grace, and thinking no more of drapery, or of its absence, than do the antelopes or the swans.

Among these groups it is a pleasure to dwell on one that affords room for unrestricted ad-

miration,—that in which the approach of the angel through a glade, throwing the glances of his own light on the seated figure of Eve, unites the charm of landscape, of figures, and of that effect of light and shade in which Doré so eminently excels.

We have reserved the landscape for the last. Although not equal to the wonderful tropical scenery of the Atala of the same artist, they are generally charming. The separation of the waters in the second day of creation is the finest representation of a chaotic scene with which we have ever met. The river pouring into Paradise is a study, and a marvel of push and movement. The evening of the sixth day, although it suffers from the fidelity of the artist to that description of the poet which cannot be graphically represented without exciting a feeling of incongruity, is another scene of great beauty; and the two recumbent elephants, in especial, are wonders of animal life. Above all, the representation of the fifth day, the sharp lines of the engraving, and yet the effect of river mist and the aerial perspective which they afford, the delicacy of the plumage and the grace and truth of the forms of the birds, the harmony of the rustic landscape, present a scene in which we find no element of discord or room for hesitating admiration. Nor must we omit to mention the wonderful train of angels descending after the fall, although the human figures in the scene are disagreeable; the departure of the angel into heaven, where the fading form of light is watched from the lower of Adam; or the steady, evil, terrible progress of the Serpent towards his unconscious victim. In these eight plates alone there is enough food for admiration to render the volume worth the purchase of those who can afford the price.

We would offer one word of suggestion to the gifted artist, and to his enterprising publishers. For the prolific pencil of M. Doré we can only express two wishes; one, that it should ever and anon be dipped into fresh scenes of living nature; that the artist seek, at times, repose from his labours in travel, especially in eastern or in southern travel; and secondly, that it should be employed on subjects of a nature germane to the genius of its master. There are two English poets who come much more naturally under this description than does Milton. The illustrations that Doré could give us of the "Faery Queen" might combine all the excellences of his best works. Satyrs would peep through the ivy, and the quaint tiling armour of the fifteenth century would gleam on the magic page. And for a Christmas look for 1867, leaving aside the historic plays, which the patriotism of a Frenchman would forbid him to illustrate to our satisfaction; avoiding Kalstaf, so eminently English; if we turn to the scene in which Shakespeare gave the reins to his imagination, we shall have all that the artist needs. No work that ever issued from the press ought to exceed the beauty of the "Midsummer Night's Dream," illustrated by Gustave Doré.

THE DESIGNS FOR THE NEW NATIONAL GALLERY.*

In our last number we described the several designs of two of the competitors, for the enlargement or reconstruction of the National Gallery, and for a building nearly or entirely new; and we noticed the design for the enlargement, by a third competitor, Mr. Street; whose views as to lighting, principles to be observed in planning, and style or decorative character, we adverted to. We have now to describe the design for a new building by this last-named competitor.

As Mr. Street does not deal with the site of the barracks, we shall be spared troubles in description. On the ground now occupied by the workmen his plan shows an open court; which, as may be understood, is not rectangular. The entrances to the building are, advisedly, two only; and they are placed, one, as directed, in the centre of the chief front, and the other at the north-east angle of the ground. The chief features of the front towards the Square are a lofty dome, in the middle of the range of building, and an advanced porch,—the latter, from its doorway and other features, very ecclesiastical in character. This porch is tripartite on the ground, and in arrangement of its roofing. It is flanked by circular features of the plan, which are dome-capped; and the general parapet would

* See pp. 23 and 40, ante.

step upon the curve, in the case of each of these small domes, in an unsightly manner: had the drawing been correct, this would have been observed. From the porch, the entrance leads into a grained hall under the large dome. The floor here is 6 ft. above the pavement outside. Opposite the entrance, is a doorway from the hall; whilst flanking this doorway are the commencements of two flights of stairs which afterwards run parallel with the transverse axis of the building, and lead to the floor above. There is a considerable slope upwards from Trafalgar-square to Hemming's-row; and instead of getting all his steps in the front, Mr. Street raises the floor-line of the portion of the building on the new ground, and places steps to the doorway from the hall. The several features of the hall are shown in one of the effective views that Mr. Street knows how to make. Right and left of the hall are the galleries for the drawings. The ground-floor, including the rooms round the quadrangle, according to Mr. Street, should provide also for the National Portrait Gallery, for engravings, and perhaps for an art-library; and we hope that the two latter requisites in a National Gallery will not be omitted in the building that is to be built. The wing to the west of the hall contains the rooms of the keeper's residence, and others. These are arranged in two floors; and the division is masked externally by a transom of tracery, which is repeated in the other windows of the front. The external decorative character of the wings is produced chiefly by a range of arches. These arches spring from columns they carry gable, or canopy-mouldings; the columns carry tabernacles; and the arches, or bays, enclose besides the windows, traceried, to which we have alluded, and which are coupled,—certain openings, apparently not to be glazed, that would light a corridor which is external to the line of galleries of the first floor. These corridors, with others, are intended to assist the free circulation of crowds; and this point seems to have been well studied by Mr. Street. His Trafalgar-square front, however, is anything but satisfactory; indeed, it is open to some of the gravest charges that the Gothicists have brought against Classicists. It reminds one of a church that has lost an aisle, where piers and arches have been filled in with new walling and windows. The portion of the front that is most satisfactory is the dome, with its octagonal tambour decorated in a manner that recalls Pisan models, and with a clever setting of the octagon upon the square of support, aided by pinnacles at the four angles. Before leaving this front, let us say that Mr. Street would introduce a flight of steps in the middle of the terrace of the Square. He advisedly dispenses with railing like that enclosing the front at present. We have no space to describe the end- and rear-fronts; though these contain parts that are sufficiently picturesque. Amongst them is a feature that is placed in a re-entering angle, near to where the raking line of St. Martin's place and the line of the main frontage meet. Another feature forms the north-east angle of the whole building, where the secondary entrance is: here the roof is carried up; the staircase is reflected in the stepped arrangement of the windows; and there is a cluster of tabernacles, or niches and sculpture, on the angle. In the east front there are arches, but somewhat different to those of the chief front. All the galleries of the ground-floor are side-lighted; but the disadvantages, comparatively, of the system, are sought to be overcome by giving great height to the rooms. This would increase the number of steps; but Mr. Street shows that his design has not more steps to the principal floor-level than there are in the cases of the Dresden, and the two Munich galleries. On the principal floor, the galleries occupy the four sides of the quadrangle (or including the galleries in the eastern half of the main front) and the western half of the front. The 50 ft. galleries are top-lighted, and, in the main front, the light to these galleries, by an arrangement of the roof, not appearing towards Trafalgar-square, is taken from the north. A double skylight is rightly deemed essential. Alongside of the large galleries, in most cases, is a range of galleries for the cabinet-pictures; and these latter galleries, which are side-lighted, are placed in two stories, that is, two in the height of one story of the large gallery. The opportunity for making this economic arrangement is certainly an argument for the side-lighting system, albeit not conclusive. The galleries for cabinet-pictures are divided into,

compartments by screens, which are 15 ft. in height.

Mr. Street's pamphlet testifies to attention that he has given to the subject of picture-galleries, aided by examination of such galleries as there are at Dresden, Berlin, and Munich. Besides general features, he has attended to details, as the provision of a lift for pictures, of closets in the walls below the pictures, and of receptacles in connexion with dust-shoots, for the sweepings of the floors. As to the 50 ft. width, prescribed, he, in common with so many others, thinks it excessive. He would have no gallery more than 40 ft. to 45 ft.: he points out that the Dresden Gallery is only 31 ft., and the Pinakothek at Munich about 38 ft.; and he justly says that the increase of height in top-lighted galleries, operates not for the advantage of the lighting, but as a temptation to hang pictures where their finer qualities cannot be seen. He differs from several of the competitors in one respect: he provides no sculpture-gallery. He regrets the omission; but he thinks, were sculpture provided for, that sculpture and paintings should not be brought close together: according to him, the effect "is generally found to be conflicting." Comparing his provision of space for paintings with that in other galleries, he gives some useful particulars of the galleries at Dresden, Munich, and Berlin, from his measurements; though we see that his dimensions are only those of floor-space. The Dresden Gallery he considers the best of the number,—that is, four, counting two at Munich. At Dresden, the gallery-floor contains 24,700 ft. The ground-floor is appropriated to engravings and casts. Of the floor, or floors, alone appropriated to paintings, 8,700 ft. are top-lighted, 8,000 ft. are side-lighted, and 8,000 ft. in the upper cabinets are top-lighted for the most part. None of the galleries are more than 45 ft. 6 in. in length by 31 ft. 2 in. in width; whilst the cabinets are generally each 14 ft. 6 in. by 16 ft. The Pinakothek Gallery at Munich is badly lighted: the cove is too large, and the skylight too small; whilst, as there is no second skylight, blinds are necessary to exclude the sun; but which then exclude light. The entrance at the end of the gallery, instead of in the middle, is said to be the cause of unnecessary traffic through the rooms at Munich; and the cabinets, 12 ft. 6 in. by 17 ft. 6 in., and 12 ft. in height, seem to be too small and too low. The Berlin Gallery, of recent erection, Mr. Street supposes to be the worst contrived in Europe. As to the Louvre, he mentions Sir Charles Barry's estimate, 62,000 ft., and that given in the Summary at the end of the Appendix to the Report of the National Gallery Site Commission (1857), which was 80,000 ft.; but he is not disposed to place any reliance on the dimensions in the Summary. The area of the exhibition-rooms in the present National Gallery, he gives as 9,734 ft., and that in the Royal Academy as 7,462 ft.; which would make a total of 17,196 ft. The area provided in Mr. Street's design, of course excluding corridors, keeper's residence, offices, and the like, would be:—

	Sq. Ft.	Sq. Ft.
On the Gallery-floor:—		
Principal Picture-galleries.....	38,833	
Cabinets on the gallery-floor.....	8,110	
Do. on floor above the gallery.....		
Total.....	8,994	50,203
On the Ground-floor:—		
Turner Gallery.....	1,680	
Gallery for Drawings of old masters, and exhibition-rooms.....	11,679	
Water-colour Galleries.....	5,589	
Library or Drawings (Eastern Gallery).....	3,467	
National Portrait Gallery.....	8,032	
Total.....		30,751
Grand total: Floor-area of Rooms for Pictures and Drawings.....		88,954

So that, without building on the barrack-yard, the ground would allow, according to Mr. Street, on the gallery-floor alone, space exceeding by about 46,500 ft. that now provided in the National Gallery, or space about equal to that of the Louvre galleries. We give these dimensions without thereby intending at all to designate Mr. Street's design as that which should be selected, and without feeling that we are bound to give the estimates of other competitors. Neither can we enter into any comparison of figures; though we must point out that it is one of the estimates for whatever interest it may have with our readers, and as affording some approximation to an idea of what the future building may be, as to the provision for pictures. We would, however, observe that difficulty of

comparison, for the judges or ourselves, is occasioned by the differences of reading of the "Instructions," as to what works of art space had to be provided for. Here, indeed, "Instructions" should have been definite. As the case is, some of the competitors provide for sculpture, inclusive of antiquities from the British Museum; others exclude sculpture entirely, or in the main, but include the National Portrait Gallery; whilst some express an opinion, not without grounds, that a collection like this last, which is interesting not chiefly in connexion with the art of painting, but otherwise, should be excluded from a gallery of art-works. We may add that Mr. Street estimates his building as likely to cost 374,000l., inclusive of 25,000l. for sculpture upon it.

Mr. Cockerell's designs are three in number, and are marked No. 1, No. 1A, and No. 2. The drawings are somewhat mixed together in the Gallery, as compared with those of designs of other competitors. The design for altering the present building is the No. 2. The design No. 1A, however, retains the portico of the centre, and would use again the columns, pilasters, and entablature of the present front; whilst by a slight modification in the arrangement of the decorative features, the existing galleries might be preserved. No. 1 is the design for an entirely new building. Galleries on the site of the barracks are shown on the plans; but description of the designs should here exclude them. The design No. 2 would involve but little pulling down of what is existing. The present dome and the "pepper-boxes" would be removed; and there would be added an attic and two domes in the centre, and two other domes to the wings, making four domes to the front. These domes would be carried on columns or iron-supports. The arrangement would involve the removal of the present staircases, and construction of a new staircase. The attic would be decorated with terminals or caryatides; and round the springing of each dome, or upon the tambour, would be obelisks. The galleries in the new ground would be the same as in the designs "1" and "1A" (which we are about to describe,) excepting as to a slight difference in the matter of floor-levels.

In design No. 1A, the dome and the lanterns of the wings are removed as before; but, whilst the present portico is in fact retained, a very different character is given to it, as also to the rest of the building. We should mention that the two staircases are not retained; but that in the centre of the front-range of building, a large staircase-hall is planned, with balconies round, which are reached by three different flights of steps from the landing between the stories; to which landing there is a single flight opposite the entrance. One of the three upper flights, without turning from the landing, leads straight to the new galleries on the line of transverse axis of the plan: the other upper flights, returned back, give access to the balcony-landing; leading from which, the galleries of the front are entered. As regards the portico: for the present podium-wall are substituted an upper and a lower stylobate; the latter being a continuation of the same feature, which is added to the whole length of the building, and is rusticated with horizontal channelling; whilst the upper stylobate, to the portico itself, has ordinary cornice- and base-mouldings of a pedestal. Flanking the portico, and not interfering with its columns at the sides, two-storied and domed masses, square on plan, are added to the main line of the building: in these are the entrances, flanked by salient columns; whilst the upper story is pilastered, and contains niches. Between these two masses, and forming the back-ground to the roof of the portico, there is an attic-wall, with niches; and above and to the rear of this is a square mass, slightly enriched, enclosing the upper part of the central space of the staircase-hall. The order is continued to the ends of the building: the columns here are salient; and they stand on the hold set-off or base which corresponds with the lower stylobate of the portico. The salient portions of the entablature, over the columns, carry scroll buttresses to an attic; and upon the latter are vases. From behind the attic rises the steep slope of the curb-roof. At the ends of the front, however, masses are carried up higher than the general line of attic, or as pavilions. Decoratively, they add a super-order to the main order,—their features being pilasters, and salient columns carrying a central pediment in each face, besides niches. As termination to the whole, there are obelisks,—which Mr. Cockerell seems to be enamoured of. A good termination, other than

statue, to the piers, or pedestals of an attic, of a building of the classic character, still remains to be designed. The intercolumns of the main order in this design, are filled with very lofty windows, each with a pediment, and a decorated million-and-transom window-frame. On the whole, we prefer the design to the No. 1. The description of the plan and arrangement of this last-named will answer for No. 1A, with the exception of what is connected with the staircase.

In his design No. 1, Mr. Cockerell, like so many of the other competitors, has adhered to the raking lines of the ground, next Hemming's-row and St. Martin's-place. To avoid the eyecore of acute angles he has substituted for them, circular forms on plan, on the principle observed in the triangular block containing the Lowther-arcade, in the West Strand. This very arrangement, however, as to the north-western angle in Hemming's-row, would become a defect in the event of a prolongation of the line of building, westward: indeed, this appears in an elevation which shows the combined or extended frontage. We may confine description, as in previous cases, to the design non-inclusive of any buildings on the site of the barracks and barrack-yard. The lines of the chief frontage are the same as in the present building, excepting that the general line for the wings is advanced 4 ft. This would preserve a view of the portico of St. Martin's Church, to any spectator standing at the portico of the College of Physicians, or at some distance westward on the opposite side of the street. One competitor, whose design we have to notice, felt so much doubt as to the interpretation of the "Instructions" on this point of the view of the St. Martin's portico, that he has prepared alternative plans. Mr. Cockerell's building would be entered, in the middle of the front, through a loggia of arches approached by side-flights of steps. This loggia has five arches in front, and has one arch at each end, or to the projection from the main line of building. Arches corresponding with those of the loggia are the chief features of the general front; where, however, they are filled in with walling containing window-openings. All these arches rest on a podium, channelled horizontally, and pierced with circular openings at long distances. The arches of the loggia and front have no impost or console. In their spandrels are wreaths. The piers have some kind of cable-formed decoration up the face of each. They stand on dwarf-pedestals of peculiar appearance. The ends of the loggia break forward slightly in front, and on the returns, to form square masses on plan: these carry dome-capped turrets. From the loggia the way leads into a circular entrance-hall; from which stairs lead, right and left, to galleries of the principal floor; and from which the galleries on the transverse axis of the plan are entered. The entrance-hall has an opening in the centre, in the ceiling, for light from the hall above. The latter hall is lighted, through a domical ceiling, from openings in a lofty outer dome which is the main feature of the building externally. We must say, however, that the external dome has been made an inelegant feature. The external details generally of the "Design No. 1" are inferior to what Mr. Cockerell can accomplish; but those of the famous of this dome—a sort of "Debased Italian"—are really bad. They are as inferior to much of the work of the period of the original "Debased Italian," as work of a village-mason striving to imitate that Italian, might be to the original. As to the dome itself, the openings proposed to be filled with glass-tiles,—by which means, according to Mr. Cockerell, "the effect of a conservatory would be avoided, and the dome would have a solid appearance,"—would not in our opinion conduce to the solidity or other ingredients of the effect externally. Internally, as to the domical lighting of the circular hall and the decoration, the case is very different. The ceiling, or vault, is divided into two parts in the height, by mouldings. The lower division, which is entirely decorative, presents, at the base, a series of lunette-spaces enclosing sculpture in relief: above these are circles enclosed by wreaths of laurel, and containing portraits of celebrated artists: in the intermediate spaces round the springing, are winged figures holding the wreaths; and ornamentation is carried up as support to the dividing-mouldings before mentioned. The space above, to a central "eye," is divided into compartments; and these are filled in with large panes of glass in bars arranged on a geometric pattern. The "eye"

is capped by a small lantern. On the walls, in the drawing, the Caricorns are shown; but these works would surely be too large, either singly or altogether, for any hall of no greater circumference than that which Mr. Cockerell proposes. Round the well-hole aperture in the floor, there is a seat; which is made an architectural feature. The entrance-hall below is divided by columns of the Phigaleian Ionic order. Besides the features of the exterior that have been described, there are pavilions to the ends of the front, somewhat as in the other designs. They have rusticated piers, and an emphasized centre, and pediment, in the lower part; whilst there is, in each case, a super-order of columns and pilasters, with arches, and niches; the whole being crowned with vases and obelisks. The general front, or between the wings and centre, also is terminated by vases, on an attic; and there are obelisks to the angles of the turrets in the centre. The lunette-spaces in the arches of the front are filled in with what seem to be raised panels. The best hit of contrivance in the exterior is comprised in the arrangement of the steps to the entrances. In this design, as well as the other, there is almost too much of building up, merely to get sky-line: indeed, this is becoming a common fault: it is seen in several designs in the Gallery. Mr. Cockerell's masses above the general cornice level, as in the case of the pavilions at the ends of his front, are indeed enclosures to portions of the actual height of rooms in that part of the plan. But the idea of two stories internally, is given by the exterior; and the question is whether the actual arrangement, of square halls at these parts, which are of greater height than the galleries intermediate, is not what should appear. In the arrangement of the galleries and rooms, taking in the new ground, a four-sided central space is first enclosed by buildings which follow the lines of the ground; and the enclosure is then divided so as to leave four courts, by galleries. Of these galleries, those parallel with the front are of but one story in height, and are lighted from above. The principal galleries are, of course, 50 ft. in width; but there are others narrower. The angles of the rooms are generally cut off, so as to allow pictures to be shown the more advantageously. Side-lighting is designed for galleries which are to contain cabinet-pictures, as also for all galleries of the ground-floor that have other galleries over them. Some portions of the plan are arranged with galleries in which are screens that are at an angle with the wall wherein the window is. Mr. Cockerell rightly advocates, and has provided in his plan, large and small rooms alternated; and he quotes Eastlake and Dyce in arguing that small pictures should not be exhibited in the same rooms as large ones.

The observations of these authorities (in a report on the lighting of the Taylor and Randolph Galleries at Oxford) have also led him to suggest a system of top-lighting modified from that one wherein a horizontal screen below the skylight is a feature; though, in his drawings, he adopts the South Kensington system, to which the attention of the competitors was called. The principle is the same as is exemplified in one of the galleries at Munich; of which gallery one of the competitors in the present case adopts the arrangement nearly. The arrangement advocated by Mr. Cockerell has for its chief feature the lighting the pictures by a direct light from the ceiling; whilst the source of light is in some measure screened from the eyes of the spectator by a breadth of central *plafond*, the length of the gallery. One objection brought to the Munich arrangement being that the result is the tricky effect of a panorama; he believes that he avoids this by leaving the ceiling at the level of the top of the cove, or little lower, instead of bringing it further down; whilst he proposes to form his ceiling with thick double-ground glass, so as to relieve the heaviness, whilst preserving the effect. A curtain would be hung in summer, from the apex of the outer skylight, or dividing the roof-space above the ceiling into halves, to screen the direct rays of the sun, without detracting from the light. The intersections of the smaller galleries are made very effective by the use of an arrangement of domical light, similar to that of Hanover Chapel, Regent-street. We should mention that the space for pictures in this design is estimated as, on the ground-floor, 1,360 lineal feet of wall-space, and 2,601 ft. of screen-space; and as on the principal floor, 3,644 ft. of wall-space, and 620 ft. of screen-space: the total being 7,628 ft.: but to this may be added 550 ft. of screen-space

in a second-floor gallery that there is towards Hemming's-row; and which is suggested as suitable for the National Portrait Collection. The building is estimated to cost 260,000l.; whilst for No. 1A, the amount would be 251,000l. Design No. 2, retaining the existing building, would be 143,500l. Mr. Cockerell proposes no alteration in the Square: indeed, the competitors who suggest alteration are fewer than we at first supposed.

We have still to notice many of the designs.

ON THE CONSTANT SUPPLY OF WATER FOR LONDON.

THE City Officer of Health having pronounced so strongly as he has done against the practicability of a "constant" supply of water for London in lieu of the "intermittent," it was desirable that some one who could speak with authority should say what there is to be said on the other side. This was done on Monday evening last, at a meeting of the Health department of the Social Science Association, by Mr. Bateman, C.E., who has constructed, in whole or in part, the waterworks of some twenty-five or twenty-six different towns and cities, varying in size from 7,000 to 600,000 persons, and containing a gross population of upwards of 2,000,000. In all these towns there are, we believe, but three which, at the present time, give an intermittent supply of water, and these are towns in which waterworks existed previously. In one of these, the town of Belfast, the system will be discontinued as soon as new works now constructing have been completed. In many places, and most importantly those of Manchester and Glasgow, the mode of supply has been changed from the intermittent to the constant system, and it was his experience specially with reference to these cities, and the change of systems, that he laid before the meeting. We give some passages from his address.

The question of constant supply is one which most materially affects the comfort and convenience of the poorer classes, and the inhabitants of smaller houses. In larger houses ample cistern space is generally provided to secure the equivalent of a constant supply; but where water is constantly laid on from the street mains there is scarcely any occasion for house cisterns, except for the supply of water-closets. By proper arrangement, little or no inconvenience is experienced from the occasional shutting off of water for the changing or attaching of house services. The first cost of introducing the water to the houses is reduced to the lowest possible point, and the pollution which more or less commonly attends the storage of water in house cisterns is entirely prevented; the water is delivered in the purest, freshest, and coolest condition; and very much of the annoyance and inconvenience arising from frozen cisterns and burst pipes, which are the common attendants of the winter season, is avoided. There is no occasion for exposed pipes in out-of-the-way places, for cisterns in roofs or the tops of the houses to be filled with soot and dust in summer and to be frozen in winter,—and a man may live in tolerable comfort without the dread of the water bursting above his head, and deluging the apartment in which he resides. But the advantage of constant supply to the consumer has been so often and so clearly demonstrated, that it is useless to dwell further on this branch of the subject. The question of its adoption does not entirely rest with the consumers; but with those who have to provide the water. It is believed by many that the consumption under the constant supply system is so great that no company or waterworks can meet the demand,—it would be ruin to them if they attempted it. I cannot but think that all this is a delusion,—it is not that more water is actually consumed for the use of the individual under the one system than under the other; but that the amount of *scasts* which results from bad pipes and bad fittings constantly supplied with water is so great as to occasion serious loss and inconvenience to a water company, and perhaps in some cases to exhaust their supplies. The experience of those towns where the supply has always been on the "constant system," and where every precaution has been taken for the purpose of securing good workmanship, the best and strongest materials, and the most improved apparatus, the consumption of water per head is certainly not more, probably less, than it is in towns similarly circumstanced in all other respects, but supplied with

water on the intermittent system. This is abundantly proved by the statistics of water-supply in such places. For instance, the average consumption of water in the manufacturing towns of Lancashire and Yorkshire is from sixteen to twenty or twenty-one gallons per head per day for all purposes, including trade, and of course, all the waste which may be taking place. In Manchester, the quantity consumed by about 600,000 persons, and by the trades demanding water within the district supplied, varies from 12,000,000 to 13,000,000 gallons per day. Of this quantity it is estimated that one-third is supplied to manufactures, leaving the net quantity consumed for domestic purposes, including waste, fourteen gallons per head per day.

The experience of Preston, Blackburn, Bolton, Stockport, Halifax, Warrington, and all the other manufacturing towns in the north of England is identical with that of Manchester; and if this be compared with the consumption which obtains in towns supplied under the intermittent system, it will be found that scarcely in any case does the supply fall to so low a point as under the constant system.

In London it is thirty-two gallons per head per day, and in Plymouth, Devonport, Shrewsbury, Oxford, and other places supplied on the intermittent system, the consumption amounts to thirty gallons or more per day.

The quantity required in different towns no doubt varies according to the class of inhabitants, the circumstances, and the habits of the people; and it is universally found that where water-closets exist as a general rule, the consumption is greater than where they are comparatively absent.

At Newcastle-on-Tyne the water has always been delivered on the constant supply system; but the consumption gradually increasing to an extravagant point, a vigilant inspection was introduced, and means taken for checking the wasteful expenditure of water, sufficient powers having been granted to the company by a recent Act of Parliament, and this was effected to a great extent.

Shortly after the introduction of a new and ample supply of water into Manchester in the year 1859, the old system of intermittent supply was superseded by that of the constant system; but it was only gradually introduced. The city was divided into small districts, and all means were taken for seeing that all the pipes and water fittings were of the best description, and suitable for use under the constant supply system before the inhabitants were allowed to enjoy that advantage. At my suggestion, the corporation in whose hands the water supply was, adopted the plan so successfully pursued in other towns of being their own plumbers; but the clamour and opposition of the plumbers of the city was too much for popular representation, and the system was gradually relaxed. They discontinued the plumbing, but they established a warehouse or shop for the sale of fittings, purchasing the very best, and, as far as possible, compelling the plumbers to purchase from them, allowing the adoption of none which were not approved.

After a time this was discontinued, and a certain number of plumbers were licensed or authorised to do the requisite work on certain conditions, with which they were obliged to comply. These regulations are still continued, and there is probably no great water supply in the world which is administered with as little waste and with as much convenience and comfort to the inhabitants.

It will be thus seen that where everything is in good order, and both the water provider and the water consumer do their respective duties properly, there is no disadvantage to either party by the supply of water on the constant supply system, while the advantage to the consumer in the facility with which he obtains water, and the trifling cost at which it can be introduced into his premises, are incomparably greater than can be enjoyed under the other system. Where, however, the intermittent system has hitherto prevailed, the desirableness, and indeed the practicability, of abandoning it, and adopting the constant supply, depends very much upon the consumers. If they will submit to such regulations as are necessary for preventing waste, there can be no difficulty in introducing constant supply; it will occasion no more waste than the intermittent system. The only changes which are required are the abandonment of all bad fittings, such as common ground taps, leaky cocks, and wasteful water-closets. The cisterns already existing in houses which have been adapted to the system hitherto

employed may remain, if it be the will of the owner or occupier that they should. If they are large enough they do now practically give a constant supply, and it is only just to the provider of water that care should be taken to prevent improper use. Those who prefer to abandon their cisterns and to take their water direct from the pipes, can do so at very little expense. In all new buildings there would be no necessity for the expensive paraphernalia of cisterns. A stop-cock on the service-pipe of the house would enable the water to be turned off whenever repairs or alterations were required to be made within the house. Little inconvenience is felt by grouping a number of houses together, commanded by one stop-cock; and, indeed, it may be said, that complaints of inconvenience arising from interruption to the supply of water are scarcely ever heard in towns where the constant supply is at work. If the public will not submit to introduce the best description of fittings, and to prevent waste, and will not subject themselves to the vigilant inspection which ought to be exercised by the provider of the water, and be willing to correct everything which requires correction, it will be difficult, and in some cases impossible, to introduce the constant supply.

I must not omit, however, to notice the great consumption of water which obtains in many of the Scottish towns, and notably in the city of Glasgow. There, under both the intermittent and constant system, the quantity supplied has been enormous; but it is easily accounted for, and might be remedied.

Under the old system of intermittent supply, when the water was pumped from the Clyde, the gross consumption was at the rate of forty gallons per head per day, thirty-six gallons of this being due to domestic consumption and waste, the latter element being mainly chargeable with the extravagant consumption.

After the ill-use of water-closets, one of the great causes of waste in Glasgow was the wretched character and condition of kitchen-taps and the water-fittings generally.

In one tenement, while one careful man wasted nothing, another negligent fellow ran down his sink-stone, for no useful purpose to himself, no less than 850 gallons a day.

This waste is principally caused by the universal custom in Glasgow, of using the common ground-tap—the worst description of tap for water under pressure which can be adopted, and which has long since been exploded in all improved and well-regulated water-works in England.

The total consumption of the city from Loch Katrine and Corhals together is 22,000,000 gallons a day, being at the rate of about 50 gallons per head, and just twice, in gross quantity, as much as Manchester and Salford take for a larger population.

This case of Glasgow will no doubt be much relied upon by the opponents of the "constant supply system;" but the extravagant consumption is clearly due to causes which may be remedied, and to the fact that the Corporation have never resolutely and perseveringly set to work to apply the requisite remedies. The people of Glasgow look upon Loch Katrine as practically inexhaustible. The works are constructed on a scale for bringing more than twice the quantity now used. They are their own property, and as the water is supplied by gravitation, the excessive waste which takes place costs them nothing at present. In conclusion, Mr. Bateman said, I see no reason to doubt that if in this great metropolis the providers of water and the consumers of water will each do their duty and work harmoniously together, the citizens may enjoy the inestimable benefit of an unlimited supply of water constantly laid on, without consuming a gallon more water, if, indeed, as much as is now supplied by the water companies.

TELEGRAPHIC PROGRESS.—A prospectus has been issued at New York, of an East-Indian Telegraph Company, with a capital of 5,000,000 dollars, for the purpose of "connecting all the principal seaports of the Chinese Empire with the Collins line, across Behring's Straits, with San Francisco and New York and the Russian Government line to St. Petersburg, and with London, Paris, and all the principal cities of Europe." It is stated that there are now wanting only 850 miles of wire to connect New York with Peking.

ARCHAEOLOGIC ITEMS FROM ROME.

The immutability of Rome and the absence of all signs even of the life that desires outward improvement or inward progress, seem particularly curious and characteristic, now that such clouds of uncertainty are hanging over her political horizon, and such inevitable destiny of change is threatening to overtake her, whether with or without her co-operation. Amidst all that can be urged against the Papal Government, and whatever the feebleness or inactivity that may be endangering its vital interests, there is still a token of some regard for intellectual claims in the activity with which certain antiquarian researches and works for the illustrating of the past are at this moment advancing,—in some instances matured, in others incipient, or but promised. We find the range of catacomb-excavations continually enlarging; we see at the S. Callisto hypogee on the Appian Way, most interesting among those subterranean cemeteries for art-objects, a set of labourers daily at work, and, in consequence, a daily admission of visitors with tickets; and at the supposed most ancient of all these catacombs, those of S. Priscilla, the diggings are also in continuance, though we are informed (and here is the other side of the picture) that—so little can authorities afford for such undertakings,—not more than sixteen men are actually employed upon all these labours in Rome's sacred subterranean! It is different at the Palatine, where the works directed by Signor Rosa, in the gardens purchased by Napoleon III., are proceeding with vigour, and where every Thursday brings crowds of visitors admitted by gratuitous tickets. And if, indeed, as Rosa concludes, the vast mass of ruinous substruction, apparently belonging to an extent of terraces, can be identified as the Temple of Jupiter Stator, or at least its enclosed promises, the discovery is indeed important for historic illustration. Not that anything like architectural elevation has been added to the monumental range on the "imperial mount" by the researches of the last year. Some beautiful sculpture-fragments are now on view in the magazine within the gardens; the finest a draped and headless female statue; but surpassed by the antiques now represented here only in plaster, a torso resembling the Faun of the Capitol, ascribed to Praxiteles, and a Cupid with part of the limbs but no head, the marble originals of both which truly exquisite works have been sent to Paris.

Other antiquarian undertakings lately announced, as ordered by Government, at a meeting of the Roman Archaeologic Academy, are the resuming of labours initiated some years since on another part of the Palatine, the slopes and low ground at the north-western angle not included in the Emperor's purchase; also the excavations at Ostia, necessarily suspended on account of malaria during the summer. Signor Guidi (a well-known explorer) is going on, at his own risk, with the some three years since commenced diggings just beyond the southern limits of the Casacella Thermana, where the extensive ruins of halls and passages brought to light far below the surface of the gardens that extend round the vast imperial buildings, must certainly pertain to some residence of superior scale and splendour. Five of the chambers, into whose dark interiors we can look through broken doorways or at depths below our feet, are at present explorable, for the sinking in of soil has frustrated much of what the labourers had accomplished, concealed (we are told) much that had been discovered of artistic character; but we penetrate, stooping, into three small chambers under the same span of heavy brick vaulting, on whose walls we see decoration in flowery and foliate designs well preserved on the stucco surfaces. And still more curious are the mosaic pavements of rooms now roofless,—one, in particular, that comprises four large figures, in black and white, and sea monsters, each ridden by a male or female figure almost nude, the designs exhibiting a certain degree of knowledge and spirit; one of the nondescript creatures having a goat's head to a dragon body, another being a robust specimen of the sea-centaur, half man, half dragon.

In dirty and dismal Trastevere, within the area of a wretched little court, amidst squalid cottages, near the old church of S. Crisogono, we find another excavation for antiquarian interests lately begun by a Signor Gaggiardi and another proprietor, also at private cost and risk, which has resulted in the uncovering of a great extent of walls in good (though not the best) ancient brickwork, tra-

CHURCH INSTITUTE, LEEDS.—Interior of Lecture Hall.

versed by two archways of large tiles above entrances into chambers, identified as a military station of the Vigiles, and reported to be that of the 7th cohort belonging to that corps; the interiors here opened being still adorned with some frescoes on walls and some mosaic pavements, but not, we regretted to find, accessible at present, owing to a similar disaster as at the other newly-opened ruins,—the sinking of the soil so as to fill up the areas just cleared out. In their present state we look down upon these structures as they rise against one side of an oblong excavated space; and if the parties interested can obtain permission to extend these diggings after the demolition of some paltry houses above, greater results may be expected. Near them rises another ruinous wall in the same ancient brickwork, with the traces of a vaulted chamber leaning to the outer side, high above, and enclosed within the filthy court of a small house,—probably another remnant of the Vigiles' station, which has long stood con-

spicuous, but scarce noticed in this wretched Trastevere quarter. Visconti has written a full report on the discoveries of this site, to be read, in translation from the Italian, to the English Archaeological Society.

As to the proceedings of that still youthful association, we have to report signs of activity, and things that promise. The nucleus of an archaeological library, hitherto collected through donations, has been formed, for the use of its members, at the consulate, the place of rendezvous hitherto. Within ten days we have attended, since the 28th of December, two meetings, before numerous audiences at the same English consulate, at the first of which Mr. Shakspear Wood, the sculptor, and secretary of the same society, read a paper "On the Appian Way," translated from the Italian of Signor Pellegrini, a Roman antiquary, conveying a very full but somewhat dry report on the entire range of monuments upon that classic way between Rome and Albano. At the second, Mr. J. H.

Parker delivered (for we should not say read, seeing that, but for the use of a few notes, all was extempore) a learned lecture "On Roman Aqueducts," referring to all the remains of those structures in the obscurer as well as the best-known examples, and illustrating his theme, as he went on, by a series of excellent drawings, plans, and photographs prepared by a French artist expressly for the occasion. Mr. Parker's support was never more ably given to the new association; and it struck us that, of all we have hitherto heard at its meetings, this lecture on aqueducts was the master-piece. Weather did not permit the resuming of the study under the same efficient guidance, on two successive days of peripatetic investigation, for which the lecturer had invited his hearers to accompany him, as well to the sites of all aqueduct ruins within the walls as to the more remarkable of such antiquities on the Campagna; which promising expeditions have not, however, been put off *sine die*.

GROUND PLAN

FIRST FLOOR PLAN

SCALE OF FEET

LEEDS CHURCH INSTITUTE.

The foundation stone of this building was laid not long ago by the Archbishop of Canterbury. The design selected in public competition is by Messrs. Adams & Kelly, architects, of Leeds.

It is in the Decorated style of architecture. The principal fronts face Abdon-place and Land's-lane. That towards Abdon-place is divided by buttresses into five bays, which are gabled and finished with stone coping and carved finials; at the spring of the coping are gurgoyles, carved with grotesques, and supported on coloured shafts. The traceried windows are of stone, and light the library and large lecture-hall. The bay next Messrs. Hebbliethwaite's premises has a projecting gabled porch, over which are flying buttresses. The principal feature towards Land's-lane is the large gable, pierced with coupled three-light traceried windows, with circular one over. This window also lights the lecture-hall: on each side of it is an arched, and beneath it traceried windows lighting library and reading-room, also secretary's-room. The clergy and council room have also windows in this front. The building is of brick, with stone dressings and coloured brick hands. The tympana and spandrels of arches are filled in with pattern brickwork.

The roofs are covered with slates, laid in bands of two colours, and surmounted with ornamental iron ridge cresting. In the centre of the lecture-hall roof rises a *cloche*, terminating with a metal cross and finial; this, together with the piercings in the end of the large gables, serves for ventilation. In the basement floor is the librarian's-room, with kitchen and pantry attached; coal-place, heating-chamber, large kitchen fitted up with boilers, &c., for institute purposes, and store-room. A lift is provided for the several floors above. The ground-floor has a spacious hall in direct communication with principal staircase, which is lighted by a stone traceried window; reading-room and library, with secretary's room. At the back of the library runs a corridor communicating with class-rooms, clergy-room, and hack staircase. On the first floor is the large lecture-hall, 48 ft. span, and extending the whole of the frontage towards Abdon-place. The roof of this room is formed of principals, with curved braces and hammer-beams, supported on moulded and carved corbel shafts. The ceiling is boarded, and divided into panels by chamfered ribs at the end. Next Land's-lane is a raised platform. At the back of this room runs a passage communicating with class-rooms and council-rooms. The second-floor is allotted to bed-rooms.

SANITARY MATTERS.

Chichester.—The report of Mr. Arnold Taylor, the inspector recently sent down to Chichester by the Home Office to report upon its sanitary state, has been presented to the Town Council. It represented the necessity of works for drainage and the supply of water, and directed that the town council should take immediate action in these respects. Upon this report being presented and considered, the town council, true to its opposition to all sanitary improvements in the city, expressed, through Mr. Councillor Adames, the opinion that Chichester did not suffer more from disease than other parts of the county which were drained; that if there were any powers under the Sanitary Act to compel them to adopt a most expensive system of drainage, it was a most despotic enactment, and more outrageous than any tyrannic ever practised in Russia or Austria; and that, with such an enormous increase in the rates as that contemplated, hundreds of people in Chichester would be ruined. It was ultimately decided that the town clerk should acknowledge the receipt of the report to the Home Office, stating that it had been laid before a meeting of the Council, called expressly for the purpose; and that, in order that the report might lie in the hands of every one interested, the council had ordered it to be printed and distributed among the council and the inhabitants generally.

Wolverhampton.—We deeply regret, says the *Birmingham Journal*, to observe that the town council of Wolverhampton, following the bad example of the town council of Birmingham, have refused to appoint a medical officer of health. The sanitary committee did their duty in recommending the appointment, but the corporation lamentably failed in theirs in upsetting

the decision of the committee. The grounds on which the council arrived at its decision—if, indeed, the grounds stated were the real ones, which we much doubt—were that the sanitary inspectors were able to do all that was necessary up to a certain point, and that at that certain point they could call in a medical man to do all that was necessary. The fallacy of such reasoning is so obvious that one would scarcely expect a deliberative body of intelligent men to fall into it. It is like setting a builder to erect a house, and calling in an architect when the builder has got into such a mess that he can get no further. When the advocates of had smells and the owners of small house property are in the majority, it is in vain to urge sanitary reformation.

Liverpool.—There is a prospect of an early accomplishment of important sanitary reforms,—the substitution of water-closets for open middens, the closing of existing slaughter-houses, and the erection of abattoirs near the Stanley market. The town council has given its sanction to the clause in the Improvement Bill, which seeks power to close the slaughter-houses and to erect abattoirs, on the proposed site outside the town; and the health committee have passed a resolution in favour of application being made to Parliament to grant compulsory power for the conversion of privies into water-closets, a proportion of the cost to be borne by the Corporation. Both schemes, however, are threatened with opposition.

DRAINAGE OF BRUSSELS.

At a recent meeting of the common council of Brussels, the mayor, M. Anspach, made an explanation with regard to the arching of the river Senne, which, as our readers are aware, has been undertaken by the Belgian Public Works Company (Limited). The question has been discussed for some years, and has been reported upon repeatedly by all sorts of commissions, committees, and boards. The citizens appear to be getting impatient, and the mayor explained at the meeting above referred to that the works were to have been commenced on the 22nd of January, but in consequence of the severity of the weather the company were not ready, and the opening has been postponed until the middle of February. The King is to perform the principal part of the ceremony, and it was felt that the opening should not be a merely formal one, but should mark the commencement of the work in good earnest. It will take four years to complete, and the purchases of the houses and compensations will be made in May; but, so far as the middle of the town is concerned, no notices to quit will be served this year at all events, as the operations in the outskirts will occupy some months. Part of the work has been sublet by the company to Messrs. Manton, contractors, of Liège. M. Cognigni is to superintend the works on the part of the Government, and M. De Rote is to look after the interests of the town of Brussels. These appointments have not yet been confirmed by the Government, which delay has in some measure necessitated the postponement of the opening ceremony.

PRUSSIA.

NAVIGATION AND TELEGRAPHY.

An influential committee is now being formed at Berlin, for establishing, under the patronage of the Prussian Government, an important line of packets between Germany and the United States, via Southampton. The service is to be made by packets of large dimensions, which will have, as an auxiliary port, that of Geestemünde, a Hanoverian port near Bremerhaven, now made Prussia by the recent annexation. It is to carry the European mails directly to New York; each of the vessels, seven in number, is to be built in France or England, and is to carry 100 first-class passengers, 100 second-class, 600 third-class, and 1,000 tons of freight. The project is said to be backed by the Count Bismarck and other ministers.

We will give some details of the telegraphic system in Prussia. The department of national telegraphs is under the superintendence of a director, who is directly under the orders of the prime minister. In the central station at Berlin may be seen an apparatus connected with all the lines of the country, and many foreign ones. Among the objects of special interest, the mag-

netic accumulators, the permutator, which is the largest in the world, are the most remarkable; also there are worthy of interest the machine for daily meteorological despatches, and that by means of which the same correspondence can be transmitted simultaneously to all parts of the kingdom.

The lines, as well as the stations, are classed in such a manner, that the system of centralization in no way prevents direct communication between neighbouring places. The service is carried on by a special staff of telegraph clerks, except on the lines called *commiss*, which are at the disposal of small towns and villages, and which are worked by the post-office employees. On these secondary lines the needle or some other simple machine is used instead of the Morse system applied to the great lines.

With a good organization, and by the adoption of the most simple mechanical combinations, the Prussian public, it is said, are served at a cheap rate and rapidly; moreover, the excess of the receipts over the expenditure has much encouraged the Government to lower the tariff. The lowest price is 8d., and the net profit for the last year has been £80,000.

FROM MELBOURNE, AUSTRALIA.

The Intercolonial Exhibition, preparatory to the Universal Exhibition of 1867 at Paris, has been opened with *clat* by his excellency the Governor of Victoria, Sir J. H. F. Mansfield, at the Exhibition, Sir J. H. F. Mansfield. The building is so arranged as to form hereafter a permanent addition to the public library. The first addition was found to be inadequate to the purposes of the Exhibition, and a new annex had to be built. The whole space available for exhibitors throughout the Exhibition buildings, is 39,500 superficial feet. The chief feature is the central hall, designed by Messrs. Reed & Barnes, containing an area of 17,200 superficial feet.

"It is noble proportions (says the *Melbourne Age*) are seen to the greatest advantage from opposite the organ gallery. Looking down the avenues on the right and left, with their annexes, some conception may be formed of the number and great variety of the exhibits. Suspended from the arched roof are the banners and insignia of the municipalities throughout the colony, which, from their variety and rich decorations, add materially to the general effect. The visitor, if he pleases, may pass into the rotunda on the right of the grand hall; or enter the eastern annex, devoted to the display of carriages and other vehicles manufactured in the colony. In the rotunda, the superficial area of which is 3,000 ft., the exhibits are of a very interesting character, consisting principally of articles of *verre*, some of which are of great value. At the southern end of the grand hall, beneath the organ loft, access is obtained to the picture gallery, where the chief attraction will consist in the numerous photographic views localities throughout the colony. A very large collection of water-colour drawings and oil-paintings, contributed by various individuals, will elicit the admiration of visitors. The department devoted to machinery is at the northern end of the grand hall. Steam power employed for the working of the machines is supplied by Messrs. Wilkie, Welch, & Co., the exhibits including the manufacture of many familiar articles of ordinary use. The quadrangles north and south of the rotunda are embellished with *fontaines*, and castings in bronze and plaster from the antique model. Extensive accommodation is provided beneath the grand hall for refreshments, access to which is obtained by steps leading from one of the quadrangles."

An excellent project is in hand for the improvement of the National Gallery in Melbourne. The Fine Arts Commissioners have renounced their labours, and taken practical steps towards procuring some additions to the gallery. On the death of Sir Charles Eastlake, it became necessary to make a new arrangement for this purpose; and it is understood that communications have been addressed to several of the most eminent artists in England, stating the circumstances under which is the project of a Victorian National Gallery originated, and requesting each to furnish such a picture as he can for the sum of 500l. The gentlemen to whom these overtures have been made are said to be Messrs. Stanfield, Crewick, Leighton, Phillips, and Macfie. Should the overtures be responded to in the genial spirit which is anticipated, the National Gallery of Victoria will become another link of intellectual sympathy with the mother country.

The inaugural ceremony of the Victorian Deaf and Dumb Institution took place on the 13th of October. The building was formally opened by the governor. The building is situated adjacent to St. Kilda-road. It was stated that the cost of the present building, including the fencing and outbuildings, was 6,800l. Towards the liquidation of that amount, the Parliament had voted 4,000l.; and a sum of 1,800l. had been received from private subscriptions; leaving

0000 still to be provided. The building is surmounted by a lofty tower.

The congregation of the Independent Church, Collins-street, are erecting a new place of worship. It is to be completed in nine months, at a cost of 12,000*l.*, and it is designed to accommodate 200 persons.

An attempt has been made to get up a demonstration of unemployed, for political purposes, it is said, but the attempt was a total failure. One of the deputation to the chief secretary, from a meeting of at the utmost 200 persons, was a working blacksmith, who confessed that he had thrown up his employment because his employer refused to give him more than 4*l.* 10*s.* a week. Other meetings were to be held, but the result was nil.

The Registrar-general's report on the vital statistics of Melbourne and the suburbs, for the month of August, is published in the *Government Gazette*. From it we learn that 218 persons died during the month. The deaths were fewer by 20 than the average of the month in seven years, and this notwithstanding the districts have greatly increased in population during the period. The deaths of males and females furnish a proportion relatively to the whole mortality of 57 per cent. and 43 per cent. respectively. Deaths of children under five exhibit a proportion of 44 per cent. to the whole, against 49 per cent. in August, 1855; 34 per cent. in August, 1864; and 49 per cent. in August, 1860. Forty-nine deaths, or 22 per cent. of the whole, took place in public institutions, viz.:—30 in the Melbourne Hospital, in the Lyong-in Hospital, 5 in the Benevolent Asylum, 2 in the Immigrant's Home, 3 in thearra Bend Lunatic Asylum, 4 in the Industrial schools, 3 in the Melbourne Gaol, and 1 in the prison hulk *Success*.

The *Geelong Register* states that the Geelong Woolen Cloth Company's building, on the banks of the Barwon, is nearly completed. The building first erected is of bluestone, and the main room is 111 ft. in length. The new building now being erected will also contain a room 111 ft. long for the reception of looms, besides an engine-room, and the long room is 44 ft. wide. Between the two buildings there is an open space about the same width as the room, which it is intended to roof over and inclose at each end, so that there will eventually be a range of three large buildings all conjoined, forming an immense factory. The building now being completed is on a plan sent from England. The main room will be the same length as that of the old building, but will be 44 ft. wide in the ar.

THE SHORT-TIME MOVEMENT.

AN experiment has recently been tried at Melbourne, by M. Jean Dolfus, so well known for his numerous philanthropic schemes, with very satisfactory success. It occurred to him that the working-day of twelve hours might be shortened one hour without any decrease in the quantity of material produced, and that the loss of one hour would be compensated by the increased power of production in the workman. For the first few weeks the quantity fell off; but it increased gradually, and eventually from one to two per cent. more work was done in eleven hours than had formerly been done in twelve. There is also a large saving in the wear and tear of machinery, and the cost of warming and lighting the mills.

THE TRADES MOVEMENT.

Stockport.—The operative masons employed at the New Connexion Chapel, Wellington-road, were on strike on the ground that Mr. Pearce was securing their work, a practice they would not permit. The masons at the St. Peter's Gate Church were all taken away. Mr. Pearce, not wishing the works to stand still, gave his word he would not repeat what was objected to. He was not required to pay them their wages for the time they had been stopped, and was informed that he would not be allowed to go on until this was done. To this last demand Mr. Pearce objected. The men, apparently ashamed of their conduct, commenced work again, having lost their time. The matter is to be brought before the master masons and the General Builders' Association.

Nottingham.—At a meeting of the Nottingham Chamber of Commerce, Mr. A. J. Mundella re-

ferred to a paragraph in the annual report which had relation to arbitration, and remarked that there ought to be something done to allay the state of chronic warfare which now existed throughout England on the question of wages. In the hosiery trade they had found a board of arbitration work most satisfactorily. During the last two years the state of matters in the hosiery trade had been of a very anxious character, but they had been able to take their contracts without fear of strikes. In fact, they considered a strike an infraction of the rules. The Board consisted of seven workmen and seven employers, and they bound themselves to stand by the decision which should be arrived at, and they were able to settle their difficulties in the most amiable and satisfactory manner. They had found that, during the last six years, all the decisions of the board of arbitration had been agreed to. Mr. Hill said the workmen appreciated the board of arbitration, and considered it a great blessing to them.

Wolverhampton.—An address and a silver inkstand have been presented to Mr. Rupert Kettle for his able services in the cause of arbitration, by the master builders and operative carpenters and joiners in this town. Most of the architects and builders were present at the presentation, as well as many operatives.

THE LATE M. INGRES.

THE town of Liège possesses a very beautiful work by this artist, which was painted by him when a very young man. It is a portrait of Bonaparte as first consul. In 1804, just previously to the establishment of the Empire, the consular government decided that the portrait of the first consul should be sent to the principal cities of the Republic, and M. Ingres was the artist entrusted with the work. The original painting, of which several copies were made, was placed in the town-hall at Liège. In compliance with the wish of M. Ingres and the French government, it was sent to the Paris Exhibition of 1855, the municipal authorities having first stipulated that it should be insured for 20,000 francs, and conveyed to Paris under the personal supervision of a deputy to be appointed by the artist, and returned immediately the Exhibition was closed.

PICTURE FOR CHRIST CHURCH, MARYLEBONE.

We have before now mentioned the large picture intended for the east end of Christ Church, Marylebone, on which Mr. W. Cavot Thomas has been for some time at work. It is now completed, and will probably be placed in its intended position next week. In form it is a flattened arc of a circle: the subject is the diffusion of the gifts of the Spirit, as suggested by the text, "And when He had ascended on high, He sent them gifts." Christ, the central figure, seated, is despatching his angels loaded with good gifts. On the one side are sailing earthwards Power, Wealth, Beauty, and Plenty; and, on the other, Faith, Wisdom, Justice, and Honour. The figure of the Saviour is one of dignity and power, the drapery admirably painted: the beads of the various angels are expressive and beautiful. The result, as a whole, is more than admirable; and we congratulate alike Mr. Cavot Thomas on his most successful completion of a not easy task, and the congregation of Christ Church on the possession of a fine work of art.

The background, according to a Russian method, is sanded and gilt, the minibus of the Saviour being alone of flat gilding.

SCHOOLS OF ART.

The Cirencester School.—The distribution of prizes gained by students of this school in local and national competitions took place at the Corn Hall, Bath, Easter in the chair. Numerous drawings by students of the school were hung upon the walls. The report states that the Cirencester School has successfully maintained the high position which it has achieved in previous years, and is now ranked amongst the best schools in England. At the last national competition Cirencester out-distanced some of the largest towns in the kingdom, carrying off, amongst other prizes, a national scholarship and

three medals. This gratifying result is attributed to three causes—the industry of the students, the careful superintendence of the committee, with their secretary, Mr. Zachary, and above all, to the great experience, ability, and assiduity of the art-master, Mr. Miller. Having obtained one silver medal out of twenty, and two bronze medals out of fifty distributed among the 100 schools in the kingdom, besides other prizes, says the report, we congratulate the students on the fact of their success in the Third Grade Examination, having ranked us with the best schools, as we have been surpassed only by nine of the largest, including the Metropolitan. Mr. J. B. Atkinson, of London, afterwards addressed the meeting at some length on the subject of art.

SOCIETY OF FEMALE ARTISTS.

THE ladies make a better show this year in the gallery of the Architectural Union, Conduit-street, than they did last year. 396 works are exhibited (three being pieces of modelling), and include some very good pictures and drawings. Madlle. Rosa Bonheur sends a graceful drawing of "Dogs and Fawns" (64); Madame Henriette Browne a good "Study of a Head" (54); and the Dowager Countess of Westmoreland, "Wellington writing his Despatch after Waterloo" (148). "The Conscript's Departure" (212), Miss E. Brownlow; "The Orphans" (215), Miss Kate Swift; "Persevere" (208), Miss G. Swift; Mrs. Lee Bridell's capital contributions; "Moved on" Miss F. Claxton; and Miss Jeykll's "Jebu" (235), are the best figure subjects. In works of another class, Madame Bodichon, Miss Williams (239), Miss Jane Deakin ("The Old Tower"), Miss S. S. Warren (77), the Misses Rayner, Miss E. Walter (127), Miss Florence Peel, Miss F. Minns ("May Blossoms"), Miss L. James (300), and Mrs. F. Marrale, who sends a number of vigorous sketches from nature, stand out prominently.

MONUMENTAL.

MR. NOBLE, the sculptor, is charged with the execution of the statue of Lord Palmerston, to be erected at Romsey; and the memorial window in the Abbey Church will be executed by Mr. Clayton.—Mr. George Wightwick, architect, has designed a public monument, which, according to the *Gloucester Chronicle*, it is proposed to erect on the Dowerstone, Dartmoor, to the late Mr. N. T. Carrington, "the poet of Devon" (father of the late Mr. F. G. Carrington, of the paper alluded to). The Dowerstone is a huge cliff, overhanging the valley of the Cad—one of the most charming scenes in south-west Devon. The design comprises a bust of the poet, placed on a pedestal resting on a platform approached by three steps, and surmounted by a canopy fixed on granite columns.—Preliminary steps have been taken for the erection of a public memorial of the late mayor of Margate, Mr. G. Y. Hunter, who died during his mayoralty.—The Emperor of Austria has given 40*l.* towards the erection of a monument, in the town of Arezzo, to the monk Guido, the inventor of the musical notes.

SOCIETY OF ENGINEERS.

ON Monday evening, being the opening of the session for the present year, the president Mr. N. H. Le Feuvre, delivered an inaugural address, in which he congratulated the members on the position the Society of Engineers had at length attained. It is at present numbered amongst its members some of the foremost practical men of our time, and not in one branch of the profession alone. It might be said, indeed, that there does not exist a society with kindred objects possessing so many and varied elements of future success within it. Amongst its members and council were men of large experience in works of design, construction, and art; in boiler and marine engineering, electrical engineering, iron ship-building; gas, ordnance, railway, and hydraulic engineering; inventors, and designers of some of the most valuable processes of machinery employed in connexion with the arts and manufactures of our time. The Society also possessed the privilege of having upon its council the representatives of leading scientific journals.

In his address the president said,—

"I would desire to call your attention also to a circumstance which has lately begun to assume a serious importance to us as engineers, and which promises to endanger one of the most extensive of our manufactures, that is, the production and manufacture of iron. This has been carried on to such an extent in Belgium, that after an interval of a very few years, the run of competition is altogether on the side of Belgian manufacture. They successfully compete with the most extensive of our iron-works in England. As examples, I mention, first, that during the progress of the Exhibition lately erected in Amsterdam, it was found that while the earlier portions were being constructed, it was cheaper to import the ironwork from England; but before the works were completed, a considerable quantity of ironwork was supplied from Belgium and Holland, as it could be obtained at a lower price, and from that period to the present the competition has run hard between those countries and our own. In the new Rimlico Wheel Works, in London, which, as may be known, perhaps, to most of you, were constructed by our firm, we had also to give way to the importation of ironwork from Belgium; and it is the case also with regard to some works we are now carrying out in India, where the ironwork is actually shipped from Belgium to London, and re-shipped to Bombay, at a less cost than it could be purchased from English manufacturers. I cannot but view these circumstances with regret and apprehension, and I hope that, before such a state of things is permitted to become more serious, some co-operation may be induced amongst our leading manufacturers, so that this branch of our industry may not be altogether wrested from us. I mention these instances as facts which have come under my personal observation and experience. We find one of our leading railway companies (the Great Eastern Railway) have procured locomotives from France, which resulted after a competitive tender, to which our leading firms were invited. The incursions of foreign competition have at length reached to such an extent, that one of our leading railway companies invited a French firm to compete with our manufacturers for the supply and erection of the ironwork of their terminal station in London. I cannot, therefore, but repeat that there are good grounds for the fears entertained with respect to this branch of our industry, and trust that these remarks may lead to some practical suggestions being made during the present session, with a view to ameliorating the present condition of our iron manufactures."

Speaking of the difficulty which the state of the roads had interposed on the occasion of the burning of Croydon Church, the speaker said,—

"Sanitary engineering has not yet sufficiently impressed itself upon our own profession, and I cannot but wish all our engineers would exercise their skill and influence in pointing out the necessity of devising the best scheme, irrespective of cost, for the drainage of our large towns and cities. The difficulty is an increasing one, and alarming to all thinking minds. The population of our large towns and cities increases daily. The sanitary measures which have already been carried out in some of our towns have had a most marked improvement in the health of those places; but here, again, the want of sewerage, materially deteriorated the watercourses of the country, many of which, after receiving the abominations attendant on sewage, are used as the only source of water-supply to large populations. From a paper read before the Society in session 1865, we were informed that a quarter of a million of money has been made out of a portion of the sewage of Edinburgh, and that every acre of land under its influence produces ten times the amount of the average of agricultural land in the country. The question of the drainage of our large towns will come under the consideration of Parliament during the ensuing session, and the conservators of the river Thames have introduced a bill with a view to prevent all sewage matter flowing into the Thames; and if this measure becomes law, it will be a precedent which will affect all the rivers and streams in this country, and no doubt it would be far preferable that Parliament should interpose, and legislate on this important subject."

The character of prevailing architecture cannot fail to be of interest to a society like ours. We have still to regret the absence of anything like conformity in the several practices of architects and engineers, and no doubt the character of our nation, judged by its architecture alone, would not stand very high. We have, of course, no modern undertaking which for style could be compared with Westminster Abbey or St. Paul's. The more we go back into the architecture of our country, the more grand and refined it seems to stand out. We have at length reached no style or character of architecture at all. I consider this to arise in a great measure from the attempted estrangement between professions which are analogous, and the failure of modern architects to accommodate their designs to the progress of engineering science. A system is now being extensively adopted with regard to modern buildings which may be called, more or less, a system of iron architecture. The immense gain in strength and durability, in building where this material is employed, is undeniable. Architecture is the science of building, and therefore the engineer, to an iron bridge or other structure in which iron is employed, is as much an architect as the designers of Gothic structures with stone roofs, flying buttresses, and pinnacles. Considering the Church of St. Peter, at Rome, and the Cathedral of St. Paul, and other so-called architectural monuments, from a constructive point of view, it will be found that what is now called civil engineering was exercised by the architects of these structures in a very great degree. They built with the materials convenient to be used, according to the locality of the structures, and their works have remained commanding and imperishable. 'Till it is conceded that there can be but one science of building, we cannot look forward to any works likely to deserve our own admiration or the admiration of others."

As to the streets:—

"Our metropolis, containing a population of 3,000,000 has been for nearly a week in a helpless state of inactivity in consequence of the inefficient means we have at our disposal for clearing away the snow, and the utter want of system and care in the paving, lighting, draining, and traffic arrangement, is well worthy the attention of our profession. The snow might be removed at night by means of snow ploughs, and rapidly melted by heat at convenient places. The relaying of our pavements and streets might be effected by improved machinery, and a diminution of time and inconvenience would thereby ensue. The introduction of subways, as suggested by

the Metropolitan Board of Works, would tend to prevent the incessant breaking up of our main street. The lighting of our public thoroughfares is a disgrace to this city; the design of our lamp-posts and lamps is neither novel nor elegant; our finest streets are in comparative darkness as soon as the shops are closed. The cleansing of our streets is effected by means of manual labour at the most inconvenient hours of the day; the watering-carts lay the dust, and, raising and suble deep, destroy the macadam, create dirt, bespatter our persons and carriages. The encounter of the mud-cart and its two or three attendants completes the delights of a summer-day's walk, ride, or drive in town.

The traffic arrangements in our streets in the metropolis must shortly receive attention, as we are informed from statistics obtained that more accidents and loss of life take place in the streets in our metropolis, than on the whole of our railway system in the United Kingdom. How is this occasioned? We may naturally inquire. The immensity of the traffic might be relieved by employing the present area of our streets in a twofold manner, viz., by constructing subways for traffic under or viaducts above our existing streets."

DESTRUCTION OF THE NAMUR THEATRE.

The theatre at Namur was totally destroyed by fire on the 14th inst. The representation of *Faust* had finished at a quarter-past eleven, and the fire was discovered at one o'clock next morning. The entire building was one mass of flame in a short time afterwards, and at two o'clock the roof fell in. Fortunately no lives were lost, and the library and part of the wardrobe were saved. The cause of the fire is said to have been an over-heated fire. The Namur theatre has been singularly unfortunate, no less than three fires having taken place within six years. The old building was destroyed on the 17th of November, 1859; it was rebuilt, and again burnt down on the 25th of September, 1862. Another building was erected from the plans of M. Fumière, and opened in October, 1863, but only to share the fate of its predecessors. The building was insured for 550,000 francs.

A BRIDGE ON BONES.

Mr. C. A. ELLIOTT and Mr. Bryant, engineer, engaged on the new Blackfriars Bridge, brought before the British Archaeological Association on Wednesday evening last the curious fact that, after they had got up the foundation of the second arch, on the Middlesex side of the river, as they were dredging up the ground from under the foundations, they dredged up a quantity of bones, fully 15 ft. below the bed of the river, and below the masonry for the whole foundation, which did not get down to the clay. In the gravel and near the clay they got up a large number of bones of the ox, the sheep, the horse, and a few human bones. It appears that the foundation of the old bridge was upon these bones. The bones were darkened, but in a high state of preservation.

THE LATEST ABOUT SIR JOHN SOANE.

The last "wills and testaments" of English architects are very little known—and yet our architects, from Bishop William, of Wykeham, to Sir Charles Barry, have died—sworn under a good figure, and with characteristic clauses, bequests, and conditions, in their wills. The writer who signs this communication was the first to turn attention to, and the first to print, the will of Inigo Jones. It is his purpose, from time to time, to print in the *Builder* extracts from the wills of English architects, or matter of interest connected with them.

The great will benefactor among architects to Great Britain was Sir John Soane. The general tenor of his will is known beyond the regions of law and lawyers. What I have now to tell about is new and of moment.

On the 22nd of November of the year just past, the trustees of the Soane Museum in London had (as by will directed) to open, and exhibit, certain locked and sealed repositories in the hidden and secure cellars of the Museum. This direction was duly performed, and in great state, and what was opened was found to contain some pounds' weight of slips of blank paper, cuttings from books and magazines—the *Gentleman's* and the *Ladies'*—a mass of old newspapers, a parcel of old circulars, sundry small and needless things, like old visiting-cards (not so good as the lot Miss Banks, Sir Joseph's sister, bequeathed to the Print-room of the British

Museum); letters (hundreds in number) addressed to him between 1780 and the last days of his vanity. All were in a mass without classification. Many, however, were endorsed, but few have proved of interest. *Beiging* and asking letters predominate;—some from John Taylor of the *Morning Chronicle*, and from B. R. Perry, of the *Morning Chronicle*, and from B. R. Haydon. There are not a few letters, too, from John Britton and Mrs. Hofand. A passage of letters between Sir John Copley (Lord Lyndhurst) touching a debt due to Soane from John Singleton Copley, R.A., the Lord Chancellor's father, will be read with interest.

We were attracted additionally by one paper—an inquiry from a man in authority relative to the charge per lamp for illuminating the Bank of England, for the rejoicings of the peace of 1814. A tender was made to the Bank architect,—10d. a lamp for one night; 7d. a lamp for two or three nights.

Lord Stanhope, the learned biographer of William Pitt, will be pleased to learn that England's great prime minister, Fox's formidable rival,—dabbled in architectural elevations (his father, the great Lord Chatham, was fond of landscape gardening), and that among "Soane's Papers" (just opened) is a brief note from the ministry, and an outline pencil plan of a house, endorsed by Soane as drawn by William Pitt.

The present curator of the Soane Museum is performing his work well.

PETER CUNNINGHAM.

SLIPPERY PAVEMENTS.

I TAKE the liberty of calling public attention, through the medium of your columns, to the incompleteness of the police practice, that every one shall keep his own door clean after a snowfall, for we may observe that pedestrians choose to walk in the road on such mornings as we have had lately, as the scraped pavement is far more slippery than where the snow is allowed to lie; and I would suggest that an addition be made to the request now in use, despatch householders to plentifully hestrew the footpath before their houses with ashes. Sand is thrown into the roads, and is of great utility; ashes cost less, and will serve the purpose equally well. Many folks already do this, and after slipping about elsewhere, it is quite pleasant to feel something underfoot that will not horizontalize you; and, although as a rule, it is not a pleasing sensation to scrunch ashes, the process is preferable to a broken limb obtained on a "clean" pavement.

J. G.

MUSICAL CHIMES AND CARILLONS.

Most persons who have listened to the delightful music of the *carillons*, in Belgium, or certain other parts of the Continent, must, I think, regret that we have so very few sets of chimes in England that can play even a plain and easy melody in a satisfactory manner. By the word "chimes," as here used, I mean a set of eight, ten, or twelve bells—of which we possess many fine examples in our church towers—tuned to the modern musical scale, and struck by hammers acted on by a pinned cylinder or barrel, which revolves by means of clockwork. Sacred or secular melodies are thus performed at certain intervals. "I never hear chimes," says Robert Southey, "that they do not remind me of those which were formerly the first sounds I heard in the morning, which used to quicken my step on my way to school, and which announced my release from it, when the same tune methought had always a merrier import. When I remember their tones, life seems to me like a dream, and a train of recollection arises, which, if it were allowed to have its course, would end in tears."

Now, the mechanical chimes at present existing in this country, with here and there an exception, have clumsy wooden barrels, the pins of which are fixtures: so that if times as inappropriate and detestable as "Drink to me only," and certain others of a similar class, have been set upon a harrel, one or other of such tunes must be played so long as the same barrel is used. A far better apparatus has, however, been made, the most prominent feature of which I will now endeavour to point out. Instead of a wooden barrel, a hollow metallic cylinder is introduced, which is so constructed that any tune or tunes of suitable length, the notes of

which correspond with the several sounds of the bells, can easily be set upon it by any intelligent musician. And as the pins of the cylinder are movable, by merely turning the nuts of the screws, new tunes can be substituted for the old ones on the same cylinder as often as you please.

These few hints are therefore offered in the hope that they may lead some of our influential countrymen to take up the subject.

With regard to carillons, or Continental chimes, we may observe that, in several instances, those from 40 to 48 bells, which are tuned to the chromatic scale, and worked by a pinned cylinder of enormous dimensions; so that a machine of such a magnitude is capable of performing appropriate selections of music, certain passages being harmonized in three or four parts.

Many towers also contain an instrument known as the carillon à clavier, having a set of keys and pedals—the former for the hands, the latter for the feet,—communicating with the bells as those of the pianoforte and organ with strings and pipes. These keys are projecting sticks, wide enough asunder to be struck with the hand sideways, without hitting the neighbouring keys." In some places an organist performs on this instrument two or three times a week.

I may take this opportunity of stating that carillon is likewise the name of a small keyed instrument, now but little known, and which consists of a peal of hand-bells, the tones being produced by box hammers striking metallic bars of different lengths. Handel, it is said, used to accompany his air in Milton's elegy, "Or let the merry bells ring round," with this instrument; and in Saul, the chorus, "Welcome, welcome, mighty king."

In conclusion, permit me to add that it appears to be very desirable to have superior machinery constructed to play at certain intervals of time upon the ordinary peals of bells at many of our English churches; and in some particular instances, if a very few new bells were added to the peal, so much the better. It, having surveyed the bells in the tower of St. Andrew's Cathedral, as well as those at the Hall of Bruges, and often listened to their music, I would say,—Do not for a moment think of introducing a set of chimes on the Continental scale unless you are in a position to order a set of bells, the largest of which shall be considerably heavier than is the tenor of any peal in Great Britain. I venture to throw out this hint, because it was proposed some time ago to place in the beautiful tower of one of our country churches a set of chimes, "equal in extent to those of the Belgian towers," by adding thirty-six smaller bells to the present peal of eight. And I happen to know at the weight of the tenor, or largest bell of a peal is only 22 cwt. It may, therefore, be safely asserted that it would be well to place within the lofty tower a set of excellent chimes, of a moderate scale; and, for this purpose, seven bells added to the present peal would be amply sufficient; but, to carry out such a scheme as the above-mentioned, would be as great a mistake as that of substituting in a very large concert-hall a small pianoforte for a "Broadwood's grand."

THOMAS WALESBY.

EXHIBITION OF DESIGNS.

With much pleasure I read in your journal some account of the desirability of prolonging the exhibition of Designs for the National Gallery until the time when those of the "Law Courts" will be on view. If, through the medium of your paper, you would endeavor to influence the minds of those who prefer to accomplish an end,—or, at any rate, to have the former on view as a fortnight, during the term allotted to the exhibition of the latter,—I believe you would be the means of affording a great convenience on country architects.

ONE OF THE NUMBER.

CEILING IN IRON HOUSES.

Among the Peninsular and Oriental Company's buildings at Bombay, is one of which the top story is roofed with corrugated iron, but in the intervals of two skins of iron are made use of about a foot apart, and free access is left for the external air into the cavity between them, and good ventilation is given to the room itself at the ridge. It has been in this room in the hottest part of the day, and its temperature was then not more than two or three degrees higher than that of the two lower floors. I considered it strange, though I did not test the fact experi-

mentally, that there must be a current of air constantly circulating in this space between the two coverings. Even if, however, there was no current, the layer of air would serve the purpose of a non-conductor of heat excellently well, just as it does when double windows are used.

Probably, therefore, your correspondent "G. P." will diminish or cure the evil he complains of by putting on a second skin of corrugated iron, a foot or more above the present one, and leaving the space between as uninterrupted open as possible, with free ingress and egress for the external air. He had better, also, point it white outside, a well-known precaution. T. R. S.

In reply to your correspondent from the Cape of Good Hope, I think the best and cheapest non-conductor of heat for his ceiling, will be some good thick brown paper, well stretched, and tacked on some slight woodwork, about 6 in. from the iron. The cost of brown paper will be from 2s. to 3s. per cwt. 1 cwt. will cover about 60 ft. square. F. F. D.

In answer to the inquiry from your correspondent, as to the best means for cooling the rooms of his iron houses, and as cheapness seems the object, the following he will find to answer his purpose.—Take a number of holes made as near as possible below the spring of the roof, the size of an ordinary air-brick, at 4 ft. or 5 ft. intervals; then place light timber midway between the holes, size about 7 in. by 1 1/2 in., and fix a small iron pipe as near the roof as possible, with bell mouth. Place a common 3-in. pipe to the outside of the building, between the timber to the middle of the room, then canvas and paper the upper sides of the joint, bringing the ends down where the holes are to the middle of the same. By this means the hot air that is generated will be expelled through the shaft; then, by flushing the under side of the joint with canvas and paper, the air circulating in different places and making a hole in the centre of pipe, will form as cool a room as any European room in summer-time. M. B. (Mechanic).

In reference to the question as to "ceilings in iron houses," I beg to remark that it is a non-conductor of heat; so, at least, it is generally admitted. The question is, therefore, how to apply it. I would suggest that a ceiling should be formed of felt, stretched or supported by a metallic wire-rope from wall to wall. This mode of construction dispenses with timber, &c. II. WALTER.

COTTAGE ARCHITECTURAL MUSEUM.

Sir,—In reply to your remark in last week's Builder, I beg to say that there has been no real delay on the part of his society. The matter has been under the anxious deliberation of the council ever since they provisionally awarded the prizes. Every effort has been made to obtain a suitable site on which the buildings are to be erected. The prizes cannot actually be given until the contracts are made, as the essence of the whole competition is, that the cottages should be erected complete for the one hundred guineas. And I now hope we are in a fair way of obtaining the land. II. MARTIN, Secretary.

HIGH-PRESSURE BOILERS FOR BATHS.

Sir,—In a new house, in course of erection, I have attached to my kitchen stove a small high-pressure wrought-iron boiler, for supplying a bath on the story above, and reading the account of the disastrous explosion at Mayor Constable's, near Hull, I begin to feel anxious lest the pipes (1 in. diameter), should ever get frozen, and then consequently (there being no valve, or any way of escape), the boiler would burst. I have spoken to the ironmonger who is doing the work, and he assures me such a thing is not likely to happen once in ten years. I tell him it might be just once in ten years too often, and that nothing will satisfy me but having some valve or other mode of outlet when the pipes are frozen, and the water thus hermetically sealed. He tells me that valves nearly always leak, and are very troublesome. Can none of your readers help me out of my difficulty? I would rather dispense with my bath altogether than run such a risk as I shall do without some outlet, in case of stoppage of pipes from any cause whatever. BETA.

DAMAGE BY FALL OF CHIMNEYS.

In the Bail Court, at Nisi Prius, before Mr. Justice Stree and a Common Jury, the case "Kingford v. Wells" has been decided.

The plaintiff was a dentist carrying on business at 54, Piccadilly, and the defendant was a jeweller at 55, Piccadilly, and the action was brought to recover damages against the defendant for negligence, in not having properly repaired his stack of chimneys, so that on November 22, 1855, the chimneys fell through the roof of the plaintiff's house and greatly damaged it.

The defence was that the plaintiff's roof was not in a proper state of repair. The defendant, upon taking possession of the premises, in 1850, gave a builder instructions to go over the premises, and put everything in a proper state of repair, and such repairs were done. The weather in October and November, 1855, was extremely bad, and stormy—a sort of "whirlpool" wind. On the 22nd of November, 1855, the stack of chimneys, which was built about fifteen years ago, was blown down.

One of the assistants of the meteorological department in the Board of Trade stated, that he was in London on the 22nd of November, 1855. The state of the weather on that day was blowing a strong gale at eight in the morn-

ing, and a more than ordinary strong gale at half-past nine. The scale went from 0 to 32. On that day the force of the wind was 11. The accounts were published every morning in the Times. If the wind blew with a force of 22 no ship could carry any sail. Such a force of wind had not been registered for several years. The jury found for the plaintiff, but thought the defendant was not aware of the dilapidated state of the chimney.

REMOVAL OF SNOW.

Sir,—On the Saturday following the recent snow-storm, I employed a number of the road-men in collecting the snow in trucks from the narrow and important thoroughfares, and had it shot down the side entrances into the sewers, where it passed away with the stream as fast as the workmen shovelled it in. I am so satisfied with that experiment, that should another fall of snow occur, carts will be employed in lieu of trucks, and by that means a considerable extent of ground will be soon cleared. The warmer temperature of the sewer air and water quickly reduces the snow to water. JAMES LOVEGROVE. Hackney Board of Works.

CHURCH-BUILDING NEWS.

Fulford, York.—A new church at Fulford, near York, which has been erected at the cost of nearly 5,000*l.*, and designed by Mr. J. P. Pritchett, architect, Darlington, has been consecrated and opened by the Archbishop of York. The style of the church is the Early Decorated, and at the south-west corner is placed a tower and spire 140 ft. high. The name of the church is St. Oswald's, and the contractor for the works was Mr. Weatherley, of York. The pulpit and reading-desk were executed by Messrs. Forsyth & Co., of London; the altarpieces were supplied by Messrs. Skidmore & Co., of Coventry; and the carving was done by Messrs. Burdall & Taylor, of Leeds.

East Rainton (near Durham).—St. Cuthbert's Church, East Rainton, has been consecrated. The church consists of nave, chancel, south porch, and vestry, and affords accommodation for 150 persons. It is built in the Early Decorated style. A simple hell-cot over the west end contains a bell. There are two stained-glass windows, by Mr. Wailes, one in the chancel of the "Good Shepherd," and one in the nave representing St. Cuthbert. The church has been built from the design of Mr. C. H. Fowler, architect; Mr. Graddon, of Durham, being the general contractor; and Mr. Thornton doing the mason-work.

Hwyam.—The church of St. James the Great, Haydock, has been consecrated. The church, which stands to the east of the highway leading from Haydock to St. Helen's, is built mostly of brick, and it adjoins a new schoolroom which has been added to the old building, while in the interior there are large doors opening into both these rooms, so that the space for those who wish to worship may be increased considerably beyond the west wall of the church proper. The style is Gothic; and, owing to the material employed, nearly the simplest form of Gothic has been chosen by the architects, Messrs. W. & J. May, of Liverpool, and carried out by the builder, Mr. George Harris, of St. Helen's. The church consists of a nave and chancel, with a porch and vestry. The porch is at the south-west, and some few of the dressings here are of stone; the nave is about 40 ft. by 20 ft., and 35 ft. high to the apex of the roof. It is lighted with nine single light lancet windows with stone sills, and filled with cathedral glass, surrounded by a border of stained glass. The roof is open to the summit, and all its timbers are stained and varnished. The sittings, which will accommodate 160 persons, are of pitch pine, stained and varnished; and the pulpit, reading-desk, lectern, and fall-stool, which stands at the chancel entrance, are of the same material. There are also seats in the chancel for the choristers. The chancel arch is, like all the other arches in the church, of coloured brick, and in addition it rests upon carved stone corbels. The chancel itself is 16 ft. square, and the floor gradually rises by six steps to the altar. It is lighted by a three-light window filled with glass of the same character as in the nave, and by a couple of smaller windows to the south; on the opposite side being the vestry. Staffordshire red and blue tiles form the floor of the church. The interior of the walls are not covered with plaster, and the effect of the red bricks, relieved with the darker shades round the arches, is not altogether a disagreeable one. The whole of the seats are free and unappropriated. The cost of the building is between 1,300*l.* and 1,400*l.*

Stockbridge.—The Bishop of Winchester has consecrated a new parish church at Stockbridge,

where the old parish church had become so decayed and dilapidated as to be wholly unfit for Divine service. The new building has been erected by Messrs. Paul & Sons of Southampton, from designs furnished by Mr. J. Colson, of Winchester, architect; the total estimated cost of the structure being 2,800*l.* The east window, of stained glass and three lights, was a gift from Mr. John Day, of racing celebrity, and cost 100 guineas.

Cheltenham.—St. Mark's Church, which was opened for divine service five years ago, has now been completed by the addition of a tower and spire, and it was opened by the Lord Bishop of the diocese, on Thursday in last week. The additions were part of the original design of the architect, Mr. Middleton; they were not carried out when the church was built on account of the want of funds. The site is high, and the spire is a conspicuous object in the town landscape; it is at the west end of the nave, with which it is connected by a lofty arch, with clustered columns. The lower part is intended for the Sunday school children; a gallery above serves for the choir. The west door and the window above are good specimens of the general style of the church. The former has blue Forest stone mixed with white in its arch, and red Forest stone jambs with foliated caps. The tracery of the west window is boldly marked and richly cusped; the upper stage of the tower is lighted by four two-light windows, with deeply-recessed jambs and arches, with red Forest shafts. The tower has a cornice and four pinnacles, hexagonal in plan. The spire is plain and severe in outline, being simply pierced with alternate rows of trefoils. The works have been carried out by Messrs. Wingate, of Gloucester.

DISSENTING CHURCH-BUILDING NEWS.

Scarborough.—The chief stone of a Baptist new chapel has been laid at Westborough. Messrs. Lockwood & Mawson, of London and Bradford (the architects of the South Cliff Congregational Church), are the architects. The chapel will form the central and prominent feature of Alhamarle-crecent, in the middle of which it will be erected. The style of the building is Geometric, and the principal front will be built of Bradford rag wall stone, and with dressings of Whithy ashlar. At the south-west angle, a tower 12 ft. square, and surmounted by a spire rising to a height of upwards of 100 ft., will be erected. Internally, the church will consist of a nave and side aisles, divided by cast-iron columns, with foliated capitals, and supporting spandrel arches and an open timber roof; also, of transepts, baptistery, and organ chapel; and minister's and ladies' vestries. A small gallery is placed across the end of the chapel, over the vestibule, and which may at any future time be carried round the whole of the interior. The seats will be of open timber work, and, with the other internal woodwork, will be carved and varnished. The accommodation will be at present for about 850 adults; and the cost, exclusive of ground, about 4,500*l.* The works are being carried out by Mr. John Barry, jun., of Scarborough.

Bishop Stortford.—The new Wesleyan Chapel has been opened. It has been raised on the site of the fire in South-street, by members of the Wesleyan denomination. The building has been erected by Mr. J. Todd, of Cambridge; the architect being Mr. J. Cowell, of London. The Gothic style of architecture has been adopted. The interior will accommodate 220 persons. The vestries in the rear extend the width of the chapel, and will afford accommodation for the Sunday schools.

Tarporley.—The Wesleyans are about to erect a place of worship in Tarporley. Plans have been advertised for, and a competition amongst the Chester architects took place, the design sent in by Mr. Krolow being accepted. The plan of the chapel is a rectangle, 62 ft. long by about 39 ft. wide. The total length, including the singing gallery, will be about 79 ft. The design is in the Gothic style. The principal front consists of a central gable containing a five-light window; beneath this there are four small windows separated from each other by a dwarf column with cap and base. The height of the tower will be about 76 ft. The chapel is seated with open pews, and accommodates about 300 persons. The main timbers of the roof are visible, but the upper part of the roof is ceiled considerably below the ridge level, to assist the

acoustics of the building. The whole of the woodwork and fittings are to be stained and varnished. The stone used in the erection is a self-faced even-bedded local stone.

Chester.—A new Welsh Calvinistic Methodist Chapel has been built in St. John-street, Chester, and opened for divine service. Attached to the chapel is a school-room, the whole structure involving an outlay of upwards of 5,000*l.* The design of the chapel is in the Early Pointed style, the French school being followed in the general details. The principal front to St. John-street consists of a gable about 65 ft. high, terminated by a foliated finial somewhat resembling a Prince of Wales's feathers. The two entrances in this front are protected by a large open porch, consisting of five pointed arches, supported on stone piers, and polished red granite columns, having carved capitals and bases. Over the porch is placed a rose window. The window is 22 ft. in diameter. The chapel is seated for about 650 persons, principally on the ground floor, there only being a small gallery at the west end. The interior is lighted by day with large windows filled with ornamental glass, and by night with a series of large wall gas brackets, in wrought iron. The school-room, situated in the rear of the chapel and vestries, is a room about 60 ft. in length. The architects were Messrs. W. & G. Audley, of Liverpool; the building being by Mr. Thomas Hughes, of Aldford. The carving was by Mr. Stirling, of Liverpool; and the whole of the ornamental iron work, by Messrs. Charles Smith & Sons, of Birmingham.

Books Received.

The Water Question: a Letter addressed (by permission) to the Earl of Derby. By J. BAILEY DENTON. London: Stanford.

In this pamphlet Mr. Denton proposes to supply the metropolis from the higher sources of the Thames, in conjunction with the storage of surplus water, in preference to the more costly schemes of late proposed. The cost of Mr. Denton's plan he estimates at 4,500,000*l.* He stipulates for the purification of the sources of supply, where requisite, by the removal of all sewage water, "purified" or not purified, from the streams used; but thinks that such water might be allowed to be taken to the sea through the Thames below such water-supply sources as are requisite. He gives evidence that no purification can render sewage water, however much diluted, fit for domestic purposes. For the water withdrawn from the streams he proposes to compensate mill-owners and others by means of surplus reservoirs for flood waters. The head of his proposed works would be the fork formed by the Thames and Severn Canal, extending from its summit at Thames Head to its junction with the Thames at Leicidale, and the North Wilts Canal, which it was proposed to convert into a railway, not being profitable as a canal, and therefore to be had at a moderate price. The supply would be given to the present companies, and would not, without lifting, provide a constant supply at high pressure, as the grander schemes would do. Mr. Denton, however, regards the expense of re-arranging the whole system of service-piping as a set-off against the cost of lifting the supply to existing reservoirs.

VARIORUM.

"BARONIES OF FORTH and BARGE, County Wexford, Ireland: an Inquiry into the Origin and Philological Relations of the Antient Gaelic Dialect formerly spoken in this District." By J. A. PICTON, F.S.A. Liverpool: Printed, for private circulation only, by D. Marples. This paper was read before the Literary and Philosophical Society of Liverpool. It gives a learned and interesting account of a dialect based upon Old English, Danish, and other ancient sources, but now obsolete. The district where it was spoken is an almost insulated corner of Ireland, jutting out south-eastward towards England, whence it was finally settled by emigration of the Anglo-Normans, who, in 1169, landed under Strongbow and his companions, and took possession. The two baronies were then created; Forth being bestowed upon Robert Fitzstephen and Barge upon Hugh de Montmorency. The dialect presents sufficient internal evidence that the population was largely recruited from Devonshire and the western coasts of England.

Vallancey, the Irish archæologist, of whom Mr. Picton speaks respectfully, seems to have first drawn the attention of philologists to this district in the "Transactions of the Royal Irish Academy for 1788." The two examples of the dialect given from Vallancey and Mr. Hore, of Wexford,—the only two in existence,—are thoroughly analyzed by Mr. Picton, and are very curious.—"Companion to the Weather Glass for 1867." By the Rev. R. Tyas, M.A., F.M.S. London: Bamrose, Paternoster-row. This seems a very useful annual to all interested in the weather,—and who are not? It contains a calendar for the present year, with a column in which to note down the weather as it occurs. It also treats fully of the barometer, the rain-gauge, and the thermometer, as well as of clouds, winds, &c.; and is illustrated by engravings.—"The Garden Oracle for 1867" contains a new selection of the best varieties of garden fruits, descriptions of new plants, new flowers, and new fruits. Also selections in all the classes of show and decorative plants, in which are enumerated the best roses, dahlias, hollyhocks, gladioli, and pansies.

Miscellanea.

THE CONTRACT FOR WORKS AT CHATHAM DOCKYARD.—The contract has been signed at the Admiralty for the construction of the basins, docks, factories, and other works connected with the intended enlargement of Chatham dockyard. The estimated outlay is a million and a quarter sterling. Although several of the most eminent of the railway, engineering, and other firms in England were invited to give in tenders for the execution of the works, they either shrank from the undertaking, or tendered on terms which the Admiralty deemed to be inadmissible, and the contract has accordingly passed into the hands of Mr. Gabrielli, the head of an Italian house. Mr. Gabrielli, we believe, executed the enlargement of the naval establishments at the Royal Dockyard, Malta. The works will be commenced in a few weeks, when 2,000 hands will be taken on in the first instance for the preliminary excavating operations.

THE LAW OF CONTRACT BETWEEN MASTER AND SERVANT.—A meeting of the subscribers and friends of the Law Amendment Committee of the Social Science Association has been held, to hear a paper "On the Law as regards Contracts of Service between Masters and Servants," read by Mr. Edgar. Mr. Clarke occupied the chair. Mr. Edgar stated succinctly the existing law upon the subject; considered the grounds upon which it is supported, and the objections to which it appears to be liable; and made some remarks upon the resolutions agreed to by the select committee of the House of Commons. He was persuaded, he said, that any legislation founded on the report of the committee would go but a short way towards putting an end to the dissatisfaction and discontent which undoubtedly existed on this subject, and which he believed would continue to exist until the same measure of justice was meted out to the working man as to the rest of the community.

DECORATION OF HORSHAM CHURCH.—The church of St. Mark's, Horsham, has been decorated in an inexpensive manner by Harland & Fisher, of London. The arrangement is as follows:—A broad band with a text is carried beneath the wall-plate. The text on the north side is, "Surely the Lord is in this place: this is none other but the House of God, and this is the Gate of Heaven!" That on the south side is, "I have hallowed this house, to put my Name there for ever, and mine eyes and my heart shall be thers perpetually." The outline of the arches has a pattern of crocketing in red, carried round, bordered with a line of grey. On the spire there is a flowing pattern in grey, while on the soffits is painted a broad red band. From the floor to the springing of the arches is filled with a pattern of masonry. The stone corbels which carry the roof are picked out with grey and gold. The chancel arch and east end are treated more ornamentally, a text, "Holy, Holy, Holy, Lord God Almighty," being painted round the curve of the arch; a row of crocketing beyond that; while a painting of the "Agnus Dei," and "The Pelican and her young," are introduced at the springing of the arch, the intervening spaces being filled with geometric diaper work. The chancel itself was decorated by the same artists a few years back.

THE LICENSING SYSTEM.—Many persons being desirous of seeing some change for the better made in the present system of licensing public-houses and beer-shops, especially in reference to that clause in the Beer-shop Act which allows of drinking on the premises, it is proposed to hold a conference on the subject in Exeter Hall on the 29th and 30th of January. The Earl of Shaftesbury will preside.

NEW CEMETERY FOR BELFAST.—The committee appointed by the town council for the purpose of investigating the various plans for the new cemetery, on the Falls-road, have, we understand, selected the design of Mr. Gray, of Bradford. The area of the cemetery is forty-five acres within the walls, and the laying out of the ground, planting, draining, and boundary-walls is estimated to cost about 10,000*l.*

MUSEUM FOR THE EAST OF LONDON.—The iron buildings at South Kensington, which years ago and when the design was only on paper we christened the Brompton Boilers in the endeavour to obtain an improvement in their appearance (a name that has stuck), are to go to a place of land in Bethnal Green. The Treasury has sanctioned the expenditure of a considerable amount of money to form a museum there for the eastern half of the metropolis.

LAND IN LONDON.—At the last meeting of the Union Bank, Mr. P. N. Laurie, chairman, said, the Corporation, having determined to widen Mansion House-street from the bottom of the quay, have taken possession of the frontage of the buildings which the Union Bank were about to erect at that spot. For this little strip of ground, measuring, according to Mr. Laurie's statement, 15 ft. l., the Corporation have had to pay 43,000*l.*; the bank having failed to establish their claim for a larger sum. Allowance must be paid for a proportion of this amount allowed for works commenced.

PROPOSED PLEASURE-GROUNDS FOR ROCHESTER.—The project is under the consideration of the corporation of this city for leasing the whole of the waste-grounds, now let for market-gardens, and converting them into properly laid-out pleasure-grounds for the inhabitants of the city; the corporation also, at the same time, taking over the ancient Castle. We understand that the agent for the Earl of Jersey, to whom the Castle and the adjacent grounds belong, has expressed a willingness to accede to the proposal, and, indeed, enters very warmly into the project. Under these circumstances there is every probability of the contemplated arrangements being carried out by the corporation.

THE FATAL GAS EXPLOSION IN GRAY'S-INN-LANE.—The coroner's jury in this case gave the following verdict:—"We find that the deaths of Smith, Villa, and Cole were caused by an explosion of gas through a fracture in one of the watered Gas Company's service-pipes; which we much regret, knowing that the company are aware this service had not been renewed many years. We are of opinion that the watered Gas Company, knowing this, should have given special instructions to their servants to thoroughly examine the whole of the service-pipes, including all pipes as far as the meter." The foreman said the jury had but one opinion on the subject, and were unanimous in returning the verdict. The coroner said that that was equivalent to a verdict of "accidental death, caused by the defective service-pipes of the watered Gas Company." He would enter that verdict, and transmit the resolution of the jury to read to the gas company.

EXPLORATIONS AT REPTON.—A discovery of great interest has been recently made in the neighbourhood of Repton Priory. The boys of the school have been for some time engaged in exploring a part of the enclosure known as the upper Paddock, with a view to form a new street ground. In the course of this work they covered a considerable number of encaustic tiles, and a structure believed to have been used by the monks for the manufacture of encaustic tiles for the Priory Church. This is not the first discovery of a tile manufactory in connexion with a monastic establishment. It was, indeed, merely a question among antiquaries whether ornamental tiles were made in Great Britain, till the kilns found several years since at Great Overton, and in Farringdon-street, London, have conclusively answered the question. The Repton excavations supply additional evidence, while in and in construction they are unlike the other examples, and are said to be unique.

DAMAGE TO PLYMOUTH BREAKWATER.—A Government survey of the damage has been made, and its amount is reported to be about 10,000*l.*

THE REMOVAL OF MUD.—A correspondent ("P. E. M.") suggests, with reference to the necessity for the immediate removal of mud from London streets, that if manual labour be too expensive, a useful combination for the purpose might be made of the old sweeping-machines and noiseless smoke-consuming locomotive engines.

A GAS FIRE-LIGHTER.—An invention has recently been patented, under the name of gas fire-lighter, which is intended as a substitute for wood and paper in lighting fires. A row of three gas burners is fitted on below and behind the grate bottom, with a tap at one side, so that when a fire is wanted the gas is lit, and the flame passing amongst the coals sets fire to them without the aid of wood or paper. In summer, water can be holed by the gas alone, as in an ordinary gas fire.

ACCOMMODATION FOR THE PARIS EXHIBITION VISITORS.—An excursion-manager has sent to the periodical press an account of the result of his inquiries as to the probable cost of accommodating visitors at hotels, and otherwise, during the Exhibition. His movements, especially if he have imitators, will simply have the effect of increasing the great expectations of Parisian hotel-keepers and landlords, and leading to great charges which will keep away thousands of visitors. Much better he quiet at present.

A GOOD SNIPPE-GROUND BUT A BAD BARRACK-YARD.—The *British Medical Journal* says,—The cantonment of Dum Dum, in India, is notoriously sickly and fatal to the European troops quartered there; it is aptly described as a good snippe ground, but a wretched cantonment. The 91st Highlanders having been judiciously removed thence, the 29th Enniskillens have been substituted for them for reasons past comprehension. Only the other day the 55th Regiment marched from Dum Dum reduced and enfeebled by sickness. The *Friend of India* presumes that, when the 29th becomes sufficiently sickly and inefficient, when a sufficient number of men have died to justify the urgent remonstrances of a medical man, it will also doubtless be removed. But why are they sent there?

MOSCOW.—A correspondent writes us from this city:—"On Sunday, 13th inst., being New-Year's day here (Russian old style), the Prince Governor General gave a grand reception at 9.30 a.m. Every person invited had to appear in full evening costume, or in uniform—the latter most gorgeous. The day was lovely, a brilliant sunshine and 4° Reaumur of heat: it was 20° of Reaumur cold a few days previously. The staircase was lined three deep with 100 footmen in gorgeous liveries, and altogether it was a magnificent sight. At the opening of the Moscow Gas Works the English engineer had to march with the Prince Governor General; and, as representing the Company, he had to be blessed, sprinkled with holy water, and to kiss the cross. The alterations in temperature at Moscow seem very great. Such a mild winter has not been known for many years.

THE TELESCOPE FOR VICTORIA.—The Legislature of Victoria having voted the sum of 5,000*l.* for the construction of a large reflecting telescope, to be erected at Melbourne, for the purpose of effecting a thorough survey of the nebula and multiple stars of the southern hemisphere, the president and council of the Royal Society (whose advice and co-operation, our readers have heard, had been requested) selected Mr. Grubb, of Dublin, the eminent optician, to construct this instrument. The impossibility of obtaining discs of glass of the requisite purity has rendered it imperative to employ *catoptrics* instead of *dioptrics*—reflection rather than refraction—when a telescope of large size is to be constructed. An image is formed in the focus of the mirror, and is examined by suitable eyepieces. The tube has a diameter of 4½ ft., and is of proportional length. The diameter of the speculum is but 6 in. less than that of the tube, or 4 ft., being 4½ in. in thickness, and weighing about 27 cwt. The grinding was performed by a polishing machine and steam-engine, constructed for and belonging to the telescope, and which will accompany it to Melbourne. The weight of the telescope, when completed, will be about 10 tons, and it will be moved by clockwork.

AN ARCHITECT'S LIBRARY.—M. Alexandre du Bois, a Paris architect, who died recently, in his eighty-second year, has left behind him a library of 20,000 volumes, exclusive of pamphlets, sedulously collected during his life. Amongst other literary works nearly completed by him at the time of his death are a *Bibliographie des Beaux-Arts et Spécialement de l'Architecture*, in three volumes; and a *Bibliographie des Architectes anciens et modernes*, also in three volumes.

GAS EXPLOSION AT SUNDERLAND.—A cottage has been blown to pieces and the furniture smashed by an explosion of gas in an instance where no gas was laid on. A street lamp stood on the pavement opposite the door, and the lamp-lighter had injured the gas-pipe so that the gas filled the hollow of the lamp-post, and got under the pavement and into the house. The smell of gas alarmed the inhabitants, and the tenant stupidly struck a light to see where the escape came from, when immediately the explosion took place. The walls of adjoining cottages were also shattered, but no one was seriously injured.

A STATUE FOR SHAKESPEARE.—A citizen of London reviving the opinion, that the Thames Embankment, fronting the present Temple Gardens, affords a good site for a statue of Shakespeare, says,—

"If the public saw a good design, I am satisfied ample for the purpose would be forthcoming. I therefore am willing, preserving a strict incognito, to offer a premium of fifty guineas for the best design, twenty for the second, and ten for the third."

The *Athenaeum* guarantees the good faith of the proposer, but something more must be done to get useful fruit from the suggestion. Precise terms must be laid down, and a proper tribunal named.

STREET BARS.—We have often urged the removal of the many bars which obstruct the metropolitan streets, and are glad to observe that the Metropolitan Board of Works are now moving in the matter. It was proposed by Mr. Shaw to apply to Parliament by petition, but eventually it was unanimously resolved,—“That it be referred to the Works and General Purposes Committee to take into their consideration the existence in the streets of the metropolis of many barriers, gates, and private tolls, to the obstruction of the general traffic, with power to take counsel's opinion thereon, and to report their recommendation to the Board.” The Chairman suggested that there might be a difficulty in the way, as proprietors might be liable for breach of contract with persons who had taken premises on the faith and understanding that they should have quiet possession of them. But is not that the case, as regards possession, where persons have been expelled altogether from premises without even compensation?

SENSITIVE AND SINGING FLAMES.—Not lovers' "Flames," but Dr. Tyndall's. At the Royal Institution last week the doctor delivered a lecture "On Sounding and Sensitive Flames," in course of which he amused his audience with a variety of very curious experiments, which culminated in his addressing some poetical lines to a flame by which he seems to have been smitten. Two gas flames were burning at the same time, one of them being long, straight, and smoky, and the other short and brilliant; and when a whistle was sounded the long flame became short and brilliant, and the other was converted into a long, dull, and smoky flame. By increasing the pressure of the gas a jet of flame about 20 inches long was produced which was peculiarly sensitive. On the slightest sound it sank down to 8 inches; and the crumpling of (pink note?) paper seemed to throw it into convulsions. By some sounds, however, it was not in the least affected; and it was interesting to observe, when Dr. Tyndall repeated the lines of poetry alluded to, how the flame was fluttered and affected by some of the expressions and was insensible to others. Whether it was a compliment or a declaration of love which most flattered it, the reporter did not note. On uttering the not very poetical word "hoot," however, the flame remained steady; but at the word "boat"—Byron's "boat is on the shore," perhaps—it started; and a very ungallant threat to "beat" it threw it into violent commotion, and no wonder; but it was yet more powerfully affected by the sentimental exclamation "ah!" To sibilant sounds it was particularly sensitive: a hiss sent it down to the lowest point of humiliation. When a musical snuff-box, however, was put in action, it ~~beat~~ got over its low spirits, and danced up and down to the tune

CHURCH WORK.—We are asked to add to our notice of the Wesleyan chapel, Rickmansworth, that the warming of both chapel and school is effected by hot-water apparatus erected by Messrs. J. Jones & Sons.—Also to the notice of church at Sydenham, that it is paved with encaustic tiles supplied by the Architectural Pottery Company.

SKATING.—A subscriber writes,—On reading your sensible observations on skating, or the "suicide of skaters," where parties will still persist; the question is whether some additional suggestion might not be made for the preservation of human life, and it has occurred to me whether some simple contrivance in the form of a raft or grating might not be adopted, and kept at one end of the ice. It should be made about 12 ft. or 14 ft. square or less, of slight timbers, say 6 in. by 6 in., bolted together, having sufficient spaces between for parties to raise their heads and shoulders above the ice; and which would still float when the ice gives way and could be propelled forward.

FURTHER DISCOVERIES AT MALTON.—Some more Roman and British remains have been discovered in the cuttings for the Malton Water-works, which, however, have now been completed. The Roman station was erected on an earlier British one, as clearly shown by the cuttings; in which Roman pottery, coins, and skeletons have been found overlying the original alluvium, in which the remains of red deer, flint implements, and bone pins were the chief relics. The cuttings just completed extend from the Lady's Spring, at the south-east corner of the great military station of Deventio, to a point just opposite the Pretorian Gate and the Roman ford across the river.

METAL DOOR.—Mentioning the works in Miss Hosmer's studio in Rome, the *Morning Post* says,—One of the most important is a door, 15 ft. high, to be cast in bronze and gold, for Lord Brownlow, who intends it for the entrance-door to a sculpture-gallery at Ashridge. The upper semicircular compartment represents, in fine bas-relief, the three elements,—earth, air, and water,—two of which, earth and water, are further illustrated, practically and poetically, by four oblong compartments, inclosing above a vintage scene on the left, and a fishing group on the right, and below centaurs and nymphs, and tritons with sea nymphs. The centre panels between these four corners are divided into twelve compartments, with charming figures and groups allusive to the twelve hours of the night. The jambs and upper arch will be of marble, inlaid with Byzantine mosaic. Another fine work, almost completed, is a fountain executed for Lady Marion Alford, surmounted by a syren, to whose song four Cupids on dolphins below are listening with upturned heads.

PROFESSOR LEONE LEVI UPON "OUR WORKMEN."—A lecture, under the auspices of the Nottingham Mechanics' Institution, has been given by Dr. Levi, at the hall of that society, the subject being, "Our Workmen: their Labours, Rewards, and Trials." The mayor, Mr. J. L. Thackeray, occupied the chair, and there was a large audience, amongst whom was the Duke of St. Alban's. The lecturer delivered an exhaustive address of about an hour and a half in duration. In speaking of trade-unions, he said, let them not do them an injustice. They did good in the discipline and order which they enforced upon the different trades, which acted as a check against riots and excesses, and how often were they made to subserve the purposes of charity and munificence. There were points in their action, however, decidedly objectionable. The restriction they put upon the number of apprentices, and every other hindrance imposed upon the freedom of labour, admitted of no defence whatever. They could not dispute the right to influence others living with them; but all coercion or intimidation used for that purpose was illegal, and reprehensible. If they desired independent action for themselves they must allow it to others. But what should he say in favour of locks-out? Not a word in their favour. Nothing could be more injurious to the masters or to the operatives than such an extreme measure. Concession on either side was better, and arbitration was better still. One great source of absorption of the working man's earnings was drink. It was a very sad fact that in the United Kingdom as much as 70,000,000 l. a year were spent in ardent spirits, exclusive of wine; and of that amount 50,000,000 l. or upwards came out of the pockets of the working men!

THE MANCHESTER ALBERT MEMORIAL.—The memorial of the late Prince Consort, in the centre of Albert-square, Manchester, has been inaugurated by Dr. Fairhair. A view of the monument will be found in a previous volume of the *Builder*.

AN OBSERVATORY BURNED.—On Sunday last, the observatory connected with St. Gregory's College, Downside, near Bath, was totally destroyed by fire. It originated apparently in the heating apparatus, which kindled the joists of the ground-floor.

MODEL DWELLINGS IN HALIFAX.—Mr. John Crossley has erected, in Halifax, a stone building, in the Venetian style of architecture, at a cost of about 3,000 l., as a model-lodging house. Mr. Crossley has conducted a model-lodging house at the Mulcture Hall, Halifax, for fifteen years, and the institution has peculiarly been successful.

THE OUTBREAK OF FIRES.—A correspondent, R. T., suggests, that while water and firemen are being sought for, every fireplug in a house, by previous arrangement, might be closed up by pulling a cord connected with an iron plate in the chimney-stack; and that a policeman, by breaking a hole in a fanlight, for example, might not only do this, but also break some fragile vase, hermetically sealed and containing fire-extinguishing materials, so arranged as to be thus brought into action. Or such a vessel could be carried to the locality of the fire and thrown in.

INAUGURATION OF A NEW BUILDING AT RYDE, FOR THE YOUNG MEN'S CHRISTIAN ASSOCIATION.—The building in Lind-street, Ryde, nearly opposite the town-hall, which has been recently erected for the use of this Association, has been inaugurated. For the designs the society is indebted to Mr. Thomas Dashwood, honorary architect. Two rooms on the ground-floor, fitted with shelves and hookcases, are set apart for the circulating and reference libraries. On the first-floor is an apartment capable of being used as a general reading and news room. There is a small apartment on the same floor, suitable for a conversation or retiring room for members. On the second floor there are two rooms of nearly equal dimensions, which are intended to be used as class-rooms.

THE "BUILDER" FIRE.—The accomplished author of "Ten Thousand a Year," Mr. Samuel Warren, Recorder of Hull, has recently borne voluntary testimony, in a letter widely printed, to the value of the mode of economically burning coals in grates which we described some years ago, and which is pretty well known in many parts of the country as our fire,—the *Builder* fire. Mr. Warren, however, omits in his otherwise excellent letter one of our special points, namely, that, when the bottom of the grate has been covered with a thin plate of iron (or, more cheaply, by spreading over it some fire-clay), and the coals have been put in, the fire should be lighted at the top. This necessitates lighting the fire some little time before it is wanted, or the mass will not have become incandescent; but the gain in point of economy, avoidance of trouble, and amount of steady heat, is very great indeed. From a fire thus lighted, properly, scarcely any smoke escapes, another very important advantage.

BRADFORD NEW EXCHANGE.—The exterior, with the exception of the final touches from the hands of the carvers in stone, is now all but finished; and the great hall, it is hoped, will in a month or two be completed. The medallions which are now being sculptured along the front of the Exchange represent men among statesmen, navigators, engineers, and manufacturers who have cleared the way for trade, and to whose lives and labours towns such as this owe their prosperity. Next to the tower, in the place of honour on the Market-street front, the head of Cobden is appropriately placed; and next to that is a head of Mr. Titus Salt. These are all that are finished on this front, but heads of Stephenson and Watt are partly completed, and there are to follow in order Arkwright, Jacquard, Gladstone, and Palmerston. The floor of the hall is now being paved with Maw's encaustic tiles. Along the sides the walls are tiled to the height of 5 ft. with encaustic tiles in relief. At their bases the beams supporting the roof are ornamented with figures carved in wood, symbolical of justice, commerce, science, navigation, &c. The crown of the roof is of stained glass. Messrs. Lockwood & Mawson are the architects.

THE COLISEUM, ROME.—According to the *Revue Artistique*, M. Visconti, architect, has been commissioned by the Pope to restore the upper part of the Flavian amphitheatre.

THE UNITED EXCAVATORS' SOCIETY'S ANNUAL MEETING.—The first annual meeting of this society was held at the Lambeth Baths, on Monday evening, under the presidency of Mr. G. M. Murphy. After an address from the chairman, the secretary stated that, notwithstanding the inclement season and the unsettled year through which they had passed, they had still fourteen lodges, comprising some 800 members, with a balance at the banker's of 320 l.

INFRINGEMENT OF A BUILDING ACT IN PALESTINE.—Mr. George Williams writes from King's College, Cambridge, on behalf of "the smallest nationality in the world." This, it appears, is the Samaritan community, consisting of only 150 souls, who have experienced a literal fulfilment of the proverb, that "He that exalteth his gate seeketh destruction." They had heightened the street-door of their synagogue at Nablons or Shechem, the ancient capital of Samaria, from 4 ft. to about 5 ft. 6 in.; they had also renewed some part of the pavement of the synagogue itself, which had become decayed. These repairs were declared illegal by the Turkish official, who, accompanied by a mob of 200 or 300 fanatics, went himself to the synagogue, in the south-west quarter of the city, where he directed and superintended the demolition of the new work, which was left a complete wreck, and its owners are not allowed to repair this their only place of worship.

TENDERS

For the erection of Premises, Leadenhall-street, for Messrs. Ponds & Sons. Messrs. Humphreys & Son, architects—

Meyers	£6,179 0 0
Rider & Son	5,594 0 0
Henshaw	6,979 0 0
King & Sons	6,900 0 0

The Builder.

VOL. XXV.—No. 1252.

Designs for the Proposed Law Courts.

THE Designs for the proposed Law Courts, submitted in competition, are admirably hung in the temporary building erected for the purpose in New-square, Lincoln's-inn. The competitors are eleven in number, it will be remembered; namely, Mr. Abraham, Mr. E. M. Barry, Mr. Raphael Braudon, Mr. Burges, Mr. Deane, Mr. Garling, Mr. Lockwood, Mr. Seddon, Mr. G. G. Scott, Mr. Street, and Mr. Waterhouse. The drawings of each competitor are hung in a separate chamber, so to speak, formed right and

left of a central pathway, and lighted from the top. Great praise is due to those who have the conduct of this competition for the endeavours so far that have been made, with a view to obtain the best possible design for the contemplated buildings. The amount of information afforded, and the completeness and clearness of the schedules furnished, are remarkable, and do great credit to those who constructed them. An impossible perfection is shadowed out by them, and to this the competitors have had to work up with such access as each could master.

The Commissioners have farther shown their great appreciation of the difficulty there is in coming to a proper decision in such a matter by granting Mr. Brnnet, the architectural clerk, a large staff of assistants for several weeks, and the further aid of Mr. G. Pownall and Mr. John Haw, to ascertain how far the various points of the instructions have been attended to, especially as to the sizes of rooms and courts, provided by each architect, and as to the comparative merits of the plans with reference to other matters ascertainable by calculation, such as light, quiet, and facility of access. There will be another examination by Officers of the Law to show the commissioners how far and how well each scheme will supply the special wants of each part and department. Mr. Pownall and Mr. Haw will doubtless give their opinion too as architects; and then, with these statements before them, the appointed Judges of Designs (the First Commissioner of Works, chairman; the Chancellor of the Exchequer, the Lord Chief Justice of England, the Attorney-General, and Mr. William Stirling, M.P.) will proceed to make their selection.

There are circumstances connected with the early arrangements for the competition that, but for the evidence before us of a strong desire to do right, would lead us to enforce the application for impartial consideration, made by one of the competitors.

It is no boy's task, as he says, which is to be dealt with as a mere trial of strength. It is,

probably, the greatest and most arduous labour ever imposed upon the members of a very laborious profession; it is a work which has employed the best thoughts, and time, and aspirations of the competitors, for three-quarters of a year. It is no academic competitive examination, but a most serious work of real life,—a herculean labour for a great practical and national object. Do not, then, we beg of you in all respectful earnestness, cast aside these labours on any trifling grounds, for they are the best efforts of carefully-selected minds, and the result of long, and anxious, and painful endeavours, stimulated by an ever-present sense of the immense importance of the object, and undertaken at a vast sacrifice of other professional demands. Above all, let us beg that the judges will rigorously impose upon themselves the rule which judges urge upon juries, to dismiss *in limine* from their minds all that they have previously heard or felt on the subject, for they have a work to perform in which justice to a number of selected and invited professors of a great and noble art is united with a most onerous and responsible duty to the nation for whose use this mighty edifice is to be reared.

With perhaps one exception, the competitors have set forth their designs in drawings of great excellence and beauty; some of the drawings, indeed, are exquisite, and by means of writing around them, called for by the Commissioners, the levels of the various floors, the extent of the departments, the purposes of the different rooms, and the general scope of each design, are made remarkably clear. All the designs are Gothic in style, only one competitor, Mr. Garling, sending an alternative design Italian in character. This gentleman, by the way, who avoids a central hall, has materially lessened his chance of success by covering the whole site, as Mr. Burges in a less degree has done by giving his building a military aspect instead of civil; and Mr. Seddon by a tower, with fourteen ranges of windows, which has little consonance with the London of the nineteenth century. His front next the Strand is very picturesque and clever. Mr. Deane's weak point, since we have fallen into this line, and with reference to appearance only, is the fact that the design takes the shape of several buildings which may or may not belong to each other. It is elegant, nevertheless. The first consideration for the judges is plain,—who best fulfils by plan and arrangements their multifarious requirements. Still the building must be a public monument, and the art-question must have full weight in making the selection. No matter how good, for example, might be the plan submitted by Mr. Abraham, to whom the other competitors are under obligations, the selection of elevations such as he has put to it is out of the question.

Mr. Waterhouse, as was to be expected, has submitted a very complete scheme, marked by thorough knowledge of the subject, and set forth in thirty good drawings. Dividing the buildings into Courts (with rooms immediately contiguous) and Offices; the first, as having the greater claim to quiet and the advantage of a central position, he masses together in two internal lines of building running east and west, with a long internal area or open street, 53 ft. wide, on each of their outer sides, and divided by a large covered hall, from which access is obtained on the one side (the north) to the Courts of Equity, on the other (the south) to those of Common Law. The offices he places in the external ranges of building which front respectively to the Strand, Carey-street, Bell-yard, and Clement's Inn, so as to form a complete barrier between all noise from the external traffic and the courts which they shelter.

By these two streets, which he calls Equity-street and Common Law-street, he lights the rooms within the building. They are on the Strand level, and are approached by carriage-archways through the outer Strand range of offices. The accompanying plan shows broadly the arrangement adopted.

As to the best arrangement for the Courts, both *inter se* and with reference to their position in the building generally, he gives the following reasons for placing them, with little exception, in two parallel lines divided only by a central hall.

1. They are thus brought as closely together as possible.
2. The greatest possible simplicity of arrangement is thus obtained.
3. The Central Hall affords for barristers, solicitors, and, in fact, for all who are within the building on business, a place of meeting from which each of the Courts is immediately accessible.
4. The arrangement is one which secures a certain amount of elasticity for any future modification in the special purposes to which each individual Court is applied. In fact, it prevents any group of courts becoming so crystallised, if I may so speak, as to make such modification difficult or impossible; e.g., if the Courts of Equity should hereafter increase in number, the Admiralty Court might be converted into a Court of Equity, and the Court shown in the plans under the former name be removed elsewhere, without any detriment to the general scheme.
5. A proximity is thus secured between the Courts of Law and Equity which may hereafter be turned to account in the event of any further fusion between their respective systems of procedure, or between the Equity and Common Law Bars.

Besides the main entrance,—which is in the centre of the Strand front,—there are two archways on the south side, each wide enough for two carriages, through the Strand range of offices into "Common-Law-street." One of these opens from Pickett-street; the other is situated immediately to the west of New Temple Bridge, and by this access is obtained not only to the eastern end of "Common-Law-street," but also by means of an archway of equal width under the offices to the east of the court blocks into the eastern end of "Equity-street" which is, for carriages, a *cul de sac*. The central portion of the archway just alluded to is lighted by

CAREY STREET.

STRAND.

four areas open to the sky. A broad pathway is provided for foot-passengers at the side of the carriage-way.

In addition to the two principal entrances in the Strand and Carey-street some twenty-five subordinate entrances have been provided at various points in the external and internal streets. These give access either to particular portions of the building, the various departments and offices, or are intended for particular classes of persons. Thus, at the north-west corner, there is a private entrance for the judges' carriages, giving an access to the judges' private corridor by means of a carriage-way up to its level. At the north and south, at the extreme eastern end of the building, at a level of 17 ft. 6 in. above Carey-street, are entrances intended for the exclusive use of the bar and attorneys, who would thus approach the apartments appropriated to them after passing along the bridges provided for their use from Lincoln's Inn and the Temple.

The entire width of the court block between "Equity-street" and "Common-Law-street" is traversed on a level with those streets by two halls in a line with each other, which, in fact, would be but one, were it not for the central hall above and between them. They are each 64 ft. wide, with an average length of 83 ft., and a height of 32 ft. The width of each is divided into a nave, so to speak, 32 ft. wide, and side aisles. Over the aisles are galleries on a level with the central hall, which are approached at their north and south ends by bridges across the internal streets opposite the main entrances in Carey-street and the Strand. The transverse halls themselves are entered by doorways in the internal streets immediately beneath these bridges. The space between these halls is open to the roof of the central hall above, excepting where crossed by the bridge uniting the two halves of the latter.

The great central hall covers an area of 478 ft. by 60 ft., and is 90 ft. high to the apex of the roof. It is divided longitudinally as to its floor space into two nearly equal portions by bridges which unite the corridors and offices on either side of the court level. The roof would be supported by ornamental wrought-iron principals, resting on projecting stone corbels, and buttressed by the main walls of the courts. The designer proposes that the roof should be divided into alternate bays of larger and smaller size, the larger being covered entirely with glass, the smaller being boarded and decorated.

The sides of the hall would be appropriated to three stories of witness and consultation rooms attached to the several courts, with windows looking into the hall itself. Between each set of these would ascend a staircase, leading from the floor of the hall to the harriers' corridor, and giving access to the witness and consultation rooms themselves.

The great hall in the centre of the building is intended for a *salle des pas perdus*; a place of rendezvous for all who have business to transact in the courts, as opposed to the general public who come only to see and hear, and who would have no access to it.

The style adopted is that of the thirteenth century. Admitting that to be the style in which a building should be erected in London in the nineteenth century the building is effectively composed. The mass includes two lofty towers for the deposit, one (284 ft. high) of Wills, and the other (354 ft. high) of Registered Copies. A clock tower rises from the Strand front, and there are two other towers appropriated to smoke and ventilation. Pricing the main building at 1s. 1d. per cube foot (obtained by adding 40 per cent. to the cost of the Manchester Assize Courts, which was 91d.), and the towers at 1s. 8d. per cube foot, we get 1,339,328l.; or, with Temple Bar, roads, approaches, and so on, 1,419,842l.

The edifice, it may be added, contains 1,141 apartments, as required by the instructions, and 163 extra rooms to meet future requirements.

The sum originally suggested to the competitors was 750,000l.

Mr. Scott has sent the largest number of drawings of any competitor, and a very fine set they are. He is greatly impressed with the magnitude of the task:—

"On first entering upon the consideration of the subject, two impressions force themselves upon the mind—the nobleness of the project, and the vastness of the labour of carrying it out, even upon paper; and, as the first impression must be of the labour to be undertaken, I think all of us must have found it so much greater in reality than in idea, that, had we on first entering upon it realized its magnitude, we might well have shrunk back from the task; indeed, it is only the grandeur of the undertaking which has enabled me to face out the almost incredible labour of the design. Others may possibly have greater facility of arrangement than myself, though I have probably had as much experience in arranging large buildings as any man; but I may say that to me the labour has been such that, though I embarked on it vigorously on the very day after I agreed to join the competition, I have ever since been hard at work upon it, often giving to it eight hours or more a day for many days together."

Broadly speaking, Mr. Scott has adopted Mr. Abraham's early plan; that is to say, an outer shell of buildings containing the departments less connected with the courts, an internal street within this shell, and a central block containing the courts with their appurtenances, and such departments as are more directly connected with them; this block including in its centre an open space round which the courts are arranged.

It is so far varied as to limit the outer shell to three sides, so as to bring the central block forward to the front. Twenty-two out of the twenty-four courts required are placed in the central block, throwing off two only into the outer shell, the Matrimonial and the Bankruptcy Courts. These are connected with the general group of courts, each by a bridge ("perhaps of sight") across the internal street.

Mr. Scott claims to have carried out in its integrity Mr. Webster's scheme of concentric circles.

"My circles (to use Mr. Webster's term, and considering the middle space as their centre) are, first, a spacious and (as I should wish) magnificent ambulatory of nearly 30 ft. wide, running round a central area (about 200 ft. by 116 ft.). This is of two stories in height, the one being used only by those immediately interested in the business of the courts, the other one by them and by the public jointly. Round this comes the second circle, consisting of the courts themselves, with their intervening areas and passages; external to this is the third circle, consisting of the judges' rooms and those for the juries, with the neces-

sary staircases and appurtenances; next to these is a corridor all round, for the bar and attorneys, beyond and opening out of which are the rooms appropriated to their use, and to that of the various officials, &c., connected with the courts."

The accompanying plan shows the position of the twenty-one courts which surround the main ambulatory. We can specify only some of them. (a) and (b) mark the Courts of the Lord Chancellor and the Master of the Rolls; (c) is the Lords Justices' Court, and (d) Vice-Chancellor Kinderley's Court; (e) and (f) are the other Vice-Chancellors' Courts. The three Courts of Queen's Bench (h h h) are to the east of the central area. On the eastern part of south side are the three Courts of Common Pleas (i i i); and on the western part the three Courts of Exchequer (j j j). The centre of the south side is given to the spare court (k), which exceeds all the others in dimensions, and which Mr. Scott calls the "Sensational" Court. The three courts at the western end of the area are severally the Exchequer Chamber (l), the Admiralty Court (m), and the extra Ecclesiastical Court (n).

It must be remembered as to the designs generally that the site, viewed roughly, may be said to be level from east to west, but to rise some 17 ft. from south to north—the lower line of boundary facing the Strand, the upper one facing Carey-street; and the sloping-end boundaries facing severally Bell-yard and Clement's-inn. The leading fact to which this gives rise is that the north frontage is an entire story above that of the south, so that what is ground-floor on the north is first-floor on the south, and what is ground-floor on the south is basement on the north.

Mr. Scott gets between the level of the Strand and the level of the floor of the courts a lofty story for public offices, and regards this as a reason why, without serious disadvantage, there cannot be a central hall in the sense in which that term may be most naturally understood; that is to say, as a hall from which the courts would directly open, like Westminster Hall, or that designed by Sir Charles Barry for the Lincoln's-inn-fields site. "This would be only practicable," he thinks, "were the courts on the ground-floor; for, if adopted in the case of elevated courts, it is clear that little or no light could be given to the space below such hall, or to the lower stories of the parts surrounding it." It is this which has led him to give a double width to his ambulatory, that it may take the place of such a central hall. He adds to it, however, a central hall in the middle of the open area. In the centre of the central hall rises the great staircase. The hall is a large octagon, overshadowed by a magnificent dome. The court level is reached from the Carey-street entrance, without the aid of the central staircase, by a direct corridor.

In adopting the Gothic style, Mr. Scott claims it as affording the greatest facilities for the developments suggested by modern requirements, modern materials, and modern modes of construction, and in many parts of his design he has evidently worked in this spirit. An immense amount of painted and sculptured decoration is shown, though not insisted on. The inner work of the Strand entrance would be a fine work; so also the interior of the dome. A massive tower for records is a prominent feature.

The cubic contents of the building at 1s. per foot cube give 1,253,626l., exclusive of figure sculpture and figure painting. 1s. per foot is taken on the ground that the Foreign Office is being built at 1s. 0½d. per foot, and that the stone fronts there bear a larger proportion to the whole mass than would be the case at the Law Courts. The contract for Glasgow University, a less expensively-finished building, gives 7½d. per foot cube: both materials and labour, however, are cheaper there than in London. We must break off for the present.

THE DESIGNS FOR THE NEW NATIONAL GALLERY.*

EXAMINATION of competition-designs, on the part of the public, the judges in the case, or the profession itself, has hitherto been, from various causes, quite out of proportion with the efforts of competitors, and with the benefit capable of being realized in whatever there might be of suggestion in the designs, or of full response to the appeal of the promoters of the competition. Advantage accruing, whether to either of the parties, or to the art and science of architecture, has been but trifling: designs on which much

* See pp. 23, 40, & 58, ante.

labour and money-outlay had been expended, have gone back to their authors, to be thenceforward lost to sight, having left no result whatever influenced by their preparation. Accumulated observation of the facts has led us, therefore, on the present occasion of the competition of designs for the National Gallery, to attempt to supply what has not been attained even in the exhibition opened in the Royal Gallery of the Palace at Westminster, and to leave on record particulars that might be valuable, and might otherwise be lost. Our readers must be content with the speed at which we acquit ourselves of our duty.

We have, so far, noticed the works of four of the competitors, comprising about ten different designs. Mr. Murray's designs, which come next, are classed by him as three in number; but with the different alternatives of plan or decorative treatment, we should count them as five or six. Of the three, his "Design No. 1" would involve an extensive remodelling of the existing building, together with the erection of new galleries on the ground to the north-east: "No. 2" is for an entirely new building "in the Greek style," and "No. 3" is for a new building, "Italian in style." The treatment of the two latter designs so entirely comprises the ground occupied by the barracks, that a western front, forming one side of a new street from Pall Mall East, is shown in each of the views. St. Martin's-street would be widened, and prolonged to Leicester-square; whilst the College of Physicians would form an effective termination, southward, to the new opening. Mr. Murray has chosen to design each of his buildings "in what is commonly termed 'Classic,' because of the character of the buildings of the locality.

As regards the first design: from the present building would be removed the dome, and the lanterns or "pepper-boxes"; the portico, which Mr. Murray regards as too small for its situation, would be taken down; a larger portico would be erected; and a colonnade would be added to each wing, for the greater portion of its length—using the displaced columns, and leaving those of the side-porticoes. The central intercolumn of these last being wider than the side-intercolumns, whilst a similar arrangement is that of the pilasters of the other projections from the wing, we doubt whether the effect would be good. The use of a long colonnade is different to that of the Vitruvian eastyle portico; as to which even, we are not sure that the effect would be quite pleasing. Above and in the rear of the central portico, would be a square attic, terminated by a cornice and antefixæ, and groups at the angles: this would form the upper portion of a hall for sculpture, of 100 ft. in length by 65 ft. in width. The terminations of the present side-porticoes would remain much as they are: but in place of each lantern on the wings, the mass of the projection on plan would be carried up as an attic, and terminated by a balustrade: four statues would be placed over the columns; and in the centre would be a panel for sculpture.

But to this arrangement there is an alternative, comprising a much larger pavilion-mass projecting from the wing. The staircases would be altered; as would the last new gallery; but the other galleries would remain. The ground would be enclosed with, in place of the present railing, a balustrade; to which would be added, lamps, and steps at the ends. The terrace and steps of the Square would remain as at present. The arrangement that the author would recommend for the new portion of the ground, is not quite clear; but we may take it to be as shown in "Design No. 2," excepting that "Design No. 1" has at the eastern end of the ground, a large semicircular double-columned portico, entirely open, or without wall at the back of its columns, other than the wall of the end of the building on the line of its diameter; whilst the other design has an ordinary portico of six columns. In each design a considerable portion of this end-ground is given up to the street. According to one arrangement, the lines of the eastern frontage would be at right angles with the chief front; whilst, parallel with the eastern front, would be galleries, covering, with the galleries parallel with Hemming's-row, the entire ground, or leaving only a very small court between the present galleries and the ends of the new ones, and allowing of mere air-shafts at the other ends. The ground-floor would be used chiefly for storage. There would be staircases in the centre of each of the three fronts. The northern galleries, of 50 ft. in width,—like the others, to which we have referred, of which the width varies from 50 ft. to 22 ft.,—would be top-

lighted, and would have rooms alongside of them, which might be lighted from the street. A design, which is an alternative to "No. 1," has the line of the end of the building, and other lines, askew, instead of at right angles with the front,—the hexastyle portico taking the place of the semicircular; whilst in place of what would be the acute angle, north-east, there is a quadrant with columns. In the latter part of the plan, a circular guard-room is shown. In this design there is an attic like that over the portico in the other case, but developed to occupy a large portion of the entire area of plan.

"Design "No. 2" is columnar; but it is in other respects different to "No. 1," though it resembles the alternative of the latter design in those features of plan that we have particularized. Otherwise the plan in "No. 2" may be described as having the whole range of buildings, including the site of the barracks, grouped about two courtyards, of which the smaller measures 95 ft. by 85 ft. The main entrance, in the centre of the Trafalgar-square frontage, is under a grand portico of fourteen columns in the front, and of six inner columns: behind this is a space of 100 ft. by 27 ft.; beyond which again are a vestibule and staircases. The landing of these latter, with the entire space, is open to the portico,—the arrangement resembling as nearly as possible that of the portico and staircases of the Museum by Schinkel, at Berlin. It is an arrangement that is of doubtful propriety,—whether for the climate of the capital on the banks of the Thames, or for that of the capital on those of the Spree. The resemblance to the Berlin structure is continued in the portico; which is without pediment. The space over the staircase-hall and entrance-hall is carried up as an attic; but in this, the resemblance to the Berlin structure is not so great as in the attic of design No. 1. The space is arched over, and hypæthral-lighted; and the external framework of this covering is a temple-like structure, with ten square antæ in front, in place of columns, and with a sculptured pediment. The order of the principal portico of the building is continued, with three-quarter columns, on a rusticated stylobate; and the angles of the building take the quadrant-form on plan. The ground-floor windows have pediments; and the wall over them is enriched with sculpture. The portico of the eastern front has a pediment. The external walls generally are ornamented by a well-designed attic, with dwarf-piers, panels, and statues. The ground-floor is devoted almost exclusively to sculpture. If sculpture be to be provided for, probably that would be the best appropriation of the ground-floor, as compared with provision there for the National Portrait Gallery along with the Turner and other drawings. Sculpture is seen to more advantage by a side-light than a top-light. In Mr. Murray's design, the larger galleries, 50 ft. in width, for sculpture, are lighted by large windows from the courts. The north-east and south-east angles of the building are occupied by the residence; and the rooms of which are joined by a corridor across the space in the centre of the east front, where one of the staircases is. Although the competitor has considered that the instructions required him to provide staircases at the north and east, he does not advise that there should be so many altogether as he has shown. On the upper floor are the galleries for paintings. The grand-staircase would lead to a vestibule, 103 ft. by 20 ft., in the Trafalgar-square front; whence on three sides galleries of 50 ft. width would open; and from these last would open galleries of 25 ft. Top-lighting is recommended for the galleries along the north, as for all the others. The elevations towards the courts have a certain decorative character, as they should have if they can be seen from windows.

The design "No. 3" is in plan a modification of "No. 2," but in decorative treatment it is very different. The wide sculpture-galleries are made external; whilst the narrow ones are lighted from the courts. The characteristic feature of the front, the staircase open to the air, is suppressed; and in place of it there is an entrance-hall, 97 ft. by 50 ft., over which the picture-galleries run in an unbroken line; whilst the staircase itself is seen, on entering, beyond the entrance-hall, and through a perspective of columns. The narrow picture-galleries would be side-lighted. The Trafalgar-square front would display two stories on a rusticated podium; the ground-story would have rusticated arch-headed windows, and the upper story a Corinthian pilastade, niches, and statues. In the middle of the front, the drawing shows a double-storied

portico of columns, coupled in the thickness,—the order below being Roman Doric, with rusticated shafts, and that above, Corinthian,—and the lower portico being approached by side flights of steps, and the upper one crowned at the top by a balustrade and statues. This is not the sort of design that we wish to see carried into effect. If a building that is now to be an art-work, there must be novelty in it. Such elements, required, need be but small; indeed, in presence of countless attempts that realize no more than novelty, and with recollection of the difficulty of combining novelty with taste, we would restrain rather than urge the flight after novelty. But some novelty is required. All which we have often said, Mr. Murray estimates the cost of his design "No. 1," or including the remodelling of the present building, at 210,000. But leaving the present structure as it is, and building upon the north-eastern ground only, he estimates that the cost would be 161,000. His estimate for the entire design "No. 2" is 326,000; whilst "No. 3" would be 330,000.

Mr. E. M. Barry's designs are marked respectively A, B, and C; but including variations of plan, they may be reckoned as more than three in number. "Design C" is that which deals mainly with the new ground, and makes only alterations in the present structure. "A" and "B" are designs, not very dissimilar to one another, for an entirely new structure; and both of these deal with the ground, entire, and inclusive of the site of the barracks. In all the designs, the principle of distribution of the galleries and rooms occupying the north-eastern ground is the same. In all, the eastern boundary of the plan is at right angles with the front; and in all, the present arrangement of the terrace and steps of the Square is retained. In designs "A" and "B" there is a frontage to a new street at the west.

In "Design C," the dome and the pediment to the portico are removed. The three principal rooms of each end of the building, for pictures, are retained,—as are also the "octagon-room" of the Academy, and the room in the projection from the front corresponding with that in which the octagon-room is. The lanterns on these projections are removed. In place of the pediment, a raised attic is shown, with balustrade and statues. This feature forms the upper portion of a large staircase-hall, which has galleries and columns on the four sides. The projections from the wings are terminated by attics similar in treatment to the large attic. In planning the buildings for the added ground, Mr. Barry has not availed himself of the ground-floor for purposes of exhibition, unless exceptionally, as for the Turner drawings. In his opinion, picture-galleries cannot be considered satisfactory without top-light; and he believes that, though a large additional wall-space would be gained should ground-floor galleries be considered admissible, a larger wall-space is provided by any of his plans than would be likely to be required for many generations. Confining our description, first, to the gallery-floor, and as regards the new ground: the plan comprises a group of buildings consisting of galleries surrounding a quadrangle, in the centre of which is another group, and of a range of buildings in the rear, or following the line of Hemming's-row. The group within the quadrangle is square on plan, but having the angles canted off: galleries of 22 ft. in width form the outer circuit; whilst the four angles are planned as octagons. In the centre of this group is a space of 56 ft. square, which is entered on its four sides by short passages. Spaces of the form of the letter L are left at the angles, between the 22 ft. galleries and the 56 ft. square space, for the object of light to the rooms below. The central space is planned somewhat after the model of the so-called *landscape-gallery* at Munich, of which the competitor gives a section. The principle is the same as that of the arrangement advocated by Mr. Cockerell,—with only this difference, that the suspended ceiling is brought much lower in the Munich example, as well as in Mr. Barry's design, than it would be according to Mr. Cockerell's suggestion, which greatly resembles what was carried into effect some years ago by Mr. F. E. H. Fowler in the gallery of the Society of British Artists. Mr. Barry, however, like Mr. Cockerell, and for much the same reasons, would relieve the heaviness of the *plafond*, by openings or coffers, which would be glazed. The method is "suggested" by Mr. Barry "as being very suitable for landscape and subject

pictures of moderate size," hint we should say, that if the principle be the right one for pictures of any kind, it can have no special suitability for either landscapes generally, or works of small size. As to the latter, the observer would necessarily approach so near to the work, that the source of light would no longer be concealed; though whether this would affect the principle, we must leave others to decide. We believe that, as might be supposed, the proposal does not find favour with those of the judges who have paid most attention to the arrangement of galleries. It should, however, be well considered. But if the principle be correct for one gallery, it would seem to be so for others. The principal galleries in Mr. Barry's plan are respectively 50 ft., 45 ft., and 42 ft. in width. He does not omit to state that the prescription of the 50 ft. has exercised an important influence on his plan, and on the extent of accommodation he has been able to provide. Whilst expressing his preference for top-lighting, he has provided a few side-lighted galleries for cabinet-pictures. In the floors of each of the large galleries are openings for light to rooms below. This arrangement is one that, having regard to chances of fire, would have to be well considered before adoption. It is a leading feature in a design that we have yet to notice. The ground-floor in Mr. Barry's design is planned so as to be capable of adaptation to different requirements. There are a staircase and a covered porch on the Hemming's-row side; and there is a large carriage-porch, with coupled columns as the main feature, to an exit-way that is at the eastern end of the building. The author thinks it right to state that he has prepared his "Design C" in obedience to the "Instructions," but that he cannot recommend it as "an adequate or satisfactory way of supplying the want" of a National Gallery.

In his designs "A" and "B," Mr. Barry has allowed himself more liberty; and, as we have said, he has dealt not only with the site of the present building, and with the north-eastern ground, but with the site of the barracks. He had some difficulty in understanding the condition that the front was "not to obscure the view of the portico of St. Martin's Church, from Pall Mall East, or from any part of Trafalgar-square," since the present building obscures the view to a certain extent. He has therefore shown alternative designs, so far as the lines of front are concerned,—involving of course in one of the designs, diminished convenience. The chief feature of the building viewed from the Square, would be a large dome, in which the newspapers have discovered too much resemblance to that of St. Paul's, and which certainly resembles that fine model in having columns about the tambour. This feature is borne upon a large square mass which has turrets at the four angles, forms the centre of the front, and projects in part as a portico or loggia of Corinthian columns carried on rusticated arches. The columns, eight in front, and eight internal, are placed between piers that carry two of the turrets. Besides the central dome, there are two other domes to the front, that is to the ends, where the angles are massed square on plan. These smaller domes are without the feature of a very lofty tambour. Each of the other two angles of the entire building would have a dome similar to those last mentioned; though the acute-angled form of the ground to the north-west, would throw the dome there out of what would be its proper place, symmetry being considered. Opposite the entrance, and beyond the space in the plan covered by the dome, is a grand staircase and sculpture-gallery, with a vaulted ceiling carried by columns which are at the sides, and which separate the side-galleries from a central straight flight of steps, broken by landings. The staircase is lighted through coiffers and lunettes. In the two recesses of the front, or between the masses of the wings and centre, in each case, is a loggia of halustrated arches, having Ionic columns on the piers. It is lower than the adjoining Corinthian order; and forms a covered way parallel with the chief galleries of the front. There is a portico to each of the end-fronts,—the columns being on the upper story. One of these is not sufficiently different from the portico of Covent Garden Theatre. The design "B" has quadrant-corners to the building; the other design, "A," has re-entering angles to the same parts of the plan, or in places of the quadrants. This appears to be the chief difference between "A" and "B." There is, however, a plan showing an arrangement of the galleries with an extra number of cross-walls for additional hang-

ing-space. Mr. Barry observes that this increase would be attained at a certain "sacrifice of grand architectural effect." There appears to be an opinion, however, that the longer a gallery, the more monotonous would it be. The truth is, that lengths of rooms, or galleries, should be varied, and the architectural features, also,—though these last are necessarily confined to the ceilings, for the most part. The difference in the levels of the ground, which, according to Mr. Barry, is about 13 ft., led him to the arrangement of the ground-story, or, it would seem, chiefly to give height. In the space under the dome, he would place allegorical groups, and statues of the old masters. The staircase and its galleries he would reserve for statues of deceased British architects, sculptors, and painters; and by such arrangement he thinks "the public would be led to form correct ideas as to the past history of art," and that "honours would thus be paid to British artists, similar in degree to those so often accorded to their foreign brethren, although not hitherto customary to any great degree in their own country." The best features of these designs, "A" and "B," decoratively, appear to us those of the interior, section or meeting of the lines of galleries on the plan, and in the hypothetical lighting of the staircase and its side-galleries. The design "C" is estimated to cost 220,000*l.*: the estimate for "A" is 460,000*l.*, excluding the portion of building in the site of the barracks and barrack-yard; and that for "B" is 450,000*l.* In a concluding paragraph of the paper accompanying his designs, Mr. Barry alludes to steps that should be taken to obtain a satisfactory selection from designs proposed. He considers that "a small body of judges, however eminent for their ability and architectural knowledge, would be liable to be led astray by strong possessions in favour of a particular style or mode of treatment;" he rightly adds,—"The consideration of such a subject, and even the power thoroughly to understand the various plans and sections, require considerable professional qualifications," &c.; and he suggests the Royal Academy and the Institute of Architects as "suitable bodies to be requested to co-operate with the Government, and such lay judges as may be appointed."

We are now obliged to depart from the order in which we had at first arranged to notice the designs.

The designs by Mr. M. D. Wyatt are two in number. A design marked "B" comprises additions and alterations to the existing building; and one marked "A" is for an entirely new National Gallery. Each design is very completely shown by drawings, including an unusual number of perspective views. They are accompanied by a brief report; in which however the author's conclusions from examination of the site, constituting the guiding principles for his design, are set forth in terms that should be duly considered: for, assented to or the reverse, they may conduce to a right decision. There can be no doubt that Mr. Wyatt has given great attention to the subject of picture-galleries. As to the present matter, he expresses an opinion that the general wish of the public is to have an entirely new Gallery, worthy of the country, and that to lose the opportunity would be disgraceful, and would prove the source of future regret. As regards the design "B," it has proved "an even more difficult task" for him than the other. In dealing with the present building, he would remove the dome, and the lantern-towers of the wings, (using doubtless the displaced columns,) and would crown each of these new porticoes with a pediment. The columns of the principal portico would be as now; but the pediment would be altered, at least so far as that it would be charged with sculpture in the tympanum, and upon the acroterium of the apex. Above the general cornice, an attic would be added to the building, composed of square ante with Corinthian capitals, and a cornice and antefixæ, and of a filling-in of panelled masonry to the interlunæ, for about three-fourths of their height, or leaving open space below the cornice, between the capitals. At each of the two projections, the drawing shows decorated masses carried up to a greater height than the general line of the attic-cornice. In the centre, beyond the portico, is a larger crowning mass; which takes the form of a structure having a portico of Caryatides in the front, and a similar portico to the rear. This mass is the termination to the entrance-hall. The hall, internally, is flanked by columns; which

separate it from two other halls, and new staircases, that are shown on the plan. Here in each of the flanking staircase-halls, a central flight, parallel with the transverse axis of the building, leads to a landing from which the upper flights branch right and left; whilst from the entrance-hall, steps in front of the entrance descend to the new galleries. The entire arrangement is capable of being made highly effective. On the further side of the ascending stairs of the eastern portion of the front building, is a second descending flight to a rotunda with columns. The rotunda forms part of the plan on the new ground, and is the vestibule to galleries in the middle of that ground, which are a cruciform in plan. The stairs of descent first-mentioned, lead to a gallery of 28 ft. 6 in. in width; at the north end of which is a rotunda similar to the other, and placed like it at the end of an arm of the cross. At the eastern end, opposite, is a third rotunda, with an intervening compartment of plan wherein there are large semicircular recesses. Several such features are to be found in the plan; which generally is devised with great regard for the pictorial effect resulting from circular forms, and from the effective introduction of columns. The particular column used would be, in design, greatly varied from those of the classical orders. The base and lower part of the shaft would approximate to the Egyptian type, in outline, and in the decoration. All the galleries on the new ground, with the exception of those which are circular, and of the gallery reached directly from the entrance-hall of the main front, are placed parallel with, or at right angles to, the raising line of Hemming's-row. The principal gallery on the north, would be 50 ft. in width; and those of the cruciform disposition would be 43 ft. 6 in. in width. Outside the latter, and between them and the present building southward, and the 50-ft. gallery northward, are four open courts, these being in addition to a court more to the east, as well as to different small courts. In the re-entering angle at the meeting of the line of St. Martin's-place with the end-line of the present building, a colonnade, or portico, quadrant-shaped and curving inwards on plan, would be placed; whilst attached to this would be an apical recess, with columns on the same radii as columns in front. The axes of the entrance, halls, and galleries are planned, to accord with one another, in a manner that deserves much commendation. In this design "B," in the other design, some alteration would seem to be contemplated. The ground-story would provide for the National Portrait Gallery and the Turner Gallery. It would be side-lighted in some parts; but generally Mr. Wyatt advocates top-lighting; and he proposes an arrangement, that is peculiar, for so lighting a story that has rooms over, which we must mention in speaking of his principal design, "A." An argument used by Mr. Wyatt in favour of an entirely new building, is that the present structure could not be made fireproof unless with almost entire reconstruction.

Mr. Wyatt's views with reference to an entirely new National Gallery, are so far important, that we feel called upon to give them at some length, prior to describing his "Design A," though we should have preferred his starting with the consideration of the internal planning of the building, and with an inquiry into modes of lighting, instead of setting out with examination of the special conditions for external effect. Looking, however, at these conditions, which are of the site, he observes, first, that the most important view of the building would be from the south-east, and that consequently, the angle next St. Martin's Church should be the central feature of the whole composition. Secondly, he observes, that the next most important view would be that from the southern side of Trafalgar-square, wherein the Gallery-façade would be cut in half by the Nelson Column, whilst the terrace-wall and steps would constitute the platform of the building. Wherefore he concludes that it would be "a grave error of judgment" to adopt any central feature of the façade, and that the existing symmetrical divisions of the terrace-wall should govern the disposition of the façade of the Gallery, so that the former might appear as the original podium to the latter. Mr. Wyatt, therefore, places a doorway of the main entrance to his building coincident with the axis of the principal flight of the steps at the north-eastern corner of the Square. The few returned steps are taken away, and others are

placed as top-steps to the present flight: the roadway is then widened; and the top of the flight is flanked by two pedestals and equestrian statues, instead of one pedestal and statue. He places a doorway opposite a correspondingly-altered arrangement of the steps westward. Thirdly, he finds that the next most important view must be from Pall-Mall East; and says that "that form of design which, dispensing with a central feature in the southern façade, provided leading eastern and western motives to close a long range of regular, large, and monumental features, say either colonnade or arcade," would, he "at once saw, compose most attractively when seen both from Pall-mall East and from Duncannon-street." He shows, in drawings, how his building would look from each of the points; and he considers that no building should be deemed satisfactory that would not look well from each. But we do not quite see that his design accords with his conditions. Having decided upon the southern eastern angle as his central feature; having placed there the doorway mentioned, which gives access to the grand-staircase to the galleries; and having also emphasized the angle by a circular feature, and by two domes,—whereof one is over the entrance in the front, and the other in the return-end, or side, of the building,—he establishes at the other end, features precisely similar, in everything, with the exception that westward there is but one dome. In short, the design is a compromise between the first-stated principle, and that of exact balance of two ends of a façade. Either there is a dome wanting; or there is one too many.

The western doorway of the façade gives access to the National Portrait Gallery; which, thus, rightly, would be as distinct as it well could be, if in the same building, from the National Gallery proper. Mr. Wyatt noted an authoritative statement in the House of Commons, that accommodation would be provided in the New National Gallery for the other collection, as well as that it might be desirable to provide in the Gallery for works of art other than pictures. General features of his design, besides what have been named, were established on conclusions, one of which was as follows: that "no building could appear monumental, and exhibit a becoming repose, which should have a ground-floor lighted by windows, and a first-floor, either without any openings, or, what would be worst of all, with sham windows." The curious reader will mark the divergence, on this occasion, of two practised enunciators of principles, Mr. Owen Jones, and Mr. Wyatt. We are scarcely overstating the facts in saying, that one allows his plan to be under subjection to a notion that a front should necessarily have windows for effect, whilst the other allows his to be subject to the idea that the front must either have windows in each of its stories, where there are more stories than one, or have no windows at all. However, Mr. Wyatt's conclusion led him to devising "means," as he says, "of lighting" his ground-floor by top-light entirely, or excepting the case of narrow galleries in internal court-yards. He considers that thus he has obtained three advantages: first, the giving the building "a fine solid plinth and dado, by way of base to rest upon"; second, the utilization of the recesses necessary for effect of light and shade; and, third, the doing away with "the distracting and dazzling effect produced by daylight, which, when seen in immediate contrast with any picture however brilliantly painted, invariably make it look dead and colorless."

The main feature of his façade towards the Square, consists of seven arches on the level of the second story, and formed at the base as large niches. Immediately under each of these is an oblong panel for sculpture. This feature has a pediment that forms the front to a little glass-roof through which light is obtained to a recess belonging to the gallery of the ground-floor. Corresponding niches and pediments appear in a portion of the front towards St. Martin's-place, and have similar use. In the former case, each of the arches corresponds with one bay in the length of the principal gallery of the ground-floor, devoted to the National Portrait Collection; where the floor above is carried by columns similar in character to those described in speaking of "Design B." In the rear, each alternate recess corresponding to one of those of the front, is similarly top-lighted, but through a larger area of glass. There are similar lighting arrangements for the galleries on the new ground. In this part of the plan, the galleries, with the exception of one that is semicircular, next a court, and with the exception also of

the gallery that is next St. Martin's-place, are at right angles to or parallel with the principal front. But there are other features of the plan besides those of the recesses, intended to be subservient to the top-light of the ground-floor. These consist of well-bore openings from the floor of the gallery above. Their purpose is of far more importance than that of the few openings mentioned as provided in Mr. E. M. Barry's design; where the rooms below are not meant for exhibition of pictures. Mr. Wyatt would seem to rely upon them for the bulk of the light that he would get to the middle of the area of his ground-floor galleries of the greater width; but, it seems to us that only the space immediately under the well-hole would be adequately lighted, or from the top-lights of the galleries of the principal floor, and that a large portion of the area in the ground-floor would be much worse lighted than it would have been had he substituted windows in the walls, combined with adequate height of the ground-floor story. Moreover, the same objection would apply to this arrangement as we have noted of Mr. Barry's, that it would negative the "fire-proof" construction that Mr. Wyatt recognizes the importance of. As regards the distribution generally, of the parts of the plan, the author of the design under notice has considered that looking to the great value of land in the situation, "and its limited extent when compared with that allotted to similar galleries in other great capitals of Europe," "as much of the land as should be consistent with ensuring due light and ventilation to every part" should be occupied with buildings; and he holds that his system of top-light for the ground-floor generally has enabled him to effect the object referred to, more completely than he could have done had he relied mainly on side-lighting; in which latter case, as he rightly says, his court-yards would have had to be larger, and his buildings fewer in number and lower, so as to admit uninterrupted rays through vertical windows. He adds that utilizing the present site to its full extent would probably render unnecessary future acquisition "of most costly land;" for it will have been understood, he has designed no extension over the site of the barracks and harrack-yard. As we have shown, however, we do not think he has quite succeeded in demonstrating the superiority of his system to that of comparatively large courts; which, indeed, are necessary for ventilation, air, and the prevention of continuance of dampness of soil and walls. The proper size for courts, with reference to light-admission to rooms, and height of buildings, should surely be better understood in the profession than it seems to be, judging from the different methods of treatment that we observe.

Mr. Wyatt appears to contemplate a considerable provision for sculpture; and there is this difference between him and Mr. Street, that whilst the latter doubts whether sculpture and paintings should be in the same gallery, Mr. Wyatt considers that it would be best not to separate them: he would rather group the works of the two kinds "freely together, as in the Tribune and other galleries of the Uffizi at Florence." He adds,— "Such a mixture greatly relieves the strained attention of the visitor, while adding to the decorative effect of the whole structure. In fact, to take sculpture from a museum and place it where it enhances rather than detracts from architectural grandeur, is to redeem it from mis-application and to restore it to its legitimate function." We incline to this opinion, whilst recognizing that what is the best manner of lighting pictures is not necessarily best for sculpture, and that the convenience of a ground-floor cannot be overlooked where weight is in question. The principal galleries in Mr. Wyatt's plan are of course 50 ft. in width, as required by the "Instructions;" but he, differing from other competitors, considers this the proper width. In place of wall-surface above the height to which pictures would be hung, he would spring a decorative vaulted ceiling from the level, agreeing with the semicircular form which is that of the main ribs of his roof. Along the middle of this would be the opening for light. He says that, besides saving brick-work, his system "offers the great advantage (for a picture-gallery) of presenting surfaces receding from the light, and so falling into half-tints, thereby enhancing the luminous effect of the vertical surfaces" on which the pictures would be hung. Between the transverse ribs of the ceiling are lunettes. At the intersection of the galleries the space is domed over from pendentives, so as to produce a good feature of effect.

The entrance to the National Gallery proper, and that of the Portrait Gallery, are, as we have explained, in corresponding positions towards the ends of the front. Beyond each of them, there is a quadrant-corner of the building, with a columnar arrangement of the lower story, affording a needed place of shelter, as for persons waiting for carriages. The entablature of the order here carries arches which are over the intercolumns. Above these there are several decorative stages or stories: but the whole is a mere piling up of incongruous parts, or quite beneath the art of the rest of the design. It should be understood that the centre of the façade, containing the niches, has considerable elaboration of detail. Each recess would contain a statue of some celebrated painter; and the relief below would set forth some incident of his life. In the spandrels of the arches would be heads representing some of the artists' scholars. In the frieze there would be decorative panels of marble or granite; and red granite columns would be attached to the narrow spaces separating the niches. These last would be coffered in the vaulting, and enriched with vitrified materials; and generally, a rich polychromatic effect would be attempted with the aid of terra-cotta. A balustrade, and ten pedestals for statues of Apollo and the Muses would crown the whole. In each of the blocks where the entrances are, and which support two of the domes, there is some beautiful composition. To the doorway itself there is a species of balcony carried by cantilevers and Persians; and above the balcony is tracery, as though to the head of the door. Flanking the doorway are very large granite tablets, that some of the newspapers say are sepulchral, for names of great painters, with the dates of births and deaths. Above the doorway is a long panel, in a frame, like that of a picture, for sculpture. Above and below the panel, the mass is enriched with good mouldings. Each dome is combined with its supporting mass in a manner that is highly effective, and, we think, new. With the tambour are grouped four dormer-windows terminating the sides of the pavilion; attached to which are seated figures. We have stated that the south-eastern entrance leads to the grand-staircase. Next to this, and so that, between the stories, there is one landing, is a second staircase. Both staircases are shown, as they would appear, in one view. In the principal staircase a vaulted ceiling is carried in the centre, by a small arch from the entablature-blocks of two Corinthian columns which stand on pedestals that are joined together by a panelled piece of masonry. Some of the principal details of this staircase have a Renaissance character. The internal colouring, with the exception of that of the staircase, it is proposed should be quiet in tone, or as vellum-colour, gold, grisaille, and sparingly in low reds, greens, purples, &c., not overpowering any of the pictures.

Mr. Wyatt has estimated the lineal feet of walls and scoons for pictures, in each of his designs; and he makes the total quantity in "Design A" about 460 ft. more than in "Design B." The figures in "A" are thus stated:—

	Ft. lin.	Ft. lin.
National Gallery:—		
Ground-floor:—		
Wall space	1,663	
Screens	538	
		1,901
First-floor:—		
Wall space		2,944
Screens, &c.		
National Portrait Gallery:—		
Ground-floor only:—		
Wall space	790	
Screens	344	
		1,944
		Foot lineal 5,889

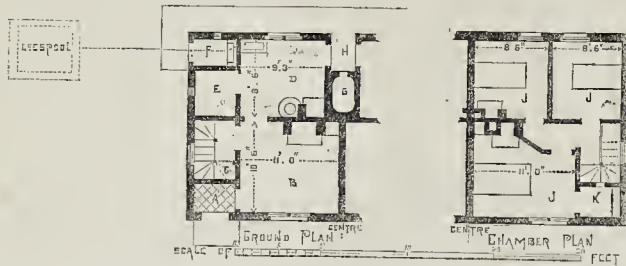

According to an experienced surveyor, the design "B" retaining the present building and making the additions and alterations, would cost 275,000*l.*, whilst the design "A" for the entirely new building, would cost 420,000*l.*

We have not yet noticed designs by three of the competitors.

MACHINERY FOR MAKING BRICKS.—Mr. C. H. Murray, in a patent dated June 8, 1866, claims cutting the clay into the form of bricks by forcing the clay forward by means of a pushing board, or otherwise, against a series of fixed wires, so arranged that the clay is pushed on or forced past the wires on to a movable board provided with handles, so that twelve or any other convenient number of bricks may be removed at the same time, as described.

FRONT ELEVATION

CONCRETE COTTAGES, SELLING, KENT.—MR. B. ADKINS, ARCHITECT.

CONCRETE COTTAGES.

Our engraving shows a pair of labourer's cottages just built at Selling, near Faversham, for Mr. E. Neame, under the directions of Mr. B. Adkins, architect, Faversham, and which from their economy of construction will, doubtless, interest those who are anxious to see the dwellings of the working classes improved.

These cottages are built of concrete, composed of gravel found near the site and Portland cement, and have been entirely completed ready for occupation at a cost of 100 guineas each. The same material was used for all paving, sinks, hearths, and other places where stone is generally used. The external walls are 9 in. thick, and the internal 6 in., and they are formed by laying concrete between sliding boards, the surfaces being floated over with a little fine cement and sand as the work is carried up. By these means a sufficiently smooth surface can be obtained to dispense with the usual inside wall plastering: the outside surface is afterwards jointed in the manner shown, and when dry enough coloured in the usual manner.

The use of concrete for these purposes enables the introduction of a common and inexpensive description of material generally found near the site, for if gravel is not handy, stones gathered off fields, or broken clinkers and burrs from the brickyard itself, mixed with a small proportion of sand, may be used, and with proper care stronger and dryer walls can be built with these than of ordinary 9-in. brickwork. Mr. W. Goodman, of Whitstable, is the builder.

In proof of the economy of this description of construction, these cottages when compared with a block of three similar brick cottages recently built in the same neighbourhood under a close competition, show a saving of about 50% per cottage. A greater question, however, even than cheapness arises, and that is the absorbent or non-absorbent qualities of materials. Bricks such as are too often used in such constructions absorb a large quantity of water, during rain for example, and retain it a long time. Experiments upon well-made stone concrete seem to show that its power of absorption as compared with that of brickwork, is very small indeed, especially if the concrete be made with cement.

THE DEATH OF ALEXANDER SMITH, THE POET.

With regard to the sanitary circumstances we have referred to as connected with Alexander Smith's death, we must always remember that an individual member of a community or a country is of necessity as subject to its malpractices in government—sanitary or otherwise—as he is to any other part of its constitution. A man who chooses to reside in Scotland must make up his mind to certain risks. Just as Count Cavour was blest to death by ignorant physicians, so may the poor poet he said, on similar principles, to have fallen a victim to the sanitary policy of his country. Those who choose to read what we printed in a recent impression (Jan. 19th) with regard to the sanitary condition of the new town of Edinburgh, will see that even the modern Athens is anything but a hed of roses. But the new town is a paradise compared to the old town; and the Edinburgh University, where Smith had his office, is situated in the very centre of the old town, which has been for centuries one of the filthiest of modern cities.

The secretary's office itself has been described to us as a sort of mural cell—excavated rather than built—in one of the piers of the stupendous arches which cover the roadway into the very handsome and stately quadrangle of the Edinburgh College. At best it is only fit for a porter's lodge. How it is heated we cannot say; but it is lighted and probably ventilated by entresol windows only, of fanlight pattern, one of which, the south window, opens upon the well-known College-street cab-stand. The opposite pier of the central archway—6 yards or so from the secretary's door—is converted into the public urinal of the college; and our readers may judge how much the atmosphere of these conveniences would conduce to the salubrity of the secretary's office. We will say nothing about the dissecting-room on the one hand, or the hospital on the other. But round the north corner, right under the "principal class-room" windows, is one of those horrible public privies for which Edinburgh has become infamous, and which of itself is enough to pollute the atmosphere within the radius of half a mile! Was ever a poor poet so environed? Yet here he sat from ten till four every day for nine months in the year.

It was in all probability in order to escape from these compound nuisances that he fixed his residence close to the sea. But here he was perhaps as badly circumstanced. The village of

Wardie lies half-way between Newhaven (one of the most uncleanly fishing villages in the British islands) and Granton, near which there has recently been erected an extensive manufactory of artificial manures, the smells proceeding from which were sufficient last year to drive Sir John Macneill and his family from Granton House just as if it had been invaded with pestilence. This was had enough, but this was not all. The beautiful slopes which spread from Edinburgh to the sea are irrigated more or less with the Edinburgh sewage, and the natural surface-drains or water-courses are thus filled with sewage. Sometimes in hot weather the flow is abated and the contents become stagnant. But we need not dwell on details which we have often given. In the midst of these "Elysian fields" the poet had his little villa, and here he cultured, we shall suppose, moss-roses and anemones, or grew some wild thyme and lobelia upon the arid banks.

He might try, perhaps, to console his nature during his sufferings by "gazing out into the ever-surg-ing waves." But here, alas! was perhaps his most fatal enemy,—a litter, cold, biting, acrid, and unextinguishable draft of north-east wind. If such a neighbourhood caused the death of the powerful and robust Edward Forbes, it is no wonder it proved fatal to Alexander Smith.

The immediate cause of his death was diphtheria—a name given by M. Bretonneau to a class of diseases which are characterised by a tendency to the formation of false membranes, and which affects all the dermoid tissues, but chiefly the mucous membranes of the throat and air passages. Such diseases have invariably their origin, it is thought, in some form or other of blood-poisoning, and the present case will add additional strength to the belief. Those profound physiologists who roundly assert that there is no danger in bad smells will take warning from this case, perhaps, and amend their philosophy. But we will not dispute with them on their nice speculations. It is enough for us that Alexander Smith is dead; and a valuable life has been prematurely extinguished,—more than possibly by sanitary neglect and misgovernment. Who is responsible for this it would be tedious to inquire. In Scotland they manage those matters so as to divide and evade, often to destroy, responsibility. In Edinburgh, at this moment, there is a medical officer of health, a superintendent of streets and buildings, two or three sanitary inspectors, besides the ordinary staff of

scavengers and their officials. But all these are subordinate to a committee of the town council, which consists chiefly of respectable tradesmen. There is a similar jury in the hurch of Leith. To discover the responsible party in this series of local authorities would puzzle a better investigator than we profess to be. We therefore rest the onus upon the whole of them.

We have little else to say, if we speak strongly on such a subject, it is because we feel strongly. Without going the length of the Pantheistic doctrine so finely illustrated by Sir Walter Scott:—

"Call it not vain! they do not err
Who say that, when the Poet dies,
Mere Nature mourns her worshipper,
And celebrates his obsequies!"

Without going this length, we may say that we hold the opinion very strongly that the death of a poet or man of letters like Smith is a loss to the country. But how much are our feelings of regret intensified when we find this death due to circumstances which we may not only control, but, with some carefulness, prevent! Indeed, we confess that indignation in such cases often gets the upper hand of our softer sentiments. But we have said enough. It only remains to add a single word concerning the poet's burial-place. Alexander Smith lies buried in Warriston cemetery, within a pistol-shot of his residence at Warriston. He lies, says a spectator of the funeral, on a sunny spot, commanding one of the finest views of the city whose beauties he had so eloquently described; and the cold but rich light of the early sunset seemed yesterday in melancholy harmony with the last scene of his bright but brief career!

ANCIENT SYNAGOGUES IN CENTRAL EUROPE.

Quoting and commenting on our recent article on this subject, and the View of the Ancient Synagogue in Worms, the *Jewish Chronicle* says,—

"It is true that no very ancient monuments are found in the cemetery adjoining the synagogue referred to at Worms, as the populace, at the repeated risings against the Jews, during the Middle Ages, was wont to vent its rage as much upon the dead as upon the living, and to destroy the tombstones. There are, nevertheless, a few monuments in it dating, we believe, from the fourteenth century. Some years ago there appeared a very interesting publication, containing copies of all inscriptions on the sepulchral stones in this cemetery, as far as they could be traced out."

If it is really true, as the writer asserts, that there still exist in the cemetery at Prago monuments of a date as early as the fourteenth century, they can only be plain inscribed stone, and as such are of no value architecturally. Many of the tombstones in this cemetery commemorate persons who lived as early as the tenth and twelfth centuries; but the original monuments have been destroyed, and those which now replace them are sixteenth and seventeenth century works.

"A splendid synagogue, almost entire, still exists in Prago. It is situated at Toledo, and was built by Rabbi Samuel Hanagid, the finance minister of Don Pedro the cruel. The synagogue, we believe, was built in the fourteenth century. A description of this ancient place of worship was given, among others, by the late E. H. Lindo, in his 'History of the Spanish Jews,' and who had paid it a visit in person."

It has been snapposed by many people that the building called the "Jews' House," at Lincoln, was originally a synagogue; but the fact of its being on two floors, and the remains of ancient chimneys, are sufficient proofs that it can never have been anything else than a dwelling-house, though one of no ordinary class. This building is a late Norman, and has a very pretty little doorway. With reference to our observation as to the isolation of the Jews, the writer in the *Jewish Chronicle* remarks,—

"There is abundant evidence to show that this isolation did not exist then, but that the intercourse between the Jews and Christians was habitual and most cordial; that there existed no ghettos and scarcely any of those exceptional laws which in subsequent ages brought about that lamentable isolation which in process of time led to a great estrangement between the followers of Moses and Jesus. It is principally two agents which brought about this isolation. The first was the fanaticism gradually infused in the general population by bigoted monks, priests, and the decrees of the councils; secondly, the influence of the guilds and the trading classes. Wishing to diminish themselves of the competition of the Jews, they were at all times ready to join in the outcry against the Jews by bigoted priests; to propagate all kinds of false reports against them; and to influence enough with the authorities to obtain decrees which either kept their rivals altogether from the field of competition, by banishing them from the cities, or deprived them of all means to interfere with trade, by confining them to special quarters,

and keeping them, as it were, in prison under lock and key. Most of the expulsions of the Jews, confiscations of their property, and even massacres, can be traced to one of these causes, or to a combination of both. The isolation of the Jews was only gradual, and the work of centuries. We need not, therefore, be surprised to find that the Medieval synagogues have so much in common with Medieval churches."

Now, although it is perfectly true as stated here, that there were no penal laws against the Jews in the earlier centuries of the Middle Ages, yet it is quite clear, from historical evidence, that the Jews kept themselves aloof from their Christian brethren, retaining their own peculiar manners, customs, and dress; and this being the case, it is difficult to imagine that they should have copied Christian churches in the erection of their synagogues.

There can be no doubt that the ill-feeling which existed against the Jews, during the Middle Ages, was not only a religious prejudice or commercial jealousy, but even a far deeper feeling than either; it was the antagonism of race. The feeling against the Jews in the Middle Ages was what we now see exemplified in the bitter hatred of the white man to the black in America; and even at the present time there are many persons who are utterly indifferent to all kinds of religion, and care little for commercial interests, who retain the most cordial dislike to the Hebrew people; and it is a singular fact, that until the year 1848, no Jews were allowed to live in Nuremberg, and no one would accuse the Nurembergers—the most Protestant people in Germany—of being led on by monks and priests.

M. Viollet-le-Duc, in speaking of the synagogue at Worms, seems to doubt the fact of its having been originally built as such. He is most certainly in error; for not only is there the strongest historical evidence, but the fact of the plan being nearly identical with the synagogues at Prago and Frankfort, forbids belief that this building could have been erected for any other purpose.

GLASS PAINTING; ANCIENT AND MODERN.

On this subject Mr. T. Gamhier Parry has been lecturing in Gloucester, and here is part of what he said:—

With peace restored at home, and leisure to return to the arts of peace, the relics of old days and old things at home, of home history, home romance, home devotion, soon begin to touch people to the quick, and to engage a warmth of cordial affection which all the copies from Athens, Rome, Spalato, or Corinth could never command. Among the relics of our national arts none engaged a more general attention than those associated with our national architecture, and pre-eminently that of painted glass. It was valuable for its heraldry, its costume, its legends; but some loved it for its beauty, and caught the first glimpse of the refinement of its art, which for centuries had shared in the contempt of all things Gothic. People had been taught to look at everything through Palladian spectacles. All avenues to really national taste had long been closed. This country had been overwhelmed by three centuries of invasions—religious invasion of the old form of faith, democratic invasion of the old forms of government, invasions of Dutch arts and notions with a Dutch king and Dutch nobility. But things began to settle down. People began to yearn for something of their own. The old national arts were revived with all the interest of novelty. Their very principles had been forgotten. Italian fiddlers, French cooks, Flemish painters, and Dutch architects had put out all memory of them. But the national arts, once dear to all our people, were soon to live and flourish again.

The first glass-painters of this modern Renaissance in England were unhappily no artists. They floundered about in a perfect mosaic of difficulties. They were staggered by multiplicity of styles; they had no good art in themselves, no good materials in their workshops. There seemed to be no standard of excellence; there was no standard of public taste. The contrast between the vigour of the old work and the poverty of the new grew more and more painful; the old savoured of art, the new savoured of the shop. What was to be done? To imitate? Yes, to imitate; and to the necessity which drove them to it will he hereafter trace the cause of the pre-eminence which I firmly believe our artists will attain. Imitation the most laborious is the very foundation for all hope of ultimate

success in the education of artists. The processes, the theory, the rationale of art, need to be analysed before the mind can digest them. Imitation is not haste, except in this—that it is the very basis of all success. The most heaven-born genius must first have learnt to spell. England did not stand alone in difficulty. In Germany the art was taken up with spirit, but the old examples were too soon cast aside. The reasons of their beauty, the nature of their materials, the very alphabet of the future language of the art, were neglected. In Germany the only real success has been in an art unvisited to the large scale of windows, in the beautiful cabinet examples of enamel-painted glass, principally of copies on a small scale of old pictures of their own school. Their merit is in technical dexterity—no more. For the high purposes of an independent art such works are but hinderances, influential only for bad. I know nothing more futile, more unhappy, in matters of taste, than the attempts to mimic the productions of one art by the processes of another. The attempt to reproduce in glass the works of the oil or fresco painter might be made in a modest admiration of the great works of other men; and so far the motive could be respected, but no further. Glass-painting is no mere supplement to any other art. It has an individuality all its own: it will stand or fall on its own merits, and for them it need not fear. The Germans have been among its most unfaithful followers. In other styles of art their painters are not strong colourists. It is strange that this should be so; for as a nation Germans are the greatest of musicians, and music is essentially the art of colour; but their painters, with rare exception, do not share in this great gift. It was therefore not unnatural that in an art of which colour is the great characteristic they should fail to seize the true ideal: they failed even to perceive the true properties of their material. Regardless of the principles of old art, they formed a dull ideal of their own; they went to work on glass as if it were canvas or paper. They worked as if they were afraid of it; they coated their glass with enamel; they did all that was possible to get rid of it; they reduced it to the condition of transparent calico, and then painted upon it, but with the worst abuse of glass,—brilliant, glancing, jewelry of glass! such as in the days of Gothic art filled their cathedral windows with a glory as yet unrivalled, and blazed and sparkled with a reckless brilliancy. With such as this, the genuine use of glass, our modern Germans have but little sympathy, at least if we are to judge them by their works. I must be understood to be speaking thus in general terms. There are honourable exceptions among German artists of glass-painting, pre-eminently in their cabinet copies of old pictures. It is hard and thankless work to try to make people see what they cannot see. In matters of this kind they are in general satisfied if only they find things, as Irish people call them, "pretty." There is little or no perception of aptitude and inaptitude in works of art. If glass is made to look like calico, or calico made to look like glass, so long as it is "pretty" indifferent people say, "Who cares?" In modern Italian glass there is very much the same radical error. But then the Italian is essentially a colonist. In glass, however, he, like the German, has begun at the wrong end. The Italians never had much sympathy with Northern art. They rather affected to despise their Gothic neighbours,—they ignored those Northern Teutonic schools of art, which nevertheless had covered church walls with paintings, and windows with storied glass, and had matured an art, marked with all the individuality of national character, well nigh 100 years before Giotto dipped his first brush in colour. And now, too, in their modern (Italian) revival of glass painting they ignore those schools again, from which the first lessons of the true art in glass can best be learnt. They have missed, too, those identical principles, even when displayed in their own glorious cinquecento windows, the principles of translucent colour. They have rather gone in for a style of art more suited to paper than to glass. They have produced some designs, tempered certainly with great beauty and refinement, and they have transferred these designs to glass. But why to glass? Why to great sheets of fragile glass, toned down with dense enamel, worked and laboured at till all the glass was lost sight of, changed, got rid of, treated just as oiled card-board might have been treated, and with precisely the same result? Again, we look in vain for the glancing jewelry of glass: instead

of it we find pictures, which in treatment, texture, and effect resemble precisely large coloured lithographs varnished into transparency—labour misapplied, art misplaced—one indeed in which we admire the frequent beauty and merit of design, and delicate execution; but it is not the Art of Glass. Refinement and tenderness are merits indeed, but they become morbid and vicious when they occupy exclusively the heart and hand of an artist, leaving no room for other qualities such as vigour and decision. Why are the glories of old glass at Florence and Venice, at Chartres and Bourges, passed by, rich as they are with many a lesson which a glass-painter need learn, examples which illustrate the entire powers of the art, and its scale complete, from gorgonousness to solemnity? Let those old works be equalled first, before there be any pretence to improve upon them.

In France and in Belgium the revival of this art has been carried on with much the same feeling as in England. The principle that has appeared to guide the best men in these countries has been to keep one hand stretched out behind with firm grasp upon the past, while the other was stretched out toward the future. They took no heed of the taunts about copying. They knew that they were but working out great secrets of past excellence to be the groundwork of their own. There has been, indeed, a most mean and miserable copyism, carried on by men who could do no better; and through their ill-doing the reproach has been misapplied to all. They knew all the while what they were about. They knew well what was good, what had in the works they studied. If in the Gothic Medieval art of France and England figures were painted in ignorance of anatomy, and architecture in ignorance of perspective, what matter! You might as well look for the word "photography" in Johnson's Dictionary as for the rules of the Academy in a Gothic window. No; the grand old fellows of those Middle Ages did their best. They felt with poetry, and they worked with earnestness; but, what is more to our purpose now, and for our study, they had a most thorough knowledge of the use of glass. That is the lesson we have to learn from them. We may draw better, our technicality and science may be greater. How could it be otherwise when each generation does but light its lamp from the one that has gone before? But those dull generations between them and us unluckily let the lamp of glass go out. So we, to light our own, must reach still farther back to the old lamp of our forefathers, which is bright and glowing still. The revival of this art on such right principles as this gives, not only hope, but confidence in ultimate success. One may grieve at the atrocities which have filled cathedral and other windows with disgrace in modern days; but there have been some grand things done. If there has been one fault more prominent than another, it has been that both the artists and the public have thought too much about the subjects painted, and too little about the glass itself. The result has been in too many cases that glass-painters have consecrated works to the genius of the arts which ought rather to have been consigned to the simpler genius of the pestle and mortar.

Of the early history of the art very little is known. There appears no reason for supposing that coloured glass was used in windows before the Christian era. The early Egyptian and Greek coloured glass, so far as we can acquaint ourselves, was but semi-transparent; commonly used for coating earthenware and in making small ornamental vessels. Somebody has lately taken out in England a patent for glass coffins. He must have a very high opinion of his friends. The Egyptians and Persians made glass coffins between 200 and 300 B.C. There are some in the British Museum. There were few colours made in glass in those times, but a good many varieties of tints. A good red is not to be found. There are tints of deep and pale blue, ochre and straw colour, browns and greens. About the use of glass in windows before our era little or nothing is known; what is described bears no analogy to our system of flat sheets set in frames. That glass was used in windows at about the beginning of our era we know from the remains at Pompeii, and Wroxeter in England. But we have no trace of coloured glass used for the purpose. Pliny's expression about glass is that "*Nulla est materia sequacior aut pictura accommodatior*," which at once suggests the idea of a pictured window. I conceive that in reality it refers to opaque enamels and to the ornaments in the glass bottles and vases of his

time, which were made with many coloured pieces, twisted or drawn out when hot, and worked into all kinds of forms by means of their extreme ductility. Many materials besides glass are described as used in Roman windows, such as tale and alabaster. The Japanese used the same expedients, and in addition to them large transparent shells. St. Wilfrid, of York, (died A.D. 703) as filled with transparent stones. The rareness of glass in windows would be inferred from the very few notices of it to be found in two such writers as Philo and Lactantius, who refer so intimately to the habits and usages of domestic life in their times.

The earliest pictorial use of coloured glass was in the tesserae of the mosaics; and it is by no means improbable that glass-coated materials and glass itself in flat sheets were used in the polychrome decoration of walls. Some of the most beautiful early examples of designs on glass are those of figures of the early Byzantine school, engraved in gold leaf inlaid between two layers of transparent glass. But the way was being fast prepared for coloured glass in windows. The use of tesserae in mosaics on walls and floors was the natural suggestion for a similar use of coloured glass in windows from the first moment that a perfectly translucent quality of it was made. Figure subjects had been common in mosaics—why, then, should they not be introduced in coloured glass? Thus the art of painted glass must naturally have begun; but the earliest positive information I can find of coloured glass being used in windows is in Prudentius's notice of it in the Basilica of St. Paul, at Rome, in the fourth century. We next hear of it at a church at Lyons in the fifth century; and the coloured glass there was arranged in patterns. The next in point of time distinctly spoken of are the windows of St. Fortunat, Bishop of Poitiers, in the sixth century; and in the same century we hear of the introduction of it in a church at Tours by St. Gregory. So that by that time the use of painted glass in windows had spread commonly and to a great distance. But in England we had not been so fortunate. St. Wilfrid, in the seventh century, laments that makers of coloured glass were not then found in England—so he went to France in search of them. In the next century, the eighth, we find Pope Leo the Third filling the apse window of the Lateran church with coloured glass in the year 795. But up to this time we hear nothing definitely of painting upon glass.

After all the pains which antiquarians have bestowed in the research, it does not appear that any account of figure subjects can be traced with any reliable authority earlier than the middle of the eleventh century; and the example cited is the subject of the mystery of St. Paschasius in a window of a church at Dijon, mentioned by the historian of the monastery of St. Benigne, A.D. 1052. The French King Charles le Chauve was the first great patron of glass-painters. Soon after his time he became universal. The treatise of Theophilus, of about that period, describes almost every process necessary for a complete window, with the whole detail of its design and colouring of patterns, figures, and draperies. So that it is impossible not to infer that an art so complete as he describes it, must, to have attained such completeness, have been practised long before, although we can find no written account of it. All that actually remains to us is in small pieces coloured separately and inlaid, as in vitreous enamels, mosaics, and encrusted ornaments, or bits of glass in imitation of gems, on book-bindings, church vessels, rings, and so forth. At about this time (the twelfth and thirteenth centuries) glass painting became a very distinguished profession. Its professors were honoured by privileges and dignities at Venice, and in Normandy by the semi-noble distinction of a title, that of "gentlemen glaziers." In those mis-called "dark ages," those "heightened" Gothic times, when Christian art first sprang forth in all its freshness and beauty, schools of art were established in religious communities, and the artists of those times, trained in the whole range of education then open to them, appear to have practised all the arts of design connected with architecture, so that wall painting, designs for sculpture, illumination, and glass were followed equally by the same persons. In the earlier styles, the artistic composition of picture subjects was made effective, and the groups of figures relieved from each other by contrast of colour, rather than (as in more recent work) by opposing and contrasted forms.

Their shadows consisted of little else than lines, so that the glass was honoured throughout, and the right principle of a window was maintained as a thing of light. But as time progressed, and the arts of mural painting and illumination became more realistic, glass-painting followed in the same strain.

Translucent glass-painting for the purpose of windows has been entirely confined to Christian use. I instance Pompeii and Wroxeter for their evidence of the use of glass used in windows of Pagan times; but they were not coloured. Coloured glass has from early times been used by Mahomedans, but it was not painted. Painted coloured glass is therefore solely Christian. In Mahomedan mosques the ornamental glass was used on the principle of transparent mosaic. The design was cut out of their plates of alabaster or stone, or moulded in plaster, and the glass, most beautiful in colour, was let into them, as gems would be set in jewelry, in patterns of flowers, foliage, or any other conventional design of geometrical ornament. The effect was exceedingly rich. Specimens of these works are still to be found in Constantinople, in the mosque of Hebron, and in other Oriental buildings. That is glass mosaic, not glass painting.

The improvements in the Christian arts of painting during the fifteenth century were very rapid. Those improvements of the oil painter and the fresco painter were, however, the first poison drops which ultimately ruined the art applied to glass.

About the middle of the fifteenth century the treatment of pictures in glass became more and more relaxed. The artists had hitherto been guided by the safe principle of deference to the architecture of which their work formed a part. After that time the architect's design seemed to be beneath the notice of the glass-painter, who spread his picture over the whole window-space regardless of all obstacles. A little later in date than this a magnificent style of glass-painting was developed in Italy. Glass was treated pictorially indeed; but, like most genuine artists, as they were, the Italian designers of those pictures felt intuitively that the compositions and resources of other styles of painting were unsuitable for glass. So they went in for light and colour like men, and designed for breadth of contrast and vigour of effect, figures, architecture, fruit, flowers, animals, and then led them all together, regardless of atmospheric effects, without much care for perspective, and with an equality of colour throughout and relief in the detail just enough to save all the objects from confusion. The effect was the most powerful that glass could produce: it was flat, architectural, and grand in the extreme. The success of those windows consisted in this, that their designers were first of all consummate artists themselves, and then that they had the genius and wit to seize the true and complete idea of the materials they had to work with. Theirs was the last blaze of that fine art for many a long year. Their ancestors adopted a new system by painting upon glass with enamel colours. The result was the rapid decline of the art. They would paint. The art of glass, therefore, was no more. It had throughout borne witness to the fact that architecture was the master art. The harmony which had ever existed between the various styles of glass-painting and architecture arose, not only from the painters employing the same general character of ornamentation, but far more from the deep current of a mutual sentiment which pervaded all the contemporaneous arts of the Middle Ages. When the purity of feeling declined in one, it declined *post passum* in the other; and it was but natural that it should do so, because art is only the reflection of the hearts and minds of men, and it rises and falls with them. Such was the fate of glass-painting south of the Alps. In the north much the same result occurred. Religious and political troubles far and wide completed its ruin. But here and there, and more particularly in Holland and Flanders, the old vigour of the art was revived. But the taste of the times was coarse, and the idea of art was too realistic to be attained in glass, without straining it beyond its proper functions. Some grand effects were, however, produced by combining the inlaid system of the best times with the enamel painting of the worst. The inferior artists revelled, as usual, in the vulgarity of violent effects. The public taste of their day was low, and was growing lower. There was no demand for good art; so there was no supply. And thus the art dwindled away, till it fell, as I described at the

beginning of this address, into the hands of the plumbers.

After this sketchy review of the progress and decline of the art, the subject which remains to us seems to divide itself into two parts, relating to its practice, viz.,—1st, the treatment of ornamentation; and 2ndly, the treatment of figure compositions. Of the first of these a great deal is to be said; but as the second would be more interesting to you and more profitable for our present purpose and limited time, I will not delay on the subject of ornament, but pass on to that of figure subjects, or what might be called "pictures in glass." It might, however, make what I have hereafter to say more clear, and be of use to those whom I address who are not well acquainted with the processes of this art, if I make a short digression to say a few words on the nature and use of the materials. This art is very little practised by amateurs. It is, perhaps, more admired than understood. When glass-painting is spoken of you should know that it does not imply the use of colours in any way similar to that of other arts. The artist makes no colours, but purchases them in the coloured glass supplied by the manufacturing glass-stainer. The process by which he produces a painted window is this. The subjects are first designed on paper (called for its size "a cartoon") in black and white. The colours for the various parts of it are determined, and glass of the colours required is chosen for them. The design is then laid out on a table, and upon each part of it, as for flesh, draperies, background, ornaments, &c., the pieces of glass, already chosen for them, are cut out and laid. The glass being transparent allows the drawing and shading of the design beneath to be seen, and these are traced and drawn upon it with a brush, as any one would trace upon tracing paper. The material used in the brush is a powdered oxide of iron and copper of a uniform colour, much like sepia, which is mixed with gum and water, and this is eventually fused into the surface of the glass by the heat of a furnace. Golden tints and ornaments are usually produced in a different manner; they are commonly added subsequently by the transparent yellow stain of oxide of silver fused upon the opposite side of the glass. And thus the work is done, so far as the artist is concerned. Each piece is then leaded together into its place, and the window is completed. All this sounds a very simple process, and, indeed, it is so; but the same might be said of the mere processes of any other art. The really great difficulty is proved by the rarity of success.

THE LATE SIR WILLIAM SNOW HARRIS.

It is with deep regret that we have to announce the death, on the 22nd ult., of Sir William Snow Harris, one of our most distinguished scientific experimentalists. He was born at Plymouth, in the county of Devon, in the year 1792, and was consequently in the 75th year of his age. He was educated in the Grammar School of his native town, and thence he proceeded to the University of Edinburgh to study for the medical profession, which he practised for several years with great success; but his whole heart and soul being in the physical sciences, he soon abandoned his practice in order to devote his attention to the study of the elementary laws of electricity and magnetism. In 1820, he made a valuable invention for the protection of ships from lightning, which he submitted, together with an interesting account of his invention, to the consideration of the council of the Royal Society, of which Sir Humphrey Davy was the then president. After much investigation on the subject, the Council of the Society warmly approved of his invention, and communicated with the Admiralty urging its immediate adoption in the Royal Navy. In 1831, he was admitted a Fellow of the Royal Society; and in 1835 the Society awarded him the Copley medal, one of the highest honours in its gift.

The value of the invention will be readily appreciated when we state that loss or damage in the Royal Navy from lightning has ever since that time been absolutely unknown, while previously the material damage alone had been estimated at 10,000l. per annum. In 1847, her Majesty, in recognition of his valuable services, had conferred on him the honour of knighthood, and he had on several occasions been honourably mentioned in both Houses

of Parliament. In 1860, he was appointed scientific referee to the Government in all matters connected with electricity; and in this capacity he had to superintend the fitting of the conductors of the Houses of Parliament, the powder magazines, Buckingham Palace, Windsor Castle, and the Royal Manoeuvres at Frogmore, in which are deposited the remains of the late Prince Albert. He was also the inventor of an improved mariner's compass, and the unit jar for measuring out definite quantities of electricity.

Sir William was one of the original members of the Philosophical Club of the Royal Society, and had been a valuable contributor to the "Transactions of the Society," and to the *Edinburgh Philosophical Journal*.

THE ART-UNION OF LONDON.

"PRY" is the title of the plate provided by the council of this association for every subscriber of the current year. The original picture, by Mr. Le Jenne, A.R.A., represents, with much feeling, three young girls, who have found a wounded robin in the snow, and are endeavouring to coax it to them. The subject is not of the high and grand character possessed by some of the other works now in progress for the Art-Union, such as Armitage's "Parents of Christ seeking Him," or Macleise's noble wall-paintings in Westminster Palace; but there is pathos about it, and the touching expression in the girls' faces will find many admirers. An institution whose aims should be catholic in matters of art, must vary the character of its productions. Mr. Lemon has engraved the plate with great delicacy in the pure line manner; and in these days when publishers demand the rapidity and cheapness of production afforded by the chalk or mixed or mezzotint process, it is to be observed that the Art-Union of London almost alone gives encouragement to the higher class of pure line work; just as in the production of high-class bronze works and medal-die engraving, it represents almost exclusively the amount of art extended in England to these branches of art.

Apocryph of those matters, we may remark that the English commissioners have gladly accepted an offer of the council to lend some of the society's bronzes for the Paris Exhibition. Some of their later engravings, also, will be found on the walls of the English Court.

A model, reduced by Mr. Birch from his statue of the "Wood-Nymph," for which he received the society's premium of 600l., has been placed in the hands of Messrs. Brown, Westhead, & Co., for production in parian.

THE NEW MARKET HALL, SHREWSBURY.

THE chief stones of this new hall has been laid. The edifice will be in the Italian style of architecture, and will be built of black, blue, red, and white brick, with Gristhill stone dressings. Its total length will be 322 ft., and its greatest breadth 138 ft. On the basement will be twenty-eight vaults for the storing of goods, with two inclined roads leading thereto. One of these approaches will be 10 ft. wide at the entrance, and in the centre about 24 ft., so as to allow a cart to turn. Both lead into Claremont-street. On this floor there will also be seven shops, and a large fish-market, with ice-house, and heating apparatus. The whole building is to be warmed by hot air. The ground-floor will consist chiefly of the general market. There will be six entrances to this portion of the building. The principal entrance will be at the Mardol end of the building, and will consist of an arcade, 17 ft. wide, with rows of shops on either side. On this floor there will also be a butcher's market, fruit market, the hall-keeper's office, water-closets, and other conveniences. On the first-floor, over the fruit-market, will be the corn-exchange, a room 89 ft. long by 45 ft. wide. Over the shops will be a gallery, suitable for the sale of light market goods. In Claremont-street a covered cartway will be erected for the landing and unloading of goods in wet weather, and the roof of the building will be covered with Bangor slate. The windows and doorways are all circular-headed, and the doors will be made to slide in a groove in preference to hinges. The front on the Shoplatch side will be 88 ft. in height, and that of the tower which rises near it, 151 ft. The latter will be surrounded with an ornamental

iron vane. This front will stand some feet further back than the line of the old buildings. The other side of the building in Claremont-street will resemble the one in Shoplatch.

The plans were prepared by Mr. R. Griffiths, of Stafford; and the contract is being carried out by Mr. Barlow, Stoke-upon-Trent.

SANITARY CONDITION OF MERCHANT VESSELS.

It is satisfactory to find sanitary reforms to the necessity for which we have long been calling attention now urged on all sides. The *Lancet* has brought its reports on the Present Sanitary Condition of the Mercantile Marine to a conclusion. The third and fourth reports deal with the accommodation provided for the men on board, their clothing and personal hygiene, and the further improvements necessary to ameliorate the condition of the men. The old forecastes and top-gallant forecastes, which in a large proportion of ships are still maintained, are rightly condemned. "Imagine a small triangular space in the bows of a ship, the maximum dimensions of which required by law are 74 cubic feet for each individual, flooded by the waves, and practically uninhabitable if above deck; filthy, dark, damp, and ventilated if below; no means being taken to provide such simple contrivances as manroves, hawse-pipes, ventilating funnels, rain-awnings, and furniture, which might exclude water, admit fresh air and light, and somewhat mitigate their comfortless condition. Compared with such abodes the worst workhouse ward or Irish cabin is almost palatial." True, in fine weather, the crew may sleep and eat in the open air; but, in bad weather or in harbour, the forecabin is the home of all: at no time is there any other refuge for the sick, whose condition is, therefore, most deplorable. Years ago we pointed out this, and the evils of the sleeping-places generally. See, too, our sketch, "A Berth that brings Death," reproduced in "Another Blow for Life," p. 104.

THE MONT CENIS TUNNEL.

THE *Turin Opinions Nationales* gives the following return of the state of this work on the 31st December, 1866:—On the Bardonnèche side 3,940 metres had been completed, and on the Modena side the work had advanced to a distance of 2,434 metres, making a total of 6,374 metres, of which 1,025 metres were excavated during the year 1866. The entire length of the tunnel is 12,220 metres, so that it is now more than half completed. Supposing the present rate of progress to be maintained, nearly six years will be required before the line is finished. It is expected, however, that this year's returns will show an increase, inasmuch as the boring on one side during the past year was rendered more difficult by a bed of quartzose rock, the position of which was predicted by the geologists, from a careful survey of the dip of the surrounding strata, within a hundred feet or so of the place where it was actually met with.

CORK WAREHOUSE, LANT STREET, SOUTHWARK.

UNDER the direction of Mr. Joseph S. Moyer, architect, Hertford-street, May Fair, a cork warehouse of considerable size and good appearance, has recently been erected in Lant-street, Borough, for Mr. Thomas Peet. The building is faced with white Suffolk bricks, jointed in black mortar, red and black bricks being introduced in the hands and arches. The cornice is also executed in white moulded bricks. The whole of the facings were supplied from the Woolpit kilns, by Mr. C. Stutter.

The warehouse has a frontage in Lant-street, of 45 ft., with a depth of 65 ft. The goods entrance is situated in Vineyard. The total height of the building from the basement floor is 71 ft. 6 in., and 60 ft. from the pavement level. The floors are carried on girders, 12 in. deep, supported by two tiers of 8 in. cast-iron columns, bolted together, and running the entire height of the building. Internally the warehouse is fitted with every convenience to suit the requirements of the trade. The contract was taken by Mr. Walton, of Museum-street, and the total cost was about 4,000l.

CORK WAREHOUSE, LANT STREET, SOUTHWARK.—MR. JOSEPH S. MOYE, ARCHITECT.

GERMAN CHURCH DOORWAYS.

GERMAN CHURCH DOORWAYS.

Even the most enthusiastic admirers of English Gothic architecture must admit that there is one point in which we were far behind our Continental neighbours in the Middle Ages, and that is the treatment of church doorways. Those who have stood before the fronts of Wells and York, and have in thought compared them with Notre Dame, Paris, or Ratisbon Cathedral, cannot help being struck with the fact that the Continental fronts owe much of their superiority to the great dignity and importance given to the doorways. At Ratisbon this is singularly the case, for the great doorway is perhaps the only really well-designed feature of the whole front; and yet who can help being struck by the grand and dignified effect of the whole?

The German architects do not seem to have turned their attention to this feature so early as the French; but when they did they made up for lost time by making the doorways the chief feature in their buildings.

The Romanesque churches in Germany have generally plain doorways with a tympanum, which is sometimes ornamented with carving; but is more commonly left quite plain. A very fine and rich example is to be found at the Scotch Benedictine Church at Ratisbon. In Transitional and First Pointed doorways the trefoil arch is frequently used generally, without the tympanum. Fig. 1 is a good specimen from the cathedral at Würzburg. The detail is singular. It is not until the fourteenth century that we find the double doorway; and even then they are never so common in Germany as in France; however, at this period the doorways are generally very lofty, and of very noble design. Fig. 2 is a remarkably elegant specimen from a desecrated church at Würzburg. The doorway in the south tower of Cologne Cathedral is about the same date. The doorways to the transcripts at Ratisbon and Erfurth cathedrals are double, and are noble examples. Later in the style double doorways become much more common, and they are generally very highly adorned with sculpture and foliage.

Fine examples exist at Nuremberg, Augsburg, Ulm, and Münster cathedrals; St. Mary's, Würzburg; Thein Church, Prague; Ochsenfurth, &c. Third Pointed doorways are generally double if of large size, and are very frequently protected by a kind of projecting canopy or suspended porch. The finest example is the western portal of Ratisbon Cathedral, where the porch projects in a triangular form from the wall of the church, and is supported at the angle by a pier profusely ornamented with statues, carving, &c. At St. Ulrich's, Augsburg, the porch is semihexagonal, and is supported upon two slender piers. At St. Martin's, Landshut, is a doorway, the porch over which forms two triangles in plan (see Fig. 4), and is unsupported by either pier or shaft; the part forming the junction of the two triangles hangs down and forms a pendant. The detail of this doorway is very rich and beautiful. The church to which this doorway belongs contains four others almost equally elaborate, although the building itself is very plain and simple. After the fifteenth century, the Germans appear to have given up large doorways. The late Gothic specimens are generally small, single, devoid of sculpture or carving, and simply ornamented with interpenetrating moldings. Sometimes the heads of these late doorways are most singular and eccentric in form, and are nearly always very ugly. This kind of doorways continued in use until the revival of Classical architecture at the end of the sixteenth century. The drawings we give have been made on the spot for us by Mr. H. W. Brewer.

THE TRADES MOVEMENT.

Illegality of Trades Unions.—At a numerously-attended meeting of trades society delegates, held at the Sussex Hotel, Bouverie-street, Fleet-street, in relation to the late Trades Reform Demonstration, at the conclusion of the regular business, Mr. G. Potter, the chairman, brought before the delegates the subject of the recent decision given in the Court of Queen's Bench, by which trades unions were held to have no

power to recover by law any sums of money that might be embezzled from their funds by any officer or member of the society. After some discussion, a delegate from the plasterers moved, and a delegate from the carpenters seconded, the following resolution:—"That the Working Men's Association be and is hereby empowered by this meeting to convene a meeting of delegates from the trades societies of the metropolis, for the purpose of taking into consideration the position in which trades unions are placed by the recent decision in the Court of Queen's Bench in the case of the Boiler-makers' Society, and to determine the course to be adopted thereon." The resolution was unanimously adopted.

Covenants.—The members of the Operative Bricklayers' Society have given three months' notice to the masters, dated January 1, that they will discontinue working under the present rules. They require the second rule to be expunged, and ask for a slight alteration in their wages. The secretary to the Coventry Builders' Association, replying to this demand, states in effect that the masters see no cause for any alteration in the rules, but are willing to submit the matter in dispute to arbitration, under Rule No. 1.

The Potteries.—The carpenters and joiners of the Staffordshire Potteries have given notice to their employers of a demand for an advance of 6d. a day in their wages, raising them to 30s. a week, and a reduction of the hours of labour to the extent of two and a half hours a week, the change to come into operation on the 1st of May. The huddlers, in reply, have offered the men 6d. an hour, making the wages 25s. a week, but they decline to reduce the hours of labour below fifty-eight hours a week. The difficulty with the bricklayers, which has been pending since May last, and has ever since prostrated the hiding trade of the district, has only just been removed by a reference of the dispute to arbitration.

Stafford.—Professor Levi has been giving his lecture on the condition of the working classes, from which we quoted last week, in the Shire-hall, Stafford. The Earl of Harrowby occupied the chair.

Plymouth.—In reference to the trades movement here, a local paper, referring more especially to a threatened strike of the masons, says,—

"There is abundant evidence daily produced by the press to show that the state of trade in almost every part of the country is in a lamentable condition of depression; there are thousands of men out of work; and the distress consequent upon that, as much as upon the recent severe weather, has been so great everywhere, that the benevolent of all classes, who can help have united in one great endeavour to relieve it, and prevent wholesale starvation. The privation and suffering found to exist in this neighbourhood as well as elsewhere, through want of food and clothing, has been startling. Money has, therefore, been readily given in large sums to provide the necessities of life; soup, bread, and blanket societies have been opened, and have daily distributed their needed benevolence. In the midst of all this, it does sound disgusting to hear of a "strike" by men amongst whose class this suffering exists, and to relieve whom this profuse benevolence has been granted. For the sum of 6d. a day extra—which they have yet to prove they are fairly entitled to—they will subornably throw themselves out of work at this critical period! The course these operative masons propose to pursue in this particular is certainly very short-sighted on the part of themselves, and inconsiderate and ungrateful to the public to say the least of it. It has especially annoyed those workmen who are solicitous for the success and reputation of trades unions in general, and who are most anxious to disabuse the public mind of an impression which is widely entertained, namely, that trades unions, as a whole, are but a means through which one class of workmen seek selfishly to promote their own interests at the expense of all other classes of workmen."

Blackburn.—The wages agitation in the iron trades has extended to Blackburn. The whole of the Amalgamated Engineers—comprising engineers, smiths, mechanics, dressers, joiners, &c., and the iron-moulders employed in Blackburn and its immediate vicinity, with the exception of those employed by Messrs. Yates, Canal Foundry, and Messrs. Clayton & Goodfellow, Park-road, have received notice that on and after the 2nd and 4th of February next, those earning 25s. per week will have their wages reduced 1s. per week. The earnings of the rest will not be for the present interfered with. A meeting of the Amalgamated Engineers has been held on the whole question. Eventually a resolution was agreed to, to the effect that if the employers persisted in making the reduction proposed, the operatives would as a body refuse to work more than four days per week so long as that reduction was kept in operation. The iron-moulders also met, and passed a similar resolution. It is calculated that there are from 4,000 to 4,500 men engaged in the iron trades of Blackburn and district,

whose average earnings are about 28s. per week, though a majority of the artisans get 32s.

Limerick.—The frequent strikes of the dock labourers in Limerick and their demands, it is thought, will have the effect of diverting the import trade of that port to other localities, as serious injury has already been inflicted on the trade of the port. The men have demanded 10s. a day on some occasions, and have now organised a society to maintain them in these demands.

New York.—In speaking of the distress in New York arising from strikes and other causes, a local paper says,—

"The Poor Association state that there are hundreds and thousands of good mechanics, artisans, and labourers in New York who formerly had permanent situations but are now left to the precarious subsistence afforded by occasional jobs, and who owe their infelicitous position and the sufferings of their families to the system of strikes which has become so fatal a habit with certain classes of labouring men. . . . In New York and Brooklyn there has been a great mass on the subject of strikes. The painters, the harness-makers, musicians, lightermen, longshoremen, carpenters, masons, plasterers, plumbers, all sorts and conditions of men, followed the example of the car-drivers, and generally attained the same measure of ill-luck for themselves and their wives and children. The community would be startled if they knew the vast numbers of unemployed men, the sick-hearted women, the hungry, shivering children that are at this time in the city of New York."

THE TRADES MOVEMENT IN SYDNEY.

DELEGATES from the joiners', painters', bricklayers', and labourers' societies in Sydney have sent a memorial to "The Amalgamated Society of the United Kingdom," a copy of which has also been forwarded to us. The chief object of the memorial appears to be to disabuse English workmen of the idea that wages are high and work abundant in the colony or city of Sydney. On the contrary, they declare, a great deal of distress exists; work is, and has long been, scarce; and wages, though apparently high, are really inadequate, from the high price of provisions, clothing, rents, &c. 8s. to 10s. a day seem to be the average wage in the building trades, while rents are something like 10s. to 20s. a week; bread 10d. a 4-lb. loaf; cabbages 8d. a-piece; milk 8d. a quart; mutton and cheese 1s. 6d. a lb., and so on. Beef and bacon, however, do not seem to be so dear, being only 5d. per lb. It is remarkable that, while our own workmen not only complain of masters taking more than a certain very small number of apprentices, but absolutely restrict them from doing it, compelling them, by threats of strike, to reduce the number of apprentices to the minimum; one of the causes of complaint urged in this memorial as being "of a very serious nature," is that "there is not the slightest inclination on the part of employers to take as apprentices any of the thousands of young Arabs, as they are colonially called; and the consequences are that they are entirely dependent on their parents."

EQUALIZATION OF THE METROPOLITAN POOR-RATES.

A DEPUTATION to the President of the Poor-law Board, composed of the representatives of various ratepayers' associations, boards of guardians, and other bodies connected with the East of London, waited upon Mr. Gathorne Hardy, at the offices of the Board, Whitehall, on the subject of the equalization of the poor-rates in the metropolis. The deputation included Mr. Locke, M.P., Mr. Ayrton, M.P., Mr. Buxton, M.P., Sir C. Bright, M.P., Mr. Hanbury, M.P., and Mr. Alderman Salomons, M.P. Mr. Earle, M.P., the Secretary of the Poor-law Board, was present. The deputation was introduced by Mr. Ayrton, M.P., and Mr. Alderman Salomons, M.P. The important subject in question was ably urged by various speakers, and especially by the Rev. Mr. Mc Gill, rector of St. George's-in-the-East, who presented a memorial from his district setting forth the facts of the case, which were really appalling. In the large district of Shoreditch half the men are now out of employment, and the consequence is a rating of the poor is made higher and more difficult to collect. In some of the parishes in the West-end the poor-rate is only sixpence in the pound, while in Bethnal-green and the surrounding parishes it is 3s., 4s., and in some cases, 5s. 6d. The memorial urged the justice and expediency of having an equalised rate on the whole metropolis, which would amount to a uniform sum of

about 1s. 5d. in the pound. These were five parishes in this great metropolis which really did not contribute justly or fairly to the relief of the poor. These were the City of London, St. George's, Hanover-square, Paddington, Islington, and Kensington. He did not believe the wealthy inhabitants of these districts wished for such a state of things, because during the late distress they subscribed cheerfully and liberally to the poor of the East-end an amount which he had no hesitation in calling "conscience money," because they paid generally but 6d. in the pound for poor-rates, while the parishes in the East were compelled to give 5s. 6d. Sir Charles Bright, M.P., drew attention to the bread riots in the east of London, which, though highly reprehensible, really arose from the inequality of the rates and the undue and intolerable pressure on the ratepayers of the East-end, and showed that an equalization was urgently called for, and he hoped they would cordially support him. In reply, Mr. Hardy said that early in the ensuing session it would be his duty to state what the Government proposed to do. His attention would be particularly directed to the question of management and the uniformity of assessment, and a great many others, that in a week or two he should bring before the House of Commons.

At a conference held at the London Coffee-house, on Wednesday night, on the subject of equalising the poor-rates of the metropolis, a resolution was passed to the effect that in the opinion of the meeting the time had arrived when it was the duty of the Government to introduce a Bill for the equalisation of the poor-rates within the metropolitan district, and a deputation was appointed to wait upon the Poor-law Board to impress the great importance of this measure upon the Government.

EXHIBITION OF ARCHITECTURAL DESIGNS.

We are requested to state that the exhibition of the National Gallery designs will not be closed till after the opening of the exhibition of the designs for the New Courts of Justice to the public. Architects from the country will thus have an opportunity of seeing both exhibitions without being detained in town. Many will feel much obliged by this arrangement of the Chief Commissioner of her Majesty's Office of Works.

EFFECTS OF SANITARY IMPROVEMENTS.

The report of the committee of the Leek Burial Society gives some important statistics *appropos* of the improvement of the sanitary condition of Leek. The members of this society compose a large proportion of the poorer inhabitants of Leek. Mr. R. Farrow had been requested to analyze the public documents of the Society during the last six years' experience out in comparison with the six preceding years, showing the results of the public drainage and other improvement works, which had now been in operation six years.

"During the first six years the mean number of members was 5,178, and the total number of deaths 984, the annual rate of mortality being a little over 19 in 1,000 of the living, and the total expenditure in funerals 3,872, 8s., which was 18s. 1d. to each living member. During the latter six years, the mean number of members was 5,988, and the total number of deaths 608, the annual rate of mortality being 17 in 1,000 of the living, and the total expenditure in funerals 2,536, 2s., being 8s. 11d. for each member."

He found on further analysis that,—

"The actual decrease of the number of funerals, corrected for the increase in the number of members, was 475, and that the actual decrease in mortality was 13 in 1,000 of the living, the increase in the value of life being 85 years to each person, and the total amount saved in funerals, corrected for the increase of members, 1,630, 4s. It was found by experience that twenty-five cases of sickness attended each death, and, therefore, the number of deaths of sickness prevented amounted to 49,400; and, supposing every case of sickness to cost 10s., which was a very low estimate, this represented a saving of 5,872, 10s. It was also found by experience that one-third of the total amount of sickness and mortality among the population occurs between the ages of fifteen and fifty-five years, and if the earnings of this portion of the members were estimated at 10s. per week for males, and 5s. for females, the loss of wages prevented amounted to 6,174, 15s., which, with the actual saving in funeral expenses, and the estimated cost of sickness prevented, amounted to no less a sum than 13,742, 9s. This saving was not prospective, but had actually taken place. There were various other items which ought to have been brought in, but which had been omitted, and taking only the three named, it would, provided that this experience continued during the mean after-life of the present members, result in the saving of 61,874, 10s., besides the addition of 81 years to the life of every member. This experience was not con-

finued to the members of this society alone, as the increased value of life in the whole population of the town had been more than seven years during the same period, the mortality being, in the first period, 31 in 1,000, and for the second period, 22 in 1,000."

The poorer classes of the people were, he contended, the greatest savers by sanitary improvement, and the greatest losers where sanitary matters were neglected. He found, as a general rule, that he experienced little difficulty in convincing the poorer classes that filth and squalor were attended with the worst possible results, pecuniary and otherwise, both to themselves and the public. He had not been so fortunate in convincing some of the wealthier members of the community.

CAPE TOWN SCHOOL OF ART.

We are glad to learn that the Exhibition made by the School of Art at Cape Town at the close of last year was a great success. More than 2,600 people visited the rooms, and the distribution of prizes at the end of the Exhibition week was a capital wind-up to the whole.

The judges who awarded the prizes said in their report:—

"Taken as a whole, these works are highly creditable to the students and their master, Mr. Lindsay. We wish especially to notice the excellence of the system, which discourages all meretricious and pretentious work and mere artistic display, and which tends to develop taste and talent in the practical shape which can benefit the architect, builder, and mechanic."

Special interest was excited in one of the students, John Brown, a youth both deaf and dumb, but who had evinced such a precocity that he had been taken from one of the orphanages of the city by Mr. W. de Smidt, and placed under the tuition of Mr. Lindsay. At the conclusion Mr. Lindsay presented to Mr. Foster, the founder of the school and its honorary secretary, an address and a silver inkstand, purchased by subscription amongst the students.

COMPENSATION CASES.

The following cases have just been decided in the Mayor's Court, Guildhall:—

(Before the Right Hon. Russell Gurney, Q.C., M.P., Recorder, and a Special Jury.)

WADMORE v. H.M. POSTOFFICE-GENERAL. Mr. Locke, Q.C., M.P., and Mr. Harrison appeared for the claimant; Mr. Coleridge, Q.C., M.P., and Mr. Collier for the Post-office.

Mr. Locke said that the claimant in this case was the Rev. H. R. Wadmore, who was the freeholder of the house No. 26, St. Martin's-le-Grand, which was to be taken down for the purpose of enlarging the General Post-office. The property, which was known as Williams's Coffee-house, had been in the possession of the family for many years. In 1859 a new lease was granted for seven, fourteen, or twenty-one years, at a rental of 150*l.* per annum, terminable by the tenant at seven years, and by either landlord or tenant at fourteen years. It was now in hand it would let for double the money. There were six years and three-quarters unexpired of the term of fourteen years. He believed that the jury would find that it was worth some 87*l.* What would the premises be worth per annum at the end of the unexpired term of six years and three-quarters? That was really the only question which the jury had to consider. He should call several experienced witnesses, who would state that the premises were really worth at least 800*l.* a-year. If the jury were of that opinion, the claim would come out at a sum of somewhere about 5,716*l.*

Mr. Trist (Norton & Trist), Mr. E. H. Burnell, and Mr. E. Farmer (Debenham, Tewson, & Farmer) all valued the premises at 300*l.* a year, and, according to their evidence, the claim varied from 5,184*l.* to 3,872*l.*

Mr. Coleridge then addressed the jury, and said that they had been brought there solely at the instance of Mr. Wadmore, because, in the first instance, he sent in a preposterously exaggerated claim. The highest that the Post-office authorities could make of it was 4,800*l.*, while Mr. Wadmore sent in a claim for 10,120*l.*

Mr. Chilton, Mr. Ellis, and Mr. Shaw valued the property at 200*l.* per annum, and the entire claim at 4,032*l.* The jury, without troubling his Lordship to sum up the case, returned a verdict for 5,000*l.*

(Before Mr. Commissioner Kerr and a Special Jury.)

FRITCH v. THE CORPORATION OF LONDON, of which fifteen was a claim for the leasehold interest in the house and premises, No. 46, Broad-street-buildings.

Mr. Huddleston, Q.C., and Mr. Piblicock appeared on behalf of the claimant; Mr. Lloyd and Mr. Holloway for the company. From the opening statement of counsel it appeared that the premises in question were held upon lease by the claimant, from the Corporation of London, of which fifteen and a quarter years were unexpired at Christmas last, at a rental of 200*l.* per annum. The total claim was valued at 3,850*l.* to 6,000*l.*

Mr. Ellis (Messrs. Ellis) valued the property, to let as offices, at 825*l.* per annum. From that he deducted the reserved rent of 200*l.*, and a further sum for repairs, rates, taxes, &c. He capitalised the improved rental upon the 6 per cent. tables, which he added 10 per cent. for forced sale, making the total claim 4,300*l.*

Mr. St. Quintin (St. Quintin & Notley) expressed his opinion that the premises, let out as offices, would fetch 825*l.* from which he deducted the reserved rent of 200*l.*, repairs and contingencies, 161*l.*, leaving a net improved rental of 464*l.*, which, capitalised on the 6 per cent. tables,

with the addition of 10 per cent. for compulsory sale, brought out a sum of 4,662*l.*

Mr. H. E. Murrell made the total claim 3,850*l.*

Mr. Farmer (Debenham, Tewson, & Farmer) valued the claim at 4,484*l.*, and Mr. Fletcher at 5,600*l.*

Witnesses were then called on behalf of the company. Mr. G. Pownall and Mr. John Shaw valued the claimant's interest at 2,200*l.* Mr. B. N. Chilton at 1,980*l.*

Mr. E. Ryds thought that the premises might let as offices for 650*l.* per annum, from which he deducted 200*l.*, the rent reserved, and 115*l.* for repairs, rates, and taxes, leaving a net improved rental of 235*l.*, which he valued at 2,200*l.*

Mr. Clark (Farebrother, Clark, & Co.), gave similar evidence. He said that chamber property was not now so valuable as it was. Everything was inflated for a time, but they were now assuming a more natural state.

The jury awarded the claimant 2,550*l.*, the loss of rent and value of fixtures to be settled out of court.

(Before the Right Hon. Russell Gurney, Q.C., M.P., Recorder, and a Special Jury.)

SHEPPARD v. THE METROPOLITAN BOARD OF WORKS. Mr. Hawkins, Q.C., and Mr. Talford Slater represented the claimant, and Mr. Lloyd the Board of Works.

Mr. Hawkins said the claimant, Mr. William Henry Sheppard, had for a period of between twenty and thirty years carried on the business of a bellringer, locksmith, gasfitter, &c., with a very considerable amount of profit, upon the premises, No. 10, Bucklebury, which premises were required by the Metropolitan Board of Works, for the purposes of the new street from Blackfriars Bridge to the Mansion House. Mr. Sheppard had the good fortune in 1861 to obtain from Mr. Nash an agreement to let the premises from the expiration of his lease for a further term of twenty-one years, at the almost nominal rental of 87*l.* per annum. This lease would expire at Midsummer, 1883. Of the lease sixteen years and a half were unexpired at Christmas last. Notice to treat was given in July, 1866, and a claim was sent in under the Act. After thirty years of persevering industry, the claimant's business now yielded a net profit of 750*l.* The jury awarded the claimant 3,192*l.*

(Before Mr. Thomas Chambers, Q.C., M.P., the Common Serjeant, and a Special Jury.)

ROBB AND DOW v. HER MAJESTY'S POSTMAN GENERAL. This was a claim for the leasehold interest of the house No. 33, St. Martin's-le-Grand, where the claimants carry on business as surgeons and chemists. There was also a claim for removal, fixtures, loss of business, &c. &c. The house forms part of the property required for the enlargement of the Post-office.

A verdict was taken by consent for 2,600*l.*

(Before the Right Hon. Russell Gurney, Q.C., M.P., and a Special Jury.)

SPON AND ANOTHER v. THE METROPOLITAN BOARD OF WORKS. Mr. Giffard, Q.C., Mr. Britcher & Mr. Horace Lloyd appeared for the claimants; Mr. Lloyd for the Board of Works.

Mr. Giffard, in opening the case, said that the claimants, Messrs. F. N. & W. Spon, were engaged in the book trade, which they inherited from their father, and which was formerly carried on in Queen-street, Chancery. In 1850 they took a lease of their present premises, No. 16, Bucklebury, of which four years would be unexpired at Lady-Day next, at a reserved rental of 105*l.* Upon their removal to the new premises in Bucklebury, which were now required for the new street, they began a business of a very peculiar kind, viz., that of publishing and trading in books of a purely scientific character. Any person requiring any book in relation to any of the arts or sciences was sure to be able to procure it "at the shop in Bucklebury." In fact, the claimants were the only publishers engaged exclusively in carrying on such a kind of business within the walls of the city. Their profits, during the first year of their business operations in Bucklebury, were 40*l.* During the seventeen years their profits had risen to 1,300*l.* or 1,400*l.* They started with a stock worth 500*l.* Their present stock worth 1,000*l.* The claimants let off the first, second, and fourth floors, at an aggregate rental of 110*l.*, so that, in fact, they carried on their business there rent free. With every desire to get suitable premises near to their old shop, they had been unable to succeed. The claimants would have to cancel the title pages in all their stock in order that the proper address of the publisher might be inserted. They only sought an indemnity, and not a profit.

It transpired that the original claim sent in was for 7,700*l.* On 3d. The jury awarded the claimants 2,750*l.*

SHOP FRONTS.

THE ARCHITECTURAL ASSOCIATION.

At the meeting of this Association held on Friday evening (the 18th ult.) at the House, in Conduit-street, Mr. Michael (Burton-crescent), was elected a member.

Mr. T. Blashill, in submitting some notes on Shop Fronts, observed that to a nation which had been termed a shop-keeping people the question of shop fronts was one of some importance and interest. The shop differs from the office and the warehouse in which goods are sold wholesale, either by sample or in bulk, and which require to be in a convenient rather than in a public situation. The shop depends upon retail trade, possibly upon casual customers, and it must be in a public situation, so as to attract business by its display of goods. We find the types of our modern fronts in the open-fronted shops of eastern and southern countries, and in the stalls of continental fairs, in which the sole shelter is given by a shutter which is hinged above; and being propped open affords shade by day, and being let down closes in the front at night. The first effect of the introduction of glazing was to diminish the convenience with which goods could be examined from the street;

but by the use of large squares we have regained the original convenience, with the most complete protection from weather and other sources of injury. The front, as we ordinarily see it, being a necessity of trade, it is useless to exclaim against it on artistic grounds; the whole elevation of the building should take its character from this, which is its most important part. There are two parts of a shop front. First, the structural arrangement of piers, columns, and bressummer, or arches which carry the superstructure—equivalent to the whole construction of ancient fronts; and, secondly, the more modern sash and its framework, which is merely a fitting of no permanent character. In construction, the bressummer is to be preferred to the arch, which requires abutment, for each building should be able to support itself without the aid of adjoining houses. Very wide spans are unnecessary, for the size to which plate-glass can be obtained at moderate cost is limited, and sash-bars are necessary. These, however small, disturb the eye, and should be dispensed with to a great extent, so that the sheets of glass may be joined only at the columns which help to support the bressummer. Columns may then be more numerous, for one of 6 in. diameter will interrupt the view less than two sash-bars of 1½ in. each. It is an error, in fronts of importance, to put the glass out to the utmost limit allowed by law. It is often better to place it behind the columns.

The increasing value of the basement has an important effect on the arrangement of shop-fronts, for it requires to be well lighted and ventilated, and therefore the stall-board should not be made too low. It is useless to place small objects so low that they cannot be closely examined without stooping, and larger objects can be so placed that a stall-board of 2 ft. in height is not too high for them. There should be a narrow glazed grating over the area, and a window of rough glass to the basement. There should be no step at the door. Glass shelves are to be preferred. Silvered glass should never be so placed in a front that it reflects the figure of the observer or objects in the street: its office is to enhance the appearance of the wares. The window-fittings should be designed by the architect with reference to the particular trade. As to gas-lighting, generally a large quantity of light reflected from white surfaces, or coming through ground glass, is favourable to the appearance of goods in respect of their colour and texture; but when their beauty depends upon their glistening appearance, light from naked flame is best. Inscriptions are intended to be read and should be as clear as possible, and not in queer characters which give trouble to those who are searching for a particular house. Signs speak all languages. No man has a right to make his shop difficult to find, inconvenient to examine, or awkward to enter; trivial things keep away hesitating customers, and their entry is essential to the proper and reasonable objects of the tradesman.

Mr. Blashill treated at length of plans, sections, fittings, and minor details, which however trivial in appearance have great influence on the success of that portion of the tradesman's premises which is often his sole means of introduction to the public by whose custom he must live.

A member observed that he quite agreed with Mr. Blashill in recommending that shop fronts should be set back two or three feet if possible, and referred to some cases in Throgmorton-street, where the plan had been carried out with the best effect. He also called attention to a new shop-front which had been put into a haker's house in New Bond-street. The proprietor had stoutly resisted the innovation of plate-glass, mahogany, or metal sash-bars and other improvements for more than half a century, but had at length conformed to the spirit of the age; and the result was a very handsome front, with not only plate-glass, but also coloured marble pillars, and some exceedingly tasteful metal work.

The chairman (Mr. J. D. Mathews) thought the first thing an architect ought to do in designing a shop-front was to take his client's opinion, who, in all probability, had thought much over the matter, and had studied the effect of other fronts in his neighbourhood. For his own part, he (the chairman) did not admire a front composed of one large sheet of glass. Such a sheet of glass was, in the first place, very expensive; the risk of putting it up was considerable, and the cost of insuring it was also a consideration. Moreover, he thought the sash-bars were an improvement in this sense, that

they relieved the eye, and at the same time enabled the shop-keeper to arrange his goods in a more convenient manner. With regard to steps up to shops, he deprecated them to the full as much as Mr. Blashill, and experience showed that the public did not like them.

Mr. Ware (an American professor of architecture now in London) observed, that for some years past the custom had prevailed in New York and other cities of the States, to do away with shutters altogether, especially in buildings containing valuable property, such as banks, jewellers' stores, &c. When business was brought to an end for the day, the curtains were drawn up, the gas was lighted, and there was nothing between the street and the interior but the plate-glass. The consequence was, that no one ever thought of breaking in by the front, while if any one were to get in from behind, the police would at once detect him. This principle had been tried with the greatest success, and robberies were very uncommon.

After a short discussion, a vote of thanks was passed to Mr. Blashill.

A member brought under notice the propriety of discussing the manner in which the Peabody Trust had been administered. He understood that the subject had been discussed at the Institute, but with what result he did not know; but it seemed to him that the benevolent intentions of the donor had not been carried out, and that the funds had been diverted from the purpose for which they were originally intended. The object which Mr. Peabody had in view was to provide decent dwellings for the very poorest workers; yet this was the very class which was virtually excluded from all participation in the fund. Indeed, so patent was this fact that he doubted whether a Court of Equity might not be induced to interfere, in order that the intentions of the founder might be carried out.

Mr. Edwards said the subject was one of great interest, and expressed a hope that it might be discussed by the Association.

The Chairman said that Mr. Darbishire, the architect of the Peabody buildings, had attended at the Institute, and had made explanations which were deemed to be satisfactory. The question now mooted had been incidentally raised in the paper read by Professor Kerr at the Institute; but as the trustees of the fund appeared to be satisfied with its application, he feared no good would result from the discussion of the subject by the Association.

FROM SCOTLAND.

Ayton (Berwickshire).—The new parish church has been opened for divine service. It is now more than three years since it was considered that, owing to the dilapidation of the old parish church at Ayton, it was desirable that steps should be taken for having a new one erected. The heritors of the parish had several meetings, and Mr. Wardrop, of the firm of Brown & Wardrop, architects, Edinburgh, was appointed to report, and in consequence of his report it was determined that a new church should be immediately erected. The necessary steps were taken, and the foundation-stone was laid on September 8, 1864, by Mrs. Mitchell Innes, of Ayton Castle. The locality selected for the erection of the church is a piece of ground near the toll-house, at Ayton, given by the lord of the manor. The style adopted is the Early English of the fourteenth century, and the edifice consists of a nave, with south transept and side aisle. The exterior is built with free dressed stone, and the principal entrance, which is at the south-west angle, is surmounted with a broached spire, 120 ft. high. On the north-east side is the vestry. The gallery is at the west end of the church. The roof is open, and the church is heated with double rows of hot water pipes, laid along the aisles. At the east end of the chancel there are three twin-light windows, all with tracery, and representing the Six Acts of Mercy. The south transept window consists of four upright lights and tracery. The subject is "The Adoration of the Magi and the Shepherds" who are represented offering their gifts to the infant Saviour. The north transept window consists of three upright lights and tracery. The subject is Christ's Sermon on the Mount. There is a large wheel-window at the west end of the church, which is filled with geometric and foliated glass. The other windows in the church are filled with cathedral glass in quarries, with coloured bor-

ders. The windows are from the manufactory of Messrs. Ballantine & Son, of Edinburgh. The contractors for the different works in connexion with the church were:—For the mason-work, Mr. James Berry, Ayton; joiner-work, Messrs. Turnbull & Son, Stow; slater and plaster work, Mr. George Whitlaw, Ayton; plumber-work, Mr. R. Sidey, Berwick. The architects were Messrs. Brown and Wardrop, Edinburgh; and the clerk of the works Mr. Taylor, Edinburgh. Mr. Mitchell Innes has been at the entire expense of the windows, besides incurring a great deal of other expenditure. It is estimated that the total expense of the church will be 10,000.

DUBLIN.

An extensive building, designed partly for hotel purposes and partly as a commercial establishment, is in course of completion at the junction of Lower Sheriff and Guild streets, Dublin. The frontages to the above-named streets are respectively 40 ft. and 60 ft., and the height to ridge about 55 ft. On the exterior of the ground floor is a series of French rusticated piers, separating the window and door openings, and surmounted by an ornamental entablature in cement, with vases over each pier; and above rise two other stories, in a superstructure composed of red bricks, with Ferguslie white brick quoins, dressings, &c. A helting course of granite, eucassite tiles, and white brick separates the first from the second floor; and a deeply moulded and bracketed cornice, with steep cantilever roof, ornamented with scalloped slating and metal crestings and finials (from the Sun Foundry, Glasgow), and displaying a series of dormers to light an attic story, crowns the whole. The angle is bevilled off and surmounted by a clock structure, with eucassite tile panelling. Ten of Clark's patent self-coiling steel shutters enclose the openings on the ground floor. Mr. Lyons is the architect; Mr. Stephen Breen is contractor for the brick and stone work; and Mr. Kearney for the plastering. Mr. Connolly is foreman of the works.

RENDERING THE FACE OF FLUES.

METROPOLITAN BUILDING ACT.

On the 15th ult. Messrs. Warno & Co.'s were summoned before Mr. Flowers, at Bow-street Police Court, for not having complied with the requisitions of a notice served by the district surveyor of St. Giles's.

It appeared that the work complained of was in a building erected by defendants in Gate-street, Lincoln's-inn-fields, for the use of the company, Messrs. Day & Sons. The brickwork internally was not plastered, and the district surveyor required that the portion forming the outside of the flues should be rendered, according to sec. 20, rule 4, of the Act.

For the defendant it was contended that the rendering of the outside was not required by the rule in question, which was worded in such a confused manner as to be unintelligible. The District Surveyor admitted the meaning of the rule was obscure, but contended that it must have some meaning, which he must leave for the decision of the magistrate.

On the 22nd instant, Mr. Flowers having taken time to consider the matter, gave his judgment:—"That the inside of every flue must be pargecoated, or lined with fireproof piping, and the back or outside (unless forming part of the outer face of an external wall), must be rendered."

THE "OVER-HEATED FLUE" MISERY.

The great importance of the subject makes me think that the following little budget of experience may not be unacceptable:—On a small scale they are, perhaps, a history of "how these things are done" on a large one. I have for some eight years past had my house partially warmed by hot water. There were concerns in doing the work, or advising upon it, a presumed "expert" who had dabbled in a patent for a stove, a practical worker in metals, and a bricklayer; besides this the employer, who had some experience in architecture, had heard what was to be said upon the subject by other persons willing to be employed, but rejected on the score of expense or otherwise.

One result of our united wisdom was the erection of a flue to our furnace, composed of glazed drain-pipes, which, curving over near the boiler, runs some 10 ft. nearly horizontally. This had not been in use very long before a conspicuous crack made its appearance in that length of pipe which formed the bend.

Without removing anything, I had the whole horizontal flue "jacketed" with bricks and tiles laid in fire-clay. I think the workmen mixed fine ashes with the clay. All has hitherto gone on without accident. There have been, however, conspicuous cracks in the outer surface of the fine clay, where it is used as a compo over the bricks. I dissected some of the work a few days ago, where some cracks were very obvious, facing upwards towards the wooden floor which stands overhead. It seemed to me that the fire-clay, where inclosed in the tiles, was not nearly so hard as on the outer surface where applied as a compo. Neither did it adhere well, for I easily scraped down to the drain-pipe within, which was bright and fresh. I draw the conclusion that the pipes are tolerably trustworthy when used for flues, provided that, while heated when they are well shielded from the contact of cold air without. Farther than this, I suggest as a subject for experiment, whether the cements, &c., found to resist the most intense heat, when used for fire-work on temporary occasions, as Stourbridge clay, founders' loam, do not habitually deteriorate with continual use in course of years in a flue.

With regard to the steps an architect should take in arranging with a contractor for heating apparatus, I suggest that the road to safety lies in this direction, namely, allow so much room for the flues and their surroundings, that a mass of earth may be placed sufficient by falling in over a cracked flue entirely to smother, choke, and extinguish the flame; furthermore to insist that such earth shall be applied by the cart-load, if needed; for I apprehend the following sources of opposition to the means of safety:—The person who makes up a fire likes to see a speedy result to his work; he has, therefore, a motive to prefer thin flues, that shall easily transmit the heat and diffuse speedy warmth. There may be no real economy in this, for a large mass of solid matter retaining its heat a long time, even after the fire has gone out, may be exceedingly useful; but the fire-maker cannot in this case perceive a quick result to his work, nor point out, "You see how soon this stove operates."

G. M.

P.S.—I take the opportunity of hearing testimony to the exceeding benefit, in point of health and comfort, of my hot-water pipes. Not to feel continually impelled to desert one's writing or drawing table, in order to shiver over a fire, and not to be thoroughly chilled in a cold bedroom, after leaving the warm fireside of a sitting-room, are a couple of negatives well worth some expense and trouble.

HOMES FOR THE MIDDLE CLASSES.

I PERFECTLY agree with your correspondent "W. A." (January 5th), and am delighted to see the subject of "Homes for the Middle Classes" taken up with such earnest discrimination. If some enterprising capitalist, and some sensible and able architect, will follow out "W. A.'s" suggestion, and erect handsome and spacious *Familistères* in the various quarters of London, they will not only do much to free this town from the reproach of being the ugliest and most inconvenient capital in Europe, but will confer an unquestionable boon on thousands of persons holding a certain position in society, but whose limited though independent incomes make the choice of a suitable home a problem next to impossible to solve.

If this class includes small annuitants, half-pay officers, rising or retired professional men with small families, or married couples with no family, to whom may be added daily governesses and other female teachers, obliged to live in expensive neighborhoods—all persons who neither acquire a whole house of ten rooms, nor are justified in incurring such an expense; yet, who, by education, connexions, and habits, are entitled to a more refined style of living than is within their reach under the present paltry English "Every-man-his-own-house" system of building, which has made of London a huge artistic overgrown Hanoverian village.

They are, therefore, reduced to the uncomfortable expedient of taking upon themselves the responsibilities of a house beyond their wants,

and their means, and letting a part of it to strangers; or of renting part of a house, subject to perpetual annoyances, as well as to the dread of seeing their furniture and personal property seized for their immediate landlord's rent and taxes,—and, in either case, advocating that home-independence which is one of those conventional myths that most Englishmen still believe in; but which is, in reality, only enjoyed by persons of good incomes—the upper one hundred thousand—as the number of small hills in parlour windows sufficiently prove.

Now "W. A.'s" proposal answers to this want in every respect; it is therefore earnestly to be hoped that it will not fall a dead letter. A few *Familistères*, the outward decorations of which will admit of every variety of style, while the inward arrangements will afford comfort and privacy to thousands such as the monotonous rows of little ill-hullt "self-contained" band-boxes called houses never can,—with the supplement of *restaurant*, baths, laundry, infant and preparatory schools, and other necessities which can only be brought within every one's reach by means of a large and comprehensive scheme,—such convenient buildings, I say, would secure at once their full complement of tenants; for in my circle, also, many "would rush to secure a chance of such homes."

But as one fact is better than a hushel of arguments, allow me to add that in our second visit to the *familistère* last September, our well-considered enthusiasm for this palace of labour only increased. The suite of apartments M. Godin-Lemaire courteously placed at our disposal were, in respect of dimensions, light, air, closets, stoves, &c., the counterpart of those which are inhabited by the least of his work-people; the only difference consisted in the papering, decorations, furniture, and so forth; and we may safely say that could we obtain six such rooms on one floor in London, we should think them cheap at 90l. or 100l. a year. We were in no wise inconvenienced by our neighbors, as the thickness of the walls and ceilings effectually prevented any sounds from reaching us, which is not often the case in London houses.

As all social reforms must ultimately fall into the hands of architects, to whom can we look for assistance but to you, sir, whose ably-conducted journal forms so essential a portion of their several professional libraries?

TUTO PAGLIARDINI.

P.S.—I should be most happy to give financial details concerning the *Familistère* of Guise to any architect or capitalist interested in the subject.

EDUCATED PLUMBERS.

A CORRESPONDENT, "P. T." complains, and with reason, of the assumption of the term plumber by men not duly qualified. He thinks the present would be a good time to test some of the whims exhibited by inventors of "closets." "Some say," he goes on, "that strength of work is the decay of trade. I believe it causes a great deal more trade to be done: it should be said bad work will create a new whim. It is economy to employ every man in his own capacity. Our class should understand the effect of temperature, atmospheric pressure with all the allowances, affinities in metals, rates of expansion, and all other technics necessary to make any holding dry, and give plenty of water in frosty weather."

THE LIGHTING OF CHURCHES.

SIR,—I am glad to see the subject of lighting churches opened out in your columns, and hope that it may be taken up by able pens than mine. The subject may naturally be divided into the consideration of the treatment of ancient and of modern churches.

The lighting of ancient churches is in itself rather a wide subject,—a subject that can only be generalised about, as each particular church may require a different treatment. Ancient churches were not designed to be lighted, at least in the manner we are now considering; for decorative effect on great festivals they were probably illuminated, but generally the old religion rather affected a gloom, that dim religious light we so often hear spoken of. Light was not required to enable the congregation to follow the service, and where light was required there it was concentrated; such as in the reading of

the epistle and gospel, when lighted tapers were held for the officiating priest. Again, at the high altar many lights were constantly burned, partly for their symbolical signification, and partly for their use during service.

From this we may infer that to light an ancient church, the object would in olden days have been to have centralised most light in the chancel, and there, where the service is mainly conducted, will be found our most effective point for our most brilliant light, due provision being made, I need hardly add, that the practical use of our light is first effected, that of affording light to the congregation.

"J. E." in his letter speaks of a church as of various compartments, each one to be lighted as brilliantly as the other; and instances the lighting of a room of any size as a problem easily solved. But if that room be of irregular shape, or, as in a hall of justice, requiring peculiar duties to be transacted at a particular part of it, the simplicity of that problem is lost, and we find it necessary to light the room up,—lead up the light, as it were,—to one more prominent part; and so in a church, our object will be best effected by lighting up to one given point, and that, as before stated, the chancel or entrance to it. We may also infer that in brilliancy the various parts should be subservient, the nave to the chancel, the aisles to the nave. I think we may all agree that we should, if possible, make our light a handmaiden to our architecture, to bring it out and more clearly define its most salient points. To speak more definitely depends so much on the exact form of the church itself that one cannot say much. If the church is very lofty, with well-marked clerestory, the string-course of that clerestory seems fittest for the light; this has been effectively done in the choir of York Minster. If, on the other hand, the church is low and straggling, the nave piers suggest themselves as a basis for our lights. If, again, our nave is lofty and open, almost a preaching nave and without clerestory, coronas seem best fitted to give that broad effect of light.

A string-course of light has always appeared to me the most effective method of lighting the chancel, if the string-course is of sufficient height; if the roof is vaulted, a corona. If neither can be had, I prefer standards. I have not mentioned standards for the nave, for the other methods suggested seem to answer the purpose better. Standards in this position intercept the view, give out great heat, and are too low to afford light, except to such as are very near.

Of the lighting of modern churches I have little to say, as the arrangement is always best effected in the design and construction of the church. I instance two as very effectively lighted—that of St. Martin's-on-the-Hill, Scarborough, and of St. Peter's, Vauxhall-road, London; the latter lighted in the nave by coronas, suspended between the nave arches.

C. J. F.

KINGSTON-ON-THAMES SURVEYORSHIP.

SIR,—Will you permit me to announce, through your columns, that the office of surveyor of this borough was, on January 24th, filled up by the Council, by the election of Mr. Charles Slagg, C.E., of Manchester. I ask you to do this partially because the advertisement for the office was inserted in your columns, and more especially because most of the applicants for the office are no-doubt subscribers to your journal.

In making this announcement it is scarcely necessary that I should notice the statement which appeared in your columns, signed "One of the Gentlemen." Whoever your anonymous correspondent may be, he appears to have been most egregiously hoaxed.

WALTER M. WILKINSON, Town Clerk.
* * * As we received letters from two correspondents to the same effect, the "hoax" was not confined to "one of the gentlemen."

HIGH-PRESSURE BOILERS FOR BATHS.

IN reply to your correspondent "Beta," I beg to describe a safe substitute for the high-pressure boiler with which he now heats his bath.

Let him fix in his boiler a coil of iron pipe, to which attach the two pipes which supply the bath. Then make a hole in the top of the boiler, and fit in a lid, like a tea-kettle lid.

Such an apparatus would be perfectly effective and safe, for if the pipes were to freeze up, the coil would not burst, as it would be surrounded by boiling water only; while the boiler having an opening in the top, and covered with a loose lid, might be heated with impunity, although frozen up solid.

It is surprising that builders and ironmongers will continue to fix high-pressure boilers for such purposes, when it is so easy to apply so simple an apparatus, which is not dangerous.

A. M. PERRINS.

"Beta" should use one of the "patent flexible plugs." If fixed rightly he need fear no explosion of his kitchen boiler. The plugs fuse and fall to pieces at a heat somewhat greater than boiling-water, so that should the pipes become stopped by frost or any other cause, the plugs melt, and thereby form an outlet for the steam and hot-water before any portion of the boiler could yield, unless it be a very bad one. The boiler of "Beta's" apparatus is of course wrought iron, and the pipes should be those known as "lap-welded steam-pipes."

W. H. COLLINGSBORN.

In reply to inquiries respecting the bursting of high-pressure kitchen boilers by the freezing of the pipes, I think where the pipes are left exposed, a branch pipe close to the boiler should have a weighted or spring valve, which can be made water-tight at a moderate cost; then there would be no danger from bursting. As a second substitute, I would recommend a draw-off cock fixed in the inlet or outlet pipe; then the servant should be instructed to draw off one gallon of water from this cock (which is the content of a pipe 1 in. diameter, and 30 ft. high). The cock should be fixed just above the range. If either of these plans were adopted, no accident from the bursting of boilers could happen.

J. EDWARDS, Hot-water Engineer.

TO TEST BLUE LIAS.

Sub.—I shall be obliged if any of your readers will inform me whether there are any simple means of testing blue lias or other limes, similar to the test employed by the Metropolitan Board of Works to test Portland cement.

L. E.

THE WIDOWS OF CLERKS OF WORKS IN THE CIVIL SERVICE.

Sub.—I trust that in begging your kind insertion of this letter, you will not consider that I am unduly trespassing on your valuable space, by referring to a subject which may not seem of sufficiently general interest to warrant it. It has recently come to my knowledge by means of the public press, that a movement is on foot amongst the clerks of works in the Royal Engineer Department to solicit Government for an increase of pay, and also for pensions for their widows. It has been truly argued that while these gentlemen hold the relative rank of officers in the army, they are at the same time debarred from many of their privileges. Requiring an education, in one branch, at least, of a much higher order than necessary in the army, they receive salaries quite inadequate to the position they are entitled to occupy, and, consequently, are often unable to make suitable provision for their families. Liable at any time to be sent, on short notice, to any station, no matter how remote nor how unhealthy the climate, they are put to considerable inconvenience and expense, in the removal of their families, and in foreign service often fall victims to the climate. As the daughter of one who for many years held the position of clerk of works in the Royal Engineer Department, I can testify to the truth of what I have stated.

My father entered the service about the year 1836, some time after a measure had been passed debarbing officers from certain privileges which they had heretofore enjoyed. At that time one of the regulations was, that each person should contribute a certain proportion of his salary—5 per cent.—to a fund, from which, in time of old age or hopeless ill-health, the members were to receive pensions. Subscription to this fund was compulsory: after many years it was abolished. After being upwards of twenty years in the service, eleven of which were spent in a tropical climate, and during the whole of which time he discharged his duties with unremitting assiduity, the continual strain on his mental and physical powers brought on an illness, from which he died, leaving a widow and child. Application was made by the widow for a pension, but in vain. A considerable sum of money had been paid into the superannuation fund; but neither he nor she had received anything from it. I ask—is it fair that such should be the state of things? Is it right that the widows of those who have paid money into a Government fund, from which they never received anything, should thus be set aside? Is it right that the widows and orphans of those who perish in their country's service, whether that service be civil or military, should be unprovided for? Is it just, that while the widows of military officers are pensioned off, whether the husband falls on the battle-field or dies at his own home in peace, the widows of civil officers, whose whole service has been one of arduous toil, amidst ever-increasing anxieties, should be neglected? Would it not be well, as some effort, at least, were made to remedy these anomalies? Would it not be well if the widows of such officers would write in seeking that a clause be inserted, in their favor, in the petition about to be presented, that if it please Government to grant the request of the petitioners, they may not be excluded from participating in the benefits which those who may hereafter become widows shall receive.

A DAUGHTER.

THE "ORANGE-PEEL" PAVEMENT DANGER.

A CORRESPONDENT writes.—Able observations have appeared lately in the *Builder* and elsewhere on the dangerous state of the pavements, but not exactly touching at the moment a "chronic" abuse.

I sincerely trust there is not another capital in Europe where there is such unheeded daily injury to pedestrians from throwing a dangerous substance on the pavements. It is actually

amazing to see either the great ignorance or want of principle in those who do this, when the least of better consideration would prompt them to throw it on the "road."

The number of accidents which occur, though not so specified, from this, can, I feel sure, be appreciated by medical men. A respectable paper said, some time back, in half jest, there might be some "conspiracy" of evil-minded persons to so injure the community; but had there been any such arrangement, the evil, which appears increasing every year, could hardly have been greater.

THREE THOUSAND POUND CHURCHES.

Sub.—In your issue of the 5th Jan., there is a notice of a new church now being built at Birkenhead, to seat 700 persons for 2,400. As the Ecclesiastical Commissioners are willing to provide the endowment for new district churches, with a population of 4,500, the desirability of giving to the public good and substantial designs of churches to seat 700, with a cost of 3,000 (exclusive of the site and fence walls), will be evident to all your professional subscribers. It generally happens that when an architect is applied to for such a design, he prepares one far too elaborate and costly for the premises. This result is, the committee is discouraged, and time is wasted. New plans have also to be prepared, or the architect changed. If the architect of the Birkenhead church, and a few others, would enable you from time to time to give the public sketches of the elevation and ground plan of such new churches built by them, at a cost not exceeding 3,000, to seat 700 persons, as a boon in a new street, great help would be afforded to those who are anxious but afraid to begin the work in other places.

A SUBSCRIBER OF FIFTEEN YEARS.

"RATES, TAXES, AND IMPOSITIONS" PAYABLE BY TENANT.

In the Court of Common Pleas at Westminster, on January 22, before the Lord Chief Justice Bovill, and Justices Willes, Keating, and Montagu Smith, the case of *Hideswell v. Whitworth* was decided. This was an action on the covenant in a lease of a house in a new street in Manchester, whereby the defendant, the tenant, covenanted to pay "all rates, taxes, and impositions whatever, except the property and income-tax, which should become payable and respect of the said demised premises, and to pay the clear yearly rent of 90l. for the same." By the Manchester Improvement Act, if any street or part of a street should not be sufficiently paved, levelled, and sewered, the Council can order the owner of the premises to pave, level, flag, or sewer it; and if he refused or neglected to do it, then the Council might do it, and all charges must be paid by the owner, and might be levied upon the occupier to an amount not exceeding the rent due by him. In this case the plaintiff, as owner of the premises, had paid charges for levelling and sewerage the street in front of his house, amounting to 225l., and in the present action sought to recover that amount from his tenant under the covenant of his lease, as a charge and imposition payable by the tenant beyond his rent under his covenant. A verdict having been obtained for the plaintiff at the trial, with leave to the defendant to move to set it aside and enter it for the defendant, a rule was accordingly obtained.

The Chief Justice said, it was manifest that the Legislature intended that the burden of these payments should be thrown on the landlord. The tenant was not to be held up to pay more than his rent, and he was not to be liable. He thought the tenant ought not to pay. The other judges concurred.

Mr. Justice Keating said, the word "imposition" was classified with rates and taxes in the covenant, and he thought the intention was, that it should mean charges of the nature of rates and taxes only. He was not at all sorry, in the present case, to be able to arrive at that decision. Rule absolute, to enter verdict for defendant.

THE CHURCH OF ST. MARY-LE-TOWER, IPSWICH.

SINCE 1863, the work of restoration has been going on in this church. The lofty tower and spire are now approaching completion. The tower is 94 ft. high, and the spire 82 ft., making a total of 176 ft. from the base. They are in the Decorated style of architecture of Edward III.'s reign, and hulk of Bath stone. There is an open parapet, with shields containing emblems of the Twelve Apostles, carved in stone, and below are carved, as hood-mould steps to the belfry windows, the heads of the Twelve Apostles. At four angles are emblems of the Four Evangelists, namely, the Man, the Lion, the Ox, and the Eagle. These figures are 4 ft. 6 in. in length. The parapet is pierced entirely through, so that the base of the spire is seen between the openings. At each angle are carved crocketed finials. Inlaid flint panelling is introduced in bands round the tower, above the door, and under the belfry windows, dividing the structure into stages. The top stage is relieved with chequered flint and stone work.

The spire is crocketed on each angle. The spire lights are filled in with ornamental iron-work, and the upper part is relieved with stone tracery. The whole of the stone-work, both in spire and tower, as it is being cleaned off, is

washed down with a strong mixture of soap and water, with the view of hardening and preserving it from the action of the air.

The niche in the old tower has been restored and re-fixed in the new one, above the south door; and in pulling down the old brick porch, the remains of the stone carved figure of the Virgin, that stood originally in this niche, was discovered. This figure, we understand, will be restored and replaced; the work of restoration having been entrusted to a London sculptor.

The entrance below will be grained in stone supported by strong clustered shafts, with carved capitals, and the deeply-moulded outer and inner doors will also have their capitals carved with emblematical figures. The two small single-light windows at the entrances will be filled with stained glass.

The ringers' floor is reached by a circular stone staircase, 5 ft. in diameter, and the belfry windows will be filled with slate louvres. Orders have been given for two more bells so that there may be a peal of twelve, instead of ten as in the old tower; and the funds to defray the cost are nearly subscribed. The cost of changing the peal from ten to twelve will be something like 700l.; and the entire value of the peal, when complete, will be about 1,600l. The weight of the tenor bell will be 31 cwt. The enlarging and re-hanging of the peal have been undertaken by Messrs. Warner & Sons.

The entrance doors will be of oak, covered with wrought-iron hinges, and the floor of the tower will be laid with Mintons' encaustic tiles.

The designs for the work were provided by Mr. R. M. Phipson, of Ipswich and Norwich, architect, under whose sole direction, this, as well as the entire work of restoration, has been carried out. Mr. J. Stanley, of Norwich, was the contractor for masons' work, and the stone-carvings were done by Mr. Barritt, sculptor, of Norwich. Mr. Miller was the clerk of the works.

A further contract has just been entered into for the completion of the south aisle and the nave. Much also remains to be done in the interior of the church in benching, heating, paving, and carving, and the entire restoration of the chancel, with new vestry, and many other works necessary to render the building complete. The cost of the tower and spire is about 4,000l., and the total outlay, we believe, up to the present time, amounts to 11,000l. or 12,000l.

AGREEMENTS.

PEEL V. MATTHEWS.

The plaintiff in this case (in Vice-Chancellor's Court, before Sir W. P. Wood), had sold in lots some land for building purposes, and had required the purchasers to execute a common deed for the purpose of preventing them from building upon land marked in front of streets which were intended to be laid out. The plaintiff alleged that defendant had broken the covenant, and the bill asked for an injunction against him.

Mr. Amphlett and Mr. Longles were for the plaintiff, and Mr. Chitty for the defendant. The Vice-Chancellor said the plaintiff, by allowing the covenant to be broken in respect of part of the land, had forfeited his right to ask for a performance of the covenant with regard to any other part of the land. The Court could not decree specific performance of part of an agreement. The plaintiff might have a remedy at law for damages, but his bill for an injunction must be dismissed.

PUBLIC INSTRUCTION ABROAD.

The report presented by the Prefect of the Seine to the Municipal Council of Paris gives the following statistical details as to public instruction in the department of the Seine. The sum allowed in the budget for 1867 for primary instruction amounts to 237,013l., including the expenses of the Chaplains College, which amount to 30,746l. This will be sufficient for the maintenance not only of the existing schools directly or indirectly at the charge of the town, but any new communal schools or asylums that may be required to be provided for in 1867. The teaching of design, which the municipal authorities are so anxious to promote among the working classes, so as to preserve for Paris its superiority in works of elegance and taste, can be extended to 122 communal schools for boys and girls, and 32 for adults of both sexes. If to this sum of 237,013l. we add 6,820l. for maintenance, repairs, and furniture of the schools, and 1,034l. as an assistance fund for assistant teachers, of both sexes, we shall have 244,867l., as the sum to be expended in 1867. Comparing this with the

preceding years we have the following items:—
 In 1862, the number of schools, asylums, adult
 class-rooms, work-rooms, and special schools,
 amounted to 403. Now, there are 522, an
 increase of 119 in four years.

The *Correspondance Russe* gives very interest-
 ing statistical details as to the establishments of
 public instruction in the town of Moscow in 1865.
 This town, which contains 365,000 inhabitants,
 possesses no less than 167 schools, 69 for boys
 and 58 for girls, and 40 mixed. The number of
 pupils is 11,366 boys, and 4,950 girls; and there
 are 1,521 masters or professors, and 70 female
 teachers. The higher branches of education are
 given in a single establishment,—the university.
 Besides this, there is an academy of agriculture,
 and a recently-founded *conservatoire*. The
 secondary education is given in five high schools
 for boys, the number of pupils being 1,719; three
 military schools, with 1,426 pupils; and six in-
 stitutes for young women, with 2,263 pupils.
 Moreover, a hundred private establishments in-
 clude primary and secondary instruction. There
 are only 66 primary schools, with 4,786 pupils,
 very small number relatively to the population
 of the inferior classes which is 72 per cent.
 of the total population. The establishments, kept
 up by the State, by the town, or by chari-
 table societies, require an annual expenditure of
 560,000 roubles. In this sum the university
 figures for 426,000 roubles, and the school of
 professors for 130,000 roubles.

PRIZES TO ART-WORKMEN BY THE
 SOCIETY OF ARTS.

The following is a list of the competitors to
 whom prizes have been awarded:—

*Works generally executed from prescribed
 designs.**

CARVING IN STONE.

- 1. Panel, after chimney piece by *Donatello*, by
J. Daymond, jun., 4, Edward-street, Vauxhall
 Bridge-road, S. Price 3*l.*—(2nd prize of 7*l.* 10*s.*)
- 2. Gothic bracket, by *E. J.* Price 5*l.*—(Prize
 of 4*l.*)
- 3. Ditto, by *John Edward Daly*, 33, Medway-
 street, Westminster, S.W. Price 15*l.*—(Prize
 of 3*l.*)
- 4. Ditto, by *John Barker*, 4, John-street, Marl-
 borough-road, Chelsea, S.W. Price 12*l.*—(Prize
 of 6*l.*)
- 5. Flowers carved in Caen stone, by *W. H.*
Holmes, 101, Dean-street, Soho, W. Price 5*l.*—
 Prize of 5*l.*
- * 8. Carving in marble, by *Owen Thomas*,
 Barnwood-street, Camden Town.—(Prize of 5*l.*)

CARVING AND GILDING.

- * 14*a.* A glass frame, designed and carved by
V. M. Holmes, principal part of the flowers by
Joanatt (deceased), gilt in double mat and
 furnished by Messrs. *Buchholz, Venning, Chowne,*
and Ethershank, Connor, and Allen; exhibited by
H. H. Wyatt, 101, Dean-street, W. Price 230*l.*—
 Prize of 10*l.*

REPOUSSÉ WORK IN METAL.

- 15. Executed in iron, after the Martelli bronze
 mirror case at South Kensington, by *G. Page*, 39,
 Duglas-street, Northampton-road, Clerkeuwell,
 E.C. Price 20*l.*—(1st prize of 10*l.*; also, North
 London Exhibition prize.†)
- 18. "Raffaello's Three Graces," in silver, by
Joseph Hakowski, 59, Frith-street, Soho-square,
 W. Price 20*l.* Copies at 15*l.*—(Prize of 2*l.*)
- 20. "Three Graces," in copper, by *Alexander*
Dufour, 36, Cleveland-street, Fitzroy-square, W.
 Price 11*l.*—(Prize of 4*l.*)
- * 22. Portrait of the late Viscount Palmerston,
 by *W. Holliday*, 14, Nailour-street, Islington, N.
 Sold.—(Prize of 4*l.*)

HAMMERED WORK IN BRASS.

- 26. Adapted for use as a bracket, by *Albert*
Edward Millward, 13, New Compton-street,
 Soho, W.—(Prize of 6*l.*)

HAMMERED WORK IN IRON.

- 27. Adapted for use as a bracket, by *Alfred*
Hilward, 35, Little Clarendon-street, Somers-
 town, N.W.—(Prize of 3*l.*)

* Those marked with an asterisk (*) are not after the
 prescribed designs.

† This prize consists of the interest of 16*l.* 7*s.* 3*d.* Consols,
 invested in the name of the Society of Arts, to be awarded
 by the Council "for the best specimen of skilled work-
 manship" at the Society's Exhibition.

- 28. Ditto, by *G. H.* Price 5*l.* 10*s.*—(Prize
 of 2*l.*)
- 29. Ditto, by *James Gwillim*, 19, Sidney-
 square, Mile-end, E. Price 15*l.*—(Prize of 2*l.*)
- 30*a.* Panel for a screen, by *W. Letheren*, Lans-
 down Iron Works, Cheltenham. Price 20*l.*—
 (Prize of 10*l.*)
- * 32. Bread-basket, designed by *Mr. A. W.*
Hornfield, architect, for East Sheen Church;
 executed by *T. Winstanley*, 7, Stanhope-street,
 Clare-market, W.C. Price 12*l.*—(Prize of 2*l.*)

CHASING IN BRONZE.

- 35. Bust of "Clytie," produced for Art-Union
 of London, by *H. R. Batehlor, Jun.*, 149, St. John-
 street-road, E.C. Price 14*l.*—(Prize of 4*l.*)
- 36. Ditto, by *T. Nichols*, 4, Everilda-street,
 Hemingford-road, Islington, N. Price 15*l.*—
 (Prize of 6*l.*)
- 37. Ornament, after *Goutier*, by *R. Reynolds*,
 15, Oak-village, Kentish-town, N.W. Price 15*l.*—
 (Prize of 2*l.*)
- 38. Ornament, after *Goutier*, by *G.*—(Prize of
 2*l.*)
- 39. Ornament, after *Goutier*, by *H. J. Hatfield*,
 16, Alfred-street, Tottenham-court-road, W.C.
 Price 15*l.*—(Prize of 4*l.*)
- * 40. Group, "Jacob Wrestling with the
 Angel," by the above.—(Prize of 3*l.*)
- * 42. Statuette of "Caractacus," by *H. Hatfield*,
sen., 46, Bolsover-street, N.W. Produced for the
 Art-Union of London.—(Prize of 5*l.*)
- 43. Engraving on metal, after arabesques, by *G.*
S. B. Price 3*l.* 10*s.*—(Prize of 2*l.*)
- 44. Ditto, by *G. Berry*, 31, Brewer-street,
 Golden-square, W. Price 4*l.* 4*s.*—(Prize of 5*l.*)
- * 49. Ditto, on silver cup, by *Gilles McKenzie*,
 Tudor-street, Sheffield.—(Prize of 2*l.*)

ENAMEL PAINTING ON COPPER.

- * 51. "Boy and Doves," after *Raffaello*, by
Walter J. W. Nunn, 10, Gardour-street, Brome-
 head-street, Commercial-road, E. Price 5*l.*—
 (Prize of 3*l.*)

PAINTING ON PORCELAIN.

- 53. "Two Children," painted on a vase, by *W.*
J. W. Nunn, Messrs. *Batam & Sou*, Gough-
 square, E.C.—(Prize of 2*l.*)
- 57. "Two Children," by *William H. Slater*,
 Oak-hill Cottages, Stoke-upon-Trent. Price
 5*l.* 10*s.*—(Prize of 2*l.*)
- 59. Ornament, by *Alexander Fisher*, 5, Clyde-
 street, Stoke-upon-Trent.—(Prize of 3*l.*)
- 60. Ornament, painted in blue, after design by
Maestro Ludovico, by the above.—(Prize of 3*l.*)
- 61. Pair of door finger-plates, majolica style, by
Miss L. Leila Hawkins. Price 5*l.* 6*s.*—(Prize
 of 2*l.*)
- * 62 & 63. Circular-plates, subjects from the
 "Signatura" ceiling, by *W. P. Rhodes*, School
 of Arts, Stoke-upon-Trent.—(Prize of 2*l.*)

DECORATIVE PAINTING.

- 64. Ornament, by *John Slater*, Field-place,
 Stoke-upon-Trent. Price 3*l.* 3*s.*—(Prize of 4*l.*)
- 66. Ornament, by *Charles Pfänder*, 28, Bayham-
 street, Camden-town, N.W. Price 6*l.* 5*s.*—(Prize
 of 2*l.*)
- 67. Ornament, after a picture-frame in the
 South Kensington Museum, by the above. Price
 13*l.* 10*s.*—(Prize of 4*l.*)

DIE SINKING.

- 71. By *Albert Heness*, 3, Egbert-street, St.
 George's-road, N.W. Price 10*l.* 10*s.*—(Prize of 2*l.*)

GLASS BLOWING.

- 72. Exhibited by *Dr. Salvati*, 431, Oxford-street,
 W. Produced by *Marco Seguso*, of Murano.—
 (Highly commended, but ineligible for a prize,
 not having been produced in this country.)

BOOKBINDING.

- 73. After an Italian specimen, "Quintus Cur-
 tius," by *John Jeffrey*, 23, Upper Marylebone-
 street, W. Price 7*l.*—(Highly commended, but
 ineligible for a prize this year, the producer
 having taken the 1st prize last year.)
- 74. Early Florentine style, "Histoire de la
 Porcelaine," by *Louis Gentz*, 30, Brydges-street,
 Covent-garden, W.C. Price 35*l.*—(Prize of 5*l.*)
- 76. Case specimen of Mosaic, by *Louis Gentz*,
 30, Brydges-street, Covent-garden, W.C. Price
 10*l.* 10*s.*—(Prize of 3*l.*)

ILLUMINATIONS.

- 77. Specimen, by *Charles Pfänder*, 28, Bayham-
 street, Camden-town, N.W. Price 5*l.* 10*s.*—
 (Prize of 4*l.*)

Works executed without prescribed designs.

WOOD CARVING.

- (a.) Human figure in the round, in alto, or in
 bas relief. Animals or natural foliage may
 be used as accessories.
- 81. "Autumn," female head in satin wood, by
G. F. Bridge, 3, Vincent-square, S.W. Price
 5*l.* 10*s.*—(Prize of 5*l.*)
- 83*a.* Panel, in Ebony, "Boy and Moth," by *R.*
Flipping, 67, Charrington-street, Oakley-square,
 N.W.—(Prize of 2*l.*)
- (b.) Animal or still-life. Fruit, flowers, or natu-
 ral foliage may be used as accessories.
- 85. Panel. "Bird and Flowers," by *E. Du-*
jardin, 46, Camberwell-grove, S. Price 10*l.*—
 (Prize of 2*l.*)
- (c.) Natural foliage, fruit, or flowers, or conven-
 tional ornament, in which grotesque figures
 or animals may form accessories, preference
 being given where the work is of an applied
 character for ordinary decorative purposes,
 as representing commercial wares.
- 86. Panel in Lime Wood, by *J. S. Booth*, 19,
 Malden-road, Kentish-town, N.W. Price 10*l.* 10*s.*
 —(Prize of 4*l.*)
- 88*a.* Panel of Flowers, exhibited by Messrs.
Gillows & Co., carved by *R. A. Brangan*, 54,
 Foley-street, W.—(Prize of 3*l.*)

Works Executed and Finished by Machine.

- Exhibited by *Charles J. Hill*, 6, Albany-street,
 Regent's-park, N.W.—
 - 96-98. Three Groups in Ivory. Price 15*l.*
 - 99. "Head of H.M. the Queen," in Ivory.
 Price 5*l.*
 - 100. "Greek Head," in Steel. Price 8*l.*
 - 101. Ditto, in Malachite. Price 5*l.*
 - 102. Case with Two Proofs from Engravings on
 Steel for Surface Printing, and two "Medusa's
 Heads." Engravings and dies in hand. Price
 4*l.* each.
- (The above are highly commended, but ineligible
 for these prizes.)

A meeting of the competitors was held at the
 Society of Arts on Wednesday evening last, but
 we must defer report of the proceedings.

CHURCH-BUILDING NEWS.

Gelliger.—The nave of the parish church of
 Gelliger, Glamorganshire, after being closed
 for sixteen weeks for the purpose of restoration,
 has been re-opened by the bishop of Llandaf.
 The work has been undertaken as an instalment
 only, the chancel still remaining to be done, the
 total cost being 1,200*l.* The church, which is
 an ancient one, is supposed to have been built
 by Maenarch, Earl of Hereford, in memory of
 Malton, an old Welsh saint, whose niche, still
 partly coloured, has been found on the side of
 the chancel-arch. There is an entirely new roof
 of Memel timber. The walls have been strength-
 ened by means of buttresses. The floor has
 been lowered to its original level, that is about
 15 in. During the excavations, which were
 necessary for this purpose and inserting the
 heating apparatus, the bones of fully 200 people
 were found. Around the wrists of some wreaths
 of box still perfect were discovered. The chan-
 cel-arch, which is a peculiarly narrow one, has
 been entirely rebuilt. On either side it is sup-
 posed an altar once stood, as in the old north
 wall the old piscina, still perfect, has been
 found, and in the south wall, immediately op-
 posite, the opening for the other, exactly cor-
 responding in dimensions, &c., has been discovered.
 The cavity for the stoop on the south side
 which has also been discovered, but the stoop
 itself has disappeared, along with the second
 piscina. The doorway to the rood-loft has also
 been found on the north side of the chan-
 cel-arch. All these old relics have been preserved
 and exposed to view. In this church, and also
 in the Church of St. Tyfaelvy, Pontloty, within
 the parish, erected in 1863, there are baptis-
 teries, which are used by the people. The
 architect of the restoration was Mr. Charles
 Buckridge, of Oxford. The east window is of
 stained glass, by Clayton & Bell. During the
 past four years a new church, three chapel
 schools, and one school-room have been erected
 in this parish, and, including this present work,
 at an outlay of 5,050*l.*, of which 550*l.* still re-
 main to be collected.

Hasleton.—The parish church of Hasleton, on
 the Cotswold Hills, has been re-opened, after
 a general restoration and the addition of an aisle.
 Prior to the restoration the edifice was in a very
 mean state, and its accommodation was alto-

gether insufficient. A north aisle has been added; a new roof has been put to the whole—panelled in the chancel, and open in the other parts; and open seats have taken the place of the old high pews. There is a new pulpit of Painswick stone, and the floor is laid throughout with Messrs. Godwin's tiles. Messrs. Medland, Maberly, & Medland were the architects, and the work was carried out by Messrs. Earle & Sons, of Northleach, carpenters, and Mr. Barnfield, mason, of Shipton, the adjoining parish. The east window, which is of Norman character, is filled with stained glass representing the Crucifixion; and a small window near the font has been filled with painted glass representing Our Lord's Baptism. This window was the gift of the architects. The glass was prepared by Messrs. Heaton, Butler, & Bayne. There are several specimens of ironwork in the church—among them the altar-rails, door furniture, and font lid, which are by Messrs. Chew, of Stroud.

Briton Ferry (South Wales).—The Church of St. Clement has been consecrated. The new edifice has been erected upon a convenient site presented by the Dowager Countess of Jersey, who, in addition, contributed the donation of 1,200*l.*, supplemented by a contribution of 100*l.* from her ladyship's grandson, the present Earl of Jersey. The church has been erected from a design by Mr. John Pritchard, the diocesan architect; the builder being Mr. R. Roderick, of Margam. The edifice consists of a nave, with north and south aisles, south porch, and north and south transepts. The chancel is apsidal, and has on its north side a sacristy and chapels for organ and choristers on either side. The nave is 62 ft. 9 in. long by 38 ft. wide, including the aisles, which are 9 ft. wide. The transepts are 17 ft. 3 in. by 13 ft. The chancel is 36 ft. 6 in. long, by 18 ft. wide. The whole affords accommodation for 468 persons. The style is First Pointed, slightly partaking of the Early French feeling, and extremely plain and simple. There is a double bell-gable over the chancel arch. The whole of the seats are entirely free and unappropriated.

Newcastle-upon-Tyne.—St. Andrew's Church has been re-opened for public worship, after having been closed for several months, during which period it has undergone an extensive restoration. Mr. T. Oliver, architect, Newcastle, was employed for the work; and Messrs. John Burnup & Sons were engaged as the contractors. The floor of the church has been lowered to its original level, and, with the exception of the modern sittings in the south transept and in the chancel, the church has been reseated throughout with open benches. There is now a free circulation of air underneath the flooring; and a solid layer of concrete has been laid upon the immediate surface within the entire area of the walls of the church. The benches are similar in design to those in the south transept, but more commodious, and having sloping backs. A considerable number of these have been retained as free sittings. By the removal of the organ gallery, the tower archway is exposed to view, and seats are placed in the tower. The pulpit is of Caen stone, with grey polished granite enrichments. It is after a design by Mr. Pugin, and the sculptors were Messrs. Potts & Moat, of this town. The ancient windows have been almost altogether restored, the original size and detail being adhered to, and their mode of construction reproduced. The last window is entirely new, and consists of three large bays separated by stone mullions and three compartments caused by their intersections under the arch, the new window having been built upon the same kees as that which it has replaced. The entire window has been filled with stained glass, the subject selected being "The Ascension." In the upper part of the central light is the figure of Our Lord, surrounded with bands of conventional cloud and rays of light; the lower portion of the same compartment being occupied by a kneeling figure of St. Andrew—the patron saint of the church. The lateral bays contain each a group of the apostles and scriptural women, numbering thirteen figures in all. The subject is elevated upon a base of foliage and surrounded by similar canopied work in the tops of the arches. The tracery openings have, at the apex, the *Agnus Dei* as the emblem of our Lord's victory over death, and two angels bearing the legend in scroll-work.—"In my Father's house are many mansions. I go to prepare a place for you." The side chancel window, also consisting of three lights, but without tracery, has likewise been filled with figure-glass. The entire light represents "The Resurrection," the figure of

Our Lord, surrounded by a halo of light, rising from the sepulchre, occupying the upper portion, and the affrighted Roman soldiers the space below. On the right are depicted the two figures of Peter and John coming to the sepulchre, and on the left two of the holy women coming with ointment and spices to embalm the body. The windows have been executed by Mr. Wailes, of this town. The nave arches and piers, the tower arch and piers, and the Norman arch leading into the chancel, have had the paint and whitewash removed from their surfaces, and the stonework exposed to view. The works have been carried out by Messrs. John Burnup & Sons, for the masons', joiners', and general work; by Messrs. Mills & Sons, for the gasfitting work; and by Messrs. W. H. Walker & Son, for the heating.

DISSENTING CHURCH-BUILDING NEWS.

Liverpool.—The foundation-stone of a Welsh Independent Chapel has been laid at the corner of Park-road and Northumberland-street, Toxteth Park. From the designs of the architect it would appear that the style of the chapel will be an adaptation of the Early Pointed period of architecture, with plate tracery, crisped and lancet windows, and circular windows in the gables. The front staircase will form features at each side of the principal gable, and the back staircase will terminate by a square tower with pointed roof. The main roof will be surmounted by a spirelet rising to the height of nearly 100 ft. above the street level, and whilst acting as a ventilator, will give effect to the building, and be one of the prominent features of the neighbourhood. The walls will be built of Yorkshire parpotts or shoddies, with all the angles, door and window jambs, arches, and other dressings, of Stourton stone. The building will be arranged as follows:—Chapel, 41 ft. wide, and extreme length 70 ft., with room for 700 people. School-room, behind same, with two vestries, water-closet, &c., on ground-floor, and large school-rooms above, together with boiler-room and gas boiler apparatus complete. The interior of the chapel will be divided into nave and aisles by light iron columns, from which will spring the main timbers of the roof, all of which will be deeply cut and moulded,—those over the nave circular, and circular or arched timbers will also run from column to column, dividing the nave and aisles. The pulpit or rostrum is to be at the west end, and will have in front of it a large raised dais or deacons' pew, with stalls on each side and a table in the centre, a screen forming a front to the choir; and a circular window in the recess behind and above, will complete the effect of this end of the chapel. Mr. C. O. Ellison is the architect, and Messrs. Nicholson & Ayre are the contractors. The cost of the building, including the site and other expenses, will be about 5,500*l.*, of which 1,000*l.* have already been subscribed. It is expected that 1,800*l.* will be realised by the sale of the old chapel.

STAINED GLASS.

Wolverhampton Collegiate Church.—A memorial stained-glass window has been placed in the chancel of this church by the family of the late Mr. Joseph Underhill, of this town. The window is situated on the south side, and is in memory of Mr. and Mrs. Underhill. The arrangements of design and spaces are effected so as to agree generally in levels, &c., with the "Campbell" window: at the same time all the details are varied, and differ from what was previously done. The main figures of the "Underhill" window are,—Abraham, Sarah, (in the centre), and Barzillai. These figures are surmounted by canopies of foliage, the feature of which is the poppy flower and leaf. Below are three groups, viz. first, Abraham buried by his sons, Isaac and Ishmael; second, Jacob setting the pillar upon Rachael's grave; third, Jacob blessing his children before his death. The tracery of the window is treated symbolically, as there was not room for figures. A meaning and subject are given to this portion by emblems having reference to the Resurrection, the scenes below portraying death: thus, in the upper portion of the centre main light is shown the Greek monogram Alpha, Omega; and in the centre of the tracery an idea of the New Jerusalem, the Lamb on the Altar, and the Four Beasts worshipping. The artists were

Messrs. O'Connor, of London, who carried out the "Parke" and "Campbell" memorial windows, and are now engaged upon the "Nesbitt" stained glass for the same church.

Pilton Church, near Quidale.—A stained-glass memorial east window has just been fixed in the chancel of this church. It is in remembrance of Mr. F. R. Hodgson, of Withington, in the county of Lancaster, father of the Rev. H. Hodgson, the present rector of Pilton, and is the work of Messrs. John Hardman & Son, of Birmingham. It comprises a story of twelve subjects; eight are from Old Testament history, commencing with the creation of Adam, and four from that of the New Testament, which are the Nativity, the healing of the daughter of Jairus, the Crucifixion, and the Ascension of our Lord.

Books Received.

The Science of Moderation; or, the Quantitative Theory of the Good and its Beautiful: Formative Ethics. By W. CAVE THOMAS. London: Smith, Elder, & Co. 1857.

MR. THOMAS has now collected his essays on "The Golden Mean," with most of which our readers are already acquainted, into a volume, under the title here given; and whatever objections may suggest themselves to the printers of this volume, its thoughtful pages cannot but be read with interest by every reflective mind. Though Mr. Thomas's theory has been developed by degrees in the *Builder* itself, we confess we do not always follow him with conviction of its truthfulness; and we have already expressed some of our ideas on the subject in a review of a previous volume of Mr. Thomas's, entitled, "The Conformation of the Material by the Spiritual; to Imperfection by the Spirit of Error; to Perfection and Beauty by the Spirit of Truth: Christian Idealism."* Since our strictures were written, Mr. Thomas inclines rather to speak of "scientific idealism" than "Christian idealism," and he now insists rather upon the power and influence of the "moral" meant to develop physical beauty and perfection in man, than on the power and influence of "the awakening of a holy spirit in the soul of man" to do so. In this we think Mr. Thomas is quite right; inasmuch as he evidently did not mean the Holy Spirit or Holy Ghost (who is the "Lord for the body," which body is the temple of that lord and master), when he spoke of the awakening of a "holy spirit"—"a spirit of rectitude" or "righteousness"—in man, as the means of bringing the human body to the perfection of physical beauty; it was simply to the cultivation or exercise of moral principle, not to the infusion of the Holy Ghost, the comforter and refresher, he alluded. And there it was we differed from Mr. Thomas. But into that branch of the subject we need not again enter.

There is another phase of the author's theory, however, of which we may here take some slight note. In speaking of vitality in positive and negative aspects, he regards the two extremes which flank what he considers to be the grand mean, or moral force, the one as being "positive or uncontrolled energy," and the other "negative or inert." But the negative is not necessarily inert, unless it be proved that there is but one species of energy; and we will venture to predict that this will not be proved of life principles; and one species of energy may be the negative of another, and yet be in itself anything but inert. In this view the awakening of the Holy Spirit in the soul of man is the infusion of another species of energy altogether from that of the soul of man himself; and although each be negative to the other, each is equally an energy, and neither is inert. If neither suffice to overpower its fellow, that is much liker inertia in the core of Mr. Thomas's very "mean" itself than anything else. So is it with physical forces: the negative electricity is no more inert than the positive. But the mean,—the neutralization of the one by the other,—is inert! So is it even with mechanical force and motion: take a pendulum, for example. The swing to one side is negated by the swing to the other; but neither of these two extremes is inert: it is the grand mean between the two which is inert! The mean, in short, in this view is liker dual death than life either single or dual. We can conceive a mean, however, of another description altogether, in the diurnal alternation (as in

* See "On Christian Idealism," in *Builder* of August 16th, 1862.

waking and sleep) of two opposites or extremes that would, indeed, be "a golden mean" consistent with life and energy, both human and divine, although enjoyable only by a daily death.

How is it,—if mere "moral" perfection or self-righteousness,—and not the transcendental and transmutative "righteousness of God," who "is our (transcendental) righteousness," or rectifier of a lost balance transcending selfhood,—be the efficient and effective cause of physical beauty and perfection,—and not be in itself the mere "fruits of the Spirit,"—that the grand exemplar of this very moral perfection is said to have had "no beauty in him that we should desire him,"—"no form nor comeliness,"—"his face narrowed more than any man, and his form than the sons of men?" Is this then what the highest moral perfection will bring us to? Ah! Mr. Thomas, there is a mystery here the depths of which your mere "moral" plummet of "righteousness" cannot fathom.

This mystery, nevertheless, the principles inculcated in our strictures on Mr. Thomas's Christian Idealism are capable of fathoming in perfect consistency with the idea that physical and moral perfection are simultaneously attainable, both of them merely as fruits, or effects, by "the awakening of the Holy Spirit in the Soul of man"—that Holy Spirit's Servant; and in the Body of man—that Holy Spirit's Temple.

Recent Excavations in Rome. By ALEXANDER THOMSON, of Banbury. Issued by the Architectural Institute of Scotland. 1866.

Mr. Thomson's papers on excavations in Rome, to which we have before now referred, having interested the members of the Scottish Institute, the Council suspended the usual issue of lithographs, and have given to each member a copy of the last paper read by Mr. Thomson. It is illustrated with thirteen lithographs, several of them showing restorations on the Via Appia, as proposed by Canina, and makes a very interesting little volume. Mr. Thomson gives a view and account of the old tomb of Eurysaces, the baker, at the Porta Maggiore. The second story of the monument is formed of the mortars which he used for kneading his dough. Placed on their sides, they look very like siege mortars. On the frieze above were represented the various works of a baker,—grinding the corn, making the dough, baking, &c. so forth. On the south front, a sarcophagus, in the form of a bread-basket, held the ashes of the baker's wife!

VARIORUM.

"Glimpses at the Origin, Mission, and Destiny of Man; with Miscellaneous Papers. By Mr. Lawrence Heyworth. Williams & Norgate, Covent Garden." The miscellaneous papers alluded to in the title of this volume compose the greater portion of it, and relate to taxation, peace, war, the Sabbath, intoxicants, &c.; and are intended to show that "unwise fiscal legislation is the great impediment of our day to universal commerce, to social amelioration, and to intellectual advancement: customs duties are human barriers, nefariously erected every where, across the Heaven-designed channels of humanizing commerce."—"Analogy of the Laws of Musical Temperament to the Natural Dissimance of Creation. By M. Vernon. London: Whittingham, Fritch-street, Solo." We candidly confess that we have not devoted sufficient time to a perusal of this little volume to enable us to pass an opinion on its merits, but it seems to be full of thought, and will doubtless prove interesting to those who happen at one and the same time to be amateurs in melodic and harmonic acoustics, geology, astronomy, and the music of the spheres.—"A Shilling Arithmetic, for Elementary Schools. By J. W. Colenso, D.D., Bishop of Natal" (Longmans, publishers), needs no recommendation from us: all we need do is to announce this cheap re-issue of a standard work.

Miscellanea.

THE LATE MR. PARKIN JEFFCOCK.—We go a little out of our usual course to mention that the Rev. J. T. Jeffcock, of St. Saviour's, Hoxton, is preparing a Memoir of his late brother, Mr. Parkin Jeffcock, civil and mining engineer, of Derby, who lost his life with an exploring party at the Oaks Colliery after the terrible accident there last December.

A NEW CHURCH FOR POPLAR.—Mr. Henry Green, the shipbuilder, has given 6,000*l.* towards the building and endowment fund of a new church at Poplar, to be dedicated to St. Stephen. The ladies of the new district have presented a stained-glass window for the chancel, at an expense of 200 guineas. The seats in the church are all free.

GLASGOW ARCHITECTURAL (ASSISTANTS') ASSOCIATION.—The usual fortnightly meeting of this Association was held on Monday evening, the 28th ult., at the Architectural Society's Rooms, 138, Bath-street. Mr. Myles, the president, in the chair. Mr. James M. Monro read a paper entitled "Symbolism in Churches." A lively discussion followed, as to the propriety of introducing symbolism in designing churches of the present day. At the close, a vote of thanks was accorded to Mr. Monro for his paper.

THE SUBURBAN VILLAGES AND GENERAL DWELLINGS COMPANY (LIMITED).—The first general meeting of shareholders has been held at the offices of the company, No. 1, Westminster-chambers. The company have held back in their operations, not having been able to procure a desirable estate to commence upon, and in consequence of the extreme deadness in the money market. They had been offered an estate situated near to four railway stations, and desirable in all other respects, from the Ecclesiastical Commissioners, upon very advantageous terms, and had accepted the offer. The sanguine expectation of the directors was, that so soon as the public saw efforts being made to carry out the objects contemplated by the company, they would have a large increase in the number of their shareholders.

THE LEAMINGTON SEWAGE CASE.—The case of Heath v. Wallington has been before the Vice-Chancellor's Court upon several occasions during the last two years, and the operation of the injunction has been from time to time postponed in order to give time for filtering or deodorising the sewage before pouring it into the river, where it was decided to be a nuisance to the complainant. The Vice-Chancellor (Sir W. P. Wood) has now granted a sequestration against the Leamington Local Board of Health, in the terms of that awarded against the Banbury Local Board in January, 1866, observing, that if the defendants were unable to discharge the sewage of Leamington into the river without creating a nuisance, they could not be allowed to pour it in at all, as they had no more right to discharge it into the river to the injury of the plaintiff and his property than into his drawing-room.

THE BARKING SEWAGE EXPERIMENTS.—Mr. Hope, as manager of the Metropolitan Sewerage Company, has addressed a letter to the *Morning Herald*, a writer in which paper had stated, in referring to the experiments on the sea-sand at Barking, that the depth of sand was only 1 ft. Mr. Hope says,—

"In reality the sand is 2 ft. deep, and was purposely laid 2 ft. deep in order to prevent the possibility of any one attributing the growth of the grass to the influence of the soil beneath. Of the 10 acres of land at Barking reservoir irrigated with sewage only one is covered with sand, the other nine remaining in their natural condition. I am, therefore, able to answer your question of 'how much less sewage would have produced the same result on rough, uncultivated ground?' And I am happy to inform you that the result on the sand was decidedly superior to that on the 9 acres. As you allude to my old controversy with Baron Liebig, and suggest that perhaps the Baron would point out that there was a difference between sand *in situ* and sand 'transformed,' I must ask you to refer back to Baron Liebig's letters to the Lord Mayor that we heard so much of about two years ago. He there complained that I had never made an experiment even with a flower-pot filled with sand, and watered with sewage, showing that he himself did not regard it as important whether the sand was *in situ*, or whether it was 'transformed.' Moreover, he entered into a long dissertation to show what he meant by the word 'sand,' and further committed himself to the following very distinct and definite statements—'First, that it 'would be necessary to form a superstratum, 1 in. in thickness, of clay above the sand before anything could grow upon it'; secondly, that 'we know with almost mathematical certainty that there must be something besides to make a plant grow in sand watered with sewage, and that an acre of sand, even with the largest dressing of it, would not produce a hundred-weight of hay'; thirdly, that 'no land plant can grow of itself in a medium of sand to which the nourishing elements are applied in the form of solution.' Nothing can be more clear and distinct than these three statements; nevertheless, off an acre of sand at Barking we have to some plots at a single cutting obtained a weight of grass the rate of average of 20 tons to the acre, and we have brought various other land plants to maturity under the same circumstances—mangel wurtzel, celery, radishes, carrots, &c., and a rape seed, which was accidentally dropped into the sand, grew into a perfect bush. I am happy also to be able to inform you that nothing can be more satisfactory than the progress of the company's larger experiments at the Lodge Farm, a short distance beyond Barking."

DANGEROUS STATE OF A RAILWAY BRIDGE.—The bridge at Dukinfield spanning the river Tame, about 100 yards below the station, was discovered by an engine-driver, while passing with his train, to be in an unsafe condition. He told the station master, who found that it had given way, and at once gave instructions to stop all traffic.

REMOVAL OF FIRE-DAMP FROM MINES.—A Mr. Williams, from Blaifin, Wales, has been illustrating, at Barnsley gas works, a scheme, which, he states, coal mines may be cleared of fire-damp. The desired result is proposed to be obtained by the use of a very simple apparatus, consisting of an inverted syphon, to which is connected a pipe from the mouth of the shaft. The short end of the syphon is inserted in the place containing inflammable gas, and the pipe from the top is attached to the other end. The air first being extracted from the pipe, the gas, which is lighter than the atmosphere, will rise to the top. The experiments were, it is said, successful, and were witnessed by several mining engineers.

WASHED THROUGH A SEWER.—A singular occurrence, which well-nigh proved fatal to two men, has taken place at Birkenhead. A mason and a labourer were working on a raft in a large sewer, connected with the great docks of Birkenhead. Suddenly the water from one of the graving-docks was let into the sewer, and the raft was swept away by the current. The mason managed to get off the raft and stay himself near the Dako-street Bridge, where he was got out, after an interval of some five hours, in a very exhausted state. The labourer was, however, swept away on the raft through two miles and a half of sewer, and at length reached the Morpheth Dock Basin, where the raft was fortunately stopped by a half-open flood-gate; otherwise it would have floated into the river. He was rescued by means of a rope.

OPENING OF THE NEW AGRICULTURAL HALL AT BRIDGNORTH.—A public dinner in the new Agricultural Hall, Bridgnorth, inaugurated the opening of the building. The Hall is situated in High-street, and adjoins the Crown Hotel, and has been erected by Messrs. Neveit, Brothers, of Ironbridge, from plans prepared by Mr. R. Griffiths. The hall is entered from the street by a lobby and vestibule. On each side of the lobby are shops and ticket-taker's office, with a large market-room over to front the street. At the south end of the hall is a settling room, a convenience long needed by the farmers. Over the settling-room, approached by a private entrance, is a billiard-room. The underground vaults are three in front and two beneath the hall. The buildings are Gothic in style. The front next the street is built with red bricks and white stone dressings. The exterior side walls are built with white and blue bricks. The roofs are covered with Bangor slates. The interior of the hall is lined with white bricks, relieved with red brick piers and arches. The hall is heated by hot water, with a double row of pipes running on all sides, covered with iron trellis-work at floor level. The room is chiefly lighted by a lantern light, running the full length of the building.

THE LEEDS AND YORKSHIRE LAND, BUILDING, AND INVESTMENT COMPANY (LIMITED).—The first general meeting of the shareholders of this company has been held. The report stated that the directors had resolved to recommend that the directors be of available profits, amounting to 4,513*l.* 19*s.* 9*d.*, they should pay a dividend at the rate of 10 per cent. per annum, which would absorb 334*l.* 5*s.* 8*d.*; to carry to the reserve fund 750*l.*; and to carry the balance 429*l.* 14*s.* 1*d.*, to next year's profits. Out of 25,000 shares of 10*l.* each, which constituted the capital of the company, it is proposed that only 10,000 shall be issued at par, and of these about 8,000 are already taken up. Two estates had been purchased, one in Meadow-lane, and another at New Wortley. The former had been sold at a fair profit, and the latter, which consisted of buildings and thirteen acres of land, was rapidly being taken up, the whole of the buildings had been sold, and land in addition for the erection of about eighty houses, a number of which were already built and tenanted, and others were in course of erection. Advances had been made on mortgage securities to the extent of 9,648*l.* 17*s.*, of which 1,489*l.* 13*s.* 10*d.* had been repaid, and the balance was repayable at short dates or by monthly instalments. The report and balance sheet were unanimously adopted.

MOSCOW GASWORKS.—We are asked to state at the company's works were designed and executed by Mr. J. M. van der Made, C.E.

THE "GOLDEN SERIES" OF PHOTOGRAPHS.—Under this title Mr. Holyoake is publishing from the Alexandra Studio in Great Cornam-street, an interesting series of portraits on a gold mount, which gives a novel and agreeable effect. The specimens we have seen, chiefly of actors, actresses, and dramatic writers, are faithful as likenesses and excellent as photographs. The studio has additional claim as being formed to afford employment to women.

MISS GLYN'S READINGS.—These readings, as we expected and they deserved, have increased in attractiveness as they proceeded. "Hamlet," given on the 25th of January, was attended by a very large audience, who went away delighted. Miss Glyn shows a power and versatility which only a few of her hearers were aware she possessed. Every character has its proper weight, and the effect left on the mind of the auditor is that of completeness. On this, Friday evening, the 31st of January, the reading of "Antony and Cleopatra," will be repeated, and will conclude the present course.

METROPOLITAN BOARD OF WORKS.—At the last ordinary weekly meeting of this Board, the Works and General Purposes Committee recommended that the request of Messrs. Doulton and Stiff that the Board would approve the formation of dock entrances under the roadway of the Thames Embankment (south), opposite their premises, in lieu of the wharves agreed to be constructed by the Board, be not complied with; and that the engineer be instructed to carry out the work in accordance with the terms of the original agreement, which was agreed to; they also recommended that a double 10-foot way be formed under the roadway of the Thames Embankment (south), at Whitie Hart Dock, with a headway increased to 8 ft., as proposed by the vestry at Lambeth, in lieu of the Ferry-street entrance, as authorized by the Act, which was adopted. They also submitted a plan of an approach to the steamboat pier at Lambeth, and recommended that the same be approved, and that the Vestry of Lambeth be informed accordingly, which was agreed to.

CO-OPERATION IN COAL: THE JOINT-STOCK COAL COMPANY (LIMITED).—This company, at its formation, in 1854, commenced with a small capital, upon the expectation of paying a good dividend to its shareholders as investors, and also special advantages to its shareholding purchasers by way of a bonus upon their coal consumed. As the result of its first year's operations the company paid a dividend of 10 per cent., and returned to its consuming shareholders 2s. 6d. upon each ton of coal they had purchased. The advantages thus obtained will be best seen by the following illustration:—A B has ten shares in the company, upon which he has paid 5*l.*, and on the shares he would receive 10s. dividend, but, supposing he has also consumed 12 tons of coal during the year, upon these he would receive a bonus of 30s., so that in reality he obtains 40s. dividend upon his 5*l.* investment. The close of the second year's working shows results equally satisfactory. The first capital of 50,000 shares was quickly subscribed, and the second 50,000 shares are being rapidly allotted.

MAIDSTONE COTTAGE IMPROVEMENT SOCIETY.—From the directors' annual report, it appears that the company now possess forty-seven cottages; and that the subscribed capital amounts to 3,715*l.*, shares to the amount of 720*l.* having been subscribed for during the past year. The rents, after deducting rates and taxes and 5 per cent. for collection, amounted during the year to 236*l.* 10s. 10d., out of which 5 per cent. dividend, clear of income-tax, has been paid. This leaves a balance of 38*l.* 13s. 8d. to be added to the reserve fund, which would thus reach the sum of 1267*l.* 8s. 6d. The amount spent for repairs, in cementing damp walls, &c., was 52*l.* 4s. Four years' working, adds the report, has shown that the company offered a sure investment, and had improved some of the worst parts of the town; but very many cottages still urgently needed improvements such as would never be made by the generality of private owners. All the subscribed capital of the company had been invested, and the directors therefore asked the shareholders and the public at large to take more shares, so as to enable the company to extend its operations.

ASSISTANT SURVEYORSHIP, MAIDSTONE.—The local Board of Health have appointed Mr. James Harrison to be their assistant surveyor, at a salary of 70*l.* a year.

THE NORWICH DRAINAGE.—We are glad to observe that after considering a report by their surveyor, Mr. Alfred W. Morant, to their Sanitary Committee as to the dry-earth closet system which it was proposed to adopt instead of a system of drainage, the Norwich Board of Health have resolved, with one dissentient, "that the system of earth closets is not applicable to this corporate district."

THE CANTERBURY DRAINAGE AND WATER SUPPLY.—Mr. Filbrow's conclusions with reference to the proposed new drainage and water supply for Canterbury have been published. He estimates the cost of drainage at 18,000*l.* It is not intended, it is said, to erect new water-works, but to induce the existing company to so perfect their property that it may be made available for the future supply of the city.

SALE OF A RAILWAY COMPANY'S PLANT.—A "great sale of rolling stock" has taken place at the George Hotel, Shrewsbury. The stock was the property of the Bishop's Castle Railway Company, whose line, running from Craven Arms to Bishop's Castle, with a projected continuation to Montgomery, was lately seized by the sheriff, and the company being unable to satisfy the claims of the suing creditors, their available property was ordered to be sold by auction. The total sum realised was 3,522*l.* A gentleman from Birmingham, stated to be the representative of the Midland Wagon Company, was the principal purchaser.

THE PROPOSED MACLESFIELD NEW INFIRMARY. The sub-committee appointed to visit various infirmaries, and report to the general committee as to the plan it might be advisable to adopt for the proposed Maclesfield Infirmary have visited those of Leeds, Birkenhead, Chorlton, and Ashton, and reported in favour of the pavilion plan of the architect, Mr. Stevens, with minor alterations suggested by medical men. The general committee have approved the plans as presented, and resolved to lay them before a general meeting of the subscribers. The probable cost of the building is estimated at 12,000*l.* It is proposed to lease or purchase additional ground from the Free Grammar School authorities, on whose ground the proposed site stands, or rather from the Charity Commissioners.

ANOTHER KITCHEN BOILER EXPLOSION IN THE NORTH.—One of these accidents, attended with fatal results, has occurred near Brochin. Towards evening, a female servant had lighted a fire in the kitchen range. The boiler had been empty, and owing to the late frosts the water in the feeding-pipe was frozen, so that no water got into the boiler until that was red hot, and then when it did reach there an explosion took place. The whole of the range was torn out, the roof of the kitchen was blown off, and the doors and windows of the wing were destroyed. The poor woman was severely injured, and thrown back on the floor. Then her clothes caught fire, but she managed to get to the snow at the door and roll amongst it, so as to extinguish the flames. She died, however, next day.

THE PROPOSED ASSIZE COURTS FOR SHEFFIELD. The Improvement Committee of the town council have unanimously resolved to recommend the council to proceed with the Bill which is now in the hands of the Parliamentary agents, the words "town council of the borough of Sheffield" being substituted for "Justices of the West Riding of the county of York." This alteration is proposed to be made in consequence of the threatened opposition of the West Riding to the Bill. If passed, as contemplated, the "Sheffield Assize Courts Act, 1867," will include the following among other leading provisions:—The council will be empowered to provide, in or near the borough, "commodious courts, lodgings of her Majesty's judges, officers, lock-ups, and all other accommodations that may be necessary or convenient." The expenses are to be defrayed out of a special rate. A plan is generally approved by the committee which will entail an outlay of from 20,000*l.* to 25,000*l.* This plan is to buy up the lease of the Black Rock, the premises immediately adjoining the old townhall, and to build new premises on the site of both structures. As there are now police offices contiguous, it is thought that the contemplated site will furnish space enough for all the necessary courts and offices. The judges' lodgings would be elsewhere.

TENDERS

For alterations at 184, Fenchurch-street, for Mr. Kinn, Messrs. Young & Son, architects. Quantities supplied:—

Ellis	41,323 0 0
Bray	1,937 0 0
Lark	1,234 0 0
Webb	1,208 0 0
Cheesum	1,155 0 0
Hanshaw	1,034 0 0
Newman & Mann	769 0 0

For the erection of two villa residences, Stoke Newington, for Mrs. Burdett. Mr. T. Hill, architect:—

Nash	42,897 0 0
Palman & Fotheringham	2,575 0 0
Carter & Sons	2,530 0 0
Longmead	2,447 0 0
King & Sons (accepted)	2,369 0 0
Mitchellian	2,152 0 0

For farm buildings, Elmbridge Court, near Gloucester, Messrs. John Money & Son, architects:—

Water Supply	—
Teague	41,988 0 0
Jones & Sons	1,376 0 0
Clatburck	1,175 0 0
—	112 0 0

For Bristol City Hotel, Messrs. Foster & Wood, architects. Quantities supplied by Mr. J. S. Clark:—

Kirk	43,100 0 0
Jackson & Shaw	45,250 0 0
Bray	4,829 0 0
Ripby	46,488 0 0
Baker	45,944 0 0
Call & Fethick	44,444 0 0
Warburton, Brothers	43,725 0 0

For alterations and additions to 533, Oxford-street, for Professor Holloway. Mr. J. Dale, architect:—

Carter & Sons	41,989 0 0
King & Sons	894 0 0
Parsons (accepted)	750 0 0
Strudler	682 0 0

For the erection of new factory, Hill-street, for Messrs. Walslow & Sons. Messrs. Lee & Beck, architects:—

Allen	43,617 0 0
Asby & Sons	12,194 0 0
Webb & Sons	12,125 0 0
Woodman	11,986 0 0
Cowder	11,496 0 0
Perry & Co.	11,189 0 0
Browne & Robinson	11,095 0 0

For additional works at the House of Correction, Cold-bath-fields. Mr. F. H. Fowall, architect:—

Sawyer	41,149 0 0
Lovatt	11,071 0 0
Gibson, Brothers	10,830 0 0
Mansfield & Price	10,843 0 0
Webb & Sons	10,778 0 0
Henson & Chapman	10,490 0 0
Mann	9,765 0 0
Eaton	8,283 0 0

For sundry alterations to premises in Goadge-street and Charlotte-court, for Messrs. Winter & Co. Mr. W. A. Baker, architect. Quantities supplied by Messrs. Richardson & Waghorn:

Scrivenner & Whitts	41,222 0 0
Munley & Rogers	1,145 0 0
Kelley & Co.	894 0 0
Tracer & Co.	825 0 0
Moultre	888 0 0

For sundry alterations to the Crown public-house, Cleveland-street, for Mr. Makepeace. Messrs. Lymes & Rivett, architects:—

Richardson	4610 0 0
Ellis	565 0 0
Moultre	532 0 0
Lawrence & Brough	449 0 0
Harland	473 0 0

For rebuilding Nos. 2 and 3, and alterations to No. 4, Finch-haus, City, for Mr. Alfred Purcell, Mr. Herbert Williams, architect. Quantities supplied by Mr. C. Kelly:—

Turner & Sons	43,269 0 0
Barzley & Sons	3,189 0 0
Asby & Hornor	2,899 0 0
Asby & Sons	2,899 0 0
Cowder	2,721 0 0
Newman & Mann (accepted)	2,637 0 0

The Builder.

VOL. XXV.—No. 1253.

Designs for the Proposed Law Courts.*

EW of the competitors seem to have managed the accesses and the retention in convenient places of the sight-seeing or idling visitors to the Palace of Justice so well as Mr. E. M. Barry. This is his strong point, and will count for much when the weighing of merits comes. The chief points, say the Commissioners, to be kept constantly in view, and to be treated as superseding, so far as they may conflict, all considerations of architectural effect, are the accommodation to be provided and the arrangements to be adopted so as in the greatest degree

to facilitate the despatch and the accurate transaction of the law business of the country; and in carrying out this design the first object should be to provide ample uninterrupted communication and accommodation for those who have legitimate business in the new building."

They further point out that the accesses to the courts for mere public spectators should be entirely distinct from all the other accesses, and as far as possible from each other, and should enter directly from the street, and never cross on a level or communicate with the accesses and passages used by the profession, the witnesses, jurors, and others engaged in the business of the courts; so that while spectators may be readily admitted to each court separately, they should not, for the purposes of mere sight-seeing, be tempted to pass from one court to the others, and to make the round of them.

Some of the competitors have overlooked altogether this determination on the part of the Commission, and have not remembered either that while the utmost facilities of communication should be afforded to departments which are associated together in the conduct of public business, it is not desirable that those facilities of communication should be a source of disturbance to other suites of offices.

In Mr. Barry's design a Central Hall, not so large as might be desired, serves as vestibule or entrance-hall to all the courts, with which it communicates by a corridor. The floor-level of the courts is 36 ft. above the Strand, as prescribed. This height appears to us regrettable, but it is said that it was well considered, and that the required number of rooms and offices could not have been otherwise obtained on the site.

The courts are parallelograms, with the corners cut off in some cases. Their widths vary from 30 ft. to 32 ft. The bench is entered from the judges' rooms behind, on a level. Separate access and stairs are provided for witnesses from their waiting-rooms under the court. Similar separate access and stairs are allotted to the jury. The jury retiring-room is placed on the floor above, and is approached from the jury-box by a private staircase. The public are altogether excluded from the court floor, which is strictly reserved for those who have business to transact. Each court is furnished with a gallery round three sides. The end gallery is for the public; that on the left of the judge is for the jury, as has been already described, and the opposite gallery is for the grand jury, magistrates, or distinguished visitors. The access to the public galleries is by separate and distinct staircases, entered directly from the street without any communication with any other part of the building. The staircases are circular on plan, and Mr. Barry describes them as arranged like the great circular staircase at the Chateau of Chambord. "This plan may be described as a screw with two threads, each thread being quite distinct and never joining the other. By this design two separate public staircases are obtained in each circular space. There are four of these circular staircases, each containing two separate sets of stairs." We must confess to no liking for circular stairs in public buildings. Private staircases are also provided for the Appellate and Spare Court, so that there are ten staircases for the exclusive use of the public for approaching their galleries in the several courts, which are arranged in groups corresponding to the number of the staircases. The approach is direct from the street, and it would be impossible for a spectator to pass from one group of courts to another without descending to the street, and ascending again by another staircase. The approach from the public staircases to the galleries on the upper level is so arranged that the public may be able to see the Central Hall and corridor, but can have no direct communication with them.

The plan includes four double and two single public staircases, six double staircases for the bar and persons engaged in business, one single staircase for a similar purpose, and six public staircases in connexion with the offices. These are exclusive of the stairs to the bridges over the Strand and Carey-street, and of numerous private staircases for the Judges, Masters, Vice-chancellors, and officials, and give a total (exclusive of the latter) of twenty-nine staircases.

The provision for the documents of the Probate Court is afforded by a dome and the central mass on which it rests. This he considers a more compact and convenient arrangement than a tower or towers, which, to afford the amount of accommodation required, must necessarily be of great height.

Mr. Barry has departed from the suggestion made by the Commissioners, that as a matter of convenience the Equity Courts should be placed on the side nearest Lincoln's-inn, and the Common-Law Courts nearest the Temple; the Chancellor and Vice-Chancellors' Courts being placed in his design at the Temple Bar and Bell-yard side.

The offices are situated, for the most part, in the building forming the outer ring of the plan: entirely distinct from the centre building and one another.

The style adopted is fourteenth-century Gothic, and the aspect of the pile is sufficiently palatial. The central dome, on a large square basement, is, of course, the principal feature externally; but smaller towers and spirelets around, and a lofty clock-tower at Temple Bar, are brought in to form the *ensemble*. Touching the cost, Mr. Barry, justly enough, is no believer in estimates by the foot cube. The cubical contents of his structure, however, are 24,751,424 ft.; and he puts these at one shilling per foot, which would

give 1,237,571l., exclusive of Temple Bar and Carey-street bridges and subways,—say 40,000l. more.

We must express our conviction that Mr. Barry has produced an excellent plan.

Mr. Raphael Brandon is one of the competitors who adopts a Central Hall, the courts being arranged round it: the judges' rooms are placed round, and open into, the courts with which they are connected; outside these a corridor or gallery is provided, by which the judges can enter their respective rooms, or communicate with each other.

The block of the building as proposed measures about 687 ft. from east to west by 445 ft. 6 in. from north to south; taken to the outer face of the external walls; for these the two Record Towers for fireproof accommodation, and the Clock Tower, stand detached. The north-eastern, north-western, and south-western angles of the plan are rounded off, and with these exceptions the building is a parallelogram in form with comparatively very small projections, so as to make all the space available, the architectural effect being produced principally by the skyline, which includes two lofty towers and spires in the west front, with the two Record Towers in front of them.

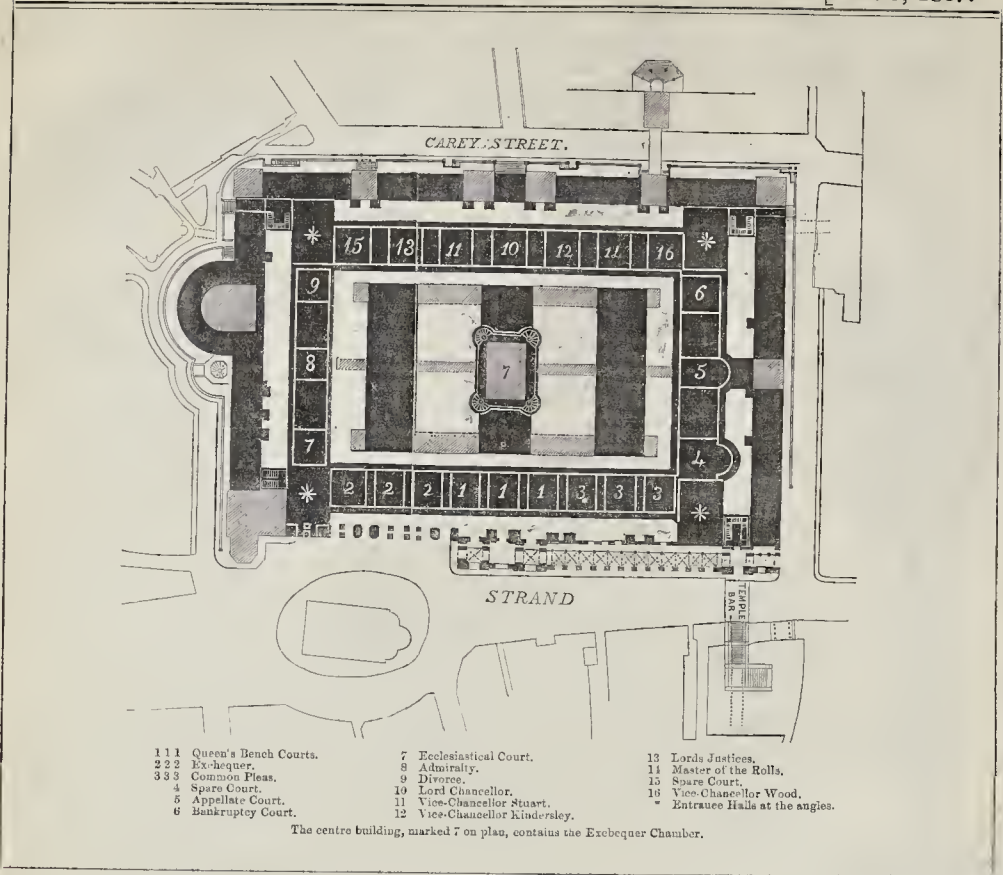

The site proposed by the Commissioners to be dealt with by the competing architects measures 510 ft. from the general Strand front northwards to Carey-street. The north front of the building is set back 15 ft. from the Carey-street line, and extends to within 33 ft. of the Strand frontage of the site, which allows the most projecting part of the building and the area walls southward to stand clear of the quadrat formed by Pickett-street on the north side of St. Clement's Church. Two large halls in this front form entrances to the Central Hall, having two other halls corresponding in position on the north or Carey-street front. Those for the public, after crossing the internal areas by means of light iron bridges, unite in a lower hall, from which a double flight of steps leads up to the large Central Hall.

The dimensions of the Central Hall may be stated as 365 ft. long by 130 ft. wide. This space he divides into a central chamber 250 ft. by 60 ft. wide; round this runs an ambulatory 17 ft. wide from the centres of shafts, and from this ambulatory the corridors between the courts are reached by lobbies 25 ft. by 17 ft.; between these lobbies areas of about 23 ft. 6 in. by 16 ft. 6 in. are formed to give light to witnesses' corridors and other accommodation below the court floor. In these areas are placed the staircases for the public spectators and all parties not engaged in the suits.

It may be objected that Mr. Brandon has adopted a thirteenth-century cathedral for his type, with the main arches dividing nave and aisles, triforium, clearstory, and groined roof. Externally, too, with its *flèche*, the Hall suggests the Paris "Sainte Chapelle" and some similar buildings. In selecting the style to be followed, he claims to have taken that which showed the greatest amount of purity, elegance, and strength, and applied it freely to the requirements of the building, "allowing [he says] no mere reproductions to creep in, but endeavouring to deal with the whole as I believe the old architects would have done if it had been built in their day, looking mainly to the wants of the several departments; and, trusting to a faithful attention to the conveniences of arrangement, clothing the whole with artistic mantles, thus producing the effects naturally, bearing always in mind the general outline and light and shade intended to be produced." Nevertheless, the details of the south or Strand front will not fail to recall Wells.

The floor of the Central Hall would be 40 ft. above the level of the Strand,—24 ft., therefore, above the level of Carey-street.

* See p. 69, ante.

As to cost, the building comes to 35,250,000 ft., and is priced at 9d. per foot, founded on the admeasurement and valuation of various portions of the work. This produces 1,395,313s., and with bridges and glass roofs, 1,414,913s. As in other estimates that we have given, this does not include water-supply (10,793s.), hydraulic lifts (13,250s.), warming and ventilating (22,680s.). Mr. Burgess, after consideration, arrives at the conclusion that a Central Hall is not desirable, and these are the reasons he gives:—

"It introduces the public, and to a certain extent public traffic, into the middle of the building, where quiet is most essential. It is also apt to place the judges' apartments and corridors on the exterior, and those of the bar and legal public in the interior, thus reversing the order of things; for the judges' apartments should obviously be placed in the interior, so as to secure quiet, and to enable them to consult with each other with facility.

A central hall is doubtless a very attractive feature, but, however much adapted to a county assize court, it appears to me that there are grave objections to it in the present instance; for, in the first place, it most materially diminishes the areas for light and air, and, should it be circular, it has the extra disadvantage of causing sandy circles of the open areas to assume an inconvenient shape. In the second place, it is a very serious addition to the expense, if carried out on a proper scale."

He adopts the "zone system;" the outer zone containing offices. The second zone contains the courts, with connecting corridors for the use of the legal public on the outside, and a similar one for the judges on the inside.

The block-plan we print will best explain his general arrangement.

The innermost buildings form a third zone, and are devoted to the accommodation of the judges. They communicate with the judges' corridor, and consequently with the courts, by means of light iron bridges. The central space is divided into two areas by means of a block of buildings containing judges' apartments, the Exchequer chamber, and a small central hall.

The courts are 40 ft. from the Strand level, and are lighted by double-glazed windows high up in the walls.

The cost, adopting an average price per foot cube of 1s. 0½d., with an addition for cost of main tower, is called 1,409,409s.; or, with heating, water-supply, sculpture, &c., 1,584,589s.

In his observations on choosing a style (strange position of our architecture that this should be necessary!) Mr. Burgess gives his reasons for arriving at the conviction that French Gothic of the thirteenth century is the best, and thinks that "the whole edifice should become one of those books in stone, telling us not only of the deeds of our ancestors, but of the wondrous progress of the nineteenth century in science and literature,"—though, as we must conclude, not in architecture.

There are some valuable points to be observed in Mr. Burgess's arrangements for the admission of the public.

Mr. Lockwood has a very lofty Central Hall, 236 ft. long and 72 ft. in width, and this is surrounded by a corridor 20 ft. wide. Between the Central Hall and the principal eastern and western entrances are secondary halls, respectively named in the plans the "Probate Hall" and the "Exchequer Hall." These halls, each 120 ft. by 60 ft., handsomely designed, give access to the courts and corridors. Along the north or Carey-street side of the great hall the seven Equity Courts are placed; to the south of the great hall, and to the right of the great corridor from the Strand, are the Queen's Bench courts and rooms; and on the left of the same entrance are the Common Pleas courts and rooms. Around the Exchequer Hall, the Exchequer courts and rooms and the Exchequer Chamber are grouped; and around the Probate Hall, the Probate Court, the Ecclesiastical Court, the Admiralty Court, and the Spare Court are arranged.

A belt 30 ft. in width separates the courts and rooms attached, from the outer mass of building, containing the whole of the departments in which the official business of the country is transacted.

On the one side of the judges' corridors (which are on a level with the bench) are the entrances to the courts, and on the other side are the judges' private and retiring rooms, each room or set of rooms being immediately opposite the court to which it belongs. At the opposite end of the courts to that occupied by the judges are corridors for the counsel and attorneys. They are connected with the great Central Hall by spacious lobbies, and with the Probate and Exchequer Halls by inclosed arcades.

The entrances for public spectators are distinct from all accesses, and are entered directly from the street. The spectators are admitted to each pair of courts separately; but cannot pass to other courts, or make the round of them.

On the subject of acoustics Mr. Lockwood speaks more dogmatically than the other competitors. He says,—

"There is probably no subject of higher importance in a court of justice than the science of acoustics. In few courts yet erected has success been achieved. Some might be named (though it would be invidious to do so) in which the amount of failure is most serious; and in nearly all various schemes have been propounded for remedying the defect. Like the laws of all other sciences, those which regulate the transmission of sound are most simple. They depend entirely upon proportion. Given, the height of a platform or bench, to this add the height of a person sitting or standing, as his duty may require, and one half the width of the room. These three dimensions, viz. the height of the platform, the height of the speaker, and half the width of room, being added together, should be the height from the floor to the ceiling. The voice of a person speaking from this position will strike the two side walls and the ceiling at the same moment of time. Reverberation is thus reduced to a minimum, and the result of repeated practice shows that this rule is perfectly successful, even to the extent of a room twice its width in length; in other words, a double square. This simple law has been adopted in many buildings with uniform success. When a room is as high as it is wide, the voice has to travel nearly twice the distance to the ceiling that it has to the side walls, and the consequence is that the auditory receive the second word from a speaker, in a direct line, before the reverberation of the first word has reached it from the ceiling." "In the case of a law court, the continuous rise of the platform for the counsel somewhat reduces the general height of the room, and, therefore, a little excess upon

the above rule may be permitted; but if the width of a court be restricted to 32 ft., it is recommended that the height should not exceed 27 ft., instead of being made 30 ft. as required by the instructions."

There are several points in the planning which deserve study; some, on the contrary, that would produce great inconvenience. For example, the "Spire Court," as it is called, is so placed that there would seem to be only one way in for everybody. The Centre Hall is handsome, with a roof of the Westminster Hall type. The cubical contents of the building as designed, is called 27,435,389 cubic feet. Nearly half of this being priced at 9d. per foot, and the remainder at prices ranging from 8d. to 2s. (the great tower), we have a total of 1,235,583l., including the bridges. In support of his estimate, the designer mentions that the Inns of Court Hotel, stone fronted and in parts an expensive structure, has cost 9d. per cubic foot.

Some little misunderstanding exists as to the names of the judges of Designs, and we may as well remove it. Although the First Commissioner of Works, the Chancellor of the Exchequer, the Lord Chief Justice of England, and the Attorney General of the time were appointed, it was by name, and with the clear understanding that a change of ministry should not change the tribunal. The judges, therefore, really are the Right Hon. W. Cowper, M.P.; the Right Hon. W. E. Gladstone, M.P.; the Right Hon. Sir Alex. Cockburn, bart.; Sir Roundell Palmer, M.P.; and William Stirling, esq., M.P., with such assistance as they may think fit to take.

THE LANDSEER LIONS.

LONDON is unrivalled among the cities of Europe for its public statues. Other towns will not be anxious to dispute the peculiar supremacy of the metropolis in this respect. In no other spot on the face of the earth has so much money been spent for purposes of decoration, not only without taste, but under the influence of the most violent and rampant bad taste. When we have a good statue, we spoil it by the selection of an unsuitable site, of which latter fault the Iron Duke on the top of the gateway is the largest example in the world.

It is, however, happily impossible to deny that great improvement in public taste, as regards decorative art, has occurred since 1851. At no period of history, and in no part of the world, have the taste and cultivation of one man done more for the artistic education of a great people than has been the case in England since the opening of the Great Exhibition. The Prince who projected that noble school of art has left for himself a monument more imperishable than brass in the improved taste of the nation. We trace this effect not only in the embellishment of domestic life,—in the glass, porcelain, and bronzes that fill the windows of the shops,—but in the nearer approach to beauty in street architecture, and in the gradual disappearance of that style of houses which owed its origin to the window-tax.

Under these circumstances every lover of art will gladly hail any approach to such an embellishment of London as he can consistently admire. The completion after so long a delay of the Nelson monument is an occasion of the kind. It is a noble work, of which any city might be proud. We do not disguise our opinion that to place an effigy on the top of a column is worse than a mistake. On this point there may be some hesitation among those qualified to decide, and we merely refer to it as a proof that it is possible to construct a fine monument on a questionable plan. Undoubtedly one of the reasons why Nelson looks so much less insignificant and unmeaning on the capital of his column than does his neighbour the Duke of York, is the shadow afforded by the Admiral's hat. A bare-headed statue in our streets gives a very painful sensation to the spectator three days out of four. It is unfitted for the climate, it is a blunder as a question of light and shade, and it is an unworthy representation of a great man, because it places him in an undignified, if not in an abject position. But, notwithstanding the dislike we feel to "mast-heading the Admiral," the column itself is graceful and well proportioned; the *bass reliefs* are spirited, and harmonize with the general design; and the presence of the lions on the base gives unity to the entire monument, and has been a greater improvement to the *coup d'œil* than it was possible to foresee. Let us not forget, what our contemporaries appear to have forgotten, that to

Mr. Railton, the architect, is due the credit of the monument as a whole.

The lions have been spoken of in terms of unmingled praise. We think them objects worthy of great admiration, but to say they afford no ground for criticism is to glorify the artist at the expense of art, and to show greater power of appreciating excellence, however displayed, than knowledge of the requisites and of the power of sculpture. Sir Edwin's lions are majestic, and life-like. Their heads are slightly conventionalised, so as to produce on the mind an impression recalling (with a difference) the Sphinxes of Egyptian sculpture. This effect, which is far from undesirable, arises in part from the mode in which all sculptors have found themselves compelled to deal with the brow of the lion. The eye is the great difficulty of the sculptor. To represent the feature which is the very seat and expression of life by a dead surface is the most severe trial to which the resources of art can be exposed. Some of the very finest statues of antiquity fail in this respect. Some of the great artists in bronze attempted to overcome the difficulty by the insertion of silver pupils. Shadow from a projecting brow, or large, downcast eyelids, hest converts failure into triumph. The statues on the tombs of the Medici have a wonderful vitality, or rather supernatural power, in their shadowy eyes. There is a Persens, well known to lovers of gems as the work of Pyrgoteles, in which the down-cast dreamy eyes give the effect of life itself. The manner in which the great Florentine laboured at this feature may be realised by study of an unfinished marble in the Kensington Museum, in which the two eyes are totally dissimilar, the best effective of the pair having no doubt been destined for conversion into the more successful form. But in dealing with the eyes of animals, every sculptor knows that the difficulty attains its maximum. There is no eyelid to cut, no shadow to be thrown. Reproduce the actual form of the glassy ball in marble or in bronze, and the result is a cold, unmeaning stone. Sculptors, therefore, since Zepos's days, have been obliged to lend a frown to the lion which does not exist in nature, and this is visible on Sir Edwin's lions.

Another reason of the somewhat Egyptian expression of these fine statues is a want of incisive finish in the mane, and particularly in the beard. Here, again, it is hard to draw the exact line between a merit and a defect. No fault can be greater than a finical minuteness of detail in colossal sculpture. Broad massive forms, intended to throw sharp defined shadows, visible from a considerable distance, are most effective when boldly handled. Too much finish weakens the effect. But then the point of view has to be regarded. A subject treated in this manner must not be too closely approached. In the present instance the main defect in these sculptures is the evidence they present, that although the work of a great artist, and, above all, of a great master in the representation of animal life, they are not the work of a sculptor. We seem to trace the very sweep of the brush or stroke of the crayon on the mane; we miss the vigorous impact of the mallet. It could not be expected to be otherwise. We do not speak merely of the technical education of the hand, for the eight years devoted to the work would have been enough to accomplish this, in a younger artist, but in the essential difference in the style by which the painter and the sculptor seek to attain their object. You can conceive of the sculptor painting. He is then only sketching his real work; but for the painter to assume the chisel is, for the most part, a mistake. Da Vinci and Michelangelo were not merely painters—they were finished and perfect artists. In the Nelson lions we think that a sculptor would at once recognize the treatment of Landseer's animals as that of a painter.

In these remarks we by no means seek to depreciate a very noble work of art. It was a bold act on the part of the Government to entrust the execution to a painter; it was a bold act on the part of the painter to accept it. The public are the gainers. It would have been difficult, if not impossible, to place the task in other hands. The want of the savage tangle of mane, which a great sculptor might have beaved out, and a certain unfinished and rather feeble treatment of the paws, exhausts the viols of criticism. Few in the millions who will gaze on this great monument will miss these features of artistic power. The few who do miss them may be made the wiser by the reflection. For a painter at Sir E. Landseer's time of life to have

produced such a work is a singular and a great success. Our tribute of admiration should be the more acceptable from the fact that it is not indiscriminating, and therefore, to some extent, unmeaning.

Another consideration appears to have been present to the artist. The monument is in honour of Nelson, not in honour of lions. They are subservient, not principal figures. What they might be supposed to signify, if ours were a people to care for such a question, it may not be so easy to say. In our earliest history lions stood for independent provinces. The two lions which the Norman kings first bore on their escutcheons were increased to three on the accession to their dominions of the rich dower of Eleanor of Aquitaine. But the number required by the architect is not thus attained. Emblems of naval victories would hest suit the base of a monument erected in honour of a naval hero. But, then, these should have been sea lions. The name of the British lion has been so often invoked in turgid oratory as to have a tendency to raise a smile. But if we regard the creatures neither as the crest nor the bearing of our kings, neither as emblematical nor allegorical, but as reproductions of our well-known heraldic cognisance, we may reconcile the herald to the architect. Thus regarded, the subservience of the four giant guardians to the central features of the memorial, when the whole is seen at a little distance, and their effect on the bas reliefs is not visible, is happy and harmonious.

No less appropriate is the material. Setting aside a sort of throb of national pride which the idea whence that material came may awaken, the thought how fully captured cannon may be employed in founding a monument to the captor, nothing is so well suited to our variable climate, and especially to the sulphur-laden atmosphere of London. Marble cannot co-exist with coal smoke. Stone, if we except polished granite, appears a poor material for sculpture, until time has invested it with an archaeological interest. For durability, for plastic obedience to the artist, for the effect of colour under cloudy skies, and for facility in being cleaned without great damage, no substance is equal to bronze. None, unless it be the very purest marble, is so noble a material for sculpture. The finest sculptures in the world are bronze. The *Tired Mercury* in the Museo Borbonico, at Naples, is the very *chef d'œuvre* of classic art. Who can forget the *Horses of the Sun* at Naples and at Trini? Very few marble statues of Venus can compare with a bronze copy of the *Venus di Medici*, that is, or was, in the possession of Lord Clarendon. A recent triumph in bronze is the grand gorgeous head by the Countess Castiglioni, now at Kensington. When time and exposure have dealt somewhat with the Nelson lions, they will take no ignoble position among works in this royal material.

One person only, it seems to us, can feel aggrieved at the completion of the Nelson Monument. The owner of Northumberland House can hardly look on with satisfaction, and see his own glories dimmed. The Percy crest, which, falling to the spindle, has become the bearing of the heirs of Sir Hugh Smithson, was, as displayed over the gateway of the ducal residence, one of the marvels of London. Our country cousins always paid it a visit. It is now shrunken to the size of a lap-dog beside its bigger brothers. Is it not consistent with historic truth that such should be the case? What were the chiefs and heroes of Border warfare,—the defenders of Alnwick or of Berwick,—the gallant knights of Lancasterian struggles for the diadem of England?—or rather, what were those intestine feuds themselves when compared to the mighty struggle in which England fought for very life,—fought at one time almost single-handed with the world? Yet in our earlier records we can see what was the stuff out of which English soldiers and sailors have been born. A high place in the educational lore of our fathers must be assigned to the ballad of Chevy Chase. The Percy lion should recall the honoured name of Widdrington no less than that of Hotspur; and all who feel proud of the history or of the hopes of England, who rightly trace how the present has grown out of the past, and how it points to the future, will rejoice that, though not completed until more than sixty years after his glorious death, a monument, in the finest site in the city of Westminster, should record the undying fame, and represent the simple and manly features of the great captain who so well sustained the honour of our flag, and who fell in the arms of Victory at "fatal Trafalgar."

THE DESIGNS FOR THE NEW NATIONAL GALLERY.*

Our detailed description of these designs approaches a termination. We arrive at the drawings of Messrs. Banks & Barry. On consideration of the question of the retention of the present building, or in connexion with the construction of new galleries in the rear, Messrs. Banks & Barry came to the conclusion that this was "practically impossible with due reference to public convenience and architectural propriety." They say that a new *façade*, long "demanded by the public taste," would be imperative on the "erection of more lofty buildings" on the side of St. Martin's-place and Hemming's-row; that the principal floor-level of the present galleries, 27 ft. above the Square, is "inconveniently high as a general level for a new building" (the italics are theirs), "and would be unnecessarily so in reference to the street-levels in St. Martin's-place and Castle-street," where the ground is higher than on the south; and that the present rooms are too large for cabinet-pictures, and too small for principal galleries,—especially when in connexion with galleries of 50 ft. in width and proportionate height; whilst that the expense of attempting to throw together and convert the galleries, added to that of the new *façade*, would go far towards the cost of a new structure entire, and be less satisfactory when done. They therefore suggest that the present structure should be retained only until galleries behind it are ready, and that, finally, new buildings next the Square should be erected. Nevertheless, they show in a design, "No. 1," a mode of connexion that would only entail the expense of two staircases and their accompaniments.

From all the considerations, they have, they say, preferred, in fact, only one complete design, "No. 2." It comprises not only the site of the present building and the north-eastern ground, but the site of the barracks and barrack-yard. A new street is contemplated on the west, precisely as in designs by Mr. Murray and Mr. E. M. Barry. Between these competitors and Messrs. Banks & Barry, there is also this agreement, that their designs would, none of them, alter the terrace and steps of the Square.

The principle of arrangement adopted in the plan of Messrs. Banks & Barry, is that of a large central area appropriated to all the galleries requiring top-light only,—and wherein as much plain unbroken wall as possible could be provided for pictures,—and of an outer circuit of buildings, of two or three stories, with highly decorated external fronts, and having on the upper floor, ranges of side-lighted rooms of moderate dimensions, which could be conveniently devoted to special collections such as those given to the nation, as in the case of the Sheepshanks collection, the Turner collection, and the Gibson sculptures. The lower floors would be for the official and residential accommodation. "Thus," they say, "the effect of huge buildings and plain walls, which would be painfully out of scale with all surrounding buildings and objects, is sought to be avoided." Excepting as to the northern range of building which follows the line of Hemming's-row, and excepting at the eastern end of the ground,—where the semicircle is adopted as the form on plan, for a side-lighted gallery,—all the galleries are parallel or at right angles with the line of the principal front. The Turner gallery would be to the east, on the line of diameter of the semicircular gallery, and inclosing, with the latter, a court. We are speaking of the principal floor. Just westward of the Turner gallery, and like it at right angles with the front, is one of the 50-ft. galleries,—separated only, at its end, from the main building, by a breadth of open court. On the transverse axis of the plan, or opposite the principal entrance, is another 50-ft. gallery. Each of these same transverse lines has upon it, northwards, or at the end of the 50-ft. gallery, a room of square form; moreover on the transverse axis, northwards, is a staircase and entrance next Hemming's-row. Between the two square rooms, there runs another gallery of 50-ft. width. Thus, omitting mention of a clear space that there is along the entire length of the back of the building of the Trafalgar-square front, the 50-ft. galleries may be said to inclose again a quadrangular space. This latter is divided by a line of galleries that are 35 ft. in width, and are at right angles with the line of the front. Between this central line and the lines of the 50-ft. galleries, but at right angles

with them, and parallel with the front, are on each side, three 20-ft. galleries,—leaving courts, of 15 ft. in width, or at one end more. The moderate sizes of the courts, and their distances from one another, have of course been settled with reference to the idea of appropriating the ground-story to other than exhibition-purposes. The large galleries and the small ones have the same floor-level; and both are lighted from above. In the proportions of skylight to width and height of room, and in their positions of skylight with reference to walls for pictures, they are similar to the galleries of the Exhibition Building of 1852. The principal staircase, in the middle of the front-range of building, has a central straight flight of steps, broken by landings, opposite the entrance; whilst on the second story, at the sides parallel with the line of ascent, are loggias. Each division of this staircase-hall is domed over, and lighted through the vaniting. The architects claim to have given much attention to ensuring easy access and circulation for visitors. In decorative character of details, the building would be a reproduction of the Venetian type of classical Italian architecture, or, we might say, of the manner of Sansovino, and that of Inigo Jones, welded together. The chief *art* of the design is in the massing of parts. A projecting centre is flanked by square pavilions rising higher; and at each angle of the building, there are two smaller pavilions, or one to each front, separated by a quadrant on plan. Each pavilion is terminated by a belvedere-story; to which, in the case of the two pavilions of each corner of the building, there are dome-cappings crowning the angles. On the pavilions of the centre-block there are domes of larger dimensions. In general features of the pavilions, the design bears resemblance to Highchere House, one of Sir Charles Barry's works,—though that building is rather Jacobean than Venetian Italian. Otherwise there is a resemblance to the character of Messrs. Banks

& Barry's design for the Foreign Office. There are three stories in the fronts. Superimposed orders, rustication to the ground-story, and ornamentation in the third story, with perfectly studied details, may be said to constitute the decoration of the exterior; which has but two faults,—the one not being as distinctively different as a building for exhibition of pictures might be, or should be, from other buildings, whether public offices, or palatial residences,—the other the fault of being deficient in the slight amount of novelty that is indispensable for art. Messrs. Banks & Barry, in making their design, felt the difficulty of observing, or understanding, the instructions as to preservation of the view of St. Martin's Church; and they offer an alternative plan, according to which their design would have the coupled towers at each end of their *façade* grouped on one plane. This design they think would be more effective than the other, as also that the National Gallery should be first considered, rather than the church. We would merely express hope that under no circumstances will the present effect of the portico be interfered with. To say that the choice is between injuring the one building or the other, is surely an erroneous statement of the position: there would be ground enough, for present needs, even after giving up a great deal in front and eastward. From our previous notices it will have appeared that the whole ground, inclusive of the site of the barracks would provide for more works of art than the nation is likely to possess,—at least exclusive of sculpture. The apprehension under which architects are, as to setting-back frontages and losing ground, has its reasons: but it becomes an evil,—architectural effect alone considered.

Messrs. Banks & Barry have made a full statement of the space that each of their designs would provide, both for pictures, and on the floors of the galleries; we give it as it stands:—

	Lineal feet in the right line.	Superficial feet of wall.	Superficial feet of floor.	Assumed available height for hanging pictures.
ACCORDING TO DESIGN NO. 1.—				
In the main galleries on principal floor	1,270	31,364	21,866	26 feet.
In cabinet galleries adjoining same	576	8,164	4,600	13 "
In Turner gallery and room for Turner drawings ..	183	3,720	4,450	20 "
In special galleries and rooms on upper floor	561	10,638	6,087	18 "
In the existing building when the rooms occupied by the Royal Academy are given up	1,800	34,400	19,100	16 "
The present accommodation for the National Gallery in Trafalgar-square	4,523	83,186	66,378	
Additional accommodation provided	950	16,200	9,550	
	3,673	71,666	46,753	
ACCORDING TO DESIGN NO. 2.—				
In new main galleries on principal floor	2,140	53,032	36,916	26 feet.
In cabinet galleries adjoining same	702	9,722	6,412	14 "
In Turner gallery and room for Turner drawings ..	186	3,720	4,450	20 "
In special galleries and rooms on the upper floor...	1,289	23,262	14,703	18 "
The present accommodation is as above	4,317	89,656	62,491	
Additional accommodation provided	950	16,200	9,550	
	3,367	73,456	52,941	

The estimate for "Design No. 2" would appear to be non-inclusive of the extension over the site of the barracks and barrack-yard; for, they say they would suggest that on the occasion of such extension, several of the halls, galleries, and rooms then to be erected should be appropriated on a liberal scale to sculpture. The "extension would also then provide additional space for paintings," or for about,—

2,300 feet lineal on the right line,
47,338 feet superficial of wall-space,
25,816 " " of floor-area.

They estimate that their design "No. 1" would cost about 283,650*l.*, and their "No. 2" about 449,200*l.*

The designs of Mr. G. Somers Clarke are two in number; but neither of them takes any account of the existing building. They are marked respectively "A" and "B." As to one of the problems submitted to the competitors,—that involving retention of the present structure or parts of it,—Mr. Clarke felt that he could not furnish drawings that would assist the Commissioners: thus he has "refrained purposely from any positive action on this head." In giving his reasons for avoiding any "patchwork modification," as by additional galleries, he alludes to "hald and meagre character of the present *façade*" (which "no professional tinkering could

successfully remedy"), and to the contracted height and width of the structure.

Each of his designs takes in the whole ground, inclusive of the site of the barracks; but he has not suggested any new street. In the general arrangement, the two designs have such features in common as would, he says, "render the adoption of either of the exterior elevations one of selection only." The plans are prepared with the object of providing for a great variety of works of art, and others, for exhibition. Besides providing for the pictures and drawings at present in Trafalgar-square, and for the Sheepshanks and Vernon collections which are at South Kensington, and for the National Portrait Gallery besides, he further proposes (and this he says is "the key" of his "scheme throughout") to "utilize the lower floors under the main galleries, having lateral lights only," as well as a "central sculpture-hall, which has both lateral and top lights," for "reception of the whole of the ancient sculpture and antiquities now very inadequately accommodated at the British Museum." His building, as shown in his "Design A" which is Venetian Gothic (the other design being sixteenth or seventeenth century Italian), would consist of three floors, namely a valued lower story, of 17 ft. 6 in. in the clear height; a second story, of 27 ft.; and the gal-

* See pp. 23, 40, 56, & 79, ante.

ry or principal floor, of 50 ft. to the horizontal light of the lanterns. In the height of 50 ft. further, there are two stories next the front. The mission of windows at the top of the building, in the case of this design, has not been compensated for by anything supplied. Such compensation we of course did not mean to say, when noticing Mr. Owen Jones's opinions, was of no importance. Mr. Clarke shows a mass of wall, of very unlike what there is in the front of the Doge's Palace at Venice. This defective manner is very striking in his elevation for the front towards St. Martin's-street. Surely those who copy should at least select. There is plenty of evidence of art-power in Mr. Clarke's work, though this is not in his details, or in the grandiosity of one or both of his projects. Is it, for example, desirable to have to ascend some eighty steps to a principal floor, when the height involves inconvenience additional to that of the secret,—in this case, one of deteriorated light to lower rooms? Mr. Clarke's lower galleries in the front range of building, as may have been understood, are lighted entirely from the courts.

The entire plan consists of buildings that surround four courts, and of a projection jutting out eastward at the north-east angle, as well as of a similar projection westward, next St. Martin's-street. In other words, there are three longitudinal ranges of building,—of which one is the principal front, another follows the line of Hemming's-row, and another is intermediate; and there are three principal transverse ranges. Of these the most important, architecturally, is the central transverse line, which is almost entirely appropriated to the sculpture-hall. The remainder of the plan, on the principal or top floor, comprises galleries; which are chiefly of the 50 ft. width; but the eastward projection contains the residence, and a large hall and staircase. Here there is a very lofty square tower, which, at first, from its position, recalls the clock-tower of the Palace at Westminster. But on examination, the details are seen to be entirely different: the straight sides and the decoration of the summit, indeed, are formed on Italian Gothic models. Besides this end-tower, there is a large dome in the middle of the front-range of building: within and beneath this is a domical ceiling, which covers a square hall that forms the vestibule to the sculpture-gallery, and staircases that are right and left of the hall. The sculpture-gallery, 225 ft. by 85 ft., without the recesses, and 105 ft. in height, is carried up for the height of three stories. The length is divided into three parts by semicircular arches across, and at the ends, and by side-arches. The niches of these arches are filled in with pendentives; and the arches and pendentives carry three domes; each of which has an "eye" at the top, for light. The three halls on each side of the hall are filled in with a halustrated gallery of communication on the level of the first-floor. This gallery is carried by pointed arches of the Italian Gothic character, which spring from columns. The spandrels of these arches are charged with sculpture of Gothic character; and above the lower portion of each domical vault there are figure-subjects, which seem intended to be sculptured also. The tympana of the end-arches, and perhaps those of the niches at the sides, would be painted in fresco. The soffits of the arches themselves are decorated with ornament of Byzantine character. It would be quite ineffective in execution. Indeed there is a general flatness in the whole decoration: though the main forms are so good, that detail that would wholly destroy effect of such a hall would have to be very bad. The building is entered in the principal front by two long flights of steps, exposed to the weather. The line of ascent of each is parallel with that of the front, and leads into a loggia which forms the lower part of the central mass of the front. This centre projects from the general line, as will have been understood; and it has six arches in front, in this upper story, with statues in them, and six openings to a loggia that is above. To these latter openings there are balconies, projecting on cantilevers. To the central mass there are angle-turrets. The openings of the lower story are continued to a loggia along the general front: those of the upper story are continued as windows, to light a narrow gallery,—one of two, on different levels, that have been already alluded to. At the ends of the front are square towers, with large windows wherein the stepped formation of staircases, that are within the tower, appears in square panelled-forms that are built in with the mullions or shafts. Only two stories of openings appear in the recessed portions of the front, or

general line,—the lowest story, excepting that there are ways through it to the courts, being blank-wall externally: the centre and ends rise higher than the general line; and the turrets are finished by elaborately-decorated pyramidal cappings. The square mass on which the dome is carried has angle-turrets. An alternative to the external dome is shown, in the form of a conical roof rising from a wall that is crowned by gables; and it is terminated by a lantern and spire-capping. The lowest floor, which is partly below ground in front, though wholly above next the courts, would be appropriated for storage, and various other purposes, and, where light from the courts would suffice, to the exhibition of the heavy sculptures and antiquities from the Museum. Next the courts, both in this story and the story above, the largest area of window-opening that could be formed and constructed, is provided. The competitor says that, similarly, openings might be introduced opposite; but he also says that "such features though diminishing the amount of dark storage, and increasing the quantity of exhibition-space, would greatly deteriorate in an æsthetic point of view from the monumental character of the building, one that I have endeavored in both designs to achieve." We must observe, once for all, that we have no faith in this sort of reasoning. We do not think, indeed, that fine-art character is to be obtained by mere provision for use: we rather urge consideration of the former, from the first starting with the arrangement of plan, and a movement *pari passu* in the direction of both ends. But we do not allow that the æsthetic expression of a building can be served whilst there is a diminution of convenience: such diminution is productive of dissatisfaction that checks any pleasurable emotion from the art-element, and is moreover opposed to the manifestation of the special art: it is under any point of view unnecessary; and it allows to be lost what are real opportunities of bringing forth new forms and phases of effect.

" 'Tis use alone that sanctifies expense,
" And splendour borrows all her rays from sense."

On the floor above, or second story of the building, the galleries between the courts would be lighted on both sides; and those of the front building would be lighted on one side from the court, and on the other from the arcade. The arrangement would allow of no wall-space; so that the sculpture or drawings would be placed on screens which would connect the narrow piers, between the windows, with two ranges of columns that there would be for the support of the flooring above, and dividing the hearing into three spans. The columns would be made ornamental. On the principal floor, besides the wider galleries (of 50 ft., and 45 ft. in width, with one gallery of 37 ft.), there would be within the 50 ft. height of one gallery, the two stories of galleries of 15 ft. wide, the lower of the two side-lighted from the front by windows, and the upper one top-lighted. Mr. Clarke gives a lengthy description of the internal finishings and decoration of his projected building; and he puts forth certain arguments in favour of his choice of a style, winding up with,— "In short, in my humble judgment, no style admits of such freedom from conventional trammels as the one I have adopted in this design;"—to wit, the Venetian Gothic.

In Mr. Clarke's other design "B" the plan is varied as to the extent of accommodation, which is considerably less than that of "Design A." The central line of galleries parallel with the front is omitted. On the level of the principal floor, the lower, or side-lighted, narrow galleries are omitted, and open loggias take their place. Thus there are loggias on two stories in this design. Above them there is a third story in the decorative treatment. Each story has a range of arches, and columns on the piers,—the top-story having the arches filled in with walling, wherein there are, we think, niches in place of windows. The central feature has considerably more importance in this design than in the other: the square mass, with angle-turrets, carries a second stage, set in, of the same form on plan, and also terminated by angle-turrets; and upon this is a dome. There is considerable merit in some of the details of this part of the design; but the whole feature of the centre is too gigantic and costly for even a National Gallery. The *raison d'être* of such a feature is not like what there would be for some kind of elevated termination in the case of a church; and the identity between the dome here, and the *requisite* covering to a hall or rotunda, is not quite satisfactorily made out.

Mr. Clarke sets forth the amount of space that he provides in his principal design "A," thus:—

	Floor-space.		Wall and Screen Space.	
	Sup. Feet.	Sup. Feet.
Ground-floor	37,200	23,050
First floor.....	30,815	37,000
Principal floor.....	73,850	119,670
Upper gallery, over loggia, south front	4,050	(wall-space) 5,820
Totals.....	136,005	186,140

In the "Design B" the areas would be as under:—

	Floor-space.		Wall and Screen Space.	
	Sup. Feet.	Sup. Feet.
Ground-floor	44,038	18,745
First floor.....	67,275	29,820
Principal floor.....	61,175	84,900
Totals.....	162,488	132,465

The cost of "Design A" he estimates at 779,000*l.*, and that of "Design B" at 788,000*l.*

Mr. Penrose's drawings have received a considerable share of the ridicule that has been so freely indulged in by those who had not the qualifications or the patience for appreciating designs of the different competitors. Such treatment Mr. Penrose seems to have got for himself, chiefly because one feature of his principal design is a circular court. One of his perspective-views however is too obviously unfinished, to escape notice of those who look at drawings without realizing what these show; and another of his views might have been better appreciated had the large dog in the foreground been omitted. Looking, however, into the principal design, we find more than a first impression from the drawings might convey. Mr. Penrose shows in his drawings, and refers in his report, to what are called *two* designs; but in both of these, the entire removal of the present building is contemplated, at least ultimately. The buildings for the north-eastern ground are the same in both cases; and no attempt is made to "harmonize" this part of the design "in respect of style with the existing buildings." But levels and communications have been "studied so that the new galleries might be used in combination with the old until the time should arrive for completing the design."

Confining attention to the "Second Design:" the buildings on the new site are arranged "round an oval but nearly circular court," of which the larger diameter is 160 ft., and the shorter 150 ft. This court would be accessible for carriages; and Mr. Penrose suggests that there might be there a garden, with a fountain, or with groups of sculpture,—a statue of the Queen being made the central object. The principal story of this court is arranged with loggia; of which each recess is covered by an elliptical arch, springing from horizontal architraves, or lintels, that are carried in front each by a column, and at the other end of the lintel, by the rear-wall. The circuit of these loggias is broken by a staircase-block, wherein the ends of the steps are expressed decoratively. In his line of front, Mr. Penrose, alone of the competitors, has thought fit to advance the south-west angle of the building up to the line of the fronts of the houses in Pall-Mall East, whilst keeping the south-eastern angle much as that of the present building is. This, he says, whilst making use of a considerable space of ground now unoccupied, is "calculated to impart more dignity to the façade." In his ground-plan he provides a museum, to be entered from the circular court, under an open arcade occupying three arches of the periphery. Two other arcades, symmetrically placed, form the carriage entrance and exit,—the former from St. Martin's-place, and the latter to Hemming's-row. The principal entrance to the galleries of the upper story is recessed in the centre of the Trafalgar-square front, and is reached by external winding-steps. The doorway, in this upper story, leads into an octagonal hall; which has two ranges of arches, and is surmounted by a dome of the same form on plan. The gallery over the lower range of arches is accessible by a special staircase, or from the repairing-room. The octagonal hall has doors leading to the galleries in three directions. The decorative character of the design is that of late, but not "debased," Italian. With much that is not inconsistent with the purpose of the building, and with even considerable beauty and suggestiveness in many of the details, there is however a lack of monumental character, and some room for revision of details themselves, as where there are busts on brackets.

We have now noticed the whole of the designs. There are reports of an intended fresh competition, of the unlimited kind; but there is no reason to believe that this course would be more likely to procure the right kind of design than the appointment of some one of the present competitors. Objection may fairly be made to every one of the designs; but there are men amongst the ten competitors who can do much better than they have here done. Each of the competitors seems to require to further study his subject; and for this, the collection of designs now being exhibited, or about to be re-exhibited, affords the best opportunity. Such an exhibition should be largely used, not only by the architects who are competitors, but by the rest of the profession, and by the public. That there are a right way and a wrong way, however, of looking at architectural drawings, requires to be apprehended; as this fact is not at all recognized at present.

THE ART-WORKMANSHIP COMPETITION, SOCIETY OF ARTS.

At the meeting of Competing Art-Workmen on the 30th ult., Sir Thomas Phillips, chairman of the council, presided. A report from the judges, and the list of rewarded candidates, which we published last week, were read. The report said,—

"The most marked progress is shown in the class of hand-wrought metal work, more especially in iron. To two art-workmen in this class—Mr. G. Page, of Clerkenwell, and Mr. W. Letherey, of Cheltenham—we have without hesitation awarded your prizes of 10*l.* each; to the former for a reproduction of the celebrated Martelli bronze mirror case, in sheet iron, *repoussé*; and to the latter for an excellent panel for a screen, a specimen emanating from the fine old smith's work of the fifteenth century. To the former we would also recommend should be given the special prize known as 'the North London Exhibition Prize,' he having produced the object which we consider masterpiece in the highest class the most skilled workmanship in the whole display. In Mr. Page's case we reward not only excellence but novelty, since we have not heretofore observed any such indication of power on the part of an English art-workman to compete with what has been hitherto almost exclusively produced in this most difficult branch of industry in France and Spain."

The secretary read a letter from Mr. Digby Wyatt, expressing his great regret that he was prevented by illness from attending the meeting that evening. A letter from three workmen was also read, stating that the piece of *repoussé* work in iron (No. 15), produced by Mr. Page, to whom the first prize had been awarded, was "not embossed from the flat, but struck in a cast die obtained from the plaster cast issued by the Society." The secretary said he had thought it right to make inquiry into the matter, and had been informed by Mr. Page that this was not the case.

After some conversation,—

Mr. Page begged to state that the parties by whom the exception had been taken were under a false impression in supposing that the work had been struck from a die; and he had no objection to let two or three of his fellow-workmen the plan on which he proceeded. In the first instance, he soldered the plate upon a piece of block tin. Having explained what he considered the advantages of this plan, Mr. Page said that, as to the work having been struck in an iron die, those who entertained that idea could have little conception of the cost of producing such a die; and it must be further considered that to strike iron into such a die would be an extremely difficult task.

It was ultimately arranged that the judges should hear the objections on the one side, and Mr. Page's explanation on the other, and decide whether, under the conditions of the competition, he was entitled to the prize or not.

The prizemen who were present having come forward, by invitation,—

The Chairman said it was gratifying to find that the appeal made by the Society had received so satisfactory a response. It appeared to him that the competitors generally, and especially those who had been successful in obtaining prizes, had creditably maintained the high character of their own class by the works they had produced,—works which, although in most cases they were merely reproductions of splendid examples of the taste and skill of former times, were, he might venture to say, scarcely inferior to them in excellence. It was certainly most gratifying to the Society of Arts, which had now for several years endeavoured to stimulate the art-workmen of England, to find that they had among them men whose taste, knowledge of colour and of form, and skill in execution, had

enabled them to produce works which had called forth the approbation of such distinguished artists as the judges in this competition. He trusted that those who now, it might be for the first time, had thus distinguished themselves, would have frequent opportunities, on future occasions, of showing their fellow-countrymen that they were resolved, as far as in them lay, that England should not be behind the rest of the world in works of industrial art. He begged to offer them his cordial congratulations, and he hoped to see them again in the same honourable position in future years. He trusted they would feel, at all events, that the Society warmly sympathised with them in the struggles they must necessarily make in endeavouring to maintain and improve the position they had acquired. He would now invite the art-workmen present to intimate to the meeting any views they might have formed as to the competition which the Society had instituted. The council desired to know whether it seemed to them that any alteration in the arrangements would contribute more effectually to the objects in view in these competitions.

Mr. Ashe desired to make the following suggestions:—That in all cases the judges should have the original article placed before them at the time of awarding the prizes, as well as the copies sent in for competition; that the copy should be made in the same material as the original, or if the material is to differ from the original, that such change should be made in the following year or years; for instance, should the material be of iron, then the copy in the first year might be of iron, in the second of brass, &c.; that no specimens sent in shall be either painted, bronzed, or have any artificial coating, except transparent lacquer; that, where it is possible, the model selected be placed in the society's rooms, or in some other accessible place; with regard to the photographs published for the use of competitors, that the background should be so arranged as not to in any way confuse the outline of the object.

Mr. Holliday, Mr. Campin, and Mr. Nichols having made other suggestions,

Mr. W. Hawes said the great object which the Society had in view in establishing this competition was to bring out the individuality of the English art-workman, and thus give him a greater incentive to improvement. In foreign countries a workman had opportunities of obtaining a personal reputation which enabled him to dispose of his services at a much more valuable rate than when his name and talents were only known within the limits of the shop where he worked, and his productions were only distinguished as those of the firm who employed him. The Society was therefore anxious, without wishing in any way to disturb the community of interest which ought to exist between masters and their workmen, if possible to stimulate the workman to strive after that excellence the attainment of which would be equally beneficial to himself and to his master. The difficulties were considerable in the first instance. They had first to find out the means of making the great body of workmen in the country acquainted with the intentions of the Society. They had then to overcome many prejudices; and besides this it happened that during the last three or four years almost every art-workman was so fully employed that but little time was left him to enter into such a competition. Indeed, on the last occasion the number of works sent in was less than in the previous year, and the number of prizes awarded was less. Considerable discussion took place as to the cause of this decrease, and the impression the Council received at the time was that the conditions required some relaxation. This was done, and in the present instance they had not only given examples to be copied, but had allowed the men to send works produced from their own or other designs. The result was that they had on the present occasion a number of works made from designs other than those prescribed by the Council, and he thought it was in a great measure to that they owed the increase in the number of works sent in, which was nearly double that on the last occasion; the number of prizes awarded being also considerably greater. He could not but feel that a society like this, established for the encouragement of arts and manufactures, was undertaking a duty which was specially incumbent upon it, in endeavouring thus to benefit, not only the working men themselves, but art-workmanship generally, in this country; and if they were doing that, there could be little doubt that they were promoting the best inter-

ests of the country at large. The works before them certainly proved that the prizes offered had stimulated men to exertion in their spare time, and had resulted in the production of a number of very beautiful works, which had called forth the warm commendation of the two gentlemen who had acted as adjudicators—than whom none were more competent for the task. He could not help hoping that in a few years this branch of the Society's operations would progress as much as its educational examinations had done, in which, from a beginning of about fifty candidates, they had now nearly 1,200. In like manner they might expect a similar increase in the number of competitors for their art-workmanship prizes. He would say a word or two with reference to the objection which had been raised against the work sent in by Mr. Page. He had distinctly told them that his work was not struck in a die, and had explained to them how he had contrived to execute it. It had, however, been suggested by a preceding speaker that nothing ought to be admitted for competition but what was done in the old-fashioned way. *Repoussé* work, they knew, was produced in a particular way, and it was argued that no specimen ought to be entitled to a prize unless it was produced in the manner in which all *repoussé* work had hitherto been produced. He thought if they imposed a limitation of that kind they would be acting in direct opposition to everything they proposed to accomplish by these prizes. They not only wished to reward the workman who had the greatest mechanical and technical skill, but also to encourage the adaptation of any improved appliances which his ingenuity might suggest for producing the required results. It had been more than once suggested that these prizes ought not to be adjudged by one or two gentlemen selected by the council, but that there should also be a jury composed of workmen and employers of labour. This, he thought, would certainly produce much delay, and would not work satisfactorily. They had had, on this occasion, two highly educated men—one much engaged personally amongst workmen, and well known as possessing special knowledge of such works; the other a gentleman whose artistic taste was of wide renown, and he thought they had thus the greatest possible security that the prizes were properly awarded, and with the most perfect good faith to the society and towards the workmen themselves.

Mr. Godwin, as a member of the committee for the selection of the examples for reproduction, was happy to be able to coincide in the opinions expressed as to the superiority of the collection of articles this year above those of previous years; still it must be remembered that not half the sum offered by the Society had been claimed; and it was to be hoped that in future years there would be a more extensive response to the munificent offers made. With regard to the piece of *repoussé* work to which reference had been made, he would state that when the design was selected by the committee they were fully aware of the great difficulty of the task, and if that by Mr. Page were a genuine piece of *repoussé* work, he accorded the greatest praise to it. At the same time he claimed that it should be found to be true *repoussé*, for he could not go with Mr. Hawes in saying that the mode of production was comparatively unimportant. For instance, by means of the electrotype a *fac-simile* might be produced without that manual skill which was required in the production of *repoussé* work. He quite accepted Mr. Page's assertion that it was a genuine work, but he felt obliged to make this observation in reference to the remarks of Mr. Hawes.* Touching the bronzes on the table, there was one figure exhibited of especial interest to him—that of Caractacus, produced for the Art-Union of London—because it reminded him that twenty-four years ago, when the Art-Union decided on producing artistic bronzes, and when Mr. Woodington executed for them a reduced copy of Sir R. Westmacott's "Nymph and Child," there were scarcely works in London in which such bronzes could be made; and so great was the difficulty in getting the castings that the artist himself erected works to produce them. They went on, however, year after year, and the late Prince Consort was so struck with the efforts that were then being made by the Art-Union in this direction, that he requested to have, and did have, at his own cost, an example of each bronze that had been produced.

* Mr. Page has since completely satisfied the judges and his fellow-craftsmen as to his right to the premium.

He might point to the bronze before him as being equal to anything of the sort that could be done abroad: it was a work well entitled to the praise that had been bestowed upon it. The hammered ironwork of Mr. Lotherton was also exceedingly good: as was also some of the brass work. Touching the glass exhibited by Dr. Salvati, all would be glad to see the ancient mode of making glass in Venice revived. At the same time he would enter a protest against regarding every form, because it was copied from old Venetian glass, as beautiful. He confessed he thought the specimen before them was essentially inappropriate in form. No doubt it presented great difficulties in the manufacture; but he thought Dr. Salvati could have exhibited others of greater beauty. In reviving the art of making Venetian glass, it was important that the models should be well chosen. In conclusion, he would express a hope that the art of drawing would form a part of every artisan's education to a greater extent than had been the case hitherto. He would like to see it made a part of the education of every artisan's child, from the conviction he entertained that the greatest advantages would result from it in after-life.

The Chairman, in concluding the proceedings, said he had to announce what he was sure it would be agreeable to the meeting to hear, viz., that another of the great City companies, namely, the Goldsmiths', had promised its co-operation in the efforts of the Society to encourage art-workmen, and had given a donation of 25*l.*, a portion of which was to be applied as prizes for workers in the precious metals, and the rest in furtherance of the educational examinations. Many of these great guilds owed their distinction, in former times, to the extent to which they contributed to the extension and perfection of various manufactures; and he thought in no other mode could they better contribute towards the same object than by co-operating with the Society of Arts in stimulating and encouraging industrial art. He was happy to find that several of them had already done so. On previous occasions it had been announced that the Salters, the Clothworkers, the Plasterers', and other Companies had agreed to contribute towards this object, and he was glad to find their example had been followed by the distinguished Company to which he had just alluded.

METROPOLITAN BOARD OF WORKS.

Injurious and Offensive Trades in London.—A deputation from the Metropolitan Association of Medical Officers of Health attended the Board at its last weekly meeting to present a memorial praying that in any Bill introduced into Parliament for the amendment of the Building Act a provision should be made to ensure proper sanitary arrangements in the dwellings of the poor, and to require that all offensive and injurious businesses should be removed from London. The following points were specially urged:—

(1). Your memorialists conceive that, as a measure of public health, every street should be efficiently paved and drained before any house in it is allowed to be inhabited. (2). They desire further provision for protecting the open area adjoining to inhabited houses. They would wish absolutely to prohibit the erection of any building (even of a lean-to) upon the minimum area of ground reserved by sec. 95 of the proposed Bill, unless the special consent of your Board, or of the Local Board of Works, had been obtained to such erection. (3). They would wish to see sec. 38 of the Bill so modified as to prevent the piecemeal construction of new dwellings, with all the faults of those which they replace, an evasion of the intention of former enactments that they know to have been put in practice. (4). They have also experience to show that houses were never constructed for human habitation having been used as dwelling-houses without alteration and being very ill suited for that purpose. They would suggest that such change in the use of a building should not be made without the express consent of your Board or of the Local Board. (5). They would urge that the provisions of sec. 95 in the proposed Bill should be extended to require at least 8 ft. of height in every dwelling-room and they desire to be assured that under sec. 96 the Board proposes to take power for regulating by by-laws the size, position, and mode of construction of windows and other ventilating openings. (6). They do not observe that provision is made for placing in each dwelling-house a water-closet in the best possible situation; or for securing that the foundation of every house shall be so planned as to prevent the rise of damp. They request that provision is made which is especially desirable to direct by by-laws.

Dr. Druitt, president of the association, supported the prayer of the memorial, and it was referred for consideration to the special committee on the Building Act.

Hampstead Heath.—The Works and General Purposes Committee presented their report upon the result of the negotiations between Sir John Thwaites, the chairman of the Board, and Sir

Thomas Maryon Wilson, as to the purchase of his rights over Hampstead Heath. The report states that,—

"Sir Thomas argued that he saw no reason why he should sell his property at Hampstead for the purpose, as he alleged, of gratifying and benefiting certain parties who had for years opposed him in obtaining his rights. Upon being urged by the chairman to favour him with his views as to the value of his interest in the heath, Sir Thomas Wilson stated that, having regard to the price which he obtained for some land at Chazeton, sold by him to the South Eastern Railway Company, he was of opinion that the property on Hampstead Heath was worth from 5,000*l.* to 10,000*l.* per acre. The chairman expressed his astonishment at the amount mentioned by Sir Thomas, in which expression of opinion your committee fully concur. Your committee, whilst they cannot but express their regret at the result of the negotiations, are of opinion that it would be advisable to refer the subject back to them to watch the proceedings now pending before the Master of the Rolls, and from time to time to report the progress of the same, together with such other particulars as they may consider desirable, and they recommended that course for adoption."

Mr. Freeman said they must all, of course, regret the way in which they had been met by Sir Thomas M. Wilson; but so long as he, the lord of the manor, considered himself as the freeholder of Hampstead Heath, it would be useless to try to negotiate any further with him. He moved that the report of the committee be approved and adopted.

The motion was seconded and carried unanimously.

THE TRADES MOVEMENT.

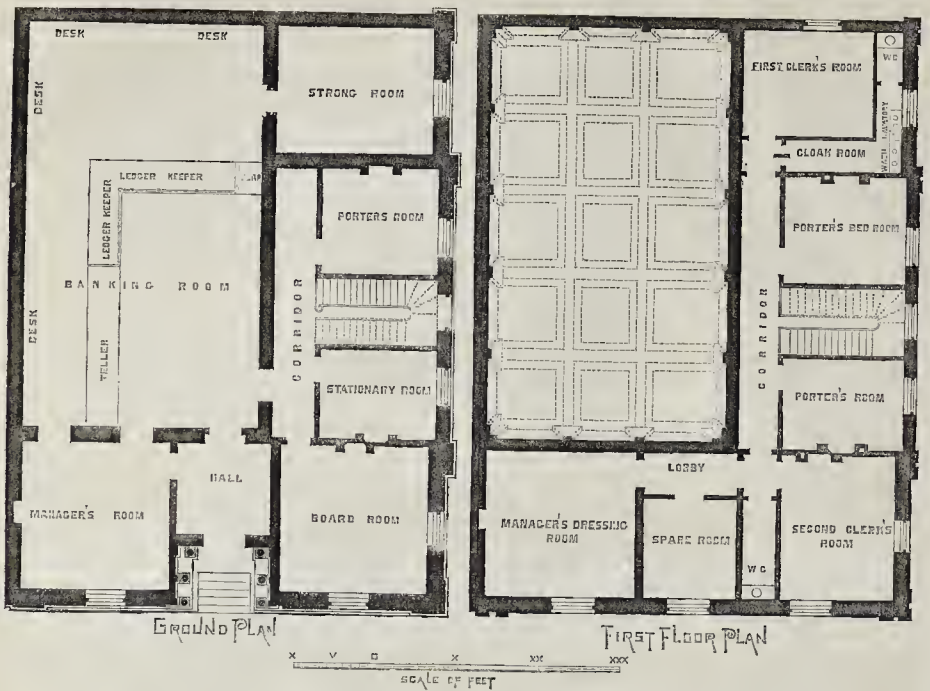

Sheffield.—A meeting of file manufacturers has taken place at the Council-hall, Sheffield, and from what transpired it appears almost certain that before long Sheffield will be visited by another disastrous strike. Two or three months ago, the file-grinders in the service of Messrs. Turtun & Co., Sheaf Works, gave notice, and left their work in a body, because Messrs. Turtun claimed the right to erect and use a file-grinding machine. The masters resolved to support Messrs. Turtun, and a general lock-out would have been resorted to, but that the trades' union permitted the machine to be used, and the grinders to resume work. During the time the grinders were out, Messrs. Turtun engaged a grinder named Jeffcock, who was unconnected with the trades' union, and had four apprentices, a number that is not sanctioned by the trade. When the men resumed work, Jeffcock was retained, Messrs. Turtun considering that it would be unjust to turn him adrift, after assisting them in their hour of need; and also, that if they deprived him of work, the union would set their faces against him, and keep him out of employment. The union applied to Messrs. Turtun to dismiss the man, and as they declined, they received notice from all the grinders that they should cease work in a fortnight. The matter was laid before the masters' association on Monday week, and it was resolved unanimously, under the exceptional circumstances of the case, to afford to Messrs. Turtun the heartiest assistance. The workmen's unions, on the other hand, are, we are told, determined to have the man Jeffcock turned out of his situation.

Braintree.—Some weeks ago a notice was given by the Society of Operative Plasterers to Mr. C. Holroyd, master plasterer, in which they warned him that, if his sons—not being partners—did not become members of the society within one week, his men would strike work, and would not return thereto till their demand was yielded, and all the expense incurred were discharged. The sons of Mr. Holroyd refused to comply with this requirement, and Mr. Holroyd's men struck work, and are at present out. The rest of the masters' strongly sympathised with Mr. Holroyd on this arbitrary proceeding, and have since made efforts, but in vain, to prevail upon the society to reconsider their decision, and to induce them to permit the men to return to Mr. Holroyd's service without exacting the conditions of their notice. The consequence is that the following employers have locked out all their men who are members of the union, viz., Messrs. Benjamin Dixon & Co., Messrs. Duckworth & Son, Mr. Hargreave, Mr. William Tattersall, Mr. Samuel Sugden, and Mr. Matthew Bell. The masters, regarding the proceeding on the part of the local society as unwarranted, are about to make an appeal to the executive of the society at Liverpool. About sixteen months since, the employers and employed agreed to a code of rules for the regulation of their conduct, signed by six masters and six operatives. One of these rules distinctly stated that no alteration should be made in the rules until twelve

months' notice had been given. At the time they were ratified the operatives gave their employers twelve months' notice of a reduction of five hours and a half per week, to take place on the 1st of May next, and about seven months ago they gave them further notice of their intention to require, also, an advance of wages from the same time at which the reduction in the hours of labour is to commence. The masters made no demur to either of these notices; indeed, the first was regarded as strictly legal. But about four months ago the employers each received, through the post, a copy of new rules which had been adopted by the Operatives' Society in violation of the rules agreed upon between the masters and the men eighteen months ago, with an intimation that, if any explanation were required they could have it on application to their committee, which sat at the Oddfellows' Hall.

Blackburn.—The journeyman plasterers have sent in a three months' notice to their employers for a reduction in the hours of labour, from fifty-five hours to forty-nine hours per week, and an advance of from 28*s.* to 30*s.* per week in wages.

York.—The half-yearly general meeting of the members of the Yorkshire Association of Master Builders has been held at the North-Eastern Hotel, York. The attendance, in consequence of the importance of the business to be transacted was large, and represented the principal building firms in all parts of the county. Mr. Archibald Neil, of Bradford (the president of the Association), occupied the chair. In the circular calling the meeting a number of recommendations of the committee were given, the first and most important of which was, "That the Yorkshire Association of Master Builders join the General Builders' Association; but that we retain our present arrangement as a Yorkshire Association." A very lengthy discussion on this point was introduced by Mr. Mauld reading the rules of the General Builders' Association. The advantage of such a junction was acknowledged on all hands, and it was urged that it was only by this that reforms which were wanted could be brought about between the masters and the men, and that architects could be persuaded to furnish and guarantee the quantities, and adopt articles of agreement. During the discussion on the amalgamation of the two societies the evils of the day system of working were pointed out, and the advantages of the hour system both to man and master descanted upon; and a variety of inconsistencies on the part of the workmen were also referred to. Of the latter it was stated that in some places bricks were not allowed to be manufactured by machinery, or stone dressed by the same means. These were fetters upon the building business which, along with others, must ultimately be broken, and with this end in view, a junction of the Yorkshire with the General Builders' Association was but the initiatory step. In fact, it was stated that, in certain places in the county (York included), notice had already been given to the workmen of the intention of the masters to adopt the hour system. Ultimately the full recommendation of the committee was carried. By further resolution the secretary of what had now become the Yorkshire branch of the General Builders' Association was instructed to give certain notices of strikes impending, and the names of men likely to be or already on strike were also requested to be furnished to him by employers. This was a step which, from the discussion, appeared to possess some importance, in order that men on strike might not migrate to other towns, and find employment from members of the Association. An important discussion next took place on the best means of adopting the hour system throughout the association. Mr. Mauld, whilst stating that the Birmingham association of masters had determined to try their strength with the men on this point, added that the General Builders' Association had deemed it unwise at present to take the initiative in such a matter. It was one, however, to which he thought it was most desirable the builders of the country should give their attention, in order that a uniform system might be adopted in this matter throughout the whole of the trade. It was ultimately resolved "that this Branch Association recommend to the General Association, at its annual meeting, the consideration of the desirability of giving a general notice for the adoption of improved trade rules, including the hour system, at as early a date as practicable." The subject of the best means to be used to induce architects to furnish and guarantee quantities, and to adopt

THE LONDON CHARTERED BANK OF AUSTRALIA, SYDNEY.

articles of agreement, was referred for consideration at the next meeting of the General Association of Builders, to be held at Bristol, and the Association was requested to bring the matter to a satisfactory settlement as early as possible. A sub-committee was then appointed for the purpose of watching over any bill or bills brought into Parliament affecting the trade, and also to consider any question not brought before that meeting.

Nottingham.—In the midst of hickering and recriminations, it is pleasant to turn to a subject such as the following:—A number of framework-knitters, who have been in the employ of Mr. Samuel Morley for many years, were lately invited to the establishment in Fletcher-gate, and after having partaken of refreshments they were addressed by Mr. Morley in a kindly manner, the substance of his observations being that he felt deeply interested in their welfare, and was desirous of promoting their happiness. Acting on these feelings, he had decided upon allowing each of them a pension of 7s. 6d. per week for life. Some forty of these aged workmen had this weekly allowance granted them, independently of their earnings, and arrangements were made for its regular payment. On a subsequent occasion, about the same number of framework-knitters, employed by the firm, but rather more favourably circumstanced, met Mr. Morley, also at the warehouse in Fletcher-gate, and after being supplied with refreshments, were addressed by him in similar terms: to each of these workmen a sum of 5*l.* was presented. The *Nottingham Express* understands that it is the intention of Mr. Morley to continue this system of kindness, the allowance being determined by age and circumstances.

Manchester.—Professor Jevons, of Manchester, has written a letter setting forth the advantages of partnerships between employers and employed. The scheme has been somewhat freely criticised, and among those who disapprove of it are Messrs. Creed & Williams. In spite of the weight of opinion, however, the Professor is confident of

the theoretical soundness and practicability of such partnerships. The working of the plan is as follows:—

"The men have advanced to them by the capitalist such ordinary wages as are sufficient to meet current expenditure. The masters receive current interest on their capital, as is done in ordinary partnership arrangements. The capital is kept intact by a sinking fund. Efficient management and labour on the part of the masters is then compensated by an additional 5 per cent. if realised; and, lastly, the zeal and care of all concerned in the works are rewarded by a fair division of all profits exceeding 10 per cent."

The scheme has been tested in the iron trade by Messrs. Fox, Head, & Co., of Middlesbrough, and in the coal trade by Messrs. Briggs. Professor Jevons holds that this arrangement, or one similar, is the only means of securing the identity of interest between masters and men, as "it contains the great vivifying principle of political economy—that reward should be in proportion to desert."

Belgium.—The *Journal de Charleroi* of Feb. 2 contains the following:—

"Yesterday morning a strike took place almost instantaneously in all the metal works of Marchienne, including the works at Couillet. This strike is attributed to a notice which was posted throughout the various establishments, and intimated that the wages of the men would be reduced by 10 per cent. from the 1st February, owing to the depressed state of the iron trade."

Telegraphic intelligence states that a violent conflict has taken place between the military and miners in the same district, who had gutted a flour-mill, and that some lives have been lost.

THE LONDON CHARTERED BANK OF AUSTRALIA, GEORGE STREET, SYDNEY.

The directors of the London Chartered Bank of Australia have recently erected a new banking-house on the site of their old premises in George-street, Sydney (illustrated by our engravings). The architect was Mr. J. F. Hilly, of Sydney. The plan of the new building includes a recessed porch for the entrance to the

bank from George-street, an entrance-hall, 18 ft. by 11 ft., with a manager's room and a board-room, 18 ft. 6 in. by 18 ft. 6 in., one on each side. The banking-room, on the left, is 50 ft. by 29 ft.; it runs the whole height of the two stories, and is lighted by a circular panelled ceiling with glass panels; over this is a second roof with sashes all round, to afford light to the panels, and also ventilation for the great room below; an arrangement of perforated beams serves this purpose. On the right of the tellers' room there is a corridor from the board-room to the strong-room (entered from the tellers' room), giving access to the porters' rooms, and a stationary-room. A private entrance in the centre of the Jamison-street front, with a staircase, leads to six rooms above, with closets, &c., and there are stairs to the roof for the porter to ascend with ease to clean the glass and attend to the ventilation. The style of the building may be called Mixed Italian. It has large arched windows with full dressings. The base course consists of very large stones, moulded; the string-courses are moulded and richly carved, with good projections. The cornice has modillions, with a carved frieze and a lofty balustrade, the piers to be surmounted with vases. The effect is sought to be obtained by mass. The tellers' room is furnished with a Corinthian entablature all round, supported by pilasters; the floor will be of marble, and the hall will be appropriately finished.

The material used is the Sydney red sandstone, an excellent and durable building stone, as we understand, from which the greater part of the city has been constructed. The bank was established in Sydney in 1852, and possesses a paid-up capital of one million, with a reserve fund of 100,000*l.* The first chairman and founder of the bank was the late eminent merchant and shipowner, Mr. Duncan Dunbar, who, upon his decease, was succeeded by Mr. Faue de Salis, also one of the founders, a gentleman long engaged in Australian commerce, and distinguished as one of the originators of steam communication with Australia.

THE LONDON CHARTERED BANK OF AUSTRALIA, SYDNEY.—MR. J. F. HULL, ARCHT.

CONDEMNATION OF THE ST.

KATHERINE'S STEAM-PACKET WHARF.

RECENTLY attention has been drawn in the pages of the *Builder* to the had condition of London wharfs. Knowing the ruinous state of some of them, we delayed to speak, hoping that steps would be taken to improve their condition. The danger to be feared at last grew so imminent that we could hesitate no longer in pronouncing an opinion,—an opinion founded on a personal inspection of the wharfs in question.

We particularly pointed out the stores and landing-stages of St. Katherine's Wharf as being in a most ruinous state, remarking that some jolting attempts were being made to stave off the danger.

The danger was so apparent that we anticipated it would not be left to exist very long. We are glad that we were right in our conjecture. Last week the wharf was visited by the Customs surveyors, and was at once condemned. Strict orders were given to land no more goods alongside, nor to use the stores in connexion with the company's steamers until the premises and landing-stages were reconstructed and put in a safe and proper condition for the shipment of goods.

We should be sorry that anything said in the *Builder* should lead to the injury of a company or an individual, or that any number of dependent working men should suffer thereby through lack of employment.

Such may now be the result, but the preservation of human life is paramount to the interests of a few, and a state of things fraught with considerable danger should not be allowed to exist from any false delicacy on the part of those whose duty it is to prevent it. We are glad to see the work of demolition as an advent to restoration is now going on at St. Katherine's Wharf. It is to be hoped that the improvement this time will be thorough, and not according to the "penny wise and pound foolish" policy. Our river architecture, if we may be allowed to use the word, should begin to exhibit a little taste. The frontages of our river warehouses offer a new field for a little fresh development.

The present appearance of the sides, except at very short intervals, is not in any way remarkably picturesque, as seen from a boat. It is, however, not too late. With a Thames Embankment above London Bridge, and the consequent river frontage that it will eventually develop, no reason should exist why improvement should be limited in extension to London Bridge.

Returning, we hope that the owners or lessees of other wharfs on the line of the river will look to the state of their holdings, and do in time what is necessary to be done, for their own credit's sake, and not from sheer public compulsion.

COMPETITIONS.

New Church, Worthing.—A church is to be erected at the east end of Worthing, and is to be of stone, with tower and spire, and to cost £5,000. The designs of Mr. Truscott submitted in competition for this church have been selected by the committee.

WESTMINSTER PALACE AND THE INTENDED PUBLIC BUILDINGS.

ADMIRAL SIR AUGUSTUS CLIFFORD, dating from the Houses of Parliament, writes to us as follows:—

We are about to erect several public buildings, namely, the Courts of Law, the Public Offices in Downing-street, and the National Gallery, and to spend large sums of money upon them, and I think it a duty to point out the defects in the one in which I am now residing,—*Westminster Palace*. Whatever may be the merit of the elevation or the beauty of the public chambers, which I do not deny, nothing can be worse than the interior arrangement of the residences. The passages and corridors are dark and gloomy; the windows a their iron frames most inconvenient; when difficult to open, and *vice versa*; and the upper diamond panes are often blown open by the wind; but above all, the ventilation,—there is scarcely a day or a week in which the rooms are not full of smoke and soot, damaging

and destroying the public furniture and the property contained in them. Instead of having built ornamental chimneys, like Burghley, Cotham, or Longleat, and many other houses in England, the smoke is attempted to be carried along a horizontal shaft to two hideous iron funnels, one over the Peers' Entrance, discreditable to those who planned and those who built them. I am sure that all I have stated would be corroborated by Lord Charles Russell, by Sir Denis le Marchant, and all who reside in the palace. It may be now too late to remedy these defects; but it will be some consolation to endeavour to prevent their being repeated.

THE PROVISION OF HEALTHY HOUSES.

MR. McCULLAGH TORRENS has given notice in the House of Commons that on Wednesday next he will bring in a Bill to make better provision for the dwellings of mechanics and labourers in large towns.

We would urge strongly that the Social Science Association and the Committee of the Society of Arts, who have jointly framed a Bill with the same end in view, should seek, rather than press their own Bill, to co-operate with Mr. Torrens, and obtain such a measure as may best meet all views.

THE HABITATIONS OF THE POOR.

AN inquest has been held by Mr. Humphreys, at the Green Gate Tavern, City-road, relative to the death of Catherine Shay, aged two years and two months.

From the evidence of the mother of the deceased, it appeared that the family, consisting at one time of the husband (a printer) and herself, with four children, occupied for some years a wretched little room at No. 10, Frederick-place, St. Luke's, the rent of which was 1s. a week. The husband and an elder daughter died there within the last two years. She was quite unable to account for the child's death. She found her dead in bed.

Mr. R. Bruce, parish surgeon, said he had constantly been busy about the people in that house. The eldest girl died under circumstances precisely similar to those of the deceased's case. He measured the room carefully, and found that it did not contain cubical space sufficient for the breathing of one adult, much less for two adults and four children. The cause of death was blood-poisoning from want of proper space in which to live. The house in question was the one in which the first case of cholera that occurred in the parish broke out. It was altogether unhealthy.

The jury returned a verdict, "That deceased was found dead from blood-poisoning, from want of proper space wherein to live."

ARTIST-LIFE.

At the meeting of the Cirencester School of Art mentioned in a recent number, Mr. J. B. Atkinson said, in the course of his observations,—I think there has seldom been a country and seldom a time in which the art student has had more to encourage him in his labour, and more promised in return for his talent and industry. What is needed is not a great work, but an honest work, downright work,—not a hasty ambition, but slow and sure steps, so that the height may be attained possibly in the end, but not too hurriedly for fear of an overthrow. And perhaps I may be allowed to speak to you of the danger which I think frequently besets art students—the danger of ambition. I think there is frequently this danger—that the student desires to be before his time an artist, and he therefore becomes rather impatient of the intermediate steps. The very fact that reward comes soon is perhaps a snare. It is a laudable ambition that a youth should desire to support himself—that he should gain an independence: and yet, I repeat, the very fact that a youth can so soon earn money is itself a difficulty in the way of future study. For this reason I hold it to be desirable that each young man should set himself this problem—to win independence, and at the same time day by day to maintain the character of an art student. It is not altogether an easy thing to do; but I believe that men who, in art and every other intellectual pursuit, have

attained to greatness, will have been met at the outset by this difficulty, and will have found means to conquer it. The best things do not immediately pay; and depend upon it, it will be better for you if, in your art studies, you seriously consider, not so much what will pay at once, as what will pay in the long run, and what your position will be ten or twenty years hence. And therefore, as I have said before, it will be well for you to combine art study with the calling of an artisan. Let the two work in harmony, and be carried on together. But I have somewhat diverged from the point to which I just now adverted—that of ambition. Ambition is laudable, but it requires to be checked and guided. Nothing is more common than false ambition—that vain and vaunting ambition; and I think that some of the most corrupt and worst periods in art have resulted from ambition ill-directed—from a vain, showy ambition; not the desire to do that which is good and great, but a desire rather to obtain the instantaneous and hollow applause of the multitude. Now, it is well that a man should make friends with his conscience,—that ambition and conscience should join hands,—that the man should feel that it is more important to do duty than to obtain applause,—and that he should try to do, however small the work may be, a *good work*—a work that will last—a work that he himself can look upon in after time, and say, "This work was honest; into this work I threw much labour; it is the result of many hours, of many days, of many weeks: it expresses the aspirations of my mind,—a desire to do something worthy of myself, and that may speak as art to the world." I will suppose, as I am bound to suppose, that you are in earnest, and wish to do something good and worthy of yourselves. I will suppose that you have the power by nature (and if you have not some power by nature it is a waste of time to devote much labour upon art),—I will suppose, I say, that you have the natural power and the industry which, under the direction of your excellent and assiduous master, will enable you to obtain a knowledge of the rudiments of art. With some expenditure of time you will master those rudiments, you will obtain accuracy of eye and precision of hand, and you will gain a knowledge of perspective, of geometry, and just those things which constitute the grammar of art. And then, having obtained these powers of expression, it will remain to be seen what thoughts are in you, what ideas you have to express. Let me just speak to you a few words of nature. Nature is the great storehouse to which you will have to go. Nature is everywhere, infinite, all around you, and your eye must be open to gather the materials: for from nature you must get all that you have to put in your pictures. Let me refer to the experiences of one or two well-known men. When I have been in Rome it has been my privilege to be acquainted with the late John Gibson; and I see among your casts one of his well-known works, a bas-relief of "The Honors." I spent one evening at his house, and I need not tell you how much interested I was in looking through a series of volumes containing pencil jottings of subjects picked up during a long life. It was his habit when walking from his studio to the *caffè*, or when in the country, to mark accurately whatever he saw. I have seen him stop as a horse passed through the street, and he would observe the points of the horse, how the rider held his seat, and he would go home and make a note of what he had seen,—not in words, for he kept his journal in lines and forms. In the same way, if he saw two children grumped, he would stop, observe the lines, notice the figures, and put down the group; and so these volumes contain the journal of a long life, and subjects too numerous for his hand ever to carry out. Let me now beg your attention while I say a few words upon the conduct of life and, perhaps, even the relation of religion to art studies. The student has need of quiet, of leisure, of meditation. Late hours, dissipation, and indulgences are absolutely destructive of the artist's life. I believe that such excesses not only lead to a waste of time and the undermining of health, but that some of the most corrupt periods in art have been allied to social dissipation. I need, for instance, only refer to the state of art before the French revolution. Art then was as rotten as the body politic. As to religion, it would, perhaps, be presumption in me here to speak of it. Of course, in the general view of art, all divisions and sects go for little or nothing. I would merely remark that almost all the great art epochs the world has known have derived

their best inspiration from religion. I may also say that there is a natural religion which will give sanctity and high purpose to art, and that the more you look at nature as Providence and the workings of an all-present God, the better will be your art developments, and the higher and purer the beauty infused into your works. And if I may speak from my own limited experience, I would say that such works as Paley's "Natural Theology" and the "Bridge-water Treatises" will give to your art studies an aspect and a direction which will make your works all the better. I think you will then, in the changing aspects of the seasons, in morning and in evening, in the twilight, in sunrise and in sunset, and in the various workings of Providence, which expresses itself in these works of nature, see that which you may presume humbly to imitate and interpret through art. I see the papers of to-day tell us of the death of the French metaphysician, Victor Cousin, whose chief work was on "The True, the Beautiful, and the Good." It would scarcely fall within our province now to indulge in such speculations, but I may remark that the theory he promulgated was that there was an indissoluble oneness between beauty, truth, and goodness, and that that is the highest work which shows that triple union. It may not fall to the lot of many of you to build a church or to paint directly a sacred picture, but the more that you can connect with the smallest humblest work a sense of duty, the higher that work will become in intention and expression, and it will then become in some sort a service to God. Pursuing art in this spirit, I think it will be delivered of much of the corruption which you cannot fall in observing throughout the course of art history. It will lose the taint of evil in some great degree, and will attain to greater purity of expression. In conclusion, I would say that if you desire to acquire what is good in art, you must make yourselves good. You must live the beauty you would seek to portray. The character of your works must necessarily be in accordance with the complexion and structure of your minds; and if you succeed in making those minds honest and good, then your art as by necessity will become praiseworthy and admirable.

ACCIDENTS.

Four men at Wolverhampton have been sent to the South Staffordshire Hospital, suffering from the effects of the giving way of some scaffolding at premises that are in course of erection at the south end of Gladstone-terrace, on the North-road; and the house-surgeon fears that two of them will not recover. The building was being put up for Mr. Baker, of Dudley-street, by Mr. Ford, builder, of the North-road, and Mr. Owen, carpenter, of Montrose-street, jointly. The scaffolding came down in consequence of the breaking of the pullock, which was of pine, 5 in. wide by 3½ in. thick, and broke at about 2 in. from the wall. Upon examination it was found that it had fractured at a knot, which ran diagonally through nearly the whole width of the beam. The scaffolding was put up chiefly by the injured workmen.

At Cirencester an accident has occurred at extensive bacon-curing buildings, which are being erected at Pit-acre, reducing a considerable portion of the structure to a state of ruin. The frost having penetrated the new material, two of the arches in the cellar collapsed, and a large wall above soon after gave way, doing damage to the amount of 300l. or 400l. The supports of the arches were removed a short time before the accident. Fortunately the men had left work before the casualty occurred. Some of the walls left standing are in a very shaky and unsafe condition, and will probably have to be pulled down and re-built.

At Bristol a workman has fallen from a scaffolding while working at some houses in course of erection in Penhocke-road. The fall was 10 ft., and the man fractured his thigh, and received other injuries.

A shocking accident has occurred in one of the tunnels on the deviation line of the Cambrian Railway, between Glandorv and Aberdovey. The tunnel is on the line to Aberdovey, and is about 700 yards in length. For some time past men have been employed in carrying out certain alterations, in accordance with the directions of the Government inspector of railways. About the centre of the tunnel there is a disused shaft, which had been formed for the

purpose of drawing up materials, and on the completion of the tunnel, this shaft was filled up and arched over. A short time since this arch was observed to have given way about 15 inches, and orders were issued that the arch should be taken down and a stronger one erected. The men, ten in number, had not been at work for more than a quarter of an hour when the props which had been supporting the shaft gave way, and a mass of material, estimated at about 100 tons, fell, burying the two men and injuring several of the others.

LIVERPOOL INSTITUTION OF ENGINEERS.

This association, which was founded in October last, has issued its rules, and is getting into work. The objects of the Institution are the reading of papers and the interchange of ideas on engineering, and kindred scientific subjects. The Institution will consist of members and associates. Members must be mechanical, civil, mining engineers, or shipbuilders. Associates shall be such persons as are not eligible as members, but who are engaged or interested in scientific pursuits. Mr. Donald Pope is the honorary secretary.

THE STABILITY OF DOMES.

AMONG the papers read at the Royal Society in the course of the past year, were two that had a direct bearing upon the science of architecture. Mr. E. W. Tarn, M.A., was the author of the papers alluded to, which treat of the strength of various kinds of domical structures, built of solid materials, as stone or brick.

In the first paper the hemispherical dome of uniform thickness was discussed; and in the second paper the same principle of investigation was extended to Gothic domes of different acuteness of "pitch"; to the parabolic dome, the elliptic dome, the ogival or Moorish dome, and the hemispherical dome of varying thickness.

We propose to lay before our readers an outline of the method of investigation adopted by the author, and of the results obtained.

A thin slice or rib is supposed to be cut out of the dome by two planes, making a small angle (say 2°) with each other at the axis of the dome; this rib is then treated as an ordinary arch, by the methods adopted by modern writers on the subject. Take EF as one of the joints of the domical rib, and let N represent the horizontal thrust of one-half of the rib upon the other half, and acting at the crown or vertex; and call P the weight of the portion of the rib included between EF and the vertex, which weight acts at its centre of gravity. Then the tendency of these two forces being to produce rotation of the upper part of the rib about the inner edge E of the joint EF, the "moments" of the forces P and N taken about E will balance each other. Thus, if ρ is the lever-arm about E of P (acting at the centre of gravity), and y that of N, the equation of equilibrium is—

$$N \cdot y = P \cdot \rho,$$

which gives

$$N = P \frac{\rho}{y}$$

from which equation N is found when P, ρ , and y have been calculated.

To find P and ρ , it is necessary to make use of the ordinary formulae of the integral calculus for finding solidities and centres of gravity, according to the curve which forms the contour of the dome. The value of ρ is at once obtained by the geometry of the section. Having thus found the algebraical expression for N for any given joint EF, its arithmetical value for various positions of the joint can be calculated, until we find that at which N is greatest, or at which the dome itself is weakest. (This laborious process is necessary, as the ordinary rules for finding a maximum will not apply to these formulae.) The position of the weakest joint is discovered, since the dome will, of course, have a tendency to fall at that part; and by knowing its position, the architect will be able to strengthen the dome and counteract its thrust on the "drum" by means of an iron belt placed around the structure at its weakest part. The following Table exhibits the position of

the weakest joint in domes of various forms, and also the horizontal thrust at that joint of a rib forming the 180th part of a dome 20 ft. diameter, 12 in. thick throughout, and weighing 125 lb. to the cubic foot:—

Form of Dome.	Position of Weakest Joint.	Horizontal Thrust at Weakest Joint.
1. Hemisphere	Makes angle with springing line of 20°	02-01 lb.
2. Oothic: the radius drawn to the vertex, making with the vertical an angle of 16°	Ditto ditto 17°	88-7 "
3. Ditto ditto 22½°	Ditto ditto 13½°	80-415 "
4. Ditto ditto 30°	Ditto ditto 11°	77-27 "
5. Parabolic: height from springing being equal to half span	At springing line.....	79-0 "
6. Elliptical: axis of symmetry vertical, major to minor axis as 6 : 5	One-third of length of semi-major axis above springing line	06-867 "
7. Ogival: contour the "curve of sines"	One-sixteenth of the span above the springing line	02-5 "

In the hemispherical dome, whose thickness of springing is twice that of the vertex, the weakest joint is found to be at a height of 4-11ths of the external radius above the springing line; and the thrust of a rib forming the 180th part of such a dome, whose span is 20 ft. and thickness at springing 12 in., is equal to 55-78 lb.

The height of the pier or "drum" which supports the dome being given, the thickness requisite to resist the thrust has to be calculated. To do this the forces N and P are transferred to the point E (by the principles of mechanics), where they act in their original directions, and have the values previously calculated. We then have four forces whose tendency is to turn the pier over on its outer edge; namely, N and P, acting horizontally and vertically (respectively) at E; F, the weight of the portion of the rib below E, acting vertically at its centre of gravity; and Q, the weight of the pier itself, also acting vertically at its centre of gravity. The moments of P, F, and Q about the bottom edge of the pier will act in the opposite direction to that of N; since the moment of N about that point tends to throw the pier over outwards, and those of P, F, and Q to draw it inwards. In order to insure stability in the structure, twice the moment of N is equated to those of P, F, and Q; and the equation thus obtained is of the third degree in respect of t , the thickness of the pier; a solution of which can be easily found by Horner's well-known process.

The following are the values of t obtained for the several domes above mentioned, the height of the pier being 50 ft. and its weight 150 lb. per cubic foot:—

Hemisphere, uniform thickness throughout	$t = 2-45$ ft.
Hemisphere, springing twice thick.	
ness of crown	$t = 1-9$ ft.
Gothic, pitch 22½°	$t = 2-259$ ft.
Parabolic	$t = 2-244$ ft.
Elliptic	$t = 2-44$ ft.
Ogival	$t = 2$ ft.

No allowance is here made for the domes being strengthened by a belt at the weakest part.

Although it was necessary to use the integral calculus in finding the formulae from which these results were obtained, yet in their practical application the only mathematical knowledge required is a little algebra and trigonometry, with which any person may calculate the strength and stability of a dome of given dimensions, whose contour and proportions agree with any of those named above.

INFANT-SCHOOL, PARISH OF ST. MARY, BATTERSEA, WANDSWORTH COMMON.

This school has recently been completed, and consists of a room 38 ft. by 19 ft., with a classroom attached, 12 ft. by 10 ft. It is built of stone, banded with red brick, the heads of the windows being filled in with herring-bone work. The roof is covered with tiles, and surmounted by a hexagonal bell-turret. The greater part of the expense of the building has been borne by Mr. P. Cazenova, of Clapham Common. Mr. Ferrey was the architect; and Mr. Jarrett, of Crofton, the contractor.

THE SANITARY CONDITION OF SOUTHAMPTON.

The sanitary committee have prepared a long report for presentation to the local Board of Health at their next meeting. In it the reporters say,—

"The committee have to report that the last death from cholera within this borough occurred on the 11th day of October last; the first death having taken place on the 15th day of June preceding. The cholera visitation, therefore, lingered in Southampton over a period of four months, and from which cause 100 deaths occurred out of 320 cases. In its early stages nearly two out of every three persons attacked died, but during its progress, and particularly towards its close, a much smaller proportion of cases proved fatal."

"The committee regard these results as being of the most satisfactory character; and, however painful it may be to lose as many as 100 of the inhabitants by cholera, there is every reason to believe that, under Providence, the means placed by the local Board of Health at the disposal of the committee, and the energy with which they were applied, tended in a marked degree to limit the spread of this epidemic—if truly to be so called—and to confine the visitation to a limited portion of the town."

"The committee call attention to the fact that the visitation in question, viewed as an epidemic, has manifested itself in the slightest possible degree. It has not traversed the town, and has not visited the neighbourhood; it has been most severe on one side of the river Itchen, it has not attacked the other; and although the west bank of the river is thickly populated, the east bank, which receives the prevailing winds that pass over Southampton and is not affected; whilst portions of Portswood and St. Denys, lying on each side of the higher part of the river, are the slightly situated, have likewise escaped. Part of Portswood is almost a continuation of Northam, which latter place suffered considerably, but cholera has not extended beyond it. The parts of the borough of Southampton, eastward of Portswood, which have suffered, are the lower portions of the town, such as are almost exclusively occupied by the industrious and poorer classes of the community; whilst the upper and middle parts of the town, with the exception of one very defective habitation, and all the better classes, as they are generally distinctly called, have escaped."

TO TEST BLUE LIAS LIME.

In reply to your correspondent "L. E.," I beg to inform him that a direct and easy method of testing blue lias lime is the following:—Calcine two or three cubic inches of the stone into a crumble; pound the calcined lime, make it into a stiff paste with water, and form it into a ball, which immerse in a glass of water. If it is hydraulic it will set under water, so as to resist the pressure of the finger, in a time varying from twenty-five hours to a fortnight or three weeks, according to the nature of its composition, and if its quality is good, in a month it will be as hard as weak limestone. S. M.

HIGH-PRESSURE BOILER EXPLOSIONS.*

In reply to the inquiry of "Beta" as to the best mode of preventing explosions in boilers under pressure of a column operated in connexion with kitchen-ranges and hot-water supplies to baths, and for domestic purposes, I beg to submit the following efficient and inexpensive plan, which I have applied with unflinching success for the last few years.

The disastrous and fatal boiler explosions which have occurred during the late severe winters led to its application and adoption.

The danger arises in consequence of the flow and return pipes connected to the boiler becoming frozen solid, thereby preventing the expansion of water, which increases according to the temperature imparted by the fire around the boiler, and unless relieved, will certainly burst the boiler or pipes at the weakest place.

To prevent this, I attach to the flow-pipe, as near the boiler as possible, or even to the boiler itself, at any part of same most convenient, a wrought-iron tube, half an inch or 3/8ths in diameter, bent U shaped, like a siphon, which being made as many inches in length from top to bottom as the height of hot-water cistern or feed-cistern to same (if the hot-water cistern is fed and worked under a column of water) is inserted from bottom of boiler to the top of feed-cistern, allowing three or four inches to spare.

This bent tube being half filled with mercury, will balance the column of water under pressure from the hot cistern and supply to same. A column of one inch of mercury will balance a column of one foot of water.

If any undue pressure arises in the interior of the boiler in consequence of the flow and return-pipes being sealed by reason of frost or deposit of lime from very hard water, the mercury is

quietly displaced, until a vent is given and boiler relieved. If one end of the bent tube have a cast-iron cup (sufficiently large to contain the whole of the mercury), and a small bend to conduct the same into the cup, will prevent loss of mercury whenever blown out, and by unscrewing the small bend, the mercury will pass into the syphon tube for future use.

This plan is perfectly self-acting, and can never fail, there being no "sticking" of valves, which never work when required, nor leaking of fusible plugs, which I have tried without success. The mercury cannot set fast or become frozen at any temperature we experience in this climate.

This plan is equally applicable to hot-water heating apparatus for churches and other buildings, where frequently, owing to the fire not being lighted during the week in frosty weather, the pipes or the boiler itself become frozen, and explosions occur, which have proved fatal in several instances.

WM. THOS. CRUMP, Engineer.

SIR.—Your correspondent "Beta" need be under no apprehension of danger with a properly-constructed high-pressure boiler, if he will take care to have the following arrangements carried out:—

The cold-water, or pressure-pipe, should take its supply from a cistern in the roof, and not direct from the street main, as in the latter case the pressure is often irregular, and generally greater than is necessary for forcing water up to the first floor only.

An expansion pipe should be carried from the boiler up to a height of a few inches above the cistern, and bent over into it; the hot-water service can be continued upwards for this purpose if sufficiently large. This is, in fact, a safety-valve, and will allow the escape of steam or water when the pressure is too great, either in the boiler, or in the high-pressure ball-tap, and screw-valve for shutting off the connexion with the boiler when required.

By means of this simple arrangement the cold water can be used at pressure, or turned off and made to supply the boiler for domestic purposes in the usual manner, and there can be but little danger of the pipes rising from the boiler being frozen. B. A.

BOULEVARD.

As a good answer may always be given to a stupid question, you may perhaps not object to answer this query:—What is the real meaning of the term "boulevard," as applied to a street? I am under the impression that it means a continuous street merely: in this sense the Marylebone and City-roads are "boulevards." The general impression is, that it means a wide road, with trees in it, as this description applies to the old boulevards so well known in Paris. Rottenrow is now very generally called a boulevard—why, I do not know; and the late Sir Joseph Paxton so designated the great glass arcade that he projected for the metropolis.

An enterprising friend of mine is about building some tenth-rate houses, in a tenth-rate street near Islington, and means to call the said project a "boulevard." I should like to have your opinion as to whether this is a correct designation for so magnificent an undertaking. IGNORAMUS.

* * Boulevard or boulevard means literally, in French military language, a bulwark or rampart. The walk formed on the site of abandoned fortifications came to be so termed.

THREE THOUSAND POUND CHURCHES.

For the information of your correspondent, I beg to state that the contract for St. John's Church, Union-road, Battersea (as advertised at the time in your columns), was 2,500*l.*, accommodating 736 persons, including a western children's gallery and space for a large organ; a few hundred pounds were afterwards spent in extra foundations, &c., &c.

This church was built to the approval of the Incorporated Society for Building Churches. And I beg to suggest that the fairest way of giving the information required would be to give a list of the churches and the names of the architects who have built them at the above cost.

It is in the details of construction that the economy is achieved, and a sketch of building would not and should not be all-sufficient for the purposes of your correspondent.

If committees require to be reassured, such a list of churches as you might give would be the best assurance they could have, and those who have solved the problem might rest the benefit.

No small sacrifice is often made by an architect in bending his mind to the design of cheap churches; although, by the study of outline and effective massing of the parts of a plain building, he is as often rewarded by the increase of his knowledge of proportion and the uses of light and shade, and so receives some compensation for the absence of those beauties of detail which especially charm his heart. A SUBSCRIBER OF SEVENTEEN YEARS.

THE POSITION OF TOWN SURVEYORS.

A SURVEYOR to a town is generally a stranger who comes from some distance, and is, at the taking up of his appointment, put to some expense and inconvenience; but in good faith he moves his family and goods to a new home. He has one thought, which gives him confidence and supports him in all his doubts and in all his embarrassments,—one thought which no other can equal; and if once lost, no other in the whole range of his mind could supply its place. It is not the fair records of his past career which helped him to success, though they are consolation; but it is the character he carries in his heart, which he knows will never deceive him as long as he never deceives himself. The inward consciousness of right, exercising itself in the standard under which he fights the battle of his livelihood.

But, sir, why must a town surveyor be a target for a party to shoot at, which, in too many instances, he is? He ought to hold his office quite independent of and invulnerable to local feuds, and he wishes to do so. His desire is to do his work, and not to interfere with anybody's hickeries and petty jealousies; and, on the other hand, these party broils ought not to jeopardise the position of a town surveyor, who really has nothing to do with them. A surveyor ought not to care who are the members of the board he serves; but he is actually made to dread a change, because Mr. Somebody is coming in who intends to upset everything that was sanctioned by Mr. Somebody else who is going out, and all done, of course, for the good of the town. Well, then, Mr. Somebody else who comes in aims his blows at the surveyor, because the surveyor was elected to office by Mr. Somebody who has just gone out. If the surveyor cannot stand all this of course he can resign, pack up his things again and be off to where he came from. And then Mr. Somebody else who has just come in will have the pleasure of voting his own man to the office of town surveyor, who will be a very clever and honest surveyor indeed, until another Mr. Somebody shall arise and repeat the ruthless game.

I have laid this matter open to you because facts which are grievances must be uncovered in order to be cured. And, I believe, the evil I complain of is national and requires to be dealt with by the Legislature. For it not only affects the position of surveyors of towns, but it affects the inhabitants as well. It must be detrimental to a town to disaffect or remove its surveyor. If he is disaffected, can you expect him to feel all that interest in the welfare of the place which he would like and ought to do? And if you discharge him, will another at once fill the office as efficiently? Will it not take some time to become familiar with the new situation? and will the newly-appointed man not bring many things the other did, and involve fresh expenditure? It always is so.

It also destroys confidence, and civil engineers will despise such appointments, rather than compete for them; though they ought to be posts of honour as well as of emolument.

Perhaps some of your readers will communicate their views upon the subject, and suggest some Legislative measure for revising the precarious tenure upon which town surveyors hold their office. A TOWN SURVEYOR.

HEIGHT OF FURNACE CHIMNEYS.

In building furnace chimneys, can any of your correspondents inform us as to what are the considerations, or data, by which to properly determine the height they should be carried? W. M.

MASTERS AND APPRENTICES.

At the Petty Sessions held on the 28th inst., at Smebury, J. J. Jordan, of Union-square, Islington, appeared to answer a summons taken out by his master, Mr. B. W. Maughan, grainer, of Goswell-road, "for that he, being an apprentice, did, on the 21st and 23rd of January, 1867, neglect and leave his work at Teddington." The plaintiff said, on the 21st of January I sent my apprentice to Teddington, to proceed with the graining at Mr. Colman's houses. He left for that purpose, but went to Kingston upon pleasure. On the 22nd he went to work, and on the 23rd I went, in company with Mr. C. Powell, my foreman, to Teddington, and found my apprentice absent from his duty. He did not arrive till 9-30, two hours and a quarter behind time. Mr. Taylor, painter, proved that the defendant went to Kingston on the 21st, on pleasure. The foreman corroborated Mr. Maughan's statement, and proved that there was nothing whatever to prevent the work being proceeded with on the 21st. That the Tuesday, when Jordau did work, was colder weather; and further said, that in the ordinary course of his duties he

* See also p. 83, ante.

visited the work on the previous Saturday, and found the defendant hiding away his time.

The defendant, in reply to the charge of going to Kingston, said he had the face-ache, and that it was too cold to work; and on the Wednesday he intended to commence his day's work at 9.30.

The Bench informed the defendant that he was liable to a month's imprisonment; that it was clearly proved that he had worked on Tuesday, a day equally cold with the Monday; and that it was quite impossible to allow him to commence his day's work at any time he pleased, contrary to his master's orders. That it was not sufficient for him to be at his work, but that he must work hard and properly. He was fined one week's wages, 15s., and 5s. 6d. costs. The Bench further remarked, that if summoned again he would receive a month's imprisonment.

POTASSIUM AND LEAD PIPES.

A QUERY.

In your very interesting and valuable scientific journal, of September, 1863, is the following paragraph:—"Dr. Schwartz, a chemist, of Breslau, has made a discovery that cannot be too highly esteemed in a sanitary point of view, which is, that by passing a hot solution of the sulphide of potassium through leaden pipes, the interior face is transmuted from the metallic state to that of a sulphide in a few minutes, at a cost too insignificant to mention."

This announcement being read by so large an amount of the public as that through which your journal finds its value pretty well ascertained, may I, therefore, be permitted to inquire, through its columns, whether any of your readers has found this simple process to answer, especially in such parts of the kingdom as, for instance, in Scotland, where the waters are naturally very free from solid constituents?

P. S.—It would be desirable that it should be stated whether the pipes tried were quite new, or that they had been some time in use.

COMPENSATION CASE.

At the SURREY Sessions—On the case of Price v. The South-Eastern Railway, tried before Mr. Justice Stirling, and a special jury of seven members.

For the claimant there appeared Mr. Montague Chambers, Q.C., Mr. J. F. M. P., Mr. T. Hughes, M.P., and Mr. J. O. Griffiths. For the company, Mr. Lloyd and Mr. Shiel.

In opening the case Mr. Chambers said that the house was the "Wellington Arms," in the Waterloo-road, in respect of which this claim was made. Mr. Price was now and had been for many years a licensed victualler, carrying on a very excellent trade in the house, which was held upon two leases that had still eighteen years to run, at a rental of 120*l.* a year. When the Charing-Cross station and London Bridge Junction were commenced, the course pursued by the company was almost incredible. There were three dwelling-houses on the right-hand side of John-street. They bought the two intermediate houses adjoining the house of the claimant, pulled them down, and only left a bit of wall standing. They then pulled the main wall that was formerly an internal wall belonging to the claimant an external wall, a wall exposed to wind and rain, which it was never intended to stand. The company pulled down the internal wall of the two intermediate houses, and did the work in such a clumsy manner that they left bits of lime and pieces of paper on the plaintiff's end of the weather. The result was that cracks soon made their appearance in the wall, which showed that what surveyors call structural damage had taken place. The company dug up at the foot of the wall, and put in a deep pit below the old foundation, put a lot of concrete in it, and then built their back pier over a portion of the greater weight put upon the footing the farther down it must go, and the consequence was that the cracks immediately appeared. If meddled with at all, the wall should have been underpinned, or, as he would call it, self-supported by concrete, just as the company supported their own wall. There was no other proper course to adopt. The result was structural damages to the wall. Some time afterwards the company set workmen to fill up the vacant space between their wall and the wall of the "Wellington Arms," and they did so with dirt and muck of a similar character, which converted a dry cellar and kitchen into unusable places, where water was continually oozing. The very carelessness and clumsiness with which the work had been done would of itself have given a claim for damages. Another ground for claiming damages was that, after a certain time, there was a right to light and air. The beads under which damages were claimed were, first, structural damage, whereby water was admitted; second, the necessity for rebuilding the wall, which had been imperatively exposed to the elements, and got cracked and dangerous; and, third, the deprivation continuously of the light and air which the premises formerly possessed.

The South-Eastern Company had since, in fact, become the landlords of the whole premises, having paid Mr. Littlejohn, Mr. Price's original landlord, 7,000*l.* for his interest; and they had, therefore, a right to insist upon Mr. Price keeping the premises in good and substantial repair, while by their own act they injured the whole building, rendered the basement useless, and, by shutting in the house, made the bed-rooms untenable, while the walls in every direction were cracked. Mr. Price had to pay 120*l.* a year rent; at that price it was a profitable investment, so long as he was not interfered with; but, when the company came and knocked down his very valuable business by buying the two houses next to him, pulling them down, and then snatching their fingers at him, it was time to seek for redress. That redress had been sought ever since April, 1863, but the company had persistently declined to give any compensation.

Mr. Richard Littlejohn was called, and examined by Mr. Griffiths. He deposed that he was formerly in business as a builder at Lambeth, and took the land in question for building six houses upon originally. They were built under the superintendence of Mr. Field, the ground-landlord, very substantially. This witness corroborated counsel's statement generally, notwithstanding cross-examination.

Mr. Marsh Nelson gave detailed evidence, illustrated by reference to plans presented to the jury, as to the nature, extent, and causes of the damages to the premises. The substance of the evidence was, that the cracks, the injury to the doors and windows, and generally the structural damage, which he estimated could not be made good, sound, and substantial, fit for habitable and business purposes, under 300*l.*, and in the mean time, while the wall was being rebuilt and repairs made, which would take about six months, the value of the house would be diminished. Light and air were so much obstructed as to materially diminish the value of the house. As the houses originally stood, they were worth 300*l.* a year; and if the plans had been carried out for building at the back, they would have been worth 50*l.* a year more. Indeed they would have very much increased the value of the premises, but that they were now precluded from building by the fact that the railway works came close up, and shut them in. He estimated the capitalised loss from light and air at 575*l.*, in addition to the cost of repairs.

Mr. Nelson was subjected to a long and minute cross-examination by Mr. Shiel, and re-examined by Mr. Chambers, his evidence in chief remaining unshaken, or rather materially strengthened by the new points brought out.

Mr. William Lovejoy, examined by Mr. Hughes—Was an auctioneer and valuer. Got experience in valuing public-house property. In consequence of the railway-bridges being built and the blocking the houses up, Mr. Price had been damaged to the extent of 500*l.* a year, and would sell for that much less than before. The other damage was lost of trade to the amount of 100*l.* a year, and the loss of beds. To capitalise that at five years' purchase would make the loss 1,000*l.*

Other witnesses were examined for the plaintiff.

Mr. Lloyd then addressed the jury at some length for the defendant. His case, he said, was that the cause of damage was in the internal alteration and construction of the house and the weakness of the walls. If any portion of damage was due to the construction of the railway they were bound to pay, but he must produce evidence to show that it could be done at very small expense. No doubt the house was worse off as to light and air. But what was it? No one feels the air. He contended that there was no damp or cracks caused by the railway; if there was it was not strange that Mr. Price should let cracks remain and deteriorate the structure of his house, when by a very slight expense it could have been prevented. It was gross negligence on his part to permit the continuance of the damp and cracks. It was his own fault and neglect, and the amount of damage caused by the railway would be very small indeed. It was not reasonable to expect him to make such a claim as that of Mr. Lovejoy. As a matter of fact Mr. Price could not claim any compensation for loss of trade profits for reason of the use of the railway. Mr. Lovejoy would not say that any amount of damage by loss of light and air; but any neighbor had a right to build and block in unless prescription right, obtained by twenty years' possession, prevented it. Neither vibration nor noise was a ground for compensation by use of the railway itself. As to "blocking up," which Mr. Lovejoy called 500*l.* loss, no such claim could be maintained against the company.

Mr. Robert Ritchie, surveyor, said he was in great practice, and accustomed to appear for railway companies and also for claimants (he thinks more for railway companies than claimants). Had examined those premises, and knew what were called structural damages. The south side had not subsided at all. He saw no fracture, nor was it necessary to look for more cracks in such a house than in one built as a single house. The cracks are superficial; if they do not go through the wall. There was no necessity to take down the wall; 20*l.* would be sufficient to stop up all cracks and fill Mr. Price's covenant to keep in good repair; and perhaps 30*l.* more, over all 50*l.* would be sufficient to make good the foundation, by stopping the penetration of the water into the cellar and kitchen.

Mr. Charles Stephenson (of the firm of Messrs. Stephenson, Government surveyors), Mr. Edward Norton Clifton, architect and surveyor, and Mr. Frederick Marsden, architect, were successively called for the defence, and gave evidence which substantially agreed with that of Mr. Ritchie.

Mr. Lloyd, in addressing the jury, offered to put the foundation of the wall in good repair, at the cost of the company, and to agree to any compensation for the loss which had been caused by their works to the basement. He also admitted that the damage from deprivation of light and air might be taken at 20*l.* a year, and capitalised at ten years and a half purchase. If the plaintiff put the case to the jury, he would stand upon his strict legal rights.

Mr. Chambers, in a lengthened reply, summed up all the facts which had been proved by the witnesses for the plaintiff, and contrasted these facts with the utter breakdown of the suggested rather than stated theories of the witnesses for the defence; but, in conclusion, rather than raise any future legal question involving possible future litigation, he withdrew any claim for either increased cost for gas or loss by non-letting of the beds, and said he would be content with a lump sum for the whole damage.

The Under-Sheriff having briefly summed up,

The Jury retired, and after an absence of about twenty minutes, returned into court, when they gave a unanimous verdict for the plaintiff—Damages, 750*l.*

PROVINCIAL.

Norman Cross.—The new Police-station and Sessions-house has been opened. The building stands flush with the iron-pike road near the Norman Cross Inn, and adjoining the field where once stood Norman Cross barracks. No money has been expended on ornamental purposes. It is a plain edifice of the grey bricks made at Whiteless, and stone dressings for the principal windows: of the ground plan an idea may be formed from the letter H, with the stroke in the lower portion. The building stands north and south, the latter or front aspect, which is of one story, having three forks. The centre fork

terminates in a hay window, which lights the sessions-rooms: on the eastern side is a flat window lighting the public room; and on the west a similar window to the magistrate's retiring-room and superintendent's office. The line across the letter H represents a two-storied part of the building which is on the floor, divided into a sitting-room on one side for the superintendent, and on the other for a constable. Between these rooms runs a corridor with fire-places, and from it access is gained to two cells for prisoners. On the line with the sitting-room are duplicate kitchens and out-houses for the superintendent and constable: above the sitting-rooms are two bed-rooms. The ground extends all round the building, the front and sides being laid out ornamentally. The sessions-room is 7 yards long by 6 yards wide. The cells are well ventilated and warmed from the corridor. The contractors were Messrs. Richardson, Treson, & Tyers, of Yaxley; and Mr. Hutchinson was the architect. The builders' contract was for 1,164*l.*

Bury.—The entire renovation of the Athenæum Lecture-hall is now nearly complete. The designs of the ceiling and cornices have been restored, and the walls coloured in the original tints. The dais under the windows and in front of the principal entrance has been removed, the orchestra taken away, and that end of the room made good, while at the same end two doors in keeping with the rest of the hall open into a lobby giving access to the street, and to two artists' rooms, the whole forming a suite, which by throwing back the folding doors will form a commodious and conveniently situated upper-room. The chandelier, purchased second-hand at a cost of 200*l.* many years ago, will be removed, and the Athenæum-hall will be lighted by seven glass gaseliers originally made for the room, the larger occupying the centre, with three on each side. The architects employed were Messrs. Bacon & Bell; and the contractors, Mr. Frewer and Mr. Jackson.

Wednesbury.—The Local Board of Health now occupy their new offices. These public buildings are situated in Holyhead-road, opposite the Post-office and Russell-street, a very prominent and convenient position. The style of architecture is Italian. The flat surfaces of the elevations are executed with best front stock bricks. The base is of Codsall stone, ashlar drafted, and pitched in square blocks, and finished on the top with a mould of Attlebury stone, in which material the principal portion of the stone work is executed. At each angle of the front are stone piers, ribbed on the face and chamfered in the joints. These project from the face of the brick work to form pilasters, running from the base to the whole height of the elevation, and are supplied with bases and caps. The doorway, in the centre of the facade, forms the principal entrance, on each side of which is a brace of columns of the Roman Doric order. Above the doorway is a central window, with a pilaster on each side. The basement consists of cellars. The ground-floor contains vestibule, entrance-hall, offices for surveyor, assistant surveyor, clerk, clerks' assistants, nuisance inspector, and collector. There are also a side entrance-hall, water-closet, and lavatory, and principal staircase. The entrance-hall is laid with blue and white Bedford squares, and has a mahogany hand-rail and ornamental cast-iron banisters. The first floor contains a landing, waiting-room, stores, committee-room, and the board-room, which is 36 ft. by 24 ft. 6 in. in area, and 15 ft. in height. The fencing forming the boundary to the Holyhead-road consists of a dwarf wall, coped with Derbyshire stone, and ornamented with cast-iron palisades of ornamental design, with spaces between for three pairs of gates. The architects were Messrs. Loxton Brothers, of Wednesbury; Mr. J. Wilkes, of Birmingham, was the contractor. The cost was 1,700*l.*

Chester.—The Custom House in Watergate-street is about to be razed to the ground. A new erection will be raised adjoining Trinity Church, now in course of construction, the plans of Messrs. Kelly & Edwards, architects, of this city, being approved of; and Mr. Hughes, contractor, Aldford, being appointed the builder.

Darlington.—There was a very severe storm at Darlington, Devonshire, lately, and the sea arrived away about sixty yards of the Terrace-walk, near Kennaway tunnel, with the piles which protected it.

Penance.—The thorough surveyor, says the *Cornish Telegraph*, has just completed plans, and accounts of the expense, of recent improvements,

with the view of submitting the same to the Secretary of State, whose approval must be had prior to permission to borrow the money on the security of the district rates. The Alexandra-road, now open for eighteen months, has cost 2,539l. 17s. 7d., viz., in works, 1,294l. 6s. 5d.; in land, the very heavy price of 1,187l. 17s. 11d.; in memorial drinking-fountain and pedestal, 57l. 13s. 3d. Alverton-jane was from 18 ft. to 21 ft. wide, it has now been made a uniform width of 30 ft., with a terrace 10 ft. wide, and a sharp hill has been very much eased; this cost, in works, 96l. 6s. 5d.; in land, 264l. 15s. 11d. = 361l. 2s. 4d. Parade Passage, from 4 ft. to 5 ft. wide, is to be made 10 ft. in the clear, for a length of 115 ft., at a cost of 65l. The eastern Esplanade is to be lengthened 100 yards, and the carriage-road widened. This is 23½ ft. above the West Cornwall Railway, and overlooks the whole bay. A wall 2½ ft. high, 4ft. thick, and 165 ft. long, must be built, and 300 ft. of curb laid down. This will cost about 650l. 2,000l. have already been borrowed; 1,600l. more are needed, and have been lent, subject to the Secretary of State's sanction.

Shrewsbury.—The foundation-stone of the new Market-hall has been laid by the mayor, in presence of the corporation and others. The architect is Mr. R. Griffiths, of Stafford, and the contractor Mr. A. Barlow, of Stoke.

Braintree.—The chief stone of the new building for the Institution for the Blind has been laid. The site of the intended building is in a new street, to be called Cambridge-street, near Christ Church, and between North-parade and Manor-row. The edifice, the style of which will be Gothic, will be erected from the designs of Messrs. Knowles & Wilcock. The plot of land on which it is to be erected has a frontage of 60 ft. to North-parade, and of 160 ft. to the new street, which will terminate at the corner of the new Club-house, in Manor-row. The buildings will consist of large work-rooms for the blind, with a shop and offices for the sale of the goods made at the institution, besides other accommodation for the purposes of the charity. Attached to the building will be two shops and premises in North-parade, which will be let for the purpose of securing a return of rent. The works have been let to the following tradesmen:—Masons' contract, Messrs. J. Burnley & Son; joiners', Messrs. Garforth & Walsley; plumbers', Mr. John Schofield; plasterers', Mr. Thos. Cordingley; slaters', Messrs. Hill & Nelson; painters', Mr. John Lupton. The total cost will be about 6,000l.

STAINED GLASS.

Roman Catholic Church, Dudley.—Four memorial windows have been placed by subscription in this church, two being to the memory of the Hon. and Rev. G. Spencer, one to the memory of the Rev. Thos. A. Moore, and one to the memory of the Rev. James O'Sullivan. The windows are in the aisle, and consist of one lancet light each, and have been designed, drawn, and coloured in accordance with the period of the architects,—the thirteenth century. The objects chosen for illustration are full-length figures of the patron saints of those memorialised, viz., St. George, St. James the Greater, St. Ignatius the Martyr, and St. Thomas; and inscriptions appear at the base of the lights, pointing out to whose memory the windows are erected. The figures are on a white grisaille ground, and the work has been executed by Messrs. Hardman & Co., of Birmingham.

DISSENTING CHURCH-BUILDING NEWS.

Huddersfield.—The large new chapel for the New Connexion Methodists, situated in the High-street, is now rapidly approaching completion; and although not quite finished, has been opened for divine service. It has been designed in the Decorated style of the fifteenth century, by Mr. William Hill, of Leeds, architect, who was selected in a limited competition of architectural designs, publicly exhibited previously to selection. It was at first thought that 5,000l. would be sufficient to cover the cost of the new structure. The Building Committee, however, by accepting the design which approved itself to their judgment, materially augmented their liabilities, making the estimated cost of the edifice, with the organ (which will be opened about April next), nearly 10,000l. The general design of the exterior of

the building—the architectural and artistic details of the *façade*—the high-pitched timber roof, together with the general finish of its several parts, has rendered the building an object of interest during its erection. The new building occupies the site of the New Connexion Methodist Chapel built in the year 1814, and stands clear of others—the four elevations being built of pitched-faced wall-stones in courses; this stone being from the Longwood-edge quarries. The ashlar and other heaving-stuff are from the contractor's quarries at Crosland-hill. The ground plan is a parallelogram, 96 ft. by 60 ft., with transepts, vestries, and staircases projecting from each side, and at the north end, making a total width of 88 ft., outside measurement, and total length 96 ft. The principal and most picturesque *façade* faces the south. The ground or floor-line is set up, or raised, 3 ft. 6 in. in the centre of the front from the causeway. Two towers flank the main or south front, and rise to a height of 84 ft. from the plinth. Above the roof, the towers are octagonal on plan, each side being ornamented with an elongated opening with pannelled base and trefoil head. The whole of the woodwork is stained and varnished throughout the building. Seats are provided for upwards of 1,300 persons, allowing 20 in. for each. The gallery is lighted by six brass polished coronas, containing each twenty-four lights, suspended from the roof. A number of stairlights light the ground floor. These and other gas-fittings have been furnished, under the direction of the architect, by Messrs. Hart & Son, of London. The total cost of the building will be about 9,500l. The contractors for the works were Messrs. Graham & Sons, for masons' work; Robert Whiteley, for joiners', carpenters', and smiths' work; H. Garton, for plumbers' work; John Brook, for painters' work; and D. Tunncliffe, for plasterers' work. Mr. William Smith has acted as clerk of works. The stone carving has been executed by Mr. S. Ruddock. The chapel has been warmed by Messrs. Haden & Son's hot-air apparatus. On each side of the organ gallery is a memorial window. The one on the right is in memory of Mr. Joseph Robinson, erected for Mrs. Robinson and her son. It was supplied by Mr. Barnett, of Newcastle. The subject is a full-length figure of Christ, with the text "Feed my lambs." That on the left side has been erected by the teachers and scholars of the Sunday school, in commemoration of the Sunday-school jubilee, held in 1866. The subject also is Christ, and the text is, "Suffer little children to come unto me."

Books Received.

The Channel Railway connecting England and France. By JAMES CHALMERS. Second edition. London: Spon, Bachelorsbury. 1867.

In this second edition of Mr. Chalmers's scheme for a tubular railway at the bottom of the British Channel, the author states that his scheme will be illustrated by drawings covering 120 ft. of space in the Paris Exhibition this year; and in a letter to railway shareholders in England and France in the Appendix, he says,—“A model of the Channel Railway, which would not cost over 6,000l., could, with the consent of the French Government, be placed in the Lake of the Bois de Boulogne. Such model, if decided on by the beginning of March, could be ready by the middle of April, when it could be submerged, and connected from shore to shore in three days; and, if only one in ten of the millions that will visit Paris next summer would pass through it at half a franc each, it would not only pay for its construction, but leave a profit of 100 per cent. As a Railway Congress in Paris during the ensuing summer could discuss this and other interesting questions with much advantage, I respectfully commend the subject to the attention of railway shareholders.”

Miscellanea.

SOCIETY OF ENGINEERS.—At the meeting of the Society of Engineers held on Monday, the 4th instant, Mr. W. H. Le Fenve, president, in the chair, a number of gentlemen were balloted and duly elected members and associates. A paper on Safety-valves, by Mr. Thomas Balwin, was read and discussed.

ST. AUDOEN'S CHURCH, CORN-MARKET, DUBLIN. The paper on this old building, read by Mr. Thomas Drew, at a meeting of the Institute of Architects of Ireland, and to which we referred at the time, has been printed, and includes a plan. Pains have been taken to make the writing to the latter as illegible as could be desired by the warmest admirers of the fashion.

ROMAN REMAINS IN BATH.—The Bath city architect, Mr. Charles E. Davis, writes suggesting the formation of a local museum, for the preservation of all portable remains of the Romans found within the corporate bounds, the corporation appointing a competent person or officer to seek after and make drawings, or obtain possession, of all antiquies discovered within these limits. Strange that such a suggestion should still be necessary!

THE "BLACK SEA," WANDSWORTH-COMMON.—This favourite spot, says a paper called the *Parochial Critic*, "is in danger of being destroyed. Herberto a long lease has preserved it, but that protection has been removed. Can Earl Spencer legally sell the 'Black Sea?' He was checked in his contemplated appropriation of portions of Wimbleton-common. Custom and long usage are against him. The inhabitants of the locality should be up and doing. Large portions have been enclosed, others destroyed, and a village is already spreading itself over the common."

BURN YOUR OWN SMOKE.—"R. T." writes,—Stir the fire and let the blaze mount amidst the reeking smoke, then note how the flame consumes it (buoyant particles of coal made light by heat before being arrested by Constable Combustion). I propose placing a gas detective up the chimney to entrap General Smoke, and his army of blacks. In an inverted funnel to receive the smoke, a round burner should blaze in the centre of the tube. It would increase the draught, and prevent the smoke from puffing into the room. [It has been questioned by men of science whether blacks once formed can be consumed in this way.]

A NEW "PACIFICATOR."—An "infernal machine" for war is described by General Daulie, of the French engineers, in *La Liberté*. It is a cannon with divergent tubes to throw musket-balls. They are so arranged that at a distance of 600 metres the balls will be spread over a space of 15 metres, and at nearly equal distances from each other. The charge of powder is calculated to propel two balls at once from each tube. Thus a field-piece will be capable of holding 16 tubes and discharging 32 balls at once, which at a distance of 600 metres will strike upon a space occupied by 50 men in two ranks, those of the second rank being liable to be struck by the balls which have passed through the first.

STONE CUTTING AND POLISHING INVENTION.—Mr. E. W. Uren has obtained a patent for two machines for dressing granite and other stone. The tools, which are of the ordinary description of those used by stonemasons, are attached to a vertical ram, which acts after the same manner as a Nasmyth hammer, and can be propelled by steam, water, or other power. The tools are so arranged as to be able, it is said, to do all the work which is at present performed by manual labour, including all the varieties of clefting, scabbling, fine pick dressing, tooth-axe dressing, &c., and at less cost. For surface polishing another machine is had recourse to, having a rotary instead of a vertical motion. A number of stones can be dressed at the same time.

THE NEW FISH MARKET AT YARMOUTH.—The whole length of the quay of the new fish wharf will be 750 ft., beginning immediately contiguous to the gas-works, and extending as far as the boat-house of the Naval Asylum. Running parallel with this, and of oblong geometrical figure, the market, 750 ft. long and 40 ft. deep, will be built. It will be paved, and quite open like a shanty to the quay, which is also, or rather was to be, paved. The market on the west side will be level with the quay, that is as to its floor. At its back will run a macadamised road 60 ft. broad, and stretching as far as the paved quay. This road is to be 3 ft. below the floor of the market, in order to make the process of loading carts with herrings as easy as possible. A double line of tramway will run along a 60-ft. road at the back of the market, and a site for refreshment-rooms within 60 ft. of the building is also provided. A look-out of good altitude is to be built.

MIDDLE-ROW, HOLBORN.—The Metropolitan Board has placed 26,000*l.* to the account for carrying on the removal of Middle-row, Holborn.

RESTORATION OF CROYDON CHURCH.—The subscriptions now amount to upwards of 12,000*l.*, which, with the money received from the insurance companies, furnishes 22,000*l.* to begin operations with. A large number of men have already been employed in removing the debris from the interior. The tower and exterior walls are to remain, being considered by the architect perfectly secure, so that the exterior aspect of Old Croydon Church will be retained.

NEW USE FOR PARAFFINE.—Dr. Stenhouse, who is well known for his applications of chemistry to practical uses, says "Chambers's Journal," has recently discovered an additional use for paraffine, namely, that it renders leather waterproof. The leather, being coated several times with paraffine and oil, is exposed to heat after each coating, by which rapid absorption takes place. Like gutta-percha soles, paraffined-leather soles give out a wooden sound when struck, and boots and shoes made of paraffined leather last as long again, it is said, as those made of ordinary leather.

THE FALMOUTH BREAKWATER AND DOCKS.—These structures have suffered a great deal of late by gales. The breakwaters are constructed with piles. The eastern one, which is most exposed to the weather, is 1,400 ft., and the westernmost one 1,500 ft., in length. Being in an unfinished state, they have been unprotected, and even the docks, although they have been used for some time past, are not yet complete. The wooden piles at the outer breakwater are much bent, and very much shaken. The giving way of the piles has caused a depression of nearly 18 inches in the causeway.

PETROLEUM AND OTHER LIQUID FUEL.—The Admiralty have permitted the petroleum boiler at Woolwich Dockyard to be worked by Mr. C. J. Richardson, the patentee, for one week, from the 4th to the 9th of February inclusive, with shale oil as fuel. By carbonising and burning water-gas it is said to evaporate with ease and certainty, with 1 lb. of oil, from 16 to 20 lb. of water, without smoke, ashes, or clinker. The exhaust steam is decomposed in the burning of the fuel. The fire is not only smokeless, but under perfect mechanical management. The price of shale oil is at present from 5*l.* to 6*l.* 5*s.* per ton; but a mixture of it with other oils of a like kind was to be tried, in order to reduce the cost to about 2*l.* 5*s.* per ton, without impairing its effect as fuel.

THREATENED ENCLOSURE OF EPPING FOREST.—A public meeting has been held at the Beaumont Institution, Mile-end-road, to consider the threatened encroachments on Epping Forest. The Marquis Townshend presided. A resolution was unanimously passed to the effect that it was of vital importance to the inhabitants of the East of London to preserve from enclosure the Forest of Epping, which for centuries had been a place of popular resort, and that the meeting viewed with especial displeasure the recent enclosure of Loughton, Woodford, and Wanstead. Resolutions were also passed providing that legal advice should be taken to ascertain the rights of the lords of the manor to enclose the waste lands within the forest, and appointing a committee with a view to raise a fund of 10,000*l.* to defray the necessary expenses.

A NEW MAGNESIUM LAMP.—The American Magnesium Company, of Boston, are manufacturing a new and improved magnesium lamp. In the *Journal of the Franklin Institute* it is thus described:—"The clockwork, by which the motion is produced, is inclosed in the square-shaped portion below, and at the back. In the rounded front are the parts for feeding the ribbons, &c. These consist of two little rollers, between which the ribbon is passed, and regularly delivered by their motion. They are placed immediately over the front opening, at which the ribbon is ignited and burned. Below this opening work eccentric cutters, which nip off the ash thread from time to time. The ribbon is supplied from flat bobbins, from which it passes into the chimney and to the rollers. The whole structure is exceedingly compact, so as to fit easily a common magic-lantern box. The most important novelty in this instrument is the arrangement of the chimney and draught. The draught blows directly into the face of the light, thus sweeping off the smoke, and making the intensest light exactly where it ought to be.

BRITISH INSTITUTION.—The collection of modern works now open consists of 624 paintings and twelve pieces of sculpture, mostly small. It includes a few pleasing pictures, principally amongst the landscapes, but does not call for detailed description.

MORTALITY.—The annual rate of mortality last week was 28 per 1,000 in London, 30 in Edinburgh, and 47 in Dublin; 31 in Bristol, 25 in Birmingham, 30 in Liverpool, 32 in Manchester, 31 in Salford, 29 in Sheffield, 32 in Leeds, 30 in Hull, 32 in Newcastle-upon-Tyne, and 35 in Glasgow.

THE LEICESTERSHIRE ARCHITECTURAL SOCIETY. The annual meeting of this Society was held on Monday in last week, in the Town Library, Guildhall, Leicester, the Rev. J. H. Hill in the chair. After the transaction of business in committee, the financial secretary, Mr. G. C. Bellairs, presented a statement of accounts for the past year, showing a balance in favour of the Society. Mr. North, honorary secretary, read a report for the year 1866. Mr. North contributed a paper showing the measures taken during and previous to the reign of Elizabeth, to ensure the destruction of Church "ornaments," which account for the paucity of specimens now in existence.

TESTIMONIAL TO THE EX-SURVEYOR OF COVENTRY.—In the Coventry City Council a resolution has been passed "that Mr. J. E. Greatorex having been appointed to the office of engineer to the Board of Portsmouth, this council do record its cordial acknowledgment of his able and faithful services during the period of fourteen years he held the office of surveyor to the Corporation and Local Board of Health of this city; and that a copy of this resolution under the common seal be delivered to him." The mover of the resolution passed a high eulogium on their late surveyor in reviewing the various important and useful works done under his superintendance at Coventry.

THE PROPOSED NEW TOWN-HALL FOR MANCHESTER.—A number of influential gentlemen have met at the Town-hall to consider the plans of the projected new Town-hall, and have resolved "That in the opinion of this meeting the ground plan of the new Town-hall is most objectionable in shape, and inadequate to the prospective requirements of the city; and that the town council be requested to revise the same, with the view of obtaining a larger square block, with easier access from the adjacent streets." The meeting appointed a committee to communicate with the town council, and adopt such other steps as may be advisable in the matter. It is to be hoped the council will agree to the request.

LECTURE UPON THE HISTORY OF THE IRON TRADE OF GREAT BRITAIN.—The third lecture this season in connexion with the Southwark auxiliary to the Society for the Improvement of Men employed in Manufactories was given in the St. Peter's School-room, Pond-yard, Newpark-street, by Mr. James Robertson, of the firm of Robertson & Macnaught, Bankside, the subject of the lecture being the "History of the Iron Trade of Great Britain." Mr. Edward Easton, presided. There was a large audience present, including some ladies. The lecture embraced a wide field, extending as to time from Tubal Cain to the present date. The information given was carefully selected. The statistics were few, and only such as were really required to illustrate the subject, and to give a correct idea of the lecturer's intention.

TENDERS

Accepted for offices, Chancery-lane, Manchester, for Mr. W. Cunliffe Brooks. Mr. Treaditt, architect.— Brickwork. Healey.....£1,365 0 0 Carpenter and Joiner Work. Bowden, Edwards, & Co..... 2,485 10 0 Mason's Work. Pattenon..... 5,888 0 0 Plasterer, Painter, and Paperhanger's Work. Lomas..... 693 0 0 Plumber and Glazier's Work. Ward..... 1,323 10 0 Ironmongery. Bellhouse & Co..... 2,075 0 0 Slater's Work. Ashcroft..... 75 10 0

Accepted for agent's house and kitchen offices at Kells, county Meath, on the property of the Marquis of Hereford. Mr. W. Fogarty, Dublin, architect.— Sharpe.....£2,600 0 0

For new stores to brewery at Staines. Mr. T. Wormacott, architect:— Dexter.....5850 0 0 Saley..... 711 0 0 Sarridson..... 856 0 0 Shepherd..... 1055 0 0 Collier..... 868 0 0 Sawyer..... 691 0 0 Johnson..... 673 0 0 Walker..... 672 0 0 Palmer & Son..... 669 0 0 Gibson, Brothers..... 659 0 0 Wilkinson & Co..... 655 0 0 Simpson..... 650 0 0 Harris..... 498 0 0 Jeffrey..... 487 0 0 Jenkins..... 465 0 0 Simonds..... 465 0 0 Wades..... 465 0 0 Warren..... 429 0 0 Poron..... 415 0 0

For reseating, &c., St. Mary-le-Bow Church. Mr. James L. Fedley, architect:— Sewell & Son.....£1,137 0 0 Coles & Son..... 1,070 0 0 Ashby & Horner..... 977 0 0 Browne & Robinson (accepted)..... 850 0 0

For additions to Laurel Villas, Dextley Heath, Kent, for Mr. A. J. Spackman. Messrs. Wm. Gosling & Son, architects:— Vickers (accepted).....£475 0 0

For alterations and additions to a villa at Hampton-on-Thames, for Mr. H. E. Knight. Mr. Herbert Ford, architect. Quantities not supplied:— Rawlins.....£847 0 0 Bond..... 747 0 0 Wood..... 708 10 0 Wheatley (accepted)..... 679 0 0

Accepted for alterations and additions to Cahereonish House, county Limerick, for Lieut. D. F. Gabbett, 2nd Life Guards. Mr. J. Fogarty, architect:— Cavanagh.....£2,400 0 0

Accepted for a pair of semi-detached villas on the Appian Way, near Dublin, for Mr. J. Sibthorpe. Mr. Fogarty, architect:— J. & W. Beckett.....£1,300 0 0

Accepted for new road on the property of the Trustees of the Wesleyan College, Belfast. Mr. Fogarty, architect:— Russell.....£1,050 0 0

For taking down and rebuilding No. 7, Pope's Head-stayle, Cornhill, for Mr. Frederick King. Mr. G. G. Judge, architect. Quantities supplied by Mr. R. L. Curtis:— Chittier.....£4,338 0 0 Simms & Marten..... 3,990 0 0 Madigan..... 3,930 0 0 Hunt..... 3,820 0 0 Bennett..... 3,469 0 0 Nutt & Co..... 3,450 0 0 Hemshaw..... 3,444 0 0 Mann..... 3,245 0 0 Kelley, Brothers..... 3,195 0 0 Nigdale..... 3,128 0 0 Eaton & Chapman..... 2,974 0 0 Langmead & Way..... 2,957 0 0 Rivett..... 2,923 0 0 Webb & Sons..... 2,895 0 0

For the erection of a station at Old Ford for the North London Railway Company:— Farman & Rothergshan.....£8,796 0 0 Abraham..... 8,398 0 0 Simms & Marten..... 8,385 0 0 Jay..... 8,363 0 0 Strivens & White..... 8,344 0 0 Eaton & Chapman..... 8,250 0 0 Bracher & Sons..... 8,200 0 0 Johnson..... 8,020 0 0 King..... 7,860 0 0 Myers..... 7,693 0 0 Hill & Keddell..... 7,676 0 0 Hemshaw..... 7,659 0 0 Axford..... 7,650 0 0 Mann..... 7,675 0 0 Kelly, Brothers..... 7,480 0 0 Perry & Co..... 7,474 0 0 Webb & Son..... 7,289 0 0 Hedger..... 7,153 0 0 Highy..... 7,148 0 0 Chappell..... 7,039 0 0 Wats..... 6,804 0 0

For alterations to Deacon's Coffee-house, Walbrook. Mr. W. Nunn, architect:— Mather & Read.....£1,900 0 0 Thorpe..... 1,769 0 0 Carter & Sons..... 1,753 0 0 Perkins..... 1,640 0 0 Sellick..... 1,519 0 0 Willis..... 1,479 0 0 King & Sons..... 1,470 0 0 Hammond..... 1,470 0 0

TO CORRESPONDENTS.

The Builder.

VOL. XXV.—No. 1254.

Ten Shillings a Day at Sydney.

HAT is the worth of money? The reply to that simple question depends very much on the fact of who is the questioner. For, practically speaking, money means different things to different people. So much is this the case, that even intelligent and thoughtful persons are by no means agreed among themselves as to many points relating to the nature of money. A ten-pound note, on the face of it, means an order to the Bank of England to pay to the bearer something more than two ounces and a half of standard gold, certified by legislative authority as to its purity and its weight. We have at this the element of certitude. What the value of gold itself may be to-day, or to-morrow, or ten years' hence, legislation can no more directly fix than it can alter the value which gold had a century ago. How many pounds of flour, or hundredweight of coal, or carats of diamonds, an ounce of standard gold will purchase, depends not on legislation, but on the relative abundance, from time to time, of gold, and of flour, of coal or of diamonds. Every man has to make his own bargains. All that Government can do to help him in this respect is to provide him with a convenient and intelligible set of counters, by the aid of which he may make them the more readily. And the value, that is to say the difficulty of obtaining the material, of which these counters are made, is one great element of their perfect convenience, and of their fitness for their object.

Even this simple, intelligible, truthful view of the pound-note is disputed by many persons, who, perhaps, ought to know better, but who would feel affronted to be told that they were, in this respect, at least, simply uneducated. But leave their case out of view for a moment. A bank-note being, philosophically considered, such as we have stated, how different an object does it appear to different persons. The very rich man has no need of money. He knows little or nothing of coin or of notes. Except on occasion of going abroad, he may not require for weeks or months together to see the colour of money. Accounts, indeed, he has to do with, and so will he tell you; but his payments are made by signing his name on a printed slip of paper. Of what use are notes or gold to him? His ordinary expenditure is regulated by his house-keeper, or his steward, or his bailiff, and paid by cheque. If he fancies any purchases, they are sent home to him, and paid for by cheque. He requires no loose cash for cab-hire, for his carriage is at call. If he wants a railway-ticket, his servant takes and pays for it for him, and it goes into his weekly account. An

odd half-crown for charity is forthcoming in the same manner. To men of this mode of life—and they are not rare in England—a ten-pound note is, an object of little more regard, and of less practical utility, than a sheet of note-paper.

Look at the other extremity of the scale. See the poor, cold, hungry child, to whom the corner of a silk handkerchief, carelessly peeping from the pocket of an infirm old gentleman, presents great and sore temptation. For it needs only a twitch and a run, and that handkerchief will be his own, and readily convertible into food and warmth. It will make to him, for some hours at least, the difference between keen suffering and positive enjoyment of life. What is a ten-pound note to him? Set aside the difficulty that he would have in cashing it—for respectable cashiers would be sharp in their inquiries as to how he obtained it, and his friend the dealer in silk handkerchiefs would exact a discount approaching close upon all per cent. for performing that needful office,—leave this out of the question, and let the symbol be the fair equivalent of two hundred shillings—of two thousand four hundred pence, and what a road to decency, honesty, and comfort might the possession of that sum open to the child who yet lingers on the verge of theft? It would form the difference between want and luxury to his parents for the whole bitter and murky winter.

To another class the ten-pound note is an object of even keener interest, for it is not absolutely unknown to them. It is an object that at times comes within their grasp,—though its visits are like those of angels, short in duration and far between. So much, with more or less certitude, is the annual income; so much the weekly expenditure. Unfortunately, it is the former that seems always to partake of the less, and the latter of the more. But somehow or other, by hard striving, or by hard pinching, or by more or less of both, ends are made to meet. Christmas comes round to a household out of debt, and respectability is maintained. How welcome to such a household, whether that of an anxious clergyman, of maiden or widow annuitant, of young professional man living on hope, or of thousands in the like condition, is an unexpected ten-pound note. It means the counsel of the physician for the sickly wife—the turning point between hope of recovery and languishing illness or death itself; it means the extra half-year's schooling for the hope and future staff of the family; it means the certitude that the faded silk or the rusty and disreputable great-coat shall not have to run the gauntlet of the centre aisle of the church for yet another winter. It is to those who can barely subsist in respectability, and who, so to do, are often compelled to live in discomfort, that money, when it comes as a godsend, brings perhaps the keenest enjoyment.

Reflections such as these arise in the mind from the perusal of a very remarkable document which the craftsmen of Australia have lately addressed to their English fellow-workmen. An idea of how different a thing the same sum of money may be to different people comes out forcibly as we read. Ten shillings a day for wages!—what a golden land! Who would stay in the old country that can secure a passage to the new? Who need chaffer about 6d. a day more or less, when he has hut to reach the antipodes in order to double his wages?

So many have thought and do think. So it is, upon paper, say those who have tried. But, first of all, wages in the new country, whatever be their amount, are more hard to be earned than in the old. There is more shifting from job to job. There is more difficulty in finding jobs at all. There are more blank days in the year, not at the order of trades-union committees, but because hands are more plentiful than work. And then work, when you get it, is harder to be performed, because there is an absence of the numerous appliances and aids to

labour which the stored-up labour of centuries has created in this country. There are no well-lighted, well-aired, well-warmed shops for carpenters; no lofty smithies, with the obedient alavery of the steam-engine urging the blast for the smiths and turning the lathe for the fitters, and doing all the drudgery for all sorts and conditions of craftsmen. In England the skilled and able workman can (if he set up no tyrant of his own manufacture), as a rule, command steady work, and perform it under circumstances of great comfort. In Australia he has to scramble for work, and to execute it, when he obtains it, out in the air, as best he may. What is a wet day to a London carpenter? It involves the expense of an umbrella. Six shillings thus laid out will serve him for two or three years. What is the result to an Australian carpenter? The loss of his day. A wet day costs the one 2s. or 3s. a year; it costs the other 10s. every time it occurs. That is one item in the account.

Thus, then, stands this account. "Employment is always hard to obtain, and, when obtained, is mostly of short duration." Under this qualification, masons and bricklayers earn 10s. per day; plumbers the same. Carpenters and joiners, 9s. per day; plasterers the same. Painters, 8s. per day. Bricklayers' labourers, 8s. per day. Quarrymen, 8s. to 10s. per day. Iron trades from 5s. to 10s. per day. In qualification of the rate of earning comes the amount of employment. Masons, carpenters, and joiners, bricklayers and plasterers, about two-thirds only employed. Bricklayers' and plasterers' labourers, only about one-half; painters only about one-third; in the iron trades only about two out of ten in employment. "They are in a most deplorable condition."

Against this hardly-earned rate of wages what is the *per contra* of expenditure. For a house of four small rooms, from 14s. to 20s. per week rent. Firing and lights, 4s. per week all the year round. Vegetables 250 per cent. more than in England; 8d., for instance, for a small cabbage. Bread and meat are cheaper: 5d. for the 2 lb. loaf; 5d. per pound for beef and mutton; pork and veal, 7d.; bacon and cheese, 1s. 6d.; milk, 8d. per quart; groceries about the same as in England, only very inferior; boots and clothes about the same, but so much less durable as to cost some 120 per cent. more than in the old country. No apprentices taken by employers; and no occupation for the young. Such is the account of their condition which the Carpenters' and Joiners' Society of Sydney have furnished to the Amalgamated Society of the United Kingdom.

At a time when the relations between the producers and the employers of labour are in so unsettled a state, it is a service to both parties to call attention to the prospect of the labour market in other countries. An accurate acquaintance with the condition of the foreign or of the colonial workmen is of no little importance to him who remains at home. Emigration is looked to as a powerful means of enforcing demands which are obstinately contested on either side. That capital can emigrate, and that readily, we all know. No less certain is it that labour can do the same. The question for the labourer to consider is, what becomes of the emigrant? Does he better his condition, or the reverse? It is in this respect that information is of value; and it will prove more reliable the more fully the facts that are reported coincide with the natural operation of any ascertained principles of social life.

There is no room to doubt that when a virgin and fertile country, possessed of a favourable climate, and unburdened with political restrictions, offers its acres, at an almost nominal price, to the tillage of emigrant labour, the benefit that may be secured by emigrants of a certain class is very great. For the man who can use the axe, the hammer, and the spade, who has youth

and health, who can put his hand to any requisite work, who can build his log-house, and clear and till his garden and his fields, and rear a teeming family with a healthy and active help-mate, emigration from the crowded courts of a great European city is almost tantamount to translation to a better world. But how few reared among such courts have the arm, or the pluck, or the wit, to snatch a homestead from the verge of the forest. Very rapidly do the outskirts of colonisation become affected with some of the worst evils of the old civilisation left behind, and that without the counterpoise that existed at home. And the moment you have to deal with occupations other than agricultural, the question becomes altered. The joiner, the bricklayer, the plumber, cannot do more work at the antipodes, provided he can get it to do, than he can do at home. On the contrary, he cannot do so much. In every craft in our own country that stored up labour of past years which we call capital has been long applied to facilitate the manual labour of the craftsman. Convenient shops, warmth, light and shelter, the greatest facility in procuring material, the best and the cheapest tools; and, above all, the ever-present, never-tiring service of the steam-engine, that most efficient of slaves,—all these are at the command of the workman in the old country,—all these are generally absent in the new. Therefore the amount of work that the craftsman can, with comfort to himself, turn out of hand in ten hours in England, will take him twelve, fourteen, sixteen, or even more hours, to execute in discomfort in a new country. The silent presence of capital, and the benefits it returns to the workman, begin to be appreciated, like so many of our blessings, most fully when their absence makes itself felt.

Look at the iron trades. Some of these workmen in our own country are more than independent. Few persons will argue that the quantity of ale consumed by the moniders, for instance, and the number of hours for which they may be relied on to work, are such as to be the most conducive to the welfare of either themselves or their families—to say nothing of their employers. Look at the perfect independence of a good foreman smith at Birmingham or at Wolverhampton. Look at the position taken by the puddlers. Now these men, able and skilled workmen as they may be, looking only to the labour of their own good right hands for a comfortable maintenance, are too apt to forget how far, in very truth, they are served and aided by capital. What has reared the lofty smithy, built the copels, and urged the incessant blast through the tuyeres? The labour of the past—that is to say, the capital of the employer. In Sydney this does not exist,—what is the result to the emigrant iron-worker? Employment two days out of ten,—such is their own account. English labour, served by English capital, can, and ever must, so far beat English labour deprived of English capital, that it is far cheaper to manufacture goods at Birmingham and ship them to Sydney, than it is to manufacture them by English hands at Sydney itself.

There is another consideration which will be readily understood by the English workman. In this country he has the choice of a market. The tools he uses, the clothes he wears, the provisions he consumes, may not be the very best of their kind, but he has his choice, and, within certain limits, is sure of his money's worth. But what is the case when a six-months' voyage lies between the producer and the consumer? What is likely to be the character of shop-goods when the purchasers are reduced to "Hobson's choice?" If in our own country we hear constant complaints of dishonesty in the manufacture and in the sale of goods, what is likely to be the case with goods that are manufactured for sale at the antipodes? If the Canadian emigrant finds that the best axe which he can purchase in London will not stand against the timber he encounters, what will be the quality of the axes shipped from London for sale at Sydney? At home, notwithstanding that the general race is for profit rather than for excellence, a wholesome competition is apt from time to time to restrain the delinquencies of the too greedy manufacturer. The pint-bottle may have shrunk to a most profitable capacity; the web of broadcloth may have contracted to the most economical number of inches; the purchaser may have been reduced insensibly to the very minimum of return for his cash, when up starts some new competitor for custom, and advertises imperial pints, or cloth of a warranted width.

Interpose an Australian voyage between supply and demand, and the tendency to make goods, not to use, but to sell, will lose its most wholesome check. Such, it is natural to expect, will be the case, and the complaints of the Sydney operatives do justice to the expectation.

What may be the state of affairs in other portions of the world to which the stream of emigration has been directed, we shall rather wait for the workmen themselves to inform us than describe from other sources of information. We know how heavy is the burden of taxation that a fierce war has imposed on the industry of the United States. The expenditure of that country for 1866, if divided among the population ascertained by the last census, amounts to no less than 27 dollars per head, which, compared to the present rate of expenditure in the United Kingdom, of 2l. 5s. per head, is about twice and a half as much! We know that conditions similar to those complained of at Sydney must be more or less present at all the great centres to which emigrants flock. In each instance, no doubt, there are peculiar features. At Sydney we see that bread and meat are cheaper than at home, while all the other requisites of life are far dearer. The disproportion between meat and vegetables is remarkable, and, in the absence of further information, not readily intelligible. It would seem as if there had been an absence of market-gardeners from the lists of emigrants. Still more surely do we trace one pernicious effect of the rapid growth of our great manufacturing towns. Thirty years ago, even in London, a garden was not out of the reach of the occupant of many an humble abode. The journeyman found time to tend his favourite flowers, or to raise many valuable vegetables, and some of the choicest favourites of the horticulturist have been first reared in the poor man's garden. As building has covered all available space, not only has this healthful and elevating occupation been denied to the workman, but his children have grown up almost in ignorance of the existence of garden flowers. Thus among those numerous young people who have no occupation at Sydney, the natural and healthful employment that may be derived from the cultivation of the merest patch of ground seems unknown. If this were not the case, we should hardly find that a small cabbage—a plant which requires so very little for its production—is not to be purchased for less than eightpence. A strong proof is thus afforded of the difference between emigrants and settlers.

Thus, then, again comes the question, what is the worth of money? The reply is of the utmost importance to the intending emigrant. Ten shillings a day in Australia is not the same thing as ten shillings a day in Middlesex. You take more counters for your day's work, but you have to pay away more counters for your day's living. And, as your earning is one, and your expenditure is manifold, the balance is likely to be very much against you. What has produced this difference in the worth of money is another question, and one into which we have not now space to enter. It is a difference that is felt more or less all over the world, and it is partly real and partly only apparent. To that subject we may hereafter recur, our present object is to call attention to the important fact that the nominal rate of wages is only one out of many circumstances that regulate the welfare of the workman.

It must be noticed that anonymous criticism has questioned the accuracy of the statement of the Sydney workmen. We can only give their figures. Right or wrong, they have brought them formally under the notice of their fellow workmen in England, and they have set their names to their statement. There may, or may not, be more or less of bias in their motives, but the very imputation thrown on the accuracy of their statement should form a fresh reason for the intending emigrant to weigh well his decision, and to sit with jealous care the information with which he is supplied.

THE LIVERPOOL TRAMWAYS.—The general good feeling entertained in respect to the laying down of street railways in this town is evinced by the fact that within a few days no fewer than 14,000 of the inhabitants have affixed their signatures to petitions to both Houses of Parliament, praying that the standing orders may be dispensed with in their favour, and that the bill authorising their construction may be at once proceeded with.

THE SANITARY CONDITION OF THE NEW TOWN OF EDINBURGH.*

In Edinburgh at the present day there is nothing to prevent (and it frequently occurs) a whole district being built upon, and drains laid down of the most defective description, without the plans being submitted to any competent authority on a matter of such vital interest, while the public officials are powerless to interfere until the new houses are inhabited, and a special complaint lodged by their neighbours.

Water-closets have been introduced into the houses in all the streets in the New Town, with certain notable exceptions, which we shall advert to presently; but from the inefficient mode in which they have been erected and the objectionable places they have been made to occupy, so as to ventilate now into the kitchen, then into one of the sleeping apartments, it has been doubted by competent authorities, such as Dr. Stark, whether they have not done more harm than good in a sanitary point of view. Few of them are air-tight, and the consequence is that the foul gases which are generated escape into the other parts of the house. The nuisance is had enough in self-contained houses; but it is still worse in those entering from common stairs. In the latter all but invariably,—it would almost seem to be one of *malice prepense* on the part of the architect,—the water-closets are made to ventilate by a small window into the common stair, and there being six or eight to each stair the pollution of the atmosphere may be more readily imagined than described. The staircase skylights (where such exist), instead of having flaps to permit the exit of foul gas, are almost invariably closed, and the inhabitants themselves increase the evil by persistently keeping the stair windows closed down. Accordingly, whenever the street-door is opened the fresh air thus admitted forces the impure hack into the houses. So offensive is this state of things that many persons living in flats,—especially in the upper ones,—cannot inhale the air at their own doors without experiencing nausea and sickness. Let not our English readers fancy that we are romancing. It is an "ower true tale," as evidenced by Dr. Littlejohn (Report, pp. 105, 106). It is even yet more extraordinary that in the most recently-built streets the architects persist in ignoring the best-known laws of sanitary science, and placing the water-closet in the very worst possible part of the house for the purpose. While it should be in a situation of easy access, it should in every case be against an external wall, and have full means of constant ventilation to the open air. Something, however, might be done to prevent the escape of foul gas into water-closets. Charcoal filters would at any rate alleviate, if not entirely remove this nuisance. As recommended by Professor Stirling, a little below the valve of the closet a subsidiary pipe should branch off from the main pipe, and be carried a few feet above the closet seat. The extremity of the pipe, across which should be stretched a few wires, should penetrate to the extent of two or three inches into a charcoal bed or filter six or eight inches thick.

Many of the streets of the New Town are totally destitute of "closets," more particularly the hy-streets, such as Rose, Thistle, Jamaica, Cumberland, and William Streets, and nearly all those in the populous and over-crowded quarter of Stockbridge. These localities are principally inhabited by artisans and small shopkeepers. Each family usually occupies but two apartments (sometimes only one); or, if more, one of them is in the ordinary case let to a lodger. In some cases, a water-cistern and soil-pipe are furnished to each family; in others, they are common to all who live on the same floor; but there is no convenience. The death-rate in these hy-streets rises far above that of those streets in the same locality in which they have been introduced. Thus in the year 1863 (and we take that year as the latest the sanitary statistics of which are at our command), while the cases of death in the upper New Town district were 17.35 per 1,000 of the population, in the side streets, Rose and Thistle Streets, situated between Prince's, George, and Queen Streets, the death rose to 20.49; so, too, in the same year, the death-rate for 1,000 persons in Jamaica-street and Cumberland-street was 22, while in the other streets of the lower New Town district it was no more than 17.35. So, also, while the death-

* See p. 35, ante.

rate of the upper Water of Leith district was only 19 per 1,000, that of one portion of it, namely, the triangular area bounded by India-place, Sanders-street, and Kerr-street, which is all but totally destitute of water-closets, was 26.86, while that of children beneath five years of age, rose to 106.67. Again, in the district of the lower Water of Leith, the total death-rate was 17 per 1,000, while in certain streets of it, such as Dean-street, Mary-place, Allan-street, Cheyne-street, Bedford-street, Hermitage-place, &c., all unprovided with conveniences, it rose to 25.02, and the infant mortality as high as 69.07. It is right to remember that in the second last instance the locality is intersected by an open mill-lade full of all abominations, and that the inhabitants are crowded in the proportion of 516.7 to the acre, and that in the last instance the density of the population is 336.9 to the acre. Making due allowance for the bad effects of overcrowding, these figures show the urgent necessity of the immediate introduction of water-closets into every house in the New Town.

And this leads us to observe that the New Town is miserably deficient in the number of public "closets" and conveniences for the outdoor male and female population. In a city like Edinburgh, which attracts so many visitors from all quarters, the duty of making such provision is all the more incumbent. For the whole of the New Town with a population (in 1861) of 61,956, there are but eight public conveniences which can accommodate fifty-seven persons only. None of these are set apart for females. In the whole of the three districts of the Upper New Town, the Lower New Town, and the West-end, which together have a population of 37,702, and which are so much visited by tourists and excursionists, there are but one water-closet range of eight compartments and four urinals, and those hidden away out of sight, and not to be come at except by the initiated. This is not as it ought to be; but both the municipal authorities and the inhabitants of the Modern Athens are fastidiously thin-skinned on this subject; and something very like a howl of indignation, if not of execration, is raised against the innocent innovator, who urges upon them the recognition and supply of such wants. The offenders against good taste are not those who point such requirements out, but rather they who object to comply with them. Let that be done, however, and there will be no need ever to mention the unsavoury subject.

We are not nearly done with our account of the nuisances of the New Town. One other is that which results from the faulty construction of the rain-water pipes, which convey it from the house-roofs to the drain. Where they are not properly trapped, they act as a shaft for the conveyance of the sewage gases, which, escaping at the top, enter in at the dormer and attic windows in the roof, and so find their way into the whole house. Numerous cases of typhoid fever and other diseases have been traced to this source. It is a most noteworthy circumstance, for which Dr. Stark vouches,* that on the second visitation of cholera to Edinburgh all the fatal cases—and, indeed, almost all the cases—occurred in two parts only of the tenements, namely, on the lowest and highest floors. While Dr. Stark ascribed the presence of the disease on the ground floor to the sewage gases, the dampness, and want of cleanliness on the part of the residents, he accounted for its appearance, after skipping the intermediate flats, in the attics to their low roofs, the smallness of the skylights, and the confined area. We have little doubt, however, that its occurrence in the topmost stories was due to the gaseous emanations from the mouths of the rain-pipes.

Yet another and frequent source of disease is the filthy and unwholesome condition of the water-cisterns and their connexion with the drains. Unless the overflow pipe, which communicates directly with the house-drain, is properly trapped, and it rarely is so, it affords a means of ingress to the sewage gases, and the water becomes perilously tainted. The cisterns, besides, are too often left uncovered, and exposed to the pollution caused by dust, rats, and mice; while, owing principally to the frequent change of tenancy, they are often left uncleaned for years. It is by no means a pleasant thought that the water you are drinking has been taken from an open lead cistern, situated in the water-closet above the seat, but that is a common occurrence in Edinburgh. There is no more

fertile source of illness than contaminated water, many eminent medical men ascribing to its use mainly all cases of cholera attacks. "No more frequent cause than this," says Dr. Littlejohn, speaking of untrapped overflow pipes, "has come under my notice in the upper stories of large tenements, which from their elevation appeared to be far removed from all possible effluvia from drainage."

On entering an Edinburgh kitchen or scullery, the olfactory nerves are apt to be assailed by an offensive smell emanating from the sink, which is sometimes made of lead, but more frequently of stone. In either case the stench arises from the chemical action of the water upon the sink. The remedy, it is well to know, is the substitution for the stone or lead, as the case may be, of slate or of glazed stoneware. This is not so unimportant a matter, as some people are inclined to think it, for the gases so generated diffuse themselves over the dwelling, and besides being disagreeable to the nose, exercise a powerful and deadly influence when the state of the atmosphere is favourable to cholera and other zymotic diseases.

We have already alluded to the leakage from badly constructed cesspools and box drains, as causing dampness of the basement floors. There is yet another very frequent cause, namely, the neglect properly to drain the back garden, which is attached to almost every house. Especially in the back gardens of those houses, which are built against the slope of the ground to the north and south of George-street, the rainfall is left to seek the lowest level, which is that of the foundation. The consequence is that the ground-floors are rendered damp and musty, the joists and flooring decay, while the debris of shavings and other vegetable matter, which are allowed to lie among the foundation, are speedily decomposed and putrefy. It cannot be too strongly impressed upon people that damp dwellings are productive of rheumatic affections, dysentery, and fever, together with mental depression, and a disposition towards, nay, an almost irresistible desire for, intoxicating liquors. In every case the soil of the back-yard should be properly relieved of the rainfall, either by laying down tile drains, or by paving the entire area. The water may then be conducted into the main drain of the dwelling, which it would assist in flushing and keeping wholesome.

Fortunately both for its cleanliness and general health, the New Town has few manufactories, and we should consequently expect to find it exempt from smoke pollution. Eleven glass, two chemical, and thirty-one metal works may be said, with the exception of the printing establishments, to be the only works which pollute the atmosphere with smoke or steam. There are no fewer than twenty-five printing establishments, and these in defiance of the Smoke Nuisance Abatement Act, and the Local Police Act are continually heaving forth volumes of steam and smoke. Perhaps it is only indirectly that this occasions detriment to health; but people resident in their neighbourhood are fair, if they would preserve their furniture, to keep their windows closed, and in this way free ventilation of their dwellings is impeded. We are not, however, surprised that this nuisance is allowed to exist, when we find that three different officials are empowered by the Police Act to prosecute offenders of this description, namely, the Procurators-fiscal in the Police and Dean of Guild's Courts, and the superintendent of streets and buildings, instead of its being the imperative duty of one of them.

One other nuisance is the condition of the many byres which exist in the New Town, or rather of the old out-houses or stables, which are used as such. Between 800 and 900 cows are housed in these, or, at least, were immediately prior to the outbreak of the rinderpest. The medical officer of health complains—and our own observation enables us to say that he complains justly—that these byres are too often kept in a constant state of dampness and filth. From the want of proper flagging and drainage the liquid refuse and byre washings saturate the court or lane, and at the same time there is a constant fermentation of the manure in the middens going on. The effluvia arising in this way, and from the animals themselves, and the preparation of their food, are highly offensive, more especially in dry weather. What are used as byres have rarely been built for the purpose, while the cows are overcrowded, and light and ventilation all but excluded. From the situation of the byres and stables, and their adjuncts, the middens, it results that many windows, which should be

opened for ventilation, are kept close to exclude the disagreeable and noxious fumes.

One decided source of discomfort, if not of disease, prevails to a great extent, and even in some of the most fashionable streets. On the walls of the butchers' and fishers' shops, which are ordinarily placed in the most prominent positions at the street corners, may be seen exposed the carcasses of oxen, sheep, and pigs, together with their skins and offal. These are not only eyesores, destroying the amenity of the neighbourhood, but they taint the surrounding atmosphere with a strong effluvia. We are glad to see in the Provisional Order, which we hope soon to see law, that such offensive exposure will be made a police offence, punishable by fine, and in default by imprisonment. The Edinburgh butchers' and fishmongers' shops, having in few instances been specially built for the purpose, are very deficient in the requisite sanitary safeguards.

There is still one other nuisance to be adverted to, which is all the more vexatious that it is of recent creation. A little to the west of the Haymarket Station of the North British Railway stands the Caledonian Distillery, the largest work of the kind in Great Britain. This distillery, without taking any steps to render its offensive and dangerous refuse innocuous, throws it into the Lochrui Burn, an unenclosed drain, which irrigates about ninety acres of meadow ground, and travels westward a distance of 300 yards or so, until it debouches into the Water of Leith, tainting and polluting the atmosphere of the whole neighbourhood, and consequently deteriorating the value of the streets and villas which have been recently erected there. It is to be regretted that the authorities do not possess, as they do in France, the power of preventing the erection of manufactories in towns, until a committee of eminent scientists have reported that the site is a suitable one, and that no injury will accrue to human health. In Edinburgh, the only remedy available to the sufferers by such a nuisance is the tedious, expensive, and hazardous ordeal of a trial by jury.

We have probably not noticed all that is deserving of condemnation in regard to the hygiene of the New Town;* but we do feel more at ease now that our invidious task is over, and that we have come to the last count in our indictment. It is with real satisfaction to ourselves that we have now to invite attention to the arrangements made by the Edinburgh authorities for the daily collection and removal of the filth and solid refuse of the city. In no other city or town, we believe, is such removal so efficiently and economically, or rather, lucratively carried out. It puts a large sum into the civic treasury, thereby saving the inhabitants as much as 3d. per pound in the rate of assessment for general police purposes, at the same time that it supplies the farmers in the vicinity with a cheap and valuable manure. During the twenty years preceding Whit-Sunday, 1859 (as appears from a report in connexion with the cleaning department, read in the town council), the solid refuse collected from the streets of the city amounted to 830,000 tons, which were sold for 158,000*l.* This gives a yearly average of nearly 8,000*l.*, which are thus saved to the city. For the year ending 15th May last the sum realised by the sale of manure was 8,972*l.* It cannot but be interesting to know how this is brought about. The Edinburgh Police Act requires that all offensive matters shall daily be taken in pails or buckets, or other suitable vessels, to the street, there to be emptied into the dust-carts by the scavengers or carters. Failure to comply with this requirement of the statute is punishable by a fine not exceeding forty shillings for each offence. Sixty-five dust-wagons are daily employed in this service. A large bell attached to one of the trams announces their approach. They visit the Old Town and the poorer quarters of the New Town, both morning and evening; but a morning visit alone is found sufficient for the greater portion of the New Town. There is a staff of 153 scavengers employed, and 147 in winter, under the superintendence of the inspector of cleaning, assisted by eight overseers or district inspectors. The scavengers, each of whom has an allotted beat, begin work

* We have barely hinted at the overcrowding, which exists in too many localities. To give a single example, the house, 23, St. James's-street, although as originally erected with good-sized airy rooms, has been so subdivided as to give, two years ago, accommodation (is the word admissible here?) to 220 human beings. 230 human creatures in a single house, in which there were but eleven sinks and one water-closet! We had almost forgotten to say that the lowest story is occupied by shops.

Inquiry into some points of the sanitary state of Edinburgh, by James Stark, M.D.

at five a.m. during the summer months, and at six a.m. in winter, and, with an hour's interval, continue at it till four p.m. On first going on duty, the scavengers prepare the ashes and refuse so as to be the more rapidly transferred to the dust-wagons, which is effected in the New Town between six and seven o'clock, and in the Old Town between seven and eight. After the dust-wagons have passed, the scavengers go over their heats again, and sweep up whatever may have been left. The staff thus swept up they convey in their wheelbarrows to covered dust-bins, which are placed in various parts of the city, and which are cleaned out once a day. These dust-bins, which are usually about 8 feet long by 4 feet broad and 6 feet high, are kept locked. The refuse thus removed from the houses and streets is taken to depôts in the suburbs if it is not carted direct to the different railways, which it usually is, as the demand for it for some years past has more than exceeded the supply. Consisting principally of ashes, bones, and decaying vegetable and animal matter, it makes an admirable manure, well adapted for soil of a cold clayey description.

The contract to remove this refuse is exposed to public competition, and the successful competitor is required to find security that he will conduct the removal within a given time to the satisfaction of the inspector of cleaning, who is directly responsible to the Town Council. Further, the contractor must possess a capital of 3,000*l.* to enable him to provide the requisite men, horses, and tools. The cleaning plant is made and repaired in central public workshops, situated near the King's Stables, which were erected at a cost of 8,000*l.* by the authorities. The horses are stabled here, and the dust-wagons and carts put up. From a paper by Mr. Macpherson, C.E., superintendent of streets and buildings, read a week or so ago, it appears that about 1,342 wagon-loads of mud from paved streets, called "sludge," which is largely mixed with horse droppings, is collected and removed to the depôts; and after lying some time is sold at a cheap rate as a manure. There are also about 4,937 wagon-loads of mud collected and removed from the macadamized roads annually, which are carted away to any place of deposit suitable and convenient at the time; no use as yet having been found for it. Such is a short account of the manner in which in Edinburgh the solid refuse is removed and utilised. Those interested in this subject will find it more fully explained and discussed in a paper read in 1863 before the Social Science Association by Dr. Henry D. Littlejohn.

The charge of lighting the city is also entrusted to the inspector of cleaning. The Edinburgh gas enjoys, it is said, the reputation of being the very best in the kingdom, and being moderate in price; not only are all the streets lighted with it, but it is introduced into every shop and private dwelling-house. So pure is that it is used without any bad effects in all the jewellers', silversmiths', and booksellers' places of business. There are two rival gas companies, the Edinburgh Gas Company and the Edinburgh and Leith Gas Company, both of which supply the whole of the city with gas at a cost of four shillings and tenpence per 1,000 cubic feet. Excellent, however, as is the quality of the gas, Edinburgh is but badly lighted after all. The street-lamps are much too few and far between. Owing to this circumstance, and to the early closing of the shops, even the principal thoroughfares, on a moonless winter's night, are but dismal promenades. The street-lamps, although of simple design, are not deficient in elegance.

The rates for watching, cleaning, and lighting the city, and maintaining the fire brigade (why is it that they have not a fire-escape?), it may be mentioned, are a halfpenny per pound on four-fifths of the rent on houses of ten pounds and upwards, and eightpence on four-fifths in the case of houses below ten pounds. They may be taken as equal respectively to elevenpence farthing and sixpence halfpenny on the gross rent.*

* A correspondent, with reference to the observation in the description of the water-supply and drainage of the New Town of Edinburgh in our pages, that "within the last twelve months the Army and Medical Commission have condemned Piershill Barracks as the most unhealthy in Scotland," says—"I have ascertained that the Secretary of State for War" is not aware "that the barracks at Piershill has been condemned. What is the ground for that statement in the *Builder*? I inquire because many are anxious to ascertain what effect the application of sewage to land has on the health of human beings?" The statement in question appeared in the local papers, and was the subject of much conversation in all circles, civil

DESIGNS FOR THE PROPOSED LAW COURTS.*

To make clearer the description we have given of Mr. E. M. Barry's project, we annex a key plan,† showing the general arrangement, the appropriation of the various portions of the building, and the mode of access to the public galleries by separate staircases, entered directly from the street without communication with any other part of the building.

Those conducting the business of the courts would in no case have to pass through or across the part in which business is transacted. Judges, jurors, witnesses, counsel, all have their separate entrances, and would have no necessity to move about the court or intrude on each other.

A general corridor has not been thought a convenient arrangement, for the reasons stated in the instructions. The offices are as far as possible distinct from each other, and separated into blocks by the interposition of the courts, party walls, or fireproof halls and staircases. By this arrangement the building is divided into many fireproof compartments, any one of which could be shut up on cessation of business, or during its vacation, without interfering with the access to the others.

The form of the plan would separate the traffic to the courts from the general and ordinary traffic of the streets. The inner street round the central block containing the courts would be closed towards the Strand by lodges and gates, and would thus be kept private for the sole use of those having business in the building. Bridges not shown in the plan connect the central block with the offices around.

Mr. Barry, and in this we agree with him, considers skylights for the courts very objectionable. He has, therefore, designed them with high side windows, and has provided that these shall open. The heating would be by hot-water pipes, and fresh air would pass into the court from a chamber under the public corridor.

"The ceiling is designed on a similar principle to that which has been found successful for accountants, lighting, and ventilation in the present House of Commons. The centre of the ceiling is perforated, and a vitiated-air-chamber is formed above it. This chamber communicates with powerful air-shafts situated over the public staircases. Gas burners are placed above the roof, and when lighted aid the ventilation very effectually, while all heat and products of combustion are prevented from entering the court, and are carried off at once by means of the vitiated-air-chamber into the air-shaft. The architect has so arranged his plan that the boiler-floes from the basement pass up the newel in the centre of the staircase. The upper part of these floes would be formed of iron pipes, the heat of which passing through the vitiated-air-shaft would create a strong upward current. As some of these boilers would be in constant use for the hydraulic machinery of the lifts and for other purposes, the system would be self-acting; but in case of the temporary disuse of the boilers by accident or otherwise, provision would be made for the power of the ventilating-towers for a fire of coke to assist the draught, as is now done at the House of Commons."

To the elegant (Gothic) detail of some of Mr. T. N. Deane's external work we have already referred. The clock-tower, at Temple-bar, is remarkably well designed. His plan is also noteworthy for the extent of open space afforded by areas throughout the building, an important consideration with reference to both light and air. The corridor by which the public gain access to the several courts is approached by four main staircases, separate from the business staircases; the first in Carey-street, the second in Bell-yard, the third in Clement's-inn, the fourth being the main staircase in the Great Hall. Mr. Deane claims that—"The public, having thus reached the court corridor, cannot possibly obstruct any one employed or having business in the courts, inasmuch as the corridor to be used by such persons is on a different floor of the building." The Central Hall is somewhat small, and heavily filled up. The weak part of the plan is its straggling character, and the want of that concentration which is being aimed at.

The cost Mr. Deane puts at 1,074,278*l.*, produced by 25,554,939 cubic feet, at 10*d.* per foot.

Mr. Street's design includes a Central Hall, 190 ft. in length and 57 ft. wide (with stone vaulted roof), round which a certain number of the courts are ranged; on the north, the Courts of Equity; on the south and east, the Common-Law Courts; and on the west, the Divorce,

and military.—the townspeople regretting the threatened loss of one of the military bands they had been accustomed to. The writer concluded that the statement, if unfounded, would have been contradicted at the time.

* See pp. 69 and 83, ante.

† See p. 112.

Admiralty, and Ecclesiastical Courts; and all these are approached as much as possible from the north and south only. On the outer boundary of the site are the offices connected with the courts; and to avoid the creation of noise these are to be entered from the outer side.

A key-plan, however, will explain with fewer words the general arrangements, and the architect shall describe it himself.*

The courts are separated by areas, which serve to light the rooms under the courts.

In his arrangements as to the admission of the general public Mr. Street seems to come a little into collision with the Commissioners' views, to which we referred in our last. He appreciates the objection there is to the way in which, in every court of justice in this country, the general public is mixed up and interferes with the work of those who have business to conduct in them. There can be no necessity, he says, for admitting any large number of curious visitors to any court. All that is required is that there shall be just so much accommodation for them as shall make the proceedings of the courts public, and, at the same time, that they shall be so isolated from those who use the business parts of the courts as to make it unnecessary that the two classes should ever come near each other. In his plan, the public have two entrances on the south, and two on the north. These are by staircases at the northern and southern ends of the public corridors, which run north and south at each end of the public hall. All these staircases are for the use of the public only, and lead to the Central Hall and public corridors; and out of these are doors leading directly to the upper part of the galleries in every one of the courts. The public corridors command each a certain number of courts, as may be seen on the plan, where also is shown the position of the grilles to keep the general public in their way to the gallery of four of the courts from spreading over the Central Hall. One of the courts (4 on the plan) would have no means of access for the public but by the Central Hall.

Now, as to checking the circulation of the general public, the Commissioners go farther than Mr. Street. He says in his explanation:—

"I observe, in the instructions to architects, a request that the gallery of each court should be separately reached from the street. This appears to me to be an impossible arrangement without vast loss of space and great expense, and therefore an impossible arrangement in so restricted a site as that with which we are dealing. With ordinary care, there is no reason whatever why any inconvenience should be felt according to my arrangement. When the public gallery seats are all full, it will be the duty of the policeman in charge of the door to refuse admittance altogether till there is a vacant seat. So that it will never be likely to happen that people will be taken round, as they now are, to all the courts in succession to see what is going on, in satisfaction of the idlest curiosity."

That the arrangement desired is not actually "impossible," is shown conclusively by more than one of the competitors; and should the Commissioners not be led to attach less importance to the requirement than they originally did, both Mr. Street and Mr. Scott will probably find this part of their plan counted against them.

Mr. Street gives two good open areas within the pile—one east, the other west. One object kept in view has been to prevent any part of the building being made use of as a passage-way from the Strand to Lincoln's-inn, or from east to west by persons who have no business in the building. For this reason he has provided no carriage exit from the inner quadrangle on the east side, so as to discourage the entrance of vehicles.

The great tower for the records, which he has placed on the triangular projection on the western, or Clement's-inn, side of the site, is well designed, and forms an effective feature. The central part of the building, including fittings, furniture of courts, warming and ventilating, lighting with gas, exclusive of subways and bridges beyond the site, is put at 1,314,360*l.*; and the additional cost of bridges and subways outside of site, viz., across Carey-street, Strand, and Bell-yard, 16,150*l.* These estimates include warming and ventilating, also gas and water. The cubical contents of the entire building are 26,485,713 ft. and are priced, after measurement and valuation of several sections of the building, at 9*d.*, 1*s.*, and 1*s.* 3*d.* per foot cube, according to position.

Mr. Abraham cubes his design to 23,500,000 ft., and prices these at 10*d.* a foot as an average. Adding certain sums for the eastern tower, the

* See p. 112.

central tower, concrete, enclosure walls, and bridges, he makes the total 1,234,166l.

Mr. Seddon brings the cost of his design to a much higher figure. Thus to the main building he gives—

Feet.	s.	d.	£.
0,698,081	cube	blocks of buildings in	
		inner courts	0 10 404,097
27,540,772	"	main blocks of buildings	1 2 1,606,545
2,614,432	"	towers commencing at about 120 ft. above Strand level	1 6 198,082
£2,206,714			
Corridors and Approaches.			
781,500	"	glazed covered way and terrace	0 4 13,025
3,188,147	"	corridors and entrance gateway, &c., &c.	1 0 159,307
Making a total cost of.....			
£2,379,046			

Mr. Seddon's plan may be described as a complete parallelogram, of 670 ft. in length by 430 ft. in width, and consists, firstly, of an outer range of building, 50 ft. wide, surrounding this area, and containing the several chambers and offices. Secondly, in the space comprised within this outer range, a central building, bisecting it centrally in the direction from west to east, parallel with the Strand, and containing a general hall, refreshment-rooms, and libraries; another, of less width, intersecting it in the centre, like a transept, containing the principal entrances and staircases; and lastly, within the four smaller areas left between these buildings are the various courts and their appropriate rooms, which are considerably less in height.

The upper floor of the offices looks over the roofs of the courts, and the lower floors into areas 22 ft. in width.

The courts are in two ranges, running east and west, one on each side of the Suitsors' Hall.

In this arrangement of the Law Courts, within the four internal areas of the buildings, the nature of the site prevents the spaces between them from being of greater width than 12 ft.; the courts themselves are lighted from the top, as well as from clearstory windows; and the rooms which are necessarily placed below them are those which are appropriated as witnesses' waiting-rooms and jury-rooms.

The author says—"The general public can enter the Great Hall by the four principal entrances in the centre of the four sides of the building, and by the recesses in front of each court to the space allotted to the public under the gallery in the court." The public, we fear, would be able to do, in short, exactly what the Commissioners have shown it must not be allowed to do, namely, range from court to court at its own sweet will.

We might fairly praise Mr. Seddon for the cleverness with which he has given an archaic aspect to his elevations, and the ability shown in some of his drawings; and we might explain as to his enormous tower, that it is for the purpose of storing the wills; that the windows are arranged, as desired by the Probate department, extending from top to bottom of each floor, and close enough to each other to throw light between each range of shelves; and that it seemed to him desirable to explain externally this practical character, rather than to design a tower having more the look of a helmy without bells. But as we are disposed to think that the plan can scarcely go into comparison with some of the others submitted, this would after all be useless.

Nor, with the best feeling, and much admiration for artistic ability displayed, can we arrive at any other opinion with reference to Mr. Garling's design. The whole ground is too closely covered; there is a want of simplicity in the arrangement; and there is no striking central feature. Mr. Garling objects to a Central Hall, and effects communication by wide corridors, one 30 ft. wide and 380 ft. long. The public, however, if we understand the plan rightly, can get access only to a gallery raised above the business portion, and communicating solely with a staircase descending at once to the basement. There appear to be some good arrangements to get under and across the courts. He objects to top-lighting, especially where the sides of the opening in the ceiling are lofty, as unfavourable to sound. A central tower, with low spire and two short towers at each end, with truncated roofs, a series of close buttresses, and ranges of pointed-headed windows, are the principal features of the Strand front.

Mr. Garling estimates the cost of his building at 1,090,061l., making the cubical contents 23,832,790 ft., and pricing these at 8ms varying from 3d. (foundations), to 1s. 6d. (central tower)

per foot: the bulk of the work being put at 11d. Touching these prices, he says,—

"I have always been in the habit of ascertaining the price per cubic foot of any buildings of which it was possible to get the price accurately calculated, and I have found that, executed by the best London builders—Offices in the City, most substantially built, and with ornamental stone fronts, cost per cubic foot 9d. to 10d. Churches of the medium expense of decoration 6d. Ordinary substantially built well-finished dwelling houses, with moderate external decoration 7 3/4d. to 8d. or 9d. Noblemen's mansion or club-house, with decorated stone front, and finished handsomely 1s. to 1s. 2d."

The Royal Exchange and the Bible Society's premises, with an expensive stone front, cost 11d. per foot.

Mr. Garling is the only competitor who has sent an alternative design of Italian character. It appears to have been understood from the beginning that the Law Courts were to be in the Gothic style, and Gothic they, doubtless, will be. Probably, indeed, such has been the course of study in England, we shall thus get a more agreeable building, for the time, than might have been the case had another style been worked on; but we should helie often-expressed opinions if we admitted that it is thus that the century is likely to arrive at the possession of a noble vernacular architecture of its own. The erection in the midst of the City of a large pile of Gothic architecture, pure and simple, would have the effect of driving off for a further time the wished-for advent. Let us hope that the Gothic adopted may be such as will best admit of the developments suggested by modern views, modern requirements, modern materials, and modern modes of construction.

THE BUSINESS OF GLASS-PAINTING, AND THE ART.*

To go to the second part of the subject, it is evident that the greatest difficulty lies in the treatment of pictures in glass. You have seen in the slight sketch of the art how as the other arts advanced the glass-painter was tempted to push his also forward, not only from an ambition to rival them, but that his eyes having become habituated to a more artificial and academic system, he followed onward with the stream of his contemporaries. But he found at last, as many other reformers have found, that advance is not always synonymous with improvement. In his time (I mean that of the end of the fifteenth and beginning of the sixteenth century) perspective had become a science. Theories of composition, of the balance of lines, and of the balance of colour, were taught as axioms of art. Pictures were no longer suggestions or reminiscences, but actual representations, with all the natural effects of sun and shadow, night and day. And why was not all this to be effected on glass as well as on canvas or on a wall? The glass-painter of that period, with his eyes confounded by the dazzle of other arts, seems to have gone on asking himself this question. And now in our time people are asking it again. They are demanding pictures for their windows—family legends and local traditions figured in painted glass for their halls, sacred subjects for their churches. How is the modern glass-painter to proceed? He certainly stands on the vantage ground of experience. The successes and failures of past days are all before him. He has, with few exceptions, the whole array of materials for an equal success; he has himself only to blame for equal failures. His difficulties are the difficulties of abundance rather than of poverty. Style after style is open to his choice. Science is at his bidding. Galleries and museums are open to him everywhere. And the skill of the modern artisan sets him at ease about matters of technicality. But it is just in all this that his trouble lies. He is impelled by all around him to the idea of advance. The notion of accepting the principles which were brought to perfection in a less educated age is to him a notion of retrogression. And there are other rocks than these also for him to wreck upon. There is the preoccupation of everybody around him in all the absorbing objects of this busy age, which unfits them for the quiet atmosphere of art, and greatly disqualifies their judgment. Thus there is the unsettled state of architectural taste, which keeps all the arts associated with it

in the same unhappy condition. Then there is that most fatal commercial element to contend with—to which, indeed, he all honour and respect paid within the broad limits of its proper action for individual and national enterprise. But when commerce invades the realm of the arts, and presses one of the finest of them, as it now does glass-painting, into its service—no loose stone in a foundation, no poison in the food, no worm in the bud, could be an element of more certain ruin than it. I know that here I touch on a very delicate subject. I know that the artist must live by his art. I know, too, that it will be replied to my objection that the artist is under great obligation to the man of commercial energy for giving him the means of constant employment. So far so good; we are quite agreed so far. The evil is not here. The evil does not lie in the man of commerce supplying the artist with the means of constant employment, but in the simple reversing of those words, viz. that it is the artist who is pressed to supply the commercial man with the constant employment of his means. That is the evil, and a serious one. The very energy of the employer is the ruin of the artist he employs—ruin I mean of his art. He may fill his pockets perhaps, but he empties his talents. His talents are over-pressed; the fertility of his invention overtaken; orders pour in, customers become impatient, work must be completed, or, in its commercial sense, "turned out," in a specified time. The result is repetition, inferiority, and routine. But a still worse state of the case is this, and a common one, that the contract price keeps down the quality of the work—and quality in a commercial view is a matter of time, and time is money; and thus a man's genius and higher feeling are fettered and crushed because one breath of it more, one step of it further would not pay. Its rich stream of genius must be diluted down to the necessities of trade. Genius is become an article of commerce, to be sold by the pound, or to be measured at so much per foot, as we see every day in glass-painting. I assert that this is utter degradation of art. No art can live long in such an atmosphere, nor come to perfection under such a pressure. Thus far indeed it might rise. And for such a purpose the lower powers of art are not improperly applied. There are, for instance, very many things, objects of universal use and trade, of which the value is very legitimately enhanced by a certain amount of artistic excellence. For such purposes let such a system prevail,—such as for carpets, curtains, silks, and ribbons, tables, embroidery, earthenware, clocks, and ten thousand other things, in which dealers must deal, and which manufacturers must supply. The more they civilise and cheapen their wares the better. But there are occasions also here, where a rather high character of art is sometimes applied; as, for instance, in the painting of the finest porcelain. But I never heard of even that being degraded as our glass is. I never yet heard of a Sevres vase, or a Dresden group, or a Chelsea bowl, being sold by the measure of their surfaces, or by any other test of value but that of their artistic excellence. I know that the glass-painter must live by the work of his hands. The greatest men before him have done the same. The greatest architects have built for money, the greatest sculptors have modelled, the greatest painters have painted for money; but where was ever one such as they found who would yield for one moment to the bondage of the money for which they worked, or who would not, with poor old Palissy, have rather burnt the last leg of his last chair, and the last rail of his garden fence, than hear to fall in the full excellence of his work? If glass-painting in our day is to be submitted to such pressure as would have crushed the genius of a Raphaelle, it has small chance of vitality, and none of perfection. But I must not be misunderstood. I desire by no means to pass a sweeping censure against the combination of the commercial man and the artist. Our whole social state is changed since the days of those peaceful contemplative poets of art who began their work with prayer, and mingled their colours with devotion, making religion as much a medium of art as art a medium of religion—men who worked the live-long day, maturing their thoughts in the quiet of the cloister, and refreshing their spirits and their eyes on the tranquil scenery around them. But do you reply, "Yes; but those men often undertook great works on contract, and at a fixed price and fixed time, too?" Yes, they did; but who made the contract? Who fixed the time? Not any commercial business partner who

* By Mr. T. Gambier Parry. See p. 75, ante.

had to make money out of the artist's brains. No; for no art can reach excellence, the complement of a man's full power can never be attained, but in the freedom of undisturbed thought. If there is any vital element in art, it is that which is akin to poetry. It is a strange mixture in itself of delicacy and power, qualities which, in the execution of its work, maintain and modulate each other. Delicacy would otherwise degenerate to weakness, and power would swell into vulgarity. Art cannot live as a slave to commerce, but it can live as the friend of commerce, to share its wealth, and raise its sentiment. When Perugino grew avaricious he prostituted his art. It was lucky for the arts and for his reputation that in his younger days he had said his prayers. In those days he had acquired a power of refinement and expression of the most exalted character, for which all after-ages have venerated his memory. He had been a poet,—he had, indeed, been a poet; but when his studio was lowered to a manufactory, the volume of his glory closed. I must repeat most explicitly that I by no means object to the combination of the man of business and the artist in an establishment for glass-painting. On the contrary, I think it would be one of the greatest service. I only demand that the two men should be in their proper places.

But I must come now to the practice of the art. If there be one error greater than another that an artist can commit, it is in transgressing the nature of his materials. The more evident, the more distinct that nature is, the greater is his offence. Now, if there be any material at his disposal, of which the qualities and resources are more clearly marked than any other, it certainly is glass. If in oil colour, the characteristic qualities are those of depth and power; if of water-colour, delicacy; if of fresco, sobriety. Of glass they are pre-eminently those of light. I by no means infer from this, what I might be mistaken to mean, a garish gaudy use of the raw material. But I certainly do mean that the degradation of so beautiful a material as glass into the condition of cardboard, as is done too often by the Germans, or into oiled calico, as is done by the Italians, or into a very bad style of white-brown paper, as is frequently done by the English and French, is an insult and an abuse. As I said before, glass is a thing of light and colour, which calico, cardboard, and brown paper most certainly are not. The abuse, as we have seen, arose at the time (the fifteenth century) when glass was manufactured thinner and more clear than before. The painters at that time, and now, too often stipple it over with brown enamel to hide its poverty. Glass is wanted for all varieties of effect, and, rightly used, it can be gorgeous without being gaudy, and solemn without being dull. The first step to its improvement for art purposes must be the work of the manufacturer. The ruby, the green, and the white, would be better made thick, the blues more grey, the whites very various hues, and a more refractive and translucent rather than transparent glass made for them all. Some manufacturers, especially Messrs. Powell, of Whitefriars, have already taken much pains in this direction, and with great success. The next step, the artist's, is not so easy to describe. If he has the right kind of glass, which certainly can now be got, there will be little need of veiling it at all, to enrich its poverty or to tone its garishness, beyond the broad lines of the drawing, the lightest possible indication of shadows, and so on. Such, indeed, I feel should be the law of the glass-painter. But now, having progressed so far, comes the great question: how is the glass-painter to treat his pictures? There can be no real difficulty in this except in the practice of humility and self-denial. The first thing for the artist under such circumstances is to make up his mind that he is in truth and indeed "a glass-painter." If only he is quite sure of that, half his difficulties are over.

Now let us for a moment compare the characteristics of a picture on canvas and a picture on glass; and the conclusion will be obvious. In the first place, then, the element of form is common to them both, and equally within their reach. Their *chiaroscuro*, the whole law of which runs in the simple sequence of "high light, half-tint, shade, reflected light, and cast shade," is also equally within the reach of both—for glass can be hickened as black as night, and high lights filed out as bright as the sun: I say they can be, I don't say they should be. Then "colour"—that is common to them both. Where, then, is the difference? I answer mainly in this, that although all things

may be possible, all things are not expedient. But now look at the opposite view of the case. Take two subjects only,—those of "roundness" and "atmospheric perspective." The way in which an artist produces the effect of roundness is by modification of colour and by loss of outline. These are among the most powerful means in the hand of a painter to produce to the eyes of others the effects of nature, and among the most favorite resources of his art. But these two, the primary essentials to the painters of pictures, are simply and entirely impossible in glass-painting, because in glass the outlines must be marked by lines of lead, and the colours can only be tempered by the common expedients of mere light and shade. There can be no modulation of colour in glass. I must not be mistaken. Of course, the surface of glass may be ground into semi-opaque white, with the texture of cardboard, white-brown paper, and calico, I mentioned just now, and painted on in many ways with water and oil colours modulated as you please; but that is not glass-painting in what is (without any quibble about words) really meant by it. It can also be effected by enamels; but that is glass-enamelling, not genuine glass-painting, and very objectionable it is. So then, truly, there can be no modulation of colours on glass. Now, for instance, can the painter get the grey between the light and the purple shadow of a ruby-coloured drapery? How can he get the thousand-and-one tints of sky and earth into its reflected light? How can he soften off its edge? Then consider for a moment the effects of "atmospheric perspective." These are mainly producible by the same processes of modulation. Things in nature are cleared from each other not by any means so much by their colours as by the air between them. There is nothing more delicate to be produced than this in all painting. But these are unattainable by the glass-painter. He can only approach them by the ingenious use of forms, and by suggesting (however untrue in a realistic point of view) the idea of proximity by strong colours, and distance by the more delicate. In spite of all these limitations to which he is subjected, I do not feel that his art is lowered. For art does not depend on perfection of representation. Such perfection would at once affect the loss of all its poetry. It would only affect the spectator's knowledge, not his imagination. I believe that each art has its distinctive genius and capabilities—that there is a something which each can do the best, and that failing that, the fault lies rather with the artist than with his materials. Michelangelo would be as great in terra cotta as in the finest marble. What, then, is the glass-painter to do? I am confident that the secret of his success lies in this;—that his designs must be made entirely with reference to the powers and limits of his peculiar materials; that the designs of Michelangelo himself would be utter failures unless made unreservedly upon such a principle. An idea is prevalent that copies may be made for windows from great old pictures, or that designs may be obtained, with great advantage, from the leading artists of the day. But I am confident that it would be an injury rather than an advantage that artists, however great in figures, landscape, or genre, should be so employed unless they do so with a thorough knowledge of the peculiar qualities and limitations of the materials in which their designs are to be executed. That in their pictures they may revel in the poetry of shadow, but that in glass they must design for the effects of light. That their canvases may be a broad open space to work for; but their design for glass, on the contrary, must be cut up into many small pieces, and bound together by the harsh outlines of lead. In a word, the composition for a picture in painting must of necessity be totally different from that of a picture in glass; indeed, if anything, the principles of glass design for figure subjects are even grander and more powerful than those in picture painting, because the very nature of the materials of glass-painting forces the design to be broad, large, simple, and consequently sculptural. I can easily imagine any one remonstrate on hearing this, and ask, why then do we generally see such wretched things in windows? I can simply answer, "Because the persons who design them have no knowledge of what they are pretending to do; that they are manufacturers, not artists; that the demand has induced them to start, not in art, for they never had any to start with, but in business, because they had plenty of capital, and the general public engaged in the various work of life have had but little knowledge or

discrimination in such matters to keep those workers of atrocities in check." *Hinc illa lacryma!* But what, then, unreservedly, are these powers, and what are the limitations of the glass-painter? His powers! He has the whole beauty of the rainbow and the whole power of the sun at his disposal. What are his limitations! They resolve themselves into two; first, the impossibility of colour-gradation, because the colour is unchangeably burnt into the glass before he touches it; and secondly, the rigid obligation of severely-marked outlines in the use of his leads. The result, therefore, is that his works are characterised by a certain flatness of effect, more in the character of sculptural relief than of the atmosphere of a picture. This peculiarity is by no means confined to the essentially Christian and Gothic art of glass-painting. At a period of classic art in Greece, perhaps unequalled by any other for severe and refined purity of design, wall-painting was constantly executed in this manner. Figures and even groups of figures were often thus painted with hardly more than a mere faint line to stand upon, and without any accessories of background. It is impossible to imagine the science of design put to a severer trial, or a more perfect and pure ideal than that which such a system affords of painting in connexion with architecture. I suspect that sculptors would mostly design far better for glass than painters. It was so with those great Florentine sculptors, Ghiberti and Donatello, who delighted in designing for glass. I admire the glass-painter not to disguise this essential peculiarity of his art, and so to falsify it. It would be as unreasonable for a musical composer to complain that his single instrument had not the powers of an orchestra, or for a sculptor that his marble was debased from the accessories of atmosphere and perspective possible to canvas, as it would be for a glass-painter to complain of the limitations of his glass. In respect to the variety of styles,—the Classic, Gothic, Renaissance, and Modern, which is most intimately connected with the subject of glass-painting,—there can be no doubt of this, that to reduce everything to the mere dead level of modernism would be to deprive the world of that invaluable means for expressing the many phases of beauty which depend entirely upon the characteristics of particular styles;—that they are, in fact, the expression of the widest range of human feeling; for, excepting literature, all that remains to earth of the hearts and souls of the best men is in their arts. The objection is made,—“But why copy them? Why bind down your wider knowledge to the limits of their comparative imperfections?” I can only ask in reply, “Who, in his senses, would ever, or what man with a spark of genius ever could, advocate such a course?” The objection is one of those bugbears which gentlemen of certain opinions are constantly raising—gentlemen whose indignance seems to a good deal affected by temper, and still more by prejudice. The imperfections of old art are most evident, and followed only by those who know and are capable of no better. But I hold it, there is a living poetry beneath the cloak of those imperfections that such gentlemen have failed to perceive;—that the works of those early artists exhibit a vigour and delicacy, an earnest purpose and a poetic sense, an adaptation of their designs to the materials they worked upon, with an utter absence of personal conceit in themselves, which it is impossible to overrate. I grieve at the discredit that has been brought upon old art by the atrocities committed by incompetent imitators. To such persons the mere archaisms and exaggerations of expressions have appeared to be the sole characteristics of those earlier arts. They have missed the latent beauty, and have made bad copies of the crust. Those artists of old days felt beauty as we do, though they had no academical rules for its display; they felt all the poetry of human sympathy and passion as we do, though they had no axioms for its embodiment in art; and under their exceeding disadvantages, with no rules to guide, no experience of the past to enlighten them, it is less their fault that they expressed their strong feelings faultily, than it is ours that we are so blind—eyes blind and heart blind—to misunderstand and misappreciate them. Neither do I perceive at all that the modified flatness of representation necessary to glass deprives it of the means of aiming at and of attaining a very high order of art. For what is high art? Surely the greatest art is that which expresses the greatest idea. And as I believe that this great result overrides all technicalities of material, I

see no reason why its attainment is not as possible for the glass-painter as for them who find expression for the yearnings of a big heart in the other poor and weak resources of stone or marble, of metal, or of paint. And I would that the glass-painter would lay such an ideal before him—that even if it were possible glass-painters could form themselves into a guild, and exclude those unworthy pretenders who do but poison public taste, and dishonour the credit of a noble profession.

But such a happy result would be disallowed by the axioms of modern liberty. The only other hope for the elevation of this beautiful art lies in this,—that those who have power should refrain from its abuse; that in all the honourableness of self-discipline they should put quality before quantity; and then work for the high aim in their art rather than for high balances in their ledger. With such sentiments, then, as these, would I close this address to all the artists and amateurs interested in this beautiful art. Let the glass-painter do honour to his glass! Let there be no hesitation about it, no wretched condescension to mislead those who gaze upon it,—let it be glass without mistake; parading nothing, pretending nothing; but honoured even in its weakness, and treated with justice even to its defects. Why envy the qualities or even the excellences of other arts? or why dread the genuine light of day, the open sun and passing clouds (which are as death and destruction to the oil-painter and the fresco-painter)?

If I were addressing glass-painters in this room, I would say, Have you not gems to play with—a very flood of gems to toss about and to let your thoughts revel in? Do you fear their gayness and vivacity? What if the diamond, ruby, and emerald, have a fire which no art can equal, except yours alone, have you not also the mellow richness of the jacinth, the softness of the chrysochase, and the tenderness of the pearl? If you fear them, leave them! If you use them, do use them and glory in them; but use them within the limits of an educated sense—treat them with that mingled modesty and confidence which have ever been and ever must be the characteristics of disciplined genius. You have entered the temple of the arts with the most precious jewels in your hands. Ignorance and self-conceit are sacrilege here—sordid notions are sacrilege here. It might have been well for the great men of former days to have played with their art, confident in their own principles, and modest in themselves. But glass-painting is no easy and light matter. The mere material itself is so beautiful that the eyes of the vulgar are dazzled and deceived by it; but it needs the utmost tact in its management, and genius and labour long and hard for its success. Let then no wilful, no untrained hand meddle with it; let no conceited spirit of self-taught genius intrude upon it; for such a one who thus violates the sanctity of the art will cut the throat of all his hopes and reputation as certainly as the glass will cut his fingers.

THE CRYSTAL PALACE.

A COMMITTEE is being formed, on the suggestion of Mr. Francis Fuller, for the collection of subscriptions for the restoration of the Fine Art Courts of the Palace; and Mr. Scott Russell has been promoting the objects of the movement by delivering a lecture on the Crystal Palace at the Royal Institution. At the close of this lecture, Mr. Russell said,—

“Surely such a building ought not to be allowed to go down. If the company are not rich enough to do it, if the insurance companies will not pay the full insurance, if the public ought somehow to help them. In other countries a great educational institution like this would be helped by the Government. In England, in such a matter as this, the people are the Government. Let them, therefore, help both the directors and themselves to restore and maintain so grand a temple of art, education, and refinement; for to do so is a matter affecting the national reputation.”

Much as we wish that the movement may succeed, we fear that a commercial company like that of the Crystal Palace are not likely to be aided in their object by public subscription to a sufficient extent, and we feel that it would be almost useless for us to urge the public to do it. Towards the restoration of the Library, however, public aid, by contributions of books, is a much more hopeful prospect. The Crystal Palace Library, which was completely destroyed, comprised upwards of 5,000 volumes, composed exclusively of presentation works.

HENRI DEUX WARE.

MR. CHAFFERS is delivering at the Society of Arts a valuable series of lectures on Pottery and Porcelain, under the Cantor foundation. In the third of them, delivered on the 4th inst., the lecturer described the very peculiar ware (of which we have before now made special reference), manufactured at Oiron, near Thouars, from 1520 to about 1550, coeval with the best period of Italian majolica, called Henri II. ware, which is of a distinct character and ornamentation to every other class of pottery. After briefly quoting the opinions of writers on the subject during the last thirty years, he alluded to the discoveries of M. Filion, who solved the problem and cleared up the mystery as to the origin of this ware. Two artists assisted in the work, a potter, named François Charpentier, and Jean Bernard, librarian and secretary of Hélène de Haugst Genlis. While in her service the latter had furnished numerous designs for ornamental book-bindings. After her death they entered the service of her son, Claude Gouffier, whose arms are found on a plateau in the South Kensington Museum.

Mr. Chaffers next described the monograms, which are those of the Dauphin Henri, Anne of Montmorency, and of Claude Gouffier—the arms, emblems, and devices which are found upon the pottery of Oiron. He then spoke of the distinguishing characteristics of this curious ware, the body of which is a creamy white pipe-clay, very compact and of fine texture, so that it does not, like ordinary fayence, require an opaque white enamel, but merely a transparent glaze. Instead of being painted with enamel colours over the surface, it is actually inlaid with coloured pastes, in the same manner as the champlevé enamels or niello work on metal. The lecturer continued,—I will endeavour to give some idea of the complicated process of constructing a piece of this ware, from a very careful examination of a fractured specimen in the Sèvres museum. The foundation of the vase being first modelled into the required form by hand—quite plain and hatched all over with crossed lines, that the outer crust might the better adhere to it—one or more thin plaques or bands of moist clay were then laid on a flat board, corresponding in size to the portion of the vase to be covered. These plaques were stamped by the bookbinders' tools into various patterns. The string borders of frets, guilloches, foliated scrolls, rosettes, &c., were accomplished by swivel-stamps, held in the hand, and rolled from one end to the other; the interlaced arabesques and diapered grounds were produced by means of metal stamps, such as were used for gilding the leather surfaces of books. These cavities or incised patterns were then filled in with different coloured clay, the superfluous portions being removed by a sharp chisel, and the bands were applied to the shaped foundation, and pressed closely to it. The next process was the application of ornaments in relief, such as brackets, masks, shells, terminal figures, &c.; these were either modelled by hand or pressed into moulds, and stuck on to the vase, together with the handle, and placed in the kiln for the first baking. The piece was then removed, and dipped into a thin, transparent lead glaze, with here and there some enamel tints of purple, blue, green, and yellow, sparingly applied, and again subjected to a less degree of heat in the muffle-kiln, sufficient to melt the glaze. From the manner in which the incrustated pattern was applied round the exterior of the vase, it would be next to impossible to make it correspond exactly at the junction of the two ends. This trifling irregularity has given rise to the supposition that the ornamentation was merely a printed design, transferred to the surface of the ware. This, to a superficial observer, appears very feasible; but if we look beneath the surface, and examine the section of the fractured vase at Sèvres, it is clear that the coloured pastes were inlaid, the sharp angles of the grooves or furrows presenting too regular an appearance to have been caused by the mere absorption of any colouring matter, either by surface transfer or with a brush. It will also be observed, that the furrows in which the coloured pastes have been inserted are slightly depressed, from shrinkage in the kiln, thus essentially differing from painted earthenware, which would rather produce a low relief. The number of pieces of this ware known to be in existence is fifty-three. They are equally divided between France and England, each possessing twenty-six. The odd one belongs to Russia.

THE CAB QUESTION.

A DISCUSSION on the metropolitan cab question, introduced by remarks from Mr. Henry Cole, C.B., took place at the Society of Arts on Wednesday in last week. Mr. Cole considered our cabs to be a disgrace to the metropolis. The sixpenny mileage fare he held to be the chief cause; not being sufficiently remunerative for a good cab and a good horse. There is much truth in Mr. Cole's views. Sir Cusack Roney said he did not think the London cab-drivers were much worse specimens of humanity than others. He had often found, too, in his railway experience, that every line of railway was the worst managed in the kingdom in the eyes of passengers by that line. Fixed fares were essential, and existed in every city. Mr. Charles Hill said Mr. Cole had shut out every other consideration except that of fares, the point objected to being their limitation by law. In most Continental cities, and in the principal towns (and especially the watering-places) of England, a municipal regulation of the cab fares existed. If the cab business in London was unremunerative, they ought to endeavour to see how it could be made more remunerative. He thought that would not necessarily follow from increasing the fares. The question was how they could create a larger demand for cabs on the part of the public. At present, from some cause or other, there was a disinclination to use cabs, and he mentioned cases in which people arriving at a railway terminus preferred walking to their destination, even in wet weather, rather than take a cab. He believed this repugnance to cabs arose, in the first place—especially in the case of ladies—from the frequent disputes that took place about fares. A remedy for this, to a great extent, would be found by some instrument being attached to the cab, by which the distance travelled would be indicated; and he thought it was quite within the province of this Society to endeavour to obtain such an instrument and get it adopted.

It is to be hoped we shall not have to return to the intolerable state of matters which existed before the late legislation on the subject. Cabmen not seldom, even now, would as soon think of voluntarily returning change as giving thanks for an extra sixpence; but, in general, avoidance of abuse is thus insured; and were the extra sixpence put upon the first mile, the minimum fare being thus laid, perhaps the present regulations might otherwise be left as they are, and the result be not only a less unpleasant intercourse between the public and the cabmen, but improved cabs, from more profitable returns and their more general employment. That cabs should be taxed to the extent of 15% per annum, or only 1% less than omnibuses, is iniquitous, and ought to be amended. So ought the power of the cab-owner to imprison his cabman for being short of his day's proceeds. There are sometimes no fewer than twenty of these poor fellows in prison at one time, it is said, on this account.

In the discussion several gentlemen spoke of the Hansom cab as being better than the four-wheeler. This we cannot see. They do go a little faster, but there their superiority, we think, ends. We have seen, on several occasions, both passengers and cabmen pitched head foremost out of their seats, by the sudden stumbling of the horse, and we think it must be a curious “safety cab” which does that. An improved four-wheeler is what is wanted. The Hansom is not only dangerous, but incommodious and draughty. First and second class cabs were suggested in course of the discussion.

Mr. Alderman Lawrence, M.P., who took part in this discussion, asked the Home Secretary, in the House of Commons afterwards, whether he will be prepared to introduce a measure during the present session to consolidate the various Acts relating to metropolitan hackney carriages; to revise the tariff, with a view of enabling the public to have the option of obtaining a superior class of hackney-carriage at an increased fare; to take away the power at present possessed by the cab owners of imprisoning their drivers in Whitecross-street Prison in the event of their failing to pay the daily hiring; and other questions bearing on the same subject.

The Home Secretary, in reply, said that a Bill in the House of Lords relating to the street traffic would contain clauses which it was hoped would improve the hackney-carriages, but he had no intention to introduce any special measure on the subject.

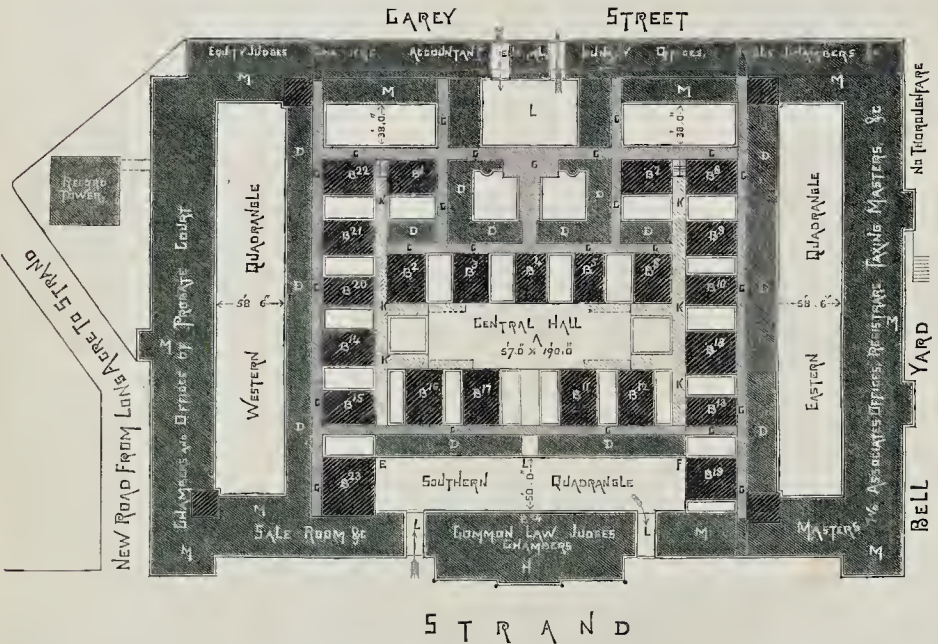

PLANS FOR THE PROPOSED LAW COURTS*

Mr. E. M. Barry's Key Plan.

- A Courts of Law.
- B Bar Attorneys and Professional Public.
- C Jurors' and Witnesses' Stairs.
- D Public Entrance and Stairs to Galleries in Courts.
- E Offices of Courts of Law and Equity.
- F Public Stairs and Waiting Halls in Offices.

Mr. Street's Key Plan.

- a. All the rooms for the Bar are under Central Hall, close to all the courts. The Bar requires the inner line of communication, having to practise in all the courts. There is a continuous passage for Bar through all the courts at the end nearest bar-rooms, under public galleries.
- b 1 to b 23, The courts. All on the same level. b 1 to b 7, Equity Courts. b 8 to b 10, Courts of Queen's Bench. b 11 to b 13, Courts of Common Pleas. b 14 to b 16, Courts of Exchequer. b 17, Exchequer Chamber. b 18, Spare court. b 19, Extra court. b 20, Probate and Divorce Court. b 21, Admiralty Court. b 22, Ecclesiastical Court. b 23, Appellate Court, b 24, Bankruptcy Court and offices.

- c c c. The judges' corridors, continuous throughout, and accessible only to judges.
- d d. Judges' rooms. Level with bench in all the courts. Each set opposite its own court.
- e f g. Principal entrances for judges.
- h. Entrances in Strand for jurors, witnesses, and parties to suits. Principal stairs here lead to a second hall on first floor, and from thence by a bridge and flight of stairs to Central Hall. There are separate entrances and stairs for witnesses and jurors who wish to go at once to their rooms without ascending to Central Hall.
- k k. Corridors for general public (each 175 ft by 15 ft.), reached by four public staircases. From these access is gained to the lobbies behind the galleries in courts. The Central

- Hall is not used by the general public, but it and these corridors are level, and persons can pass by permission from one to the other by means of doors in the iron screens which separate them.
- l l. Carriage quadrangles, with arched entrances from Strand and Carey-street. These are for the judges' access to their porches.
- Below c c c is a corridor for the use of the Bar and attorneys only. It opens to the consultation-rooms, which are under d d all round.
- Below this is another corridor for jurors and witnesses only. The jury-rooms are under the consultation-rooms (d d), and the witness-rooms are all under the courts.
- m m m. Enclosing block of law offices.

N.B.—The Scale of the Plans is different.

* See p. 108, ante.

CLOCK TOWER OF THE RATH-HAUS, PRAGUE.

A. Detail of Arcade.

B. Detail of Portion of Clock Face.

BELL AND CLOCK TOWERS.

No one who has been in the habit of looking over old views of cities and towns as they appeared two or three centuries ago can help being struck with the fact, that although these same towns may have gained in size and importance, their general aspect has, in nearly every instance, decreased in grandeur and dignity. This is of course more the case in England than on the Continent. Oxford and Durham are nearly the only towns in this country that present a grand and magnificent outline when seen from a distance; whereas all modern English towns, such as Liverpool, Manchester, and Birmingham, when seen from a distance, appear like a collection of dirty villages. Some people will be inclined to lay the blame on the tall factory chimneys; but suppose the chimneys removed, and what have we? a long, dull, dismal, flat, and unbroken sky-line; look, for instance, at Brighton; what can be more thoroughly uninteresting than the view of that immense and fashionable town from the sea? One is really inclined to wish that there were a few tall chimneys, or in fact anything to break the dreary monotony of that everlasting horizontal sky-line. Those who have seen Prague and Würzburg from a distance, or have gazed upon the even more glorious panoramas presented by Rome, Venice, or Verona, cannot help being struck with the squalid and beggarly appearance of our large towns when the first glimpses of them strike the eye. Now why should this be so? What is it that we miss when looking upon modern towns? It is simply this,—we see no towers. And why have we no towers? Of course we no longer require them for purposes of defence, but we still make use of bells and clocks of large size, both of which seem to suggest that we have not yet overcome the requirement for towers. And how many fine examples of towers, applied to these purposes, are to be found in the ancient cities of Germany, Italy, and Belgium. The great "belltowers" in the last-named country are celebrated, but in Germany nearly every little town has its watch-tower or bell-tower. Prague possesses very many examples, the finest of which is represented in our engraving. It is attached to the Rathhaus, and is a fine specimen of fourteenth-century architecture. The clocks, for there are two,—occupy the basement and the top story of the tower; the upper one has four faces. It is much to be regretted that they have all been modernized, but the face of the lower clock is wonderfully interesting. There are two dials, one chronological, the other astronomical; both, together with the framework which surrounds them, are of stone, beautifully and delicately carved, and retaining vestiges of coloured decoration.

A tower of very similar arrangement and design is to be found at Würzburg. Here the clock is in the highest story but one; the dial is ancient—fifteenth-century work,—and there is a very interesting wooden canopy over it. The basement portion of this tower is Romanesque work, and there is a singular arrangement of shafts supporting a trefoil-headed arch, which looks uncommonly as if it had formed part of a clock-face in a similar position to the one described at Prague.

At Ratibon is a lofty clock-tower attached to the Rathhaus; the clock is in the top story. This tower is capped with a low pyramidal roof; the story below the clock is occupied by large three-light windows. It is a work of the latter part of the fourteenth century.

The clock-tower adjoining the Rathhaus at Cologne is a magnificent structure. It is in plan octagonal, with four large and four small sides. The whole tower is covered with niches and panelling, and lighted with two-light pointed windows in each story. This tower is capped with a tall octagon spire of slate, at the base of which is an open balcony; half-way up the spire is another balcony and open spaces, through which the bells are visible. The clock-face is in the top story, and is partly ancient. The tower of the Rathhaus in the New Stadt at Prague is very similar in general arrangement to the one already described in that city; it has, however, no clock-face at the basement, and is inferior in design, and later in date than the one we have illustrated. At Sweaburg, in Bavaria, is a very picturesque example, very similar to the Prague ones. At Kitzingen, near Würzburg, the clock-tower is circular in plan, and quite isolated from the Rathhaus: it is capped with a tall slate spire. At Rothenburg,

in Bavaria, is a very original and pretty example: it grows out of the gable of the Rathhaus, and is square in plan for two stories; it is then broadened into an octagon, with four statues standing on the "braches;" at the top is a projecting cornice supporting a light iron parapet railing; the whole is capped with a hulions spire of two orders.* At Augsburg is a very tall tower, over 300 ft. high, detached from the Rathhaus. It has been rather modernized, and is not earlier than the beginning of the seventeenth century; it is, however, very good in outline. It is square three-fourths of the way up; the remaining portion of the tower forming an octagon lantern, crowned with an ogee dome. The tower of the Rathhaus at Gotha is probably of the same date; it is attached to the building, and is neither very lofty nor beautiful. At Oberwesel, one of the towers of the fortifications has been converted into a clock-tower at a late period. The clock-face is placed in a kind of large dormer: the effect is very picturesque. The same arrangement occurs in one of the towers of the castle at Wertheim.

During the seventeenth and eighteenth centuries building towers for these purposes was discontinued, and the modern pepper-box was used in their place. Great praise is due to the late Sir Charles Barry for his hold revival of this noble feature in his new "Palace of Westminster."

THE NATIONAL GALLERY DESIGNS.

The rumour gains ground that it is intended to throw all the competitors overboard wholesale, without making any selection. This would be a clear breach of faith, as Mr. Cowper gave them distinctly to understand that one of them would be employed.

It would make the having been invited to compete a serious professional injury to each one of the competitors. If one be selected, the rest cannot complain; but if no one be chosen, all will have a right to complain, as they will thereby be stigmatized as ignorant and incompetent.

The Chief Commissioner personally is incapable of an act of injustice, but our information is good, and we fear the matter has not been fully explained to him. We trust it may not be too late to obtain re-consideration.

A NEW FARMSTEAD.

A LARGE farm-steading, arranged for a system of feeding cattle entirely under cover, and carrying on all indoor farming operations under the same roof, has just been completed at Grinkle Park, Yorkshire, for Mr. Charles M. Palmer. The building may be described as forming a hollow square, covering nearly half an acre of ground, the centre of the square being occupied by the feeding-boxes, twenty in number, each 10 ft. square, and sunk 3 ft. below the surface; the roof rises high over this portion, and is supported by thirty metal columns. Around this centre are arranged the following departments:—Commencing on the north side with the barn and the threshing machinery (supplied and fitted up by Mr. William Trotter, of Stocksfield), with engine-house, smith's shop, spacious straw-horse, implement-house, cart-sheds, &c. On the west side is a range of ten stalls for the farm horses, with harness compartments for each horse, and behind these, again, ranges of loose-boxes for brood mares, with hay-horse and corn-stores, &c. On the south side are a large fold-yard for the store cattle (open by archways to the south), pig-house, bull-house, &c. On the east side is provided accommodation for the milk cows, and calf-pens, with boiling-house, oil-cake store, turnip-house, &c. The patent metal fittings in the stable, loose-houses, byre and cattle-boxes, have been procured from Messrs. Musgrave & Co., Belfast, each animal having a separate trough for water, supplied through a system of pipes, and of which there is a never-failing supply (of pure spring water) at a high pressure. The system of cemented passages throughout the building, in connexion with storehouses, and the use of small rolling wagons for the purpose of carrying the food, enable the feeding operations to be carried on with the most economical employment of labour. The lighting and ventilation of the building, which are mostly effected in

* We will give a sketch of this on another occasion.

the roof, are quite successful, as well as the system adopted for collecting and saving the manure, both solid and liquid. The stackyard stands to the north of the buildings, adjoining the barn. At the west side, at a short distance from the building, a semi-Gothic house has been built for the farm-bailiff, to which is attached a roomy garden; and on the east side are six new cottages of four rooms each, with gardens in front. The architect is Mr. Archibald M. Dunn, of Newcastle-upon-Tyne, and the buildings, including machinery, have cost about 4,600*l.* The contractor for the whole of the works is Mr. Thomas Linford, of Whiteby; and Mr. John Dixon acted as clerk of the works.

FROM IRELAND.

Dublin.—In Stephen's Green an enormous pile of building is almost finished. This is the new Shelbourne Hotel, erected by Mr. William Jury, of Dublin and Belfast; Mr. Charles Cotton, of Cork; and Mr. Goodman, late manager of the Killarney Railway Hotel. The front to Stephen's Green, overlooking the grounds, seems to be about 170 ft., while that along Kildare-street is as much more, presenting a square of 170 ft. The edifice overtops the mansion of the borough member, hitherto considered one of the finest on the north side of the Green, by two stories. A telegraph office, lift for guests from story to story, several exits, with fire escapes, baths, and all modern improvements, have been provided. Besides the gentlemen's coffee-room and public dining-rooms, there is a ladies' coffee-room furnished, and a newsroom equal to that of the Reform Club. The kitchen is detached from the main building, so that there is no smell from the culinary department. In a separate wing are smoking and billiard rooms. The whole cost will be over 80,000*l.*

GIFT OF THE MAYER MUSEUM TO LIVERPOOL.

The celebrated Mayer collection of antiquities has been presented by Mr. Joseph Mayer to the town of Liverpool, and will form "The Mayer Collection," under the superintendence of the Library and Museum Committee. This collection, as is well known, is a very valuable one, in many respects unique, and has cost many thousand pounds, and taken many years to form. In one department—the illustrations of Wedgwood—as remarked by Mr. Picton in announcing the gift, there is no collection in existence which at all equals it; and in gems and in Mediaeval works of gold and silver, and works of that class, it is also exceedingly rich, as it is in Egyptian antiquities. The celebrated Fawcett collection of Anglo-Saxon antiquities is included in it, with many other valuable and beautiful works. Altogether, the gift is a very noble one, and entitles Mr. Mayer to the gratitude of more than his townsmen.

ACCIDENTS.

London.—In boring a tunnel from a building in the northern or South Hackney enclosure of Victoria Park to the main sewer for the insertion of drains, the excavation fell in while four men and a boy were at work, burying all but the boy. Two were got out alive, but the other two were dead when dug out. There is said to have been some neglect in the securing of the sides by planks and cross struts.

Chatham.—An accident has occurred at the drill-shed now in course of completion at the rear of the Royal Marine Barracks. While a number of painters were engaged in painting the inside of the roof, one of them overbalanced himself, and fell a distance of 30 ft. with fearful violence, striking against a block of stone. His head was badly cut and his thigh broken.

Belford.—A bricklayer in the employ of Mr. Mercer, whilst at work on the third story of new buildings now in course of erection on the east side of St. Mary's-street, was in the act of pulling up a bucket of mortar, when the rope broke, and the sudden jerk throwing the man off his balance, he was precipitated head foremost to the basement, and was seriously injured.

Kirkdale.—Just now there is in course of erection an additional wing to the gaol premises

at Kirkdale, and a large number of men are employed at the work. There is a shed supported by two arches at the north-west corner of the gaol. About forty men had assembled in this place at dinner-time, when suddenly, without warning, some twenty-two or twenty-three of them were precipitated into the cellar below, and partially buried in bricks and mortar. Unfortunately some of the men were seriously injured.

Brighton.—At the new Brighton West Pier an accident has happened to the structure. The hull and a large portion of the framework of a brig stranded near Shoreham drifted along the coast, struck the pier near its shore-end, and smashed through the iron piling by which it is supported. Seven of the piles, with all the intermediate stages and bracing, were carried away, and the pier was thereby rendered unsafe for public use.

Hastings.—The drainage works on the beach have been damaged by the sea during a gale. A hoarding and piles were carried away, and the trench filled up to the original level of the ground, so that the work is all to do over again.

THE DRAINAGE OF KIDDERMINSTER.

A SCHEME for the drainage and water-supply of the town of Kidderminster was submitted to the Sanitary Committee on the 30th ult., by Mr. Curley, C.E., of Hereford. He proposes to filter and clarify the sewage in filtering tanks, near the point where the Hoo Brook joins the river Stour, and to convey the filtered water into the river below the dam at the Wilden Iron Works. The total area to be drained is 450 acres, for which Mr. Curley considers that a main outlet sewer 3 ft. in diameter is sufficient. The total length of main sewers, as laid down in the plans, is 15 miles; and the estimated cost, including gullies, flushing wells, overflow chambers, filtering and deodorising tanks, is 20,000*l.* He also submits a scheme for water-supply,—a water-tower 56 ft. high, and surmounted with a wrought-iron cistern capable of holding half a million gallons, is to be erected near the site for the filtering-tanks. The water is to be pumped from the Hoo Brook, the stream which supplies the motive power for the Wilden Ironworks, and which is said to be of very good quality, by two 25-horse engines. The rates proposed to be levied are,—one penny per week for cottages of 5*l.* per annum, twopenny per week for 10*l.* houses, threepenny per week for 20*l.* houses, fourpenny for 30*l.* houses, and so on. There are about 4,000 houses in the borough, the population, according to the last census, being about 18,000. The total annual revenue from the waterworks is estimated at 2,138*l.*, and the cost of construction at 20,000*l.*

DWELLING-HOUSES FOR THE WORKING CLASSES.

A DEPUTATION from the Metropolitan Building Society waited on the Earl of Derby on Saturday last, by appointment, at his official residence in Downing-street, with the object of obtaining a loan of 500,000*l.* for building extensive ranges of workmen's houses in the metropolis.

The prospects of the company, which had been previously sent to Lord Derby, states that the want of workmen's houses was so great and pressing that it would require at least 500,000*l.* per annum to be expended for the next five years, to mitigate the evil in any sensible degree. That outlay would supply house accommodation for 100,000 persons. Without Government assistance, nothing like that accommodation could be had, as it pays much better to invest capital in high-class houses, showing the absolute necessity of Government interference, if the evil is to be remedied.

Lord Derby called the attention of the deputation to the Workmen's Houses Act of May, 1866, and read several extracts from it, showing that any company might obtain loans under that Act to the extent of one-half the cost of the buildings, at 4 per cent. interest. Mr. Alison stated that that Act was passed when the interest of money was 10 per cent., and then it offered great inducements to the public to act upon it by obtaining money at 4 per cent. But now it offered no inducements, as the interest of money is 3 per cent., and loans to the extent of one-half can now readily be obtained from private

sources. If that Act was amended, so as to give three-fourths instead of one-half, the company would avail itself of it, but not otherwise.

Lord Derby said that although the Act of last year had not yet been acted on, he fully expected that it would. Should, however, the Act remain inoperative, the question of amending it might then be considered; in the meantime he was not prepared to advise Parliament on the subject.

On Tuesday evening Mr. McCullagh Torrens obtained leave to introduce a Bill to provide better dwellings in towns for artisans and labourers. He introduced a similar Bill last session, and it was referred to a select committee, who reported, and the Bill he now proposed was, on that report, the same as the House and committee left it. All the information he had received since last session led him to the conclusion that matters were getting worse rather than better, for the amount of misery and overcrowding far exceeded any supply of their remedy which voluntary enterprise could afford, notwithstanding that many good people, from henceforward, had endeavoured to supply the want. They, no doubt, improved certain parts of the town, but nothing had been done adequate to what was really required by the metropolis.

Mr. Walpole expressed his approval of the Bill, but, of course, he would endeavour to carefully guard the property of private individuals. The Bill was read a first time.

SITE FOR MANCHESTER TOWN-HALL.

THE Manchester City Council on Wednesday last came to a decision regarding the proposal to enlarge the site of the Town-hall about to be erected, and to make a square instead of a triangular building. The latter is estimated to cost about 500,000*l.*, and it was asserted that the adoption of the new proposal would add about 300,000*l.* to the amount. The Council decided to keep to their original site. Surely the shape of the site might be improved without necessarily spending such a large additional sum as that named. The shape of the original site is very awkward. We must applaud Alderman King for his endeavours to get it improved.

IMPERILLING HOUSES.

THE METROPOLITAN BUILDING ACT.

At the Wandsworth Police Court, on the 6th inst., Messrs. Mulliner & Cooper, builders, of Wandsworth, were summoned for neglecting to give notice to the district surveyor, under the Building Act.

Mr. Hiscocks, the district surveyor, said the defendants had dug out and formed a cellar under the ground-floor, below the foundations of the walls of a dwelling-house and shop, in the High-street, Wandsworth, within or less than 3 ft. of the footings of the walls, and for a length of 60 ft., thus forming an embankment, thereby imperilling the safety of the house.

The Magistrate (Mr. Ingham) said he could not find anything in the Metropolitan Building Act relating to digging below the house for a cellar.

The District Surveyor said he could only refer to the general rules laid down (1st Schedule, Preliminary), as to walls being built on solid ground, and this could scarcely be called solid ground; and to Part I, rules 1 and 2, determining the thicknesses, lengths, and heights of walls; and he submitted that, although he could not point to any rule that required walls to be underpinned, yet, sec. 9, he considered, taken with the context, was intended to embrace all that was necessary for the due security of the walls.

The Magistrate said it was a very proper case to bring before him, but there was a defect in the Act; and that would be pleased if Mr. Hiscocks would take it to a higher Court, and get their decision. He therefore dismissed the summons.

The District Surveyor said he did not wish to press the case against the defendants, as it was this particular point only that he wished decided; and stated that a Bill would be introduced this session for the amendment of the Act. The Magistrate hoped this case would be mentioned.

* * * We are forced to differ from Mr. Ingham. The Act is perfectly sufficient to prevent the dangerous irregularity complained of. "First Schedule: Preliminary," says,—"Every building shall be inclosed with walls constructed of brick, stone, or other hard and incombustible substances;" whereas the lowest story of the building in question is now inclosed merely with earth,—no walls at all. If the district surveyor did not point this out to the magistrate, he should obtain another summons at once. If he did do so, the magistrate might find himself in an awkward position should an accident occur.—Ed.

THE TRADES MOVEMENT.

Courts of Conciliation.—In the House of Lords, Lord St. Leonards has laid upon the table a Bill for the establishment of courts of conciliation and arbitration. He explained that the Bill was similar to the one which he had introduced last session, and its object was to provide for the settlement of disputes between masters and workmen. Courts of conciliation already existed in France, and had been found to work satisfactorily. He believed that the establishment of similar institutions in this country would tend greatly to put a stop to strikes. The Bill was read a first time.

Sheffield.—A meeting of the members of the File Manufacturers' Association has been held in reference to an attempt on the part of the trade unions to compel Messrs. Turton & Sons, Sheaf Works, to require a file-grinder in their employment to conform to the rules of the union. Messrs. Turton refusing to do so, their file-grinders and smiths have given a month's notice. The file manufacturers, after hearing the circumstances of the case, resolved:—"That the File Manufacturers' Association claim the right to employ such workmen as they please, and will not submit to unreasonable dictation on the part of the trade unions." This resolution is understood to apply not only to the case of Messrs. Turton & Sons, but to all attempts on the part of the unionists to compel manufacturers to employ union men or pay the contributions of men who get in arrears with their payments to the unions.

Retford.—The bricklayers are out on strike at Retford. It appears to be principally directed against Mr. Thomas Hopkinson, builder, who is engaged in erecting the new town-hall, shambles, and corn and butter markets. Mr. Hopkinson has kept on his men at full wages during the short days of the winter months, and now that "full time" is approaching the men want their time reduced and their wages advanced.

GAS.

THE Ramsey Gas Company have declared a dividend of 7½ per cent. for the last year, besides adding to their reserve fund.—

THE Wymondham Gas Company have declared a dividend of 8 per cent. for the past year.—

THE Frodsham Gas Company have declared a dividend of 7½ per cent. and a reduction of price to 5*s.* 10*d.* Mr. Edwards, in advocating "an increased dividend and a reduction in the price of gas," gave a statistical account of the progress of the company since its formation in 1857. The price then charged for gas was 8*s.* 4*d.* per 1,000 ft. He had succeeded in persuading them to reduce the price on three previous occasions, and the result had been remarkable. When the higher price was charged the company paid 11 per cent. dividend, but when it was reduced to 7*s.* 6*d.*, 6*s.* 8*d.*, and lastly to 6*s.* 3*d.*, the consumption doubled, and the dividend rose to 5 per cent. He strongly advocated a reduction in price as a true principle in commercial economy. Mr. James Rigby stated that when Mr. Edwards proposed the last reduction in price he opposed him, but he was glad that he was wrong and Mr. Edwards right, and he now supported the further reduction.—

The new gasometer at Yarmouth, capable of holding 100,000 cubic feet of gas, was almost destroyed in a great gale early in December last. Since then the contractors have undertaken to restore the works at their own expense. The cost will be about 1,000*l.*

THE METROPOLITAN WORKHOUSE INFIRMARIES.

THE medical officers of the metropolitan workhouses have had a number of questions submitted to them in a circular from the Poor Law Board, with respect to the condition of the infirmaries; and their answers, given in a Parliamentary paper, show the shortcomings a very little since.

Mr. Strimonds, the medical officer of St. Mary's, Newington, states that accommodation should be made for 250 patients, epidemics not existing; that the existing accommodation would properly admit 135, including insane, itch, and another class of diseases, and that on a specified day there were 233 cases in the wards. He had no exact experience as to the cubical space;

but he could say, "At night our wards stink overpoweringly." The remedies he proposed for the many evils he knew to exist are very suggestive, and point to a shocking condition of things.

The deficiencies of Bermondsey workhouse infirmary were described by Mr. Cuolahan, the medical officer. The space was insufficient in all the day and night wards, and he believed recovery from illness was retarded in diseases of the lungs through deficiency of space and consequent overcrowding and irregularity of ventilation arising from the efforts made to compensate for deficiency of space. He considered there was room only for 51 sick, while provision should be made for 94. The cubical space he recommended was 1,000 feet, and 80 or 90 superficial feet for floor space for each patient.

Bethnal-green infirmary was described by Mr. Smart, the medical officer, as having accommodation for 318 sick, while accommodation was needed for 600. The beds were too close and crowded. Recovery from illness, he said, was retarded by the overcrowded state of the wards: more space, better ventilation, and increased supervision, both by medical help and by nurses, were needed.

Of Clerkenwell workhouse infirmary, which is considered by the authorities very defective, a few of the defects, and not by any means the worst, are given in the answers of Mr. H. J. Brown, the medical officer. He states that by the existing accommodation from 100 to 125 could be properly admitted, but that room should be provided for 250. The space, ventilation, light, and air, nursing and attention to the sick, are all marked as "deficient." Recovery from illness was retarded in the house, but the causes were not specified. The remedies suggested were "day rooms for the insane and other patients able to leave their beds, increased space in the wards, exercising grounds, paid nurses to each sick ward (not paupers) both for day and night, improved system of ventilation, and water-closets."

These illustrations of workhouse infirmary management are taken haphazard from the official papers.

In the House of Commons, Mr. Hardy, the president of the Poor Law Board, has brought in a Bill for the establishment in the metropolis of asylums for the sick, insane, and other classes of the poor; and of dispensaries, and for the distribution over the metropolis of portions of the charge for poor relief, and for other purposes relating to poor relief in the metropolis.

OPENING OF SHEEPSHAR IRON CHURCH.

The first of the temporary iron churches now in course of erection under the auspices of the Leeds Church Extension Society, was opened at Sheepscar on the 30th ult., and the long and much-experienced want of additional church accommodation for New Leeds and its now populous and fast-increasing neighbourhood, happily no longer exists. Although a temporary church, the building of which we now speak is by no means flimsy and unsubstantial.

The edifice has been erected in an open space on the Chapel-town-road, fronting Bedford-terrace. It is in this space also where the permanent stone church will be erected, the foundations of which have been commenced. The total cost of this church has been 490*l.*, in addition to which 25*l.* have been expended in gas and warming apparatus, and 10*l.* in the formation of roads and approaches to the several entrances. The principal entrance is placed at the west end of the church, and at the north-east and south-west corners a special entrance is contrived for the vestry and the choristers. The seats in the body of the church are arranged to accommodate 300 persons, and, like the side walls, are composed of polished deal. Three large windows on each side, and one still larger at each end, serve to dispel all signs of gloominess, and the whole has a very cheerful aspect. In respect to the lighting and warming of the place due consideration has been observed for the comfort of the congregation.

The erection of the church was entrusted to Messrs. Francis Morton & Co. (Limited), of Liverpool, engineers and contractors. Two other temporary churches are now in course of erection by the Leeds Church Extension Society, one at Woodhouse Moor, and the other at Hunslet. A fourth is also under contemplation.

THE LATE MR. WILLIAM DARGAN.

IRELAND has lost a benefactor under very sad circumstances. Mr. William Dargan expired on the 7th inst., in Fitzwilliam-square, Dublin, after a prolonged and painful illness.

Mr. Dargan was an Irishman and a self-made man. He was the contractor for the first line of railway in Ireland, and then but little known. In the execution of the extensive works carried out under his direction there was observable a marked improvement in the condition of the labourer, in striking contrast to the demoralising influence which the public works in other districts but too often exercised; so that it may be said that Mr. Dargan really did more to elevate the character of the labourer of his country than perhaps any individual of his time. One of the first occasions upon which he occupied a prominent position in connexion with those public works with which he was subsequently so closely identified, was in the construction of the great Holyhead road designed by Telford. When this was completed he returned to his native country, and the experience he had gained in England pointed him out as the person best fitted to construct the then proposed line between Dublin and Howth. The line of railway from Dublin to Kingstown was the first and, for several years, the only one in Ireland. Considering the locality through which it passes, its construction must have been then attended with considerable difficulties. There was, however, no hesitation on the part of the directors in confiding the execution of it to Mr. Dargan, and, taking everything into account, this line must be considered a triumph of engineering skill and ability. On being asked, at the outset, how much he thought the line would cost, he made some calculations in pencil on the back of a used envelope, and announced the result. On being told that not much dependence could be placed on such an estimate, he at once offered to construct the line on that estimate, and he did so, to the entire satisfaction of the directors.

After the completion of the Kingstown Railway many years elapsed before much progress was made in extension of the system in Ireland. The tender given by Mr. Dargan for the construction of the Ulster Canal was accepted, and the work completed within the specified time. The manner in which the great work was executed increased his already established reputation, and the formation of the Ulster, the Dublin and Drogheda, the Great Southern and Western lines of Irish railway followed in rapid succession, in all of which the services of Mr. Dargan were invaluable in effecting an extension of the system. The Great Southern and Western, and the Midland and Great Western Railways of Ireland are, however, his great works. To enumerate all his works of this class would be to give a list of the railways, there being but one or two exceptions, and these of comparative insignificance. In connexion with the development of the railway system in Ireland, Mr. Dargan rendered much more important services to the Irish railways than the mere construction of lines. At the time, railway enterprise in Ireland was at a fearful discount: even for the completion of the smallest lines funds were with difficulty made available. It was in vain calls were made upon shareholders; and the Government refused to advance any subsidy until certain portions of the capital had been paid up by the shareholders. These were the circumstances under which Mr. Dargan was found to render indispensable services. He came for ward, and invariably contributed out of his private purse until the undertaking was completed.

The next memorable work with which Mr. Dargan identified himself was the great Industrial Exhibition of 1853, in Dublin, of which he may be said to have been the originator and founder. This was undertaken with the patriotic view of developing the resources of his native country, and giving an impulse to native enterprise. For this purpose he placed 30,000*l.* in the hands of a committee consisting of the leading citizens, empowering them to erect a building, and to defray all the expenses connected therewith. He undertook, moreover, to guarantee whatever additional sums might be required to carry the enterprise to a successful issue. In fact, before the Exhibition opened on May 12, 1853, his advances were said to amount to nearly 100,000*l.* It had been arranged that if at the close of the Exhibition the profits were sufficient, Mr. Dargan was to be repaid his advances, with 5 per cent. interest: if insufficient the loss was

to be entirely his own. Mr. Dargan experienced a loss on the transaction of some 20,000*l.*

When the present National Gallery in Dublin was erected, a bronze statue of Mr. Dargan, subscribed for by his fellow citizens, was placed in front of the building. Her Majesty offered him the honour of knighthood, which however he declined. His subsequent career, though not of such a prominent character, was associated with every great work promoted in this country.

About a year ago, Mr. Dargan had a fall from his horse, by which his system was so shaken that his recovery was for some time doubtful. Since that he had had another fall, but not so serious. Probably the ill state of his health brought on a confusion in his affairs which recently resulted in his stopping payment, and in an arrangement with his creditors; though his assets, it is confidently said, will pay much more than 20*l.* in the pound. His embarrassments, however, seem to have deeply affected his health and habits, and brought on a disease which his powerful constitution failed to withstand. We should think the truth, nevertheless, if we omitted to say it was aggravated by a personal failing.

THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held on Friday evening (the 1st instant), at the House, in Conduit-street.

The chair was occupied by Mr. R. W. Edis.

The following gentlemen were elected members of the Association:—Mr. A. W. Hand, Mr. Humphries, and Mr. A. Welsh.

The Chairman announced that the annual *soirée* would be held on the 1st of next month, and expressed a hope that, as its object was to bring the members into friendly association with each other, as many as possible would attend, and also contribute drawings and suitable works of art.

Mr. Turner called attention to the library, and to the increasing demand for the books. He suggested that a special appeal should be made for donations of books and money.

The Chairman observed upon the importance to architectural students of good books of reference, and remarked, that it means could be taken to bring the wants of the Association more directly under the notice of the members of the profession, many persons having duplicate copies of books might be willing to present them to the library.

Mr. J. P. Seddon then read a paper on "Oyster-culture architecturally considered."

In the course of a short discussion which ensued, Mr. E. W. Godwin observed that the main question opened up by the paper just read was, what was the pure, healthy, educated style from which the young architect should start? His own experience led him to believe that thirteenth-century art was not sufficient, for it was as full of variation and of bad architecture as that of any other age. He did not know any Perpendicular or Renaissance building which could be inferior to certain modern specimens of thirteenth-century art. Then with regard to the "thoroughness," or rather want of thoroughness, of the works, he was found to say he was often disappointed and disgusted at the absence of that quality in Gothic buildings. The outside was Gothic enough, but the inside presented the appearance of the ordinary vernacular building of the age. Where, he asked, was the Gothic roof or the Gothic wall? There was a large building in the west of England to which he would not further refer save as an illustration of want of thoroughness. His recommendation, therefore, was that whether the building be Classic or Gothic, it was always desirable to keep "thoroughness" in view, because there could be no good architecture without it. Then there were the Rationalistic and the Conventional styles, and if they wanted to see good examples of them, let them study the Assyrian work in the British Museum.

Mr. Burges having been called upon, said that having promised to read a paper on "Our Architectural Future" (May 24th), he would reserve his defence, merely observing that he intended to treat the subject as a very serious one indeed.

Mr. P. Edwards commented upon the extraordinary want of unanimity that appeared to exist among architects, which he thought was more marked and striking than even that which characterized the members of the medical profession. As an illustration, he stated that he had on one occasion submitted the same design to the criticism of three architects, and that all three had expressed different opinions upon its merits.

Professor Ware (of Boston) remarked that he quite agreed with what had been said as to the necessity of thoroughness in work, whatever might be the style. It should, however, he thought, be borne in mind that the interior of a building should be founded upon the needs and requirements of those who were to use it. This might always be accomplished, while at the same time harmony might be observed between the exterior and the interior.

Mr. L. W. Ruge denied that architects of particular schools differed upon the principles which governed their art, although they might not agree upon details. In his opinion, the true principle to keep in mind, when designing a building, was to combine utility with beauty.

A vote of thanks having been proposed,

The Chairman, in putting it, observed that the paper of Mr. Seddon was useful, as calculated to remove hallucinations on the one hand, and as an incentive on the other to cast aside the prejudice of the schools, in order to produce

works exhibiting earnestness, truth, and study. Those who were acquainted with what might be termed the inner life of the Architectural Association, were aware of the exertions which its members were making to obtain that knowledge of true principles which could alone guide the architect to just conclusions, and enable him to produce thoroughness in his works. The majority of the Association was composed of young men who were at work, for many hours each day, in the offices of their employers; but, notwithstanding, they found time to devote three or four evenings a week to study in classes, and to obtain that practical knowledge of their profession unobtainable in the ordinary routine of business. While schemes for architectural education were still in *vulgaribus* in other directions, the Architectural Association had put its shoulder to the wheel, and had provided for itself a life school, a class of design, a class for practical subjects, and other aids and appliances, which proved that whatever short-comings might exist elsewhere, they were at least earnest in their work, and deserved sympathy and encouragement, instead of apathy, and possibly sneers. There was no doubt a great deal of frivolity in the art-work of the last two or three centuries, and anything like perpetuating it in modern times was to be deprecated. It was not, however, to be supposed that the influence of bad examples could be obliterated in a moment, nor was it to be supposed that the architect of the present day could do just what he pleased. He might desire to avoid the reproduction of old works, and to carry out something altogether original, but he was frequently controlled by clients, who, as a general rule, objected to art-work on the score of expense.

At the next meeting of the Association, Mr. T. Wells will read a paper on the influence of Eastern and Western Art.

WESTMINSTER PALACE.

MR. E. M. BARRY writes to us as follows:—
I have seen the letter of Sir Augustus Clifford, which was copied into other papers from your columns, and in which he complains of the inconvenience he suffers from smoky chimneys. I join with Sir Augustus Clifford in hoping that what has happened at the Westminster Palace may be remembered as a warning by those now in power. Perhaps he is not aware that a general system of dispensing with chimneys was forced upon my late father after his design was matured, and in spite of his earnest protest. After this system had been pronounced against, the building, which had been constructed in accordance therewith, was consigned again to the architect to deal with as he could. Under these circumstances I am only surprised that the evils of which Sir Augustus complains are not far worse, as indeed they would have been had not my father's foresight provided extra flues and other arrangements, so as to provide, as far as he was able, against the failure he foresaw, but was powerless to avert.

"THE ORANGE-PEEL PAVEMENT DANGER."

I WAS much struck lately at Florence by the perfectly clean state of the streets, and the entire absence of orange-peel. I found that orange-peel is not allowed to be thrown into the streets—the act is punishable. The perambulating vendors of the fruit carry on their trucks baskets to receive the peel—a convenience for those who wish at once to devour their purchases. And why should we not have a similar law in London, and get rid of what is certainly a most fruitful cause of accidents? P. E. M.

STAIRCASES.

SIR,—I saw whilst in Florence a geometrical stone staircase totally free from any wall support, with a central stone shaft crowned by a statue of Ceres or Flora. It was in the building just being appropriated by the Government from the Convent of Santa Maria Novella. I thought it one of the most beautiful objects in modern architecture. Can any of your readers kindly direct me to any similar object in or near London, and thus oblige one who is
No ARCHITECT.

TRAFALGAR SQUARE.

SIR,—I believe the *Dudler*, with reference to the Nelson column, early pointed out the absurdity of putting up the statue of a man so high in the air that it is impossible to see his face. Now that the guardian lions are round him, this is even, if possible, more provoking than ever; and poor Nelson, for whom the whole square was built, is completely lost sight of, and, it is to be feared, well-nigh forgotten: for his sake, therefore, will you allow me to offer a suggestion?

I would propose to take Nelson down from his present uncomfortable perch and place him on a worthy pedestal, between the two fountains; to take off the capital from the column and raise it some hundred feet or more by a bronze shaft, terminating in a gilt crown, and thence to convert it, the column, into a colossal flag-staff, from which a Union Jack should always float. This would be a novel and perpetually commemorative idea, and would always remind people of the meaning and intention of the monument. Nelson facing it would make it still more intelligible and significant. He stood by his flag in life, why not now he is dead, in idea at least, and as reminding all that he did so? This, too, would give some little significance to the lions, as supporting and guarding; now they mean nothing. You know the three flag-staffs in the square of Venice; pray let us have one worthy of London! C. B. ALLEN.

"ARCHITECTS AND DEALERS IN PROVISIONS."

SIR,—Permit me to direct your attention to the enclosed circular of a new firm in Liverpool, where (as it would appear) the profession is so numerous, that it is requisite to couple with it a trade in provisions. You have frequently pointed out the incoherence of a person being an architect and builder; is not this more incoherent? And it may lead to worse; for, if the issuers of the circular succeed in business, they will have imitators, one of whom will probably astonish the world as an ARCHITECT AND LIQUOR DEALER.

* * * * *
The advertiser in question positively set forth with all gravity that they are building surveyors, and are thoroughly competent to prepare plans, take out quantities, and value property; and that, having a connexion in the provisions trade, they can dispose of every kind of American and home produce to undoubted parties, on the very best terms!

"HIGH-PRESSURE BOILERS FOR BATHS."

SIR,—I observe your correspondent, "Beta," is afraid of his bath-boiler exploding during frost. If the work is properly done, and he uses in connexion with his boiler a hot-water circulating cistern containing from fifty to eighty gallons, it is an impossibility for his boiler to burst, if the range is in use every day; for as the water continues to circulate as long as there is a unequal temperature between the hot-water cistern and boiler, there is not time between 11 o'clock p.m. and 7 a.m. (being about the time the fire would be out) for the entire quantity of water to get down to freezing point.

If the cold-water supply ceases, and through evaporation the boiler becomes empty (which would be a very tedious process), and then if the cold water is suddenly introduced into the almost red-hot boiler, an explosion must be the result; but such an accident could only arise from gross carelessness, as the want of water would be felt for several days previously. The boiler should always be full of water, and consequently cannot contain any steam. There should never be more than two holes drilled in the boiler, viz., for the flow and return pipes; a draw-off cock from side or bottom of boiler should always be avoided. J. W.

STRENGTH OF PIPES.

WILL one of your readers inform me if 12-in. diameter fauset-jointed fire-clay pipes, ordinary thickness, jointed in cement, and laid in puddle, are capable of bearing 50 lb. head of water, and if they have been successfully used as mains? P. B. L.

GRINDING MONEY.

At Clerkenwell, Mr. William Langmead, builder, Gray's Inn-road, was summoned before Mr. Barker by Frederick Wilfen, a carpenter, lately in his employ, to show cause why he did not pay him for six hours' work which he alleged he had done while he was the defendant, and by his orders. Mr. Bannister, solicitor, attended for the defence; Mr. Ricketts, solicitor, watched the case for a society that was interested in the matter. The complainant stated that he did not employ the defendant in the erection of a public-house on Clerkenwell-green, and on the day named in the summons he was told to leave that job, and to take his tools to the establishment in the Gray's Inn-road, where he did so he told the foreman that his tools required grinding, and the foreman told him that he had better grind them, and sent a man to assist him to do so. When he had finished, the foreman told him that he did not require his services any longer, and discharged him, and when he applied for payment of the money he had earned while grinding his tools he was refused payment, and on the present proceedings. It was a rule of the trade that the men should be paid for the time they were occupied in grinding their tools, and every shop in London paid the money, and he was surprised that the defendant refused. Mr. Bannister submitted that this was not a case in which the magistrate had jurisdiction, and he was surprised to find that the process of the court had been issued. He supposed the facts had been kept from the knowledge of the learned magistrate. Mr. Barker said he told the complainant at the time he asked for the summons that if it was only on the question of grinding that he had better not take the summons, but the applicant then said that he wanted the summons for actual work and labour done. The applicant replied that the foreman at a job always estimated a man's basket or chest as he commenced work, and that was why a man before he left a job was allowed time to put his tools in order. Besides,

part of the time which he claimed for was occupied in going from one place to another at the request of the defendant's foreman. Mr. Barker said that the summons would be dismissed, and if the complainant had a remedy was not at the court. The work for which he had power to make an order to pay in case of the default of the master to pay was clearly laid down in the statute, and the work here sought to be paid for was not such work. The summons was then dismissed.

"192, Gray's Inn-road, Feb. 5, 1867.

SIR,—Concerning the above, as we had not an opportunity to give evidence, we shall feel extremely obliged if you will allow us to trespass on your valuable space with the following statement of facts.

The plaintiff, F. Wilfen, was discharged from an outdoor job, and received from the foreman of the works a ticket for the number of hours he had worked, as well as an additional half-hour to enable him to collect his tools. This ticket he produced at our office, and received money equivalent to the number of hours stated thereon, even before the time expired. After receiving the same he demanded grinding-money, which was refused; but at the same time he was informed that the yard grinding-stone was at his service, of which he availed himself, and also the assistance of several men and labourers.

The value of the time thus occupied was the cause of the summons to appear before the magistrate, who immediately dismissed it; and we now hope the plaintiff will give us an opportunity of having his over-looked question settled by a decision in the County Court.

W. LANGMEAD & WAY.

Books Received.

A Dictionary of Photography. Edited by THOMAS SUTTON, B.A., editor of "Photographic Notes;" and GEORGE DAWSON, M.A., Lecturer on Photography, King's College, London. Sampson Low & Co., Ludgate-hill, 1867.

The first edition of this work has been for some years out of print. The present editors have remodelled, condensed, and improved the work, adding new matter and deleting obsolete and inferior processes. Many of the articles have been rewritten in a spirit more consonant with the present comparatively advanced state of the art, and a description given of the preparation and properties of the various chemicals; and of the theory and construction of the different optical instruments in use. It would have been well, in condensing the matter, had such repetition as that given under the heads "Lead, Protoxide of, or Litharge," and "Litharge; Massicot," been avoided: the articles are nearly word for word the same throughout. The volume, however, is a valuable one to photographers.

Notes for a History of Sanitary Legislation. By EDWIN LANKESTER, M.D., F.R.S. London: Chapman & Hall, Piccadilly, 1867.

THESE notes are an extension of the paper on Sanitary Science written by Drs. Lankester and Letheby for the "Encyclopædia Metropolitana," and were to have appeared in their extended form in the *Journal of Social Science*, had not that journal ceased to be published. The pamphlet contains an interesting review of sanitary progress so far as regards legislation, and the additions made to the original notes bring the subject up to a recent date, the whole forming a useful refresher to the minds of sanitary reformers as to what has been done for the science by legislation which is still requisite.

We may quote a passage from the conclusion of the pamphlet:—

"In spite of all this activity and spread of sanitary knowledge in various directions, there is still a want of a sound understanding of the laws of life manifested in all classes of society. The deficiency in teaching the natural sciences in the Universities of Oxford and Cambridge acts most seriously on the whole educational system of our country. Our legislators enter Parliament utterly unprepared to discuss sanitary questions on a scientific basis. Their clerical brethren, with whom so large a power of instruction is vested, are equally ignorant of sanitary matters throughout the country, frequently pass from our universities without the slightest knowledge of the structure or functions of the human body. Our lawyers are alike unacquainted; and it is not sufficient that our distinguished magistrates and judges have to decide upon cases concerning public health, the facts of which, for want of any training in natural science, they are unable to comprehend. If amongst those who are the natural leaders of society this knowledge is not appreciated, it is not to be wondered at that those lower in the social scale should neglect to cultivate it. There is, in fact, no systematic attempt made to teach in any of our educational establishments the great laws by which the health of the body is maintained, and preventable disease and death avoided: the consequence is, that the mortality of the large towns of England is in many instances augmented; and in proportion as the nation gets wealthier, and the means of indulgence increased, the population becomes more subject to epidemic disease and early death. This ought not to be. Increasing intelligence and wealth ought to be powerful aids to health, and they would do so, provided the minds of the people were directed to the causes of avoidable diseases and untimely death."

Miscellanea.

POST-OFFICE SAVINGS BANKS FOR FRANCE.—M. Rouher, it is said, in addition to a Public Works Loan, means to import into France our system of Post-office Savings Banks.

RESIDENT ENGINEER FOR THE MONTROSE COMMISSIONERS.—The Police Commissioners of Montrose have appointed Mr. Charles Tebbutt, C.E., of Loughborough, to be their resident engineer, in order to carry out, under his personal superintendence, the works of the proposed drainage scheme for the burgh. The engineer's salary will be 250*l.* per annum.

THE METROPOLITAN WATER SUPPLY COMMISSION.—A meeting of the Water Supply Commissioners has been held at 6, Adelphi-terrace, Charing-cross. There were present—The Duke of Richmond, Sir Benjamin Phillips, Colonel Harness, R.E., Mr. Joseph Prestwich, F.R.S., Mr. Thomas Harrison, C.E., Sir John Thwaites, and Mr. Arthur Lennox, secretary of the commission.

THE RENEWED OUTBREAK OF CATTLE PLAGUE IN ISLINGTON.—Dr. Ballard attributes the outbreak of cattle plague in the exact spot (Mrs. Nicholls's dairy, Liverpool-road), where it before broke out, to the use of old bricks for repaving, taken from a shed used at the last outbreak as a hospital shed. Whether this be the case or not, one can only wonder at the carelessness of the act.

THE AGE OF BRONZE.—M. Delmille, a Belgian advocate, has just found in the Lake of Virelles, belonging to the Prince de Chimay, the remains of a lacustral station similar to those explored for many years past in the lakes of Geneva, Constance, and Neuchâtel. The drag has brought to the surface of the water remains of all kinds, the nature of which authorises the assumption that the locality was inhabited in the pre-historic period called the age of bronze.

THE BRECHIN BOILER EXPLOSION.—A Brechin professional correspondent informs us that in this case the boiler was full of water, as also all the pipes in connexion with the same, and all frozen up when the fire was lighted. The consequence was—first, the frozen water in the boiler expanded, and there being no room for steam, and no escape while the pipe was frozen, the boiler was overcharged with steam before the pipes got thawed and clear of ice, which was the cause of the accident.

THE HYDE PARK RAILINGS.—Mr. Nicol asked (in the House of Commons) when the present barricade around Hyde Park was likely to be removed, and what description of fence was to be erected in place of it. Lord J. Manners said the Park-lane section was under contract to be finished by the 15th of October next—(laughter)—and the other parts by the 15th of July in next year. (Renewed laughter.) The character of the fences would be, he believed, substantial, and, he hoped, to a certain extent ornamental.

ROUND TOWER OF ARDMORE.—The pointed stone forming the apex of that venerable relic of antiquity, the Round Tower of Ardmore, in the county of Waterford, which had withstood the storms of many centuries, was hurled from its position by a terrific storm last week. Being a remarkable object in the neighbourhood, the stone was missed from its old place. It was at once sought for, and found embedded deep in the earth at the foot of the tower. The rector of the parish had the stone removed to a chamber in the building, where it now remains for the inspection of the curious. The stone stands 2 ft. 6 in. in height.

INQUIRY AS TO TRADES UNIONS.—The Commons have allowed the Home Secretary to bring in a Bill for facilitating, in certain cases, the proceedings of commissioners appointed to make inquiry respecting trades unions and other associations of employers or workmen. The trades outrages at Sheffield are to form a special branch of the general inquiry, which has been agreed to at the request both of trades unionists and masters. The president of the commission will be Sir William Erie, late Lord Chief Justice of the Common Pleas; and the other commissioners will be Mr. Thomas Hughes, Mr. Roebuck, Lord Elcho, Sir D. Gooch, Mr. James Booth, and Mr. Herman Merivale to represent the Board of Trade; and Mr. W. Mathews and Mr. F. Harrison as members in whom the trades unionists have special confidence.

INSTITUTE OF PAINTERS IN WATER-COLOURS, LONDON.—At a meeting of this society, held on the 4th ult., Mr. Edward Hargitt was elected an associate by twenty-four out of twenty-seven votes recorded. There were above a dozen candidates.

HONOUR TO ART.—Her Majesty has signified her intention to confer the honour of knighthood on Mr. George Harvey, president of the Royal Scottish Academy of Painting, Sculpture, and Architecture; and on Mr. J. Noel Paton, R.S.A., her Majesty's Limner for Scotland.

PROPOSED FEVER HOSPITAL FOR BRADFORD.—Mr. Alfred Harris has given 3,500*l.* for the purpose of founding a fever hospital, the principal to be expended on the erection of a suitable building whenever that shall be held desirable, and the interest to be applied till then to the payment of rent for convenient premises.

CHESTER ARCHEOLOGICAL SOCIETY.—The fourth monthly meeting of this session has been held at the Society's Room, St. Peter's church-yard, with a good attendance of members and friends. The Rev. Canon Blomfield took the chair, and introduced Mr. Thomas Rigby, the lecturer of the evening, as a gentleman well known among the agriculturists of the county as an able writer and speaker. Mr. Rigby then read a paper "On Delamers Forest and some of its Associations, with a short Account of the ancient City of Edisbury."

NOTING LOCALITIES.—We are glad to be able to say that the Society of Arts has commenced the work of publicly marking localities interesting for their connexion with notable men or historical events. A tablet noting the place where Byron was born has just been attached to the house No. 24, Holles-street, Cavendish-square, by permission of the occupiers, Messrs. Boosey & Co. It is intended to follow up this with others from time to time, as permission can be obtained from the owners of houses. The tablet is of terra-cotta, with a deep-blue face, the inscription being in white letters upon it.

PRINCESS'S THEATRE.—The new drama, "Shadow Tree Shaft," written by the author of the very excellent play called "Ours," has many elements that go to ensure success: it includes a number of good parts, two or three situations of remarkable power and interest, and some most effectively painted and built-up scenes. Although very well played throughout, it is, with the exception of the parts sustained, admirably, by Mr. Vining, M. J. G. Shore, Miss Katharine Rodgers, and perhaps Mr. H. Forrester, underacted. Sir Walter Kenyon and Richard Darkyn are capital parts. Mr. Neville in one, and Mr. Belmore, for example, in the other, would make a sensation. We mention this not in disparagement of what is done, but as showing what the play is capable of. Mr. F. Lloyd has evidently studied his Mine on the spot. The descent is very cleverly arranged, and the view of the Black Country, when the spectator rises from the mine, as it were, and finds himself on the surface, is admirably painted. The fir copice covered with snow is another realistic creation of remarkable merit.

GOVERNMENT INQUIRY AT SLOUGH.—Mr. Robert Morgan, an inspector under the Local Government Act, has held an inquiry at Slough, by direction of the Home Secretary, to whom the local government Board had presented a petition, praying him to authorise the Board to put in force the powers of the Lands Clauses Consolidation Act 1845, with respect to the purchase and taking otherwise than by agreement, of two pieces of land,—viz., a site for the water tower and well for flushing purposes, proposed to be constructed in a field adjacent to the place at which the Windsor branch of the Great Western Railway crosses the Bath-road, and a site for the sewerage outlet and deodorizing tanks, which the Board propose to erect upon a piece of land in the Slough and Datchet road, immediately contiguous to Upton Park. Mr. Sawyer, instructed by Mr. C. T. Phillips, appeared as counsel for the local Board; Mr. Darvill appeared, by order of the Court of Chancery, for the owners of Upton Park, and also for the trustees under the will of the late Mr. John Pocock, whose property adjoins the park; and Mr. F. Charsley, the registrar of Eton College, appeared on behalf of the provost and fellows, who had dissented from the project that their land should be taken as a site for the water-tower. Evidence was taken *pro* and *con.*, and the inspector will report the result to the Home Secretary.

METROPOLITAN LOCAL GOVERNMENT.—The following is a list of the Select Committee on Metropolitan Local Government, &c.:—Mr. Ayrton, Mr. Tito, Mr. Bazley, Mr. Locke, Mr. Alderman Lawrence, Mr. Knatchbull-Hugessen, Mr. Mill, Mr. Hanbury, Lord J. Manners, Mr. Boscroft, Mr. Turner, Sir W. Galloway, Mr. Bentinck, Mr. Sandford, and Mr. Kekewich.

SANITARY STATE OF CHESTER.—The town council have agreed to a proposal for publishing regularly the registrar's returns of births and deaths in Chester, and the first week's return has been issued. The death-rate was 25: the week before it was higher, and this time last year it was 42. The general average for last quarter was 36½, including 27 cholera cases, and even without these it was 28.

ART GALLERY, BIRMINGHAM.—At a meeting held in the Town-hall under the Mayor's auspices, it has been resolved, "That it is desirable to form an association, having for its object the acquisition of works of art for presentation to the Corporation Art Gallery, and that a committee be appointed to consider the best means of accomplishing that object." Accordingly a committee was appointed at the meeting.

MONEY SPENT ON LONDON WORKHOUSES.—A Parliamentary return states that since the passing of the Poor Law Amendment Act of 1834, sums amounting to 1,069,459*l.* have been by the Poor Law Board authorized to be expended in building, altering, or enlarging workhouses in the metropolitan district; about three-fourths of the amount in building, and one-fourth in altering or enlarging. This is exclusive of the value of workhouses provided before 1834, many of which are still in use, and the value of them very great.

THE SPREAD OF FEVER IN CHORLTON, MANCHESTER.—Mr. Greaves is following up his investigations as to the way in which fever is propagated in Chorlton. He has traced it in a way to prove that there is a total want of efficient preventive measures, or of sanitary police. Goods taken from infected houses are allowed to be sold and scattered about, and new tenants to take possession of the houses without proper disinfection. Persons ill of fever are allowed to change their residence, and infect others, without any attempt being made to prevent it. Details of such matters have been published by Mr. Greaves in the local papers, and it is to be hoped that his important and useful exposures will show the necessity for better sanitary supervision by the local authorities.

THE HOARE MEMORIAL.—At a meeting of the representatives of the Church Institution, the Convocation Society, and the Churchwardens' Association, convened to consider the best mode of commemorating the labours of Mr. Henry Hoare, lately deceased, it was resolved, having regard to the essentially practical character of Mr. Hoare, and to the fact that an attempt is now about to be made, in accordance with the suggestions of the Queen's Advocate, to provide for a great want, by building upon freehold ground a church house, that in the opinion of this meeting a chapel or hall for the said house would be a most appropriate memorial, and that a copy of this resolution be forwarded to the Bishop of Oxford (who had previously expressed his personal approval of the scheme), with a respectful request that his lordship would communicate the same to the committee of convocation upon the subject.

FIRST SANITARY REPORT ON NEW YORK.—In March, 1866, the Metropolitan Board of Health created by the Legislature of the State of New York began its operations, and the first report is more a bill of indictment than a record of improvement. It describes the mortality of New York as much exceeding that of London, and attributes this partly to the annual arrival of large numbers of immigrants. In New York and Brooklyn the Board found 250 slaughter-houses, the sewers leading from them being often obstructed, and the refuse making its way under the floors of buildings. The tenement-houses of New York, more than 4,000 in number, were found crowded, ill-ventilated, ill-drained, and in a filthy state. The Board are setting to their work in earnest, and have already made more than 25,000 peremptory orders for the abatement of nuisances. The deficient drainage, except in first-class houses, is a constant source of disease, although about 60,000 loads of night-soil are removed from New York every year in carts.

THE NATIONAL GALLERY DESIGNS.—We are requested to state that the public will be admitted to view the designs for the New National Gallery on Wednesday, Thursday, Friday, and Saturday, from ten to four o'clock, until the 16th of March.

ASSISTANT BUILDING SURVEYOR TO BIRKENHEAD COMMISSIONERS.—Mr. John M'Neil has been appointed as assistant building surveyor to the Birkenhead Commissioners on the recommendation of their Health Committee, at a salary of 120l. a year; and Mr. William Halsall, as assistant inspector of nuisances, at 30s. a week.

HEALTH IN THE YEAR 1866.—In the United Kingdom 1,013,070 births and 665,859 deaths were registered in the twelve months, thus making the natural increase 347,211, or at the rate of 951 daily. The recorded number of emigrants was 204,882, or 561 daily. The difference between the emigrants and the registered natural increase was 390 daily. The birth-rate per 1,000 of the year was 35.47, the death-rate 23.03, for the United Kingdom, after a correction for the defective registration of Ireland. The birth-rate per 1,000 of England proper was 35.51, the death-rate 23.62, the numbers for the previous year, 1865, are 35.63 and 23.41; the shade of excess in the death-rate of 1866 being due to cholera, for the mortality is lower in all the divisions except those in which cholera prevailed. The eleven divisions may be thus arranged in the order of annual mortality.—The deaths per 1,000 were, in the South-Eastern Counties, 19; Eastern Counties, 20; South Midland Counties, 20; South-Western Counties, 20; North Midland Counties, 21; West Midland Counties, 22; Monmouthshire and Wales, 23; Northern Counties, 24; Yorkshire, 26; London, 26; North-western Counties (Lancashire and Cheshire), 29.

BREAKING OF A WIRE BRIDGE AND CURIOUS ELECTRICAL PHENOMENON.—During the late intense frost, the small river which waters the valley of Clonagh was, like others, covered with ice varying from 6 in. to 9 in. in thickness. This, when partially dissolved by the thaw, was broken up into large plates, and rapidly carried to the sea, except where it met with obstacles. One of these consisted of a slight wire foot-bridge, which formed a communication between two parts of the minister's glebe, which the river divides. This bridge was supported by four pairs of wooden posts, standing in the bed of the stream, and against these a great quantity of the ice had been collected, until the water, obstructed by it, rose several feet above its natural level. The whole structure was at last carried away, some of the wires being broken, and the others torn from their fastenings. A vivid flash of coloured light accompanied every fracture of the wires. This appearance was observed by several persons, one of whom had just crossed the bridge. The phenomenon was probably caused by the wires being strongly charged with electricity, developed by the breaking up of the ice and the friction of the detached masses,—separation of parts and friction being both known sources of electric action.

THE NEW DOCKS AT THE ISLE OF DOGS.—Enormous excavations for these docks have now been made, by 3,000 men, who have of late been at work on them, and the outline of docks, wharfs, and warehouses can now be traced. The freehold property purchased by the company comprises an area of 200 acres, having a circumference of about 2½ miles. Thirty-five acres and a half have been excavated for the purposes of a floating dock, having two basins, one of 25 acres in extent, the remaining 10½ acres being occupied by the other. The depth of water in each will be about 28 ft. or 29 ft. All the materials excavated have been available for making embankments and a roadway. Every foot of excavation has added 2 ft. to the depth of the projected dock, for the sand and mud dug out have been thrown up on the embankment, so that in some places the surface has been raised as much as 10½ ft. A large graving dock is being constructed. This dock is 420 ft. by 86 ft., and will have an entrance 65 ft. wide. The docks will have a frontage of 7,700 ft., which is to be occupied as wharfs or sites for warehouses and manufactories, while the other parts of the land will be hereafter made available for dwelling-houses. The portion that has been quayed has been formed to a level of 4 ft. above high-water mark. All the gates, bridges, warping capstans, and other machinery are intended to be worked by hydraulic power. The contract, according to its terms, ought to be completed on the 1st of September.

TENDERS

For two houses at Wimbledon. Mr. Henry W. Broadbridge, architect:—
Surridge..... £987 0 0
Sawyer..... 883 0 0
Kemp..... 818 0 0
Wilkinson & Co..... 899 0 0
Colliner..... 820 0 0

For house at Fairfield, for Captain Pearson. Mr. John Newton, architect:—
Field..... £5,220 0 0
Rebble..... 4,600 0 0
Bracher & Son..... 4,402 0 0
Piper..... 4,485 0 0
Wilson..... 4,272 0 0
Dove..... 4,255 0 0
Till..... 3,718 0 0

For constructing brick sewer in old Brompton-road, for the Kensington vestry. Mr. J. Broadbridge, surveyor:—
Williams..... £2,880 0 0
Goodair..... 2,392 0 0
Thirak..... 2,219 0 0
Whitrick..... 2,098 0 0
Wigmore (accepted)..... 1,968 10 0
Moxon & Mutton..... 1,950 0 0

For warehouse, Brunswick-road, Poplar, for Mr. Coler. R. W. R. Knipple, arc.itect:—

The Builder.

VOL. XXV.—No. 1255.

The Grosvenor place and Pimlico Improvements of the Marquis of Westminster.

F the shade of Sir Charles Grandison, or "Sir Plume's conceited Ghost," could see the many changes wrought in the aspect of London since he handed ambrosial toast to ladies who rejoiced in black patches on their cheek and black pages behind their chairs, it would be, perhaps, most astounded at those now progressing on the Grosvenor estate in that last-century region of which Tattersall's may be said to baters behind the heart and Ranelagh the head, or *vice versa*. Could his Sedan-chair be summoned to carry him down Grosvenor-place, his chairmen would lose their way before they passed the first turning. The irregular belt of brick houses, sloping down

hill, and built or fitted with various contrivances for obtaining good views into the Green-park before them, is gone. The buildings whence patched and painted dowagers watched the gay doings of "hot blood" when George III. was newly seated on his grandfather's throne, have vanished. And not only these but those in the rear of them, for many a valuable acre, and those facing them, after the boundary of the Green Park is passed, and those departing to the right and to the left of them in brown, dingy streets, have been razed to the ground; in a word, the site of hundreds of houses occupied by the wealth and fashion of a former age now lies as bare as the bottom of a gravel-pit. Nowhere else, too, could Sir Plume's shade gain a more impressive realization of the progress in social life and sanitary requirements made since his day than that which would be afforded it from an examination of the scheme which supplants the former disposal of the site and of the details of the mansion of which it is comprised. The cramped, low, many-paned plain brick houses which Clarissa, Belinda, and Pamela filled with chintz, china, mirrors, cabinets, and card-tables, appear seedy and unattractive to the last degree by the side of the lofty, airy, ornamented dwellings for which their descendants have created a demand. This magical clearance of a neighbourhood so famous in the chronicles of fashion, most of our readers will be aware, is the result of the determination of the Marquis of Westminster to remodel his estate on the expiration of the leases granted by his predecessors. The large tract of land we have mentioned, with the substantial crop of houses upon it, comes into his hands, at the present day, as an expired lease on a large scale; and he has set about improving this accession of property in a correspondingly grand manner. A magnificent scheme has been laid down, and time, money, and space have been given to carry it out. Unfettered, to any considerable extent, by the tedious and sometimes inconsiderate claims, or requisitions, of owners of intermediate pro-

perties, Lord Westminster has been able to make new roads, leave garden spaces, or build mansions, exactly on the positions recommended to him by his architect, Mr. T. Cundy, jun., the destination of these being governed only by the exigencies of existing public thoroughfares. Thus the new district is the well-considered and comprehensive scheme of a trained mind, instead of the thwarted, curtailed vexations which too many improvers' plans become through such opposition. There was, indeed, one unexpired lease, in the occupation of an ironmonger, upon an important corner site which appeared, at one time, likely to be a blemish of an ugly kind upon the improvements for forty years to come; but this has now been purchased for 4,000*l.* by the National Bank, whose directors will proceed to remove the weazen metal mart, and replace it with a structure more in accordance with the new neighbourhood that is rising around it. And, again, there are instances in which the new district will be extended, probably before the whole of that now proposed will be brought to completion, by the falling in of more leases of adjoining areas which have ten years longer to run. This is the case concerning the large site occupied by Mr. Goding, near the present gateway through Barrack-yard, into Knightsbridge, which will be covered with convenient stables at the expiration of that period. Large ground landlords would do well to observe the imperative necessity of granting all leases of adjoining properties for periods of duration which will bring the ground into his hands, or those of his descendants, intact or nearly so. A neighbourhood, where only street by street, or house by house, can be treated, will never be able to rise in importance as this will now do. But the Marquis's scheme ceases with the planning of the site and furnishing the exterior designs for the mansions. The actual building operations are in the hands of various building firms, who have obtained leases of the newly set-out sites from him. The several blocks appear, however, to remain in as many hands, each builder undertaking a separate one. We proceed to more exact details.

First, as to the roads. What we may call a main artery is to be made from Hyde Park-corner to the Grosvenor Hotel. It is to be a wide, straight road of grand houses running as straight as may be from Piccadilly to the open space in the Chelsea-road, on which stands the great hotel. After passing the wall of the Royal gardens, where it is intersected by Lower Grosvenor-place and Grosvenor-street West, this main artery runs through the centre of a St. Andrew's Cross formed by four additional roads. The four limbs of this cross are formed by Ranelagh-street, running from the south across the main artery to the north; and by Upper and Lower Grosvenor-gardens, which cross the main road nearly due east and west. These roads are not, it must be understood, uniformly bounded by houses on each side of them, as we shall presently describe. The Ranelagh-street arms of the cross give spacious access from Lower Grosvenor-place to Belgrave-street South and Lower Belgrave-street, and so on into the heart of Belgravia. The Upper and Lower Grosvenor-gardens arms of the cross stretch from Grosvenor-street West to the point in the Chelsea-road which opens into Vauxhall Bridge-road.

Starting from St. George's Hospital down the gently declining hill, we come upon continuations of a new crescent, to be called Grosvenor-crescent, which is to turn out of Grosvenor-place towards Belgravia, immediately upon the boundary of the site of this institution. This new feature, opening out the *cul de sac*, will be an immense boon to the public, and will add a third frontage to the noble, and certainly fortunate, charity. The odd corners which will result from the sweep of this curved road will be probably planted as gardens, and will give the

approach a pleasant leafy freshness. We might call this crescent the phoenix that is about to arise out of the ashes of Tattersall's, if it were not for the fact that the horse institution in question is by no means consumed, but, on the contrary, re-organized and removed westward, where it is flourishing with unimpaired vigour, and to the great annoyance of the neighbourhood, especially on Mondays. Londoners, however, will be long before they forget to point out that it was hereabouts that the head-quarters of the turf once existed. No formidable commencement has been made here towards the new works, save the wonderful clearance of the site and erection of sheds, as extensions of the hospital are in contemplation, and the nature of these will in great measure depend upon the arrangement made with Lord Westminster as to the ground, and this accommodation will in its turn have to be considered in reference to the prospects of the crescent. Passing the entrance into the proposed crescent, Grosvenor-place follows its former route for some little distance. A handsome block of houses will occupy the frontage between it and Halkin-street, consisting of five mansions, the fifth, which is at the corner of the street mentioned, being destined for a magnificent town mansion for the occupation of the heir of the Marquis of Westminster, Lord Grosvenor. This is undertaken by Messrs. Smith & Taylor. In the rear of this block will run Pembroke-mews North, which will open into Halkin-street, at the termination of the return frontage of Lord Grosvenor's house. His lordship's stables, on the west side of these mews, are expected to be the most complete in London. Grosvenor-place proceeds thence in another fine range of houses, eleven in number, bounded by Halkin-street on the north, and Chapel-street on the south, Pembroke-mews stretching in the rear between these two streets. It may be as well here to state, that each block of new buildings is arranged as a distinct feature of the whole scheme. Every block is treated separately, and has a centre or double centre, with well-marked terminal distinctions. The width of each house in the block is varied according to its position or the composition, and thus the vain repetitions which produce the effect of being manufactured by dozens at a time are not perpetrated. Every block looks like what it is,—a palazzo divided into separate dwellings. Besides the contractors we have mentioned as having undertaken Lord Grosvenor's house, Messrs. Jackson & Shaw and Messrs. Piper & Wheeler are at work in this field.

It is, however, when we come to the large clearance to be intersected by the roads in the form of St. Andrew's cross that we are most struck with the gigantic nature of the scheme. Two of the triangular spaces between the central main road and those intersecting it transversely are to be left open as gardens—one to the right, and the other to the left some distance beyond; and the rest are marked out as plots. And here considerable progress has been made. Already, vast piles have reached their full height, and are roofed in. These we shall presently describe, but we must first remark upon the absence of a church in the scheme. In many of our new districts new churches have formed leading features in the first disposition of the site; but the Marquis, though sacrificing space for gardens, and lending an open hand to St. George's Hospital, has not appropriated space for a church. We must not omit to add that the poor he has not forgotten. Besides the snug houses occupied by the wealthy in this fashionable quarter, there were mews, and small dark streets of small smelly houses, in which dwelt the industrious poor who ministered to their rich neighbours, in the shape of small tradesmen, workmen, and work-women, laundresses, &c., as well as stables for horses, and dwellings for coachmen. These have

shared the fate of more important structures, and have been swept off the face of Pimlico. Their inhabitants, however, have not been uncared for. With the present demolition of the mews, the coachmen found their occupation removed, if not gone; there was, therefore, no necessity to provide for these; and the small shops, too, could scarcely be required in a region now hared to a desert; but the working classes who found homes in the locality have been provided for by the erection of two model lodging-houses in the Commercial-road, Pimlico, out of means lent for the purpose by the Marquis.

After the roads, before we give details of the buildings, we must mention the great boon to the neighbourhood afforded by the proposed underground railway. One of the plots into which the estate is divided has been apportioned for a station for this subterranean roadway. By means of this communication the inhabitants of the superb mansions will be placed within a few minutes' distance of the Houses of Parliament, and in connexion with all the railways that depart from London. As Londoners are gradually ceasing to talk of miles in favour of reckoning distances by minutes, it is, perhaps, of the first consideration that the builders of these mansions should be able to state that they are within four or five minutes' distance of the heart of Westminster. The Victoria Station already places them in direct communication with Paris, and thence with all the civilized parts of the globe.

As a specimen of the character of the houses we will first take one of the mansions in plot No. 1, now in course of construction by Mr. Waller, and approaching completion, premising that plots 1 and 2 are grouped into one composition, consisting of a fine frontage, overlooking one of the triangular garden-plots, which has two central towers covered with Mansard roofs, and large double houses at each end. Ten of the northernmost houses are undertaken by Messrs. Waller & Son, of Lyallstreet, Bolton-square; the remainder by Messrs. R. Watts & Sons. The new offices of Mr. Cundy, with a flat over them, at present occupy a portion of the site immediately in the rear of the latter. This gentleman's staff includes six clerks of works,—one for the estate generally, and five for various plots in progress.

The designs of all the frontages are from the pencil of Mr. Cundy; and beyond the necessity of seeing that these are faithfully carried out, there are various clauses in the leases which are necessary to be observed and enforced. The interior arrangements are left to the discretion of the builders, or the convenience of purchasers, and are to some extent dependent upon the size of the houses, as these are not uniform. Thus the fittings of the houses in this block, built by Messrs. Watts, are slightly different from those erected by Messrs. Waller; and again, both vary them to meet diversified requirements. The frontage of this magnificent block of houses shows five stories above the basement. It is built of the best brown Portland stone, from Whit bed, with bands and panels of red Mansard stone and terra cotta, and roofed with slate placed in red and green bands, ornamented with Vieille Montagne zinc. Four lofty mansards break the sky-line, one at each end of the block, and two in the centre. Each house has a portico, the columns of which are made of polished red granite, or serpentine. The fenestration and the ornamentation of the whole facade, from the ruddy coloured portico to the very lofty chimney tops, in Portland stone and Mansfield sand, may be called Renaissance of the Château Henri Quatre type, for the sake of conveying some idea of it. The windows of the dining-room and drawing-room floors are square-headed; those of the two principal bedroom floors are round-headed; the third bedroom floor lights are dormers, of a French character. The balconies are stone, and balustraded at the first-floor and porticoes, and richly and boldly ornamented in iron for the other stories.

We will examine No. 10, of plot 1, or Upper Grosvenor-gardens, as a sample of the houses Messrs. Waller are now finishing. The value of the ground is made evident at the first step into it, in the economy with which every inch of it is used. Not only do the domestic offices exceed the bounds of the site by spreading underground in front of the house, but the space generally left at the back of houses for a yard is covered in for a kitchen, and the scullery is actually thrown out underground below the coach-house, till the innermost limits are gained at the back of the house; and the coaches on the way to

their places must be wheeled over the window that gives part light to necessary offices. The basement within the walls of the main house is occupied by a housekeeper's room, with closets, cellars, and a servants' hall; projecting beyond this, and lighted from the area, are the footman's room and pantries, and projecting behind it is a large kitchen, lighted and ventilated by sky-lights, the larders, and the scullery spoken of as extending below the coach-house into the mews beyond. There are also two W.C.s in the basement. The lighting has involved some skilful management; and the ventilation on so closely covered a space has not been without its difficulties; but it is supposed that the long passage-way extending from the scullery in the rear to the area in the front will afford sufficient security for the latter; and gas must, if needs be, be brought to the assistance of the former. The footman's room is fitted with slate sink and slate filter; and the housekeeper's room has a convenient locker on either side of it. In her room, too, we perceive the contrivance that is one of the special features of the interior economy. This consists of six metal plates in the wall, which open into many flues, and enable a man to sweep all the chimneys in the house from the basement floor. A second set of metal plates rearwards, which open much in the same way as so many oven doors, provides access to all the flues of the back rooms of the house. No sweep need ascend a single stair in the house, and the defeacement of furniture, the great discomfort and labour attendant upon the necessary cleansing operation in question, when chimneys are swept in the host rooms, are nearly done away with. As the broom ascends the flues, it closes the double-action register-door belonging to the grate of the room it passes in its passage upwards to the top of the chimney-stack. There is a clause in the lease which prohibits the erection of the multi-form pipes which disfigure so many of our buildings for the purpose of curving smoking chimneys. To meet this prohibition extra precautions have been taken to provide against the perpetration of a misfortune for which external remedies are thus out off, by the insertion of ventilating flues, and tubes below the floors to bring a draught of outer air immediately in front of each grate. We hope it may answer. It does not always do so. Leaving the basement, we find the floor, slightly raised above the level of the road, to consist of an entrance passage-way divided into two parts, so as to form a lobby, and three rooms. The dining-room occupies the frontage. Behind this is a breakfast-room, which looks, through ground glass, out upon the glass skylight of the kitchen, occupying the adjoining space below. At the end of the passage, beyond the back as well as front staircase, which are both built of stone, is a third chamber, which has a bow window also abutting upon the skylights of the basement floor. Upon nearly the same level, are the fire-stalled stable, the loose-box, and coach-house, which are entered from the mews. Some houses built upon the estate have internal communication with the stables by means of a light iron bridge and stair; but this has not. We may as well mention here that over the stable there is a loft with a shaft down which to throw the corn, &c.; and over the coach-house is a dwelling-room fitted with a kitchen grate, and two bed-rooms for the use of the coachman and his family. Part of the light for one of the bed-rooms is gained through the shaft mentioned. The ascent is made by means of a steep straight staircase between the coach-house and stable. The drawing-room floor contains but three rooms,—two drawing-rooms opening into one at will by the withdrawal of sliding-doors, and a bow-windowed houndoir over the third room below. The front drawing-room measures 23 ft. 6 in. by 23 ft. 6 in., and is 13 ft. 10 in. high. Out of the back drawing-room opens a conservatory, which overhangs the buildings on the basement. This can be also approached from the houndoir. The first bed-room floor is divided into four rooms; the next into three. The one above this, and counting from the basement we are now on the sixth flat, is quartered; and the roof contains six small rooms without fireplaces. Along the whole length of the block of houses on the outside of the roofs is a passage-way by which to escape from fire.

The ceilings of the principal rooms are delicately panelled, with flat cinque-cento ornaments in low relief, and have cornices and brackets. They are of different degrees of richness, the richest being apportioned to the front drawing-room. In like elegance the chimney-

pieces of the chief apartments are of white marble. It is expected that the selling price of houses in this class will be from 10,000l. to 12,000l., and they seem to find purchasers as fast as they are built.

Plot No. 3, which also looks upon the triangular garden faced by plots Nos. 1 and 2, only from the opposite point of view, is also well advanced. This is a block of first-class mansions in the hands of Messrs. Trollope. Plot No. 4 is situated in the rear of this, forming what we have heard called a flat-iron, between Ranelagh-street and Lower Grosvenor-place, and it provides for the inevitable exigencies of life in the form of a block of first-class shops. These are also the speculation of the Messrs. Trollope. The fifth plot is not yet commenced, but it is destined to receive a group of first-class mansions, to be erected by Messrs. Holland & Hannen. This is in the form of a triangle, bounded by Belgrave-street South, Ranelagh-street, and the direct or main road through the estate. The sixth plot, close to Victoria-square, will be covered expressly for a coach manufactory, erected expressly for the well-known carriage-builder, Mr. Thorne, by the Messrs. Trollope. This will be surmounted by handsome ranges of dwellings in flats. The seventh plot is allotted to the Belgrave Mansions Company (Limited), for the erection of a series of *Hôtels meublés*, or first-class furnished lodgings. These are now nearly completed, and require further description at our hands. One of the triangular garden-spaces we have mentioned lies in front of them, and beyond this the view in front will be bounded by the handsome mansions we have mentioned as being about to be erected by Messrs. Holland & Hannen. One side is bounded by Ranelagh-street, and the other returns into the Chelsea-road, just where it takes the name of Victoria-road.

The Belgrave mansions are built of pink brick, with white stone ornamentation, and with their carved *cornoumens* to windows and doors, their oval, carved trussed and pedimented *lucarnes*, their *profil de Ventablement*, consisting of massive Portland stone cornice, and their casements, *mobiles* and *dormants*, present an appearance as thoroughly French as the Tribunal de Commerce, on the Boulevard des Capucines. First-class shops will exhibit their attractive stores on the street level. Over them, to the vivid realization of their French character, is an *entresol*. And above rise the suites of ready-furnished apartments, suitable for the occupation of the wealthiest classes, which have hitherto been unattainable nearer than Paris. The central shop is apportioned as another French feature, a first-class restaurant, from which the lodgers can procure any dish they choose to order, at a fixed price. The proprietor is bound to provide a handsome coffee-room, into which the lodgers may descend to take their meals as at a French hotel, but they are equally at liberty to be served in their private apartments. Every kind of facility for extraordinary attention to the wants of the residents has been provided. A wine and beer merchant's office has been organised; landresses and tradesmen of every kind appointed to call daily for orders, whom the residents may employ or not as it suits their convenience. Gas, fires, baths,—sponge, hot and cold,—and attendance, are to be found by the company, and charged for in weekly rent-bills. In fine, it will be possible to enjoy in these mansions the Parisian mode of life. We will now describe the plan of the apartments. The length of the frontage of the block of apartments is 232 ft. Midway down the breadth of the principal floor runs a corridor, out of which open doors giving admittance to the various suites of rooms on either hand, the more costly lodgings, of course, occupying the front of the block, and the less so the rear. The back front is not a plain surface, but consists of a series of receding wings, with a small open court between each, a suite of rooms occupying, for the most part, each wing. Three ample staircases give access to the corridor from the street, one at the centre, and the others at each extremity. Besides the apartments there are offices on this as on every floor, consisting of a still-room, which is the head quarters of all the *services* of the mansions, porters' and waiters' rooms, servants' hall, besides lifts, speaking-tubes, and bath, &c.

We will now enter a mansion built by Messrs. Trollope, and now ready for occupation, in plot 3. It is at the corner of Upper Grosvenor-gardens and Lower Grosvenor-place, one of the most magnificent sites in London, as far as prospect is concerned, for there is a view from

it of Grosvenor-place and into the gardens of Buckingham Palace, and into the maze of flower-heds that will occupy the triangular enclosure at the side of it, called Grosvenor-gardens. It contains about thirty-five rooms, has taken only two years to build, and is worth about 20,000*l.* It is five floors high above the basement, and has another flat of rooms in the high Mansard roof, and is altogether one of the finest mansions on the site. As this is a corner house, it is larger than those in the composition forming the rest of this group, except that which will balance it at the other extremity, which is the National Bank about to be built on the ironmonger's long-withheld site. The design for the facade is perhaps a trifle bolder than that of plots 1 and 2, and that it is equally pleasing is seen in the fact of the immediate purchase and occupation of the first two of them that are completed. The plan, too, differs from those on the plots mentioned. On the basement-floor, the Grosvenor-gardens frontage is occupied by the servants' hall and footmen's room, and beyond these by the butler's room and strong room. The frontage round the corner looking towards the Royal Gardens contains the housekeeper's room, larders, cook's room, scullery, and kitchen, in the order we have mentioned them. To make the last of these offices shapely, in consequence of the retreating line of site, it has been necessary to excavate under the footway for more space, and the scullery is vaulted in that position. There is the same contrivance for sweeping the chimneys from the basement used here as in the house previously described.

The principal entrance from the street, through a richly carved and decorated stone portico, with red granite columns, gives access to a spacious entrance-way, 10 ft. wide, which extends from the Lower Grosvenor-place front to the main wall which divides the Upper Grosvenor-gardens frontage from the next house. In the centre of it, on the right-hand side a door opens into a noble dining-room, 33 ft. square and 15 ft. high, and on the left hand another, opposite to this, gives access to a bay-windowed library, 21 ft. 6 in. by 15 ft., and of the same height as the dining-room. A corridor in the rear of the library conducts to a cloak-room, a gentleman's room, and bath, the two latter being built over the kitchen, which is not kept down in height, as in the house first described. A staircase, 10 ft. wide from wall to wall, rising from the entrance-way opposite the street-door, carries us to the drawing-room floor. This possesses two handsome salons de reception, extending over dining-room, entrance, and library, being thrown open into one of 65 ft. in length, 16 ft. high, and lighted with six windows and a spacious bay over that in the library. There is also a houndoir on this floor, with a dressing-room. The ceiling of the front drawing-room and that of the dining-room are both divided into nine coffered panels, elaborately enriched with cinque-cento plaster ornaments. The bedrooms, on the next floor, are 11 ft. high. A large bedroom, with dressing-room, is over the drawing-room, a dressing-room over the entrance-hall, a bedroom over the library, and a suite of bedrooms over the houndoir. A "closet" on the landing is lighted and ventilated by a shaft. The floor over this is arranged with a similar sequence; and the mansard roof contains three more rooms, which, in their turn, are surmounted by one more at its utmost height.

Stepping into the next-door house, whose only frontage looks upon Upper Grosvenor-gardens, and which is of smaller dimensions generally, though of equal magnificence as to arrangement and fittings, we find the entrance only proceeds through the house as far as the dining-room extends on the right-hand side of it, when the stone staircase, with its iron balustrade, begins to ascend, and a passage-way, turning aside, after skirting the breakfast-room, affords communication with a gentleman's room. The latter is lighted by a bay window abutting on to the skylight of the kitchen, which is treated in a similar manner to those in Mr. Waller's house, first described, being covered with a skylight, and thus affording ventilation and light-spaces for the rooms on the upper floors. The corner-house having two frontages was free from this necessity. Neither are the rooms of this second house so lofty as those of the spacious corner mansion. The dimensions of the dining-room scarcely exceed those of the library of its superior neighbour, being 26 ft. 6 in. by 16 ft., and 13 ft. 6 in. high. Here, however, as in other instances, special dispositions have been made to suit intending purchasers and occupiers. The drawing-rooms, in this instance, are

thrown into one large apartment, the necessary supports between the two being provided in Corinthian columns. In other cases, in the houses completed in this group, we observed similar deviations, such as provision of good nurseries. We may add that preparations are in active progress to continue the works. Foundations are being put in, scaffolding and travelling-machines are ready, and large quantities of stone are lying about the site, and being sawn by machinery on the spot. Coach-houses and stabling, with residences for coachmen and their families, form part of this group, as in the first-mentioned.

Plot 4 is separated from the corner mansion we have just mentioned by the entrance to the mews, which contains the stabling and coach-houses in rear of it, and the group of which it is so conspicuous a feature. This contains a set of first-class shops, over which are built, also in the French fashion, handsome private dwelling-houses, which have quite distinct approaches. One of these shops is already let to a confectioner, another to a picture-dealer, another to a dealer in China, and the fourth, which is a corner site, to a chemist.

We may add that the whole scheme is a wide piece of comprehension. In the first instance, mansions are built for the ultra wealthy; a smaller class of house, equal as to taste and locality, is provided for those equal in degree, though not in requirements; first-class shops are brought into the district to provide for them; their dependents are provided for; and a bank established; the result promising to be an ornament to the metropolis, and creditable and profitable alike to the Marquis, the purchasers, the speculators, the architect, the tradesmen, and the builders.

In these improvements of the Marquis of Westminster at Piccadilly and Grosvenor-place, the immediate sacrifices made correspond with the largeness of the projects. More than 200 houses have to be razed to the foundations, varying in rentals, from Tattersall's, at 2,000*l.* a year, and first-class residences in Grosvenor-place, at 500*l.*, to smaller dwellings at 50*l.* The total sacrifice of rent fallen in is probably not less than 12,000*l.* per annum. The improvements, however, will realize an income to a future generation of more than 100,000*l.* per annum.

CONTAGION IN BILLS.

THE fable of the goose and the golden eggs conveys a lesson not less needed in our days than in those of *Æsop*. Self-interest, according to the economical philosophy of the day, may be relied on as a safe guide to individual welfare. But in all self-acting machines a great deal of preliminary work has to be done before the automatic action commences. So it is enlightened self-interest alone on the guidance of which you can rely, and when you have to go through the previous process of enlightenment, the task is not so simple. Among those members of society who may be regarded as somewhat cannibal, living upon their fellows, subsisting for the whole year on the profit earned during two or three months of touring or holiday-making, the conviction of the folly of killing the goose has not yet made much way. Probably one reason is that the slain bird is not the only one of the species. *Les badauds*, Robert Macaire observed, *ne passeront jamais*. Individual travellers may vow that they will never enter such and such a town again, but they are succeeded by others, who, in their turn, are to be fleeced and to be disgusted, and in their turn are fated to gain an experience that is but little available for the common advantage.

Perhaps, after all, the goose-stickers are in the right. We will not dwell longer on the question, as we are interested, not in their welfare, but in that of the goose. Pure skies, and golden sunlight, and glorious prospects, have such a magnetic power over those who can afford to flee the capricious inclemency of an English winter, that the hotel-keepers and lodging-house keepers of southern Europe, whatever be their delinquencies, are pretty sure of an annual supply of those on whom, or, at all events, by whom, they live. Advice from us would not be likely to reach their ears. It would certainly, if it did so, be regarded as interested and suspicious, and therefore proper only to be read backwards. But it may be an essential service to those whom the fear or the presence of pulmonary disease drives to seek an Italian winter, to call their

attention to one of the modes in which Italian housekeepers often effectually slaughter the gold-dropping bird.

Throughout Southern Italy the convenient prejudice exists that consumption is contagious. We say convenient, because the superstition on the subject is so framed, like others we might name, as to have a direct pecuniary force. It is not the living patient that is to be shunned. Such a sufferer is a good source of income, and therefore is to be welcomed and cherished as long as possible. Not a word do the anxious relatives hear of the danger incurred by the family of their well-paid host in consequence of the residence of the fading object of their solicitude. But when the end comes that comes to all, the tone of welcome is changed. The establishment is broken up; the survivors are on the wing; and as a rider to the last account comes mine host's charge. "*Indemité pour réfaction des meubles et de la chambre occupée par le défunt, 100*l.* sterling.*" And the most curious part of the affair, that which shows how thoroughly obedient superstition is to covetousness, is, that it is the mere accident, so to speak, of death in the house, on which the charge is based. A consumptive patient may have lingered for months in a set of apartments, may have left them half an hour before death, and no charge will be made; but let him breathe his last in tranquillity in his bed, and the necessity for burning the furniture, for scraping, lime-whiting, and papering the walls, arises from that sad and simple fact. We are wrong—we should not say the necessity for so doing—but the necessity for paying for its being done. As to the application of the rule, the hotel-keeper may settle that as best he likes between his conscience, his doctor, and his priest; and very likely, in the hurry of business, poor man, may delay consulting the two latter enlightened guides until the circumstances of the case have somewhat faded from his memory.

It does not seem that the faculty of medicine unanimously back this atrocious demand. It is true that the physicians with whom we are familiar in the pages of *Molière* are to be found in flesh and blood in many a Southern city. Were this the fit occasion, we could tell many an anecdote of the fraternity worthy to have been immortalised by the author of "*Tartuffe*." But to affix the damage with scientific precision to the moment of expiration would baffle even the acumen of those learned men who bled Count Cavour seventeen times before his hearty constitution succumbed to their insatiate lancets. So we find that in the Hospital of the *Incurabili* at Naples, consumptive patients are placed with the other sick, although a separate ward exists for their accommodation. Thus, after all, the prevalent superstition on the subject can peep under the handgaw with which it is blindfolded.

The important thing for English travellers to know is, that there is no legal ground for a claim that is often made just at the moment when the power of resistance is most feeble. It is not necessary for us to enter into the merits of the sanitary question. The infectious or non-infectious character of consumption is not a theme for our pages; the communication by the patient of a fatal miasma to the walls of the chamber, or to the furniture it contains, is not a subject on which English physicians have raised doubts, or English builders been called on to obviate any possible danger. Nor is it a question of moral justice to the foreign landlord; it can hardly be called a question of respect for his habitual prejudices. The manner in which the claim originates is one that seems to prevent any hesitation in forming the conclusion that the demand is purely and simply extortionate. So it is well to know that it cannot be enforced. The civil law is silent on the subject. The case can be regarded alone according to custom, and to support such a claim a previous contract explicitly or implicitly including a provision to that effect is necessary. In most cases of casual tenancy no such contract exists. Where, however, a house or an apartment is taken for longer time than a weekly tenancy a document is advisable, and is customary. In these documents a clause is very frequently inserted (as a matter of pure formality, an Italian lawyer will tell you), under which the tenant will find himself saddled with this ill-timed and distressing penalty, in case of the loss of a member of his family by pulmonary disease. The very question of the nature of the complaint, or of the cause of a death that may in no way be referrible to consumption, will be discussed by greedy claimants. We can not too strongly advise any of our friends who seek a

temporary abode in the garden of Europe to refuse signature to any contract containing a clause of this nature; and, in the event of losing a friend by death in an Italian apartment, to refuse and ignore *in toto* a charge that is a scandal to the nineteenth century.

NEW ART-TREASURES AND REPRODUCTIONS AT SOUTH KENSINGTON MUSEUM.

We perceive that some valuable additions have been recently made to the art-collections at South Kensington. Great activity prevails among the officers, and several of the courts are occupied by workmen engaged in unpacking and putting together recent acquisitions. The last of these new arrivals are some full-sized plaster casts of magnificent candelabra, which are now in the process of being put together. The finest of these is a cast of the seven-branched colossal candelabrum in Milan Cathedral, that was the gift of Giovanni Battista Trivulzio, the archpriest at the cathedral in 1562. It is of sixteenth-century workmanship. The seven branches depart from a richly-ornamented stem, rising from a base of extraordinary beauty, four dolphins forming the angles of a mass of interlaced and complicated bossed and figure open scroll-work of much delicacy. It has been cast by Pietro Pierotti, Milan. A second candelabra is a cast from the bronze of Annihale Fontana, in the Certosa of Pavia. This has no branches. The four sides of the base are decorated with groups of ecclesiastical utensils in low relief, the corners representing winged male figures in high relief. Above these, four monsters support a stage having four sides, on which are represented, in low relief, the Annunciation and Presentation in the Temple, both subjects, with singular fragility of design, being repeated. A third candelabrum has figures of exquisite grace to form angles to the base, and a duplicate of Faith and Charity to form a four-sided stage in the course of the height of the stem. This is also from a bronze by Annihale Fontana, in the Certosa of Pavia. They are all, at present, mere white casts, and of course, therefore, give only a fac-simile of the design, not of the effect. We may draw attention, too, to a plaster cast of a fountain in the gardens of the Royal Palace at Munich. A wide basin is supported upon an ornamented baluster-formed pedestal, out of which rises a rocky or rustic base, upon which elevation is a fine group of sculpture, representing Persens standing on the prostrate and decapitated body of Medusa, whose head he is holding up in the air in his left hand.

A much larger and more important work, however, is the full-sized cast of the great triple western portal of the cathedral of San Jago de Compostella, known in the realms of Christian art as the Porta della Gloria. It was this superb piece of decorated architecture that Mr. Street chose as a frontispiece to his work on Spanish Gothic Architecture; and, truly, it is as noble a frontispiece for a cathedral as mortal man has yet designed, and therefore a fit preface for any description of kindred works. It consists of three semicircular-headed doorways, the centre one being 22 ft. 4½ in. wide, and those on either side of 16 ft. 4 in. in width. The central portal is divided into two by a richly-sculptured column carrying a full-sized, or more than full-sized, representation of St. James. Its jambs are supplemented with pillars also carrying figures,—Moses, Isaiah, David, Peter, Paul, Santiago, John; and from these springs an immense label, or archivolte, in which are closely seated twenty-four crowned figures, playing various musical instruments. The tympanum is still more remarkable: it is one vast group in alto-relief, showing our Lord seated in the centre, with Matthew on his right hand, John on his left; behind him and immediately below these, Mark on his left hand, and Luke on the right. On either side of this central group of five figures stand, on the ground line, three angels, the last on the right holding a large cross before it. In the background, above this noble company are rows of smaller angels, worshipping. The august subject, the startling whiteness of the material in which it is rendered, give, at first sight, an impression as of a vision of a multitude of angels, whose raiment is too bright to look upon. The theme of the whole conception seems to be praise. Our Lord blessing all; the Evangelists hearing witness; angels holding the objects that represent the Passion, with the cross erect; crowned musicians rejoicing. Some

portions of the superb portal are now lying in the north court, where it was at first thought it would be erected. But its colossal proportions would have entailed a cost of 2500. to put it up, an expense which has precluded the intention from being carried into effect; and it is now being placed, temporarily, in the lobby leading to the long gallery in which architectural casts are now hung. As there is not sufficient height here to admit of its being put together, the various portions are treated as separate works, and placed apart from one another. Thus the archivolt, so densely full of seated figures, that should surmount the tympanum, is placed on an adjoining wall. The general effect will, therefore, not yet be realised, although the marvellous, powerful details may be studied.

We note, in another department, a fine copy of a gorgeously-coloured fresco from the Riccardi Palace, Florence, some 12 ft. or 13 ft. high, and about 16 ft. wide. The subject of it is a hunting procession, and the artist, Benozzo Gozzoli: date, circa 1408—1478. In the foreground are, perhaps, fifty figures in swift procession; and in the background and distance are as many more. The ripeness and intensity of colour are well reproduced by the Italian copyist, who, we understand, received 2500. for his work.

In the electrotype department there are some valuable additions in Russian art. Copies of these have been made, by arrangement, by Messrs. Franchi & Son, in triplicates, for the convenience of the public. They consist chiefly of noble tankards with covers, bowls, cups, chalices, other drinking-vessels, and salt-cellars. They may be seen in the case containing the reproductions of the gilded christening font, 3 ft. high, of Charles II., the ivory sceptre of Anne Boleyn, the altar-dish of William and Mary, and other of the glories of the regalia preserved in the Tower of London, close to the east of the grand chimney-piece for the Château de Seigneur de Villeroy. The originals of most of this gorgeously glittering store are in the possession of Mr. Moffat, M.P. They are silver gilt. One globular bowl, rising to a height of 5½ in., and spreading itself out to a diameter of 7½ in., before contracting again to receive an inscribed belt at its mouth, was a presentation from the Czar Peter the Great to a Cossack chief. It is ornamented with elliptical bosses of diaper-work, alternating with conventional foliage, in *repoussé* or beaten work.

A copper-bronzed copy of this can be purchased by collectors or others, of Messrs. Franchi, for 2*l.*, or a silver and oxidized copy for 4*l.*, or a gilt copy for 6*l.*, or, still more highly priced, a parcel-gilt copy, such as an abbot of my of our richest monasteries would have been proud to place upon his hospitable board, for 7*l.* One of the noblest of the Russian tankards stands 11½ in. high, on three ball-and-claw feet. It is embossed with flowers and foliage, in *repoussé*. Like most of the other specimens, it is of eighteenth-century workmanship. Another fine plain tankard, 8½ in. high and 8½ in. wide, having a plain burnished drum, supported on three foliated hall feet, is considered to be of Swedish workmanship, as in the centre of its cover, within a series of rings, in *repoussé* work, is a medal of Ulrica Eleonora, Queen of Sweden, 1719 to 1741. A copy of this royal flagon, in gilt or parcel-gilt, is worth 12*l.* A second tankard, attributed to Swedish artists, has a medal of Gustavus Adolphus, King of Sweden, 1611 to 1633, inserted in the cover. This is scarcely so large as that of Queen Ulrica, being but 7 in. high and 6½ in. wide, but, like it, it is embossed with foliage and flowers in *repoussé* work, and is supported on three foliated ball feet. A tankard and cover, indisputably Russian, is gracefully surmounted with the figure of a swan.

The Russian salt-cellars are peculiarly interesting, as their character is so markedly different from that of familiar Italian models. The largest is about 5½ in. in height and 5 in. in diameter. It is of a cup-form on a short stem with a broad base resting on three ball feet. The base and cup are both ornamented with rude foliage and scroll pattern in *repoussé* work. A duplicate can be purchased of Messrs. Franchi for 4*l.*, and a copy in bronze for 2*l.* 10*s.* The next salt-cellar is of a somewhat similar form, though of 2 inches less height; but the third example is a circular dish, only 1½ in. high, and 2½ in. in diameter. This is chased with conventional foliage, and has two scroll and mask handles: it rests on four small ball-and-claw feet. A cup or drinking-vessel near them is worthy of note. It is of hemispherical form on a circular foot, and has a flat projecting handle. The inside is embossed with

marine monsters; the outside, with less questionable taste, is ornamented with birds and foliage. Around the cup runs a Russian inscription, of which a translation is engraved under the handle, "Cup of an honest man to drink to health and to joy." It stands but 1½ in. high: the diameter is 2½ in. That all seventeenth-century Russian drinking-cups were not of this low stature we have evidence in a choice of the same period standing 7½ in. high, though but 3½ in. high. This has no inscription, but a band of filigree work round the lip, and three scroll ornaments on the stem. Before turning from these gilded novelties, which summon up picture after picture to the mind's eye, beginning with the Bee-eaters and the Tower, and ending with El Dorado, we must enumerate among them a delicate tazza of beaten work having figures of Jupiter, Diana, and two other deities whom the authorities on such subjects hesitate to name. Sir Walter C. Trevelyan, bart., of Wallington Hall, Northumberland, is the owner of the original, which is of silver, and bears the English Hall-mark for 1683. Like the articles in the possession of Mr. Moffat, it has been triplicated by the Messrs. Franchi.

Those who take interest in Scandinavian relics will hear with pleasure of the addition of casts of the remains of the two fine crosses in the graveyard of Kirk Braddon, in the Isle of Man. They are small compared with some of the Celtic crosses. Three sides of one of them are covered with serpentine decoration, the fourth bearing an inscription in Runic, which, being translated, tells that "Thorlaf Neaki erected this cross to Fraoh his son, the brother's son of labr." There is but a portion of the shaft of the second cross. The front and back of this are also ornamented with serpentine decoration, and one side shows a Runo inscription, which has told the waves and the winds, and the sweep of sea-gulls, and all who have looked upon it, far more than a thousand years, that "Otar erected this cross to his father Frakka, but Thorjorn, the son . . ." and here the pious record ceases.

Newly unpacked, and still lying on the ground in pieces, are two plaster casts of fifteenth-century altar-pieces, of large dimensions, which will also form valuable additions to the art-treasures already on view. The original of one of these is in the Certosa, Pavia, in marble. The subject represents, in high relief, the disciples and the holy woman weeping round the dead body of Christ. In the background the various events of the Passion are represented in low relief. In the predella is the Annunciation. The pilasters are decorated with Renaissance scroll-work. The original is attributed to Giovanni Antonio Amadeo, a Milanese sculptor, circa 1490. The second is also taken from a marble altar-piece in the Certosa, Pavia. The central subject of this one is the Adoration of the Magi. The predella shows Christ in the sepulchre with groups of men and angels adoring. From amidst the Renaissance scroll-work of the pilasters project bosses of the prophets in high relief. Recently placed upon the walls of one of the principal courts is the retable of an altar, of which which was formerly in the Church of San Francisco, and is now in Campo Santo, Pisa, sculptured by Tomaso Pisano in the latter half of the fourteenth century. The centre is over-shadowed with a canopy in three compartments, and flanked on either side by three niches, with a figure in each. The Virgin with the Child stands beneath the canopy.

A fine bronzed knocker, of a circular medallion form, must be mentioned among the miscellaneous novelties as being a reproduction of one attached to one of the doors of the Castle at Lausanne, of Germ workmanship, in the second half of the twelfth century. From the centre of it projects a finely-marked lion's head, holding in its mouth a foiled ring. And when treating of bronzes, we may call attention to a recent purchase of a bronze bust of La Gorgone. The artist is the Duchess Castiglione-Colonna, and the price realised by her work, 105*l.* The beautiful determined face is wreathed with locks of snakes, and from the shoulders depends a lion's skin. It would be difficult to conceive a face that tells its own story better than this does.

Some modern Bavarian fictile ivory casts and statuettes, by Schwanzler, produced between the years 1802 and 1848, are of new interest. And among the curiosities of modern foreign art, those who have sympathies with Oriental taste will look with pleasure at a set of circular playing-cards from Seinde, painted in gold and colours, and covered with transparent lacquer,

placed in a painted and lacquered wood-box. A Persian mirror-case and lid, too, is curious for the portraiture of a girl in European costume, in contrast to a Persian lady and her attendant, amidst embossed ornaments of birds on "strange bright wings," and flowers scarcely less uncommon.

But we have not yet exhausted the list of recent acquisitions in European art. Amidst the sparkling and jewelled collections that make each court like the sumptuous interior of a palace, we come, here and there, upon bits of the exterior world of old time, calling up rugged contrasts to the richness, luxury, gracefulness, and splendour of surrounding objects. Standing within reach of glorious items kings would prize and contend for, here expressly purchased and preserved for public instruction and delight, we may turn to treasures brought from all parts of the earth, to the simplest, quaintest curiosities which, perhaps, but a handful of clay has sufficed to produce, their sole value consisting in the skill with which they have been so formed. Here we have a tile of enamelled earthenware, faced with blue, of Moorish work, from the ancient casbah or citadel at Tunis. There is a brick, the upper surface of which is ornamented with figures in low relief, apparently representing the arrest of a prisoner in civil costume, in Flemish workmanship, though found at Walsoken, Norfolk. We need take but a few steps to see a dulcimer over which ran the fingers of a fair Signora in the sixteenth century, whose armorial shield is displayed upon its front; or an ivory diptych, carved in high relief, with the flagellation and crucifixion, by an impassioned German in the thirteenth century; or, say, a pectoral golden cross, set with diamonds upon white champlevé enamel, containing relics beneath a crystal plate, made by an inspired Spaniard in the sixteenth century; or a silver-gilt sweetmeat box, bright with enamel plaques of flowers on a white ground, into which the tips of an infant's fingers may have dipped in the seventeenth century, all of which are recent acquisitions to the Museum.

A mahogany table, presented by Ferdinand VII. of Spain to the Marquis de Altamora in the latter part of the eighteenth century, ornamented with gilt metal masks and festoons, with a top of Sicilian alabaster, has been purchased in Madrid for 161. 16s. 8d. A silver-gilt cross, for professional use, of Spanish workmanship, ornamented with statuettes of saints and their emblems, amidst foliage, has been lately purchased at a cost of 210l. 10s. 5d. And two other additions from Spain have been recently made; one being an oblong, ivory group, carved in high relief, and sunk within the thickness of the task, representing St. Francis translated to Heaven, ascribed to Alonso Cano, an artist who lived in the first half of the seventeenth century; and the other, a reel, with distaff, winder, and two spindles, turned and carved in walnut wood, with box-wood collars and carved ivory stands. The former of these cost 36l. 16s. 8d.; the latter, 2l. 14s. 7d. Both were purchased in Madrid.

The long gallery, recently occupied by the Architectural Museum, now contains the fine series of pictures embodying incidents in Chevy Chase, which are destined to fill the spandrels of the arcade in the reception saloon and loggia, Wallington Hall. Mr. W. B. Scott has divided his very choice subject into four parts, the going out and the chase, the battle, and the morning after. No one can look upon these without wishing they were destined for Alnwick Castle to supersede or supplement the foreign decorations there, with a narrative in colours so closely associated with the history of that edifice and its owners. Mr. Scott also exhibits in this place cartoons for a series of wall paintings for the circular (nowel) staircase, Penkill Castle, Ayrshire, illustrating the deliciously quaint and regal poem of "the King's Quair," written by James I. about 1420. We hear that this artist is to decorate one of the staircases in the museum.

Preparations are in progress to add the proper representation of English art and industry at the Paris Exhibition. Many of the specimens are exhibited on skillfully contrived rotatory stands, out of which project frames which move to and fro upon hinges, so that one stand of frames will exhibit conveniently upwards of fifty subjects, and yet not occupy much space. The history of labour is about to be exemplified in these stands. Finished instalments are placed, temporarily, in the museum for public edification.

SHAREHOLDERS AND CUSTOMERS.

THE decision of the Vice-Chancellor's Court in the important case known by its connexion with the name of Overend, Gurney, & Co., is one that deserves more than a hasty glance or a casual comment. The question before the court was in itself of no trifling nature; but the questions incidentally raised by, or involved in, the main investigation, are yet more serious. The pecuniary interests dealt with are measured by millions sterling. Creditors from all classes are directly concerned, the loose cash of the millionaire and the hard-earned savings on which the age of a laborious life had depended, being alike swallowed up by a great catastrophe. Still more grave than the pecuniary questions are those affecting character. Who was responsible for a failure that shook the city of London, now nine months since, with a financial earthquake, from the terror of which it has not yet recovered? There are thousands of men now pining in enforced idleness who would have been honestly and merrily at work but for the results of the failure of Overend, Gurney, & Co.; and, if we could fairly test the statistics of the case, we should, no doubt, find that the evil indirectly caused by the destruction of public confidence, has been far greater than the evil directly caused by the loss of deposited money. Beyond all this there are certain questions affecting the character, and indicating somewhat of the tendency, of our social life, which it did not fall to the province of the lawyers to investigate, but the elucidation of which seems to be about the only valuable result to be gained from this national disaster.

It is true that the shareholders in the "Limited" Company who have sought to escape from the consequences of having joined it on the plea of having been fraudulently induced to do so, profess themselves dissatisfied with the decision of an Inferior Court, and promise to do what in them lies to prolong uncertainty by the process of appeal. Without assuming how far the decision of the Vice-Chancellor's Court may or may not be assailable in matter of law, we may yet draw sufficient light from accepted and acknowledged facts to point a moral, if not to adorn a tale.

It is admitted on all hands that the late partners in the long-established and most lucrative business of Overend, Gurney, & Co., dissatisfied with the profit of 190,000l. per annum, which a quiet and regular course of business assured them, entered into speculative business of such a magnitude as not only to swallow up, by taking the wrong turn, this enormous income, but to place them as a bouso and as individuals in a position which, if squared up, was half a million worse than nothing. It has probably been thought that the fact was its own punishment, and little comment has been made on the haste evinced by these gentlemen to grow more than rich.

It is further admitted that the sudden stoppage of a house as well known as the Bank of England itself was a calamity to be deprecated no less for the public interest than for that of the partners in the house. Nor did it seem other than a sound practical view that a business commanding such an income was not, even with its large liabilities, to be sacrificed without wanton loss. The steady business over the counter would pay a handsome interest on a new capital of three millions sterling, and the idea of purchasing it for half a million, with the introduction of new owners of a new capital to replace that which had been swallowed up, was in itself sound and just.

The hitch lay here. The aid of the public was wanted to find this new capital. But this aid would not be obtained if the facts of the case were known. So it became—we cannot say necessary, but it was resolved—to obtain the support of the public by telling them only so much of the facts as would induce them to come in. That the new directors, who did this, were sanguine of a great success, and themselves largely invested in anticipation of this success, is, no doubt, true. Let them have the merit of this error of judgment, if error it was; but that can in no way alter the fact that they drew together a large proprietary and raised a large capital by the *suppressio veri*.

From active participation in this, which legally is termed a fraud, and which moralists of the old school would have called by quite as unqualified a name, every one seems anxious to exonerate the old partners, who have paid, it is thought, penalty enough for their unsound business. There is something to be said on both

sides in this part of the case. It may be urged that, the new directors having made their bargain, the old partners were *functi officio*, and had no business to prejudice the property of other people by any lato qualms of conscience. On the other hand, it must be remembered that the fact of the double deed implied, to some extent, double-dealing; that the private and the public documents were as much the act of the old proprietors as of the new; and that the intent of hoodwinking the public (for their advantage, may be, but none the less hoodwinking), must have been that of both parties at the time of executing the two deeds. Perhaps this part of the question would have received less scrutiny but for the position of the persons in question as members of a sect professing straighter morality than their neighbours, and assuming by broad marks of dress and speech the motto, "I am bolier than thou." The lesson that those who would excel the men among whom they dwell in religion, should be in the first instance doubly careful not to fall behind in the decent principles of morals, is perhaps the most certain inference from the story of the double deed.

We are not about to complain that certain of the new proprietary, on finding how they had become thus qualified, endeavoured to escape the consequences of their leap into the well. For the entire new proprietary to have agreed on one definite course of action would, no doubt, have been far more respectable for all parties. But such is not our English way, and it often happens that the obstinate creditor or the unreasonable jurymen, who refuses to make things pleasant by going with the rest, does, indirectly, good service to the state. Small thanks, perhaps, are due to him for so doing. His motives may be questionable, or purely selfish,—his breeding may be detestable; but he stands out till the full breadth of complete investigation sweeps through every hole and corner of the case, and thus the public are the gainers, after all.

The point that comes out most clearly at this stage is, that whatever be the amount of fraud and concealment between the projector and his flock, third parties are not to be endangered by it. Whether this be law or not, it will be for the Court of Appeal to say. That it is justice, no one can doubt who takes the trouble to state the case plainly to himself. A, B, and C enter into partnership, and trade with D, who trusts to their joint responsibility. After a time the business turns out amiss; B and C turn round upon A, and say, "You have misled us. You induced us to think that we should gain money, and instead thereof we have lost." Now if they go on to say, "Therefore refund to us our venture," they have a certain degree of right on their side; but if they go on to say, "Therefore we will not pay D what we unjustly owe him," they endeavour to redress one wrong by perpetrating another. The whole gist and practice of social equity in such a case is the decision,—first pay D his just claim, and then get your revenge out of A. It is lucky for the directors of the "limited" company that the recalcitrant shareholders have been more discontented than logical.

There remains the investigation of those questions to which we have referred as touching the state and development of our social relations,—questions of confidence between man and man in the conduct of the daily business of life. The point to which we more especially refer is this: How far is each man responsible for taking care of his own interest, and how far is he to look to the law, or to the public code of morals, to do this for him? There has been, since the earliest dawn of civilization, a great disposition to place private interest under the safeguard of public officer. The whole ancient law relating to debt testifies to this disposition. The prison of the Mamertine at Rome was an early instance of this mode of legislation. Forasmuch as he had nothing to pay, the unfortunate debtor was condemned to be sold. In our own time we take it for a bappy augury that the tendency of legislation is in the opposite direction. The importunate creditor is told that he should have better heeded whom he trusted. It is a less paying speculation to lure the young collegian into debt, with the good hope of making his ill-used father pay the piper, than some of us can remember to have been the case. It is obvious that public morality is the gainer by the change. Credit, enforced by law, is a pernicious and demoralizing form of speculation. Credit, based on confidence in known uprightness of charac-

ter, is one of the most ennobling bonds of society. The less law can interfere in any cases but such as are criminal, the better for the tone of society. Empty prisons are a sign of improved morality among tradesmen. The movement of the day is to place moral responsibility in the place of artificial responsibility enforced by law.

Now in this respect the result of the great Overend case is, we think, matter of congratulation. It is a further warning to us all to see to our own business. It is the want of this old-fashioned principle that underlies all the financial trouble of 1866. People who knew nothing of banking, or trading, or of manufacturing, thought that they should at once become rich as bankers, tradesmen, or manufacturers, by the simple process of taking shares in a new company. "I am a director of so and so," says Colonel A.: "rather a good thing." So the good colonel, who would have shown any one the door who proposed to him a sound *bona fide* trading partnership, takes his shares, and his seat at the board, and his guinea or two for attendance, and is much disgusted when his natural unacquaintance with the details of his new business, joined to the equal ignorance of many of his coadjutors, produces its natural result. Now here we have a fresh proof that this haste to gain the tradesman's profit without the tradesman's education is dangerous. If the shareholders in Overend's Company could have backed out of a loss because they had been misled, it would have been an encouragement for the incautious, and therefore for the designing. The reality of business has been lost sight of. People have thought they would have all the sweet, and none of the bitter. By gigantic combination of capital the humble tradesman was to be extinguished, and his means of livelihood were to be made over to the limited shareholders. We have another ruse, but not antinomy, lesson that this plan will not succeed. We must mind our own business; and if we go to the Law to complain that we have not done so, the Law tells us, from the bench of the Vice-Chancellor,— "That, gentlemen, is your own fault, and your own misfortune."⁶

REFLECTIONS ON THE POSITION AND PROSPECTS OF ARCHITECTURE.

In offering a few remarks on this subject, I feel that I may not unreasonably be accused of taking too much upon me, in putting forward my immature ideas on a topic so important, the adequate treatment of which might furnish scope for the abilities of the most learned and experienced among us. But if it be thought that "age should speak, and multitude of years should teach wisdom," it may be pleaded, on the other hand, that it is to the younger among us—to those just about to commence the practice of their profession—that the subject is most personally interesting. The older architect, the man of long standing in the profession, has in most cases settled into his groove; he has long since chosen the particular style of art which commended itself to his fancy or his judgment, and pursued it with that steadiness of purpose without which no success in life can be attained; but with the younger man, pausing to choose his path amid the multifarious styles of the present day, the case is different; and if he be one determined to carry on his profession with a fixed aim, and not as a series of per-centage jobs, his position is not a little perplexing. Like the lady in Milton's "Comus," he seems to be surrounded by—

"Calling shapes and beckoning shadows dire,"

On the one side he sees vistas of columned porticoes and long vanishing lines of cornice, flanked by the neat respectability of engaged columns and pedimented window-heads; on the other hand, he is courted by every variety of style which the use of the pointed arch is supposed to comprise under the general term "Gothic," from the direct reproductions of feudal architecture which now stand somewhat modestly in the background, to the last new freak of coloured brickwork which glares pertinaciously in the foreground in all its fantastic ugliness, the varieties of which succeed each other as rapidly as the fashions of dress, and with apparently no better reason than that furnished

by the tailor, who, if you inquire concerning the change in the cut of a coat, replies, with a bland smile, "We're making them so now, sir!" What wonder, then, if the beginner, in the midst of this chaos of styles, is sometimes fain to sit down bewildered, and to wish that he had chosen a profession where at least the path to be followed was clear and unmistakable.

There is a remark made by Coleridge in the course of a poetical criticism (in the *Biographia Literaria*), which seems to throw some light upon the path before us. He says,— "To admire on principle, is the only way to imitate without loss of originality." Leslie, transferring this maxim to his own art, has placed it on the title-page of his "Handbook for Painters." We, in turn may surely, with equal propriety, adopt it; for is it not evident that architectural history for the past fifty years is simply a succession of failures, the result of imitations adopted from fashion and the desire of change, independent of any principle of selection? Had there been the slightest approximation to such a principle, could two styles so utterly opposed to each other as pure Greek and pure Gothic have been successively adopted as the one thing needful, and successively dropped, during that short period?

This state of things, however, should not surprise us, if we consider how few there are who have leisure or inclination to take that comprehensive view of past and present by which alone our actual position and requirements can be correctly estimated. For broad principles in art, as in other things, result from the application of former precedents to present conditions: and as the soldier engaged in actual fight knows less of the battle than the spectator who from an eminence takes in the whole field, so the man who never lets his thoughts travel beyond the practical routine of his profession is in no position to judge of the real tendency or value of the movements going on around him. It may be worth while, then, to place ourselves in imagination at a distance from the scene of action,—to take a rapid survey of the field, and arrive, if possible, at some definite conclusion with regard to our present position, whereon to base our principles for the future.

Glancing at the past history of our art, to read what lessons it may have to give us, we are naturally attracted to two points at which alone there have arisen, out of the medley of immature and uncompleted national architectures, two styles perfectly complete in their artistic expression, and consistent in all their parts. And it is remarkable that not only are these two styles (as before observed) totally opposed to each other in character, but that the institutions of the countries and periods in which they flourished—the Hellenic Greece of the third century B.C. and the Teutonic Europe of the fourteenth century A.D.—exhibit the same definite consistency and the same sharp contrasts. In politics we see in Greece the spirit of federalism, in Mediæval Europe that of feudalism—in religion the Pantheism of the one is opposed to the Asceticism of the other—in the art of the two countries represents, in its most complete and unalloyed form, the antagonism of the two great schools now known as the Classical and the Romantic. This definite and complete character, then, of these two periods, renders them in some degree typical positions, in which we may with more than ordinary advantage note the relations between architectural styles and their surrounding circumstances.

What then were the conditions under which Greek art arose? In a country remarkable for the clearness and purity of its atmosphere, and of a character of scenery which we may call elegantly picturesque (being equally removed both from tame flatness and rugged sublimity), and possessing a climate warm but temperate—in such a country we find a people ardent, vivacious, and quicksighted; with a keen perception of sensuous beauty, an inquiring intellect, and a high critical faculty; of no very high standard of morals, little given to deep thought, but characterized rather by a certain childlike buoyancy of spirits which is only found in the early history of a nation; and naturally, under these circumstances, practising a religious form which appealed much more to the intellect and the senses than to the moral faculty. What style of architecture a people so conditioned might have evolved, had they been entirely unbiassed, we can only conjecture; for the Greeks were not, more than any subsequent people, independent of those who preceded them. In the background loomed the dark recesses, the colossal statues, and the vastæd colonnades of Egypt,

casting their shadows over the sunny landscape of Greece, and giving the starting-point of her architectural style. Here was undoubtedly the source of the massive and thickly-columned Doric order, which in its general proportions is no offspring of the Greek mind; but the form which it took on Greek soil is highly characteristic of the people, and of their climate and scenery. For it is in those countries where, as in Egypt, man is dependent on or overawed by natural forces, that there is fostered that spirit which gives to art and religion the gloomy grandeur which is the outward expression of that indefinable dread of external nature which we call Superstition. But to the Greek,—

"From him who on the mountain leas
By dancing rivulets fed his flocks,
To him who sat upon the rocks,
And dined to the morning sea,"—

there were none of these terrors; his landscape was sufficient to delight, but not to overawe, the mind; and his religion, and consequently his temple, taking their tone from the scenery, lost indeed in mystery and grandeur, but gained immensely in concentrated effect and cheerful aspect. The influence of the critical intellect of the Greek was even more marked: he could not be satisfied with the mere optical gratification derived from the profuse employment of colour, nor allow of the incongruity obvious in the use of natural forms, such as the palm and lotus, to support a heavy architrave; but transformed the column and capital into regular, angular, and strictly architectural forms, in harmony with the other lines of the building, but designed, nevertheless, upon broad natural principles.⁷ But it is in sculpture that the peculiar genius of the Greek mind is pre-eminently shown. Here we see on the one hand the most intense love of physical beauty, and triumphant skill in the delineation of it, in figures and friezes suffused with that blithe and joyous spirit which could only subsist in an age when men had not learned to think deeply, and were undistracted by the questionings, the doubts, the anxieties, which in later days were to stir the human mind; but, on the other hand, we cannot but be sensible, both in the building and the sculpture, of the entire absence of that spiritual feeling which gives the last and highest value to a work of art.

The great characteristic of Greek art, in addition to this tone of buoyancy and severity which pervades it, is the artistic self-restraint displayed in the breadth and simplicity of treatment, both in the building and the sculpture. But, as it has been well remarked by a recent writer in the *Westminster Review*,—

"This generality or breadth has nothing in common with the lax observation and unwarmed thought, the flaccid execution, which have sometimes claimed superiority in art on the ground of being 'broad' or 'general.' Hellenic breadth and generality come of a culture minute, severe, constantly renewed, rectifying and concentrating its impressions into certain pregnant types."

Passing from the antique, we are led into the more modern world through the gates, as it were, of that great city where, though little was practised that could really be called art, the arts, sciences, and literature of the then known world, amid a luxury and wealth almost incalculable, were collected together, as in one huge reservoir, ready for the use of the Gothic nations who were to form the new blood of Europe. Long, however, was it before any order was evolved out of the chaos which succeeded; and for centuries architecture wandered in bye-ways, trying her hand at this and that fashion, struggling between the old forms and the new spirit; and when at last a consistent style was struck out (simply by the substitution of the constructively correct buttress for the constructively false engaged column and pilaster), we are indeed in a new world. The chief monuments are still temples; but this very fact serves to emphasize the contrast with the Greek style. Nor are the causes of such contrast difficult of comprehension. The writer in the *Westminster Review*, before quoted, remarks that "religious brighten under a bright sky; they become liberal as the social range widens; they grow intense and shrill in the clefts of human life, where the spirit is narrow and confined, and the stars are visible at noonday." No words could more precisely describe the condition and origin of Mediæval religious art. De-

⁶ For some striking remarks on the genesis of the Doric column and capital, see Garbett's treatise on the "Principles of Design," pp. 114 and 149.
⁷ January, 1857, under the heading "Winkelmann." This admirable essay is well worth the attention of those who are interested in Greek art.

* It has been arranged that the appeal from the judgment of the Vice-Chancellor shall be carried direct to the House of Lords.

⁷ Read before the Liverpool Architectural Society.

prived of the cheerful influences and free thought under which Greek art was nourished; placed, both metaphorically and literally, under a gloomy sky; the lamps of science and literature withdrawn; hemmed in on every side by doubts, fears, and superstitions, what could the human mind do but rise upward, in almost frantic aspirations, in the only direction permitted to it; leaving us, in default of hooks, the record in stone of its struggles to be free? The men who worked, too, are in strange contrast to the Greek artist; a race of little refinement, little endowed with physical beauty, and with very limited power of delineating it, but possessing much of that sense of moral beauty, that spiritual feeling, which we noted as absent in Greek art; and, on the other hand, entirely deficient in that invaluable quality of breadth and simplicity, that faculty of "knowing where to stop," without which a man must always run the risk of spoiling his own work. We see also that the feeling of dread or superstition, which is again present as the dark background of life, has induced that prevalence of gloom and mystery that we notice in the Egyptian style, giving also an intricacy and extension to the building, which makes it approach more nearly to the feeling of landscape art than any preceding style. The influence of climate is of course obvious—we can no longer do with fittings and facias and such delicate sources of effect; under this dull northern sky, we must have deep hollows and large rolls in the mouldings, deep shadows in the foliage and capitals; indeed, the Mediæval mason would sometimes cut and gash into the stone with a certain grotesque vigour, which has led to the remark that genuine Gothic has something "wolfish" about it.

Amid the commercial towns of North Germany, with their Federal constitution, we do indeed find, in their cloth-halls and stadd-houses, something more of breadth and repose, some escape from that uncompromising spirit of aspiration which pervades the religious edifices of the period; and in the sunny Republic of Venice something of the old Greek brightness shines through its Gothic veil. But, on the whole, the art of the time is that of minds cut off from the lessons of the past, and pressed upon and encephed by feudal and religious terrorism, the joint influence of which cast a gloom over both the visible and the invisible world, and justified more than any other consideration the often-applied epithet of the "Dark Ages." This darkness, however, was ere long to be dispelled. Already, through the resuscitation of the long-buried literatures of antiquity, men's minds were awakening to the perception of a far wider horizon of thought and feeling; already the first streaks of sunshine were appearing, and the feverish dreams of Mediævalism were growing faint and pale in the morning light. So rapid, indeed, and yet so blending, was the transition, that the last and greatest temple built under the dictates of the old feeling took, nevertheless, as it were unconsciously, the artistic expression of the new. The peculiar and significant position occupied by St. Peter's Cathedral in history has been so eloquently commented upon, in one of the most remarkable hooks lately written, Mr. Lecky's "History of Rationalism," that I cannot do better than quote the passage:—

"Of all the edifices which have been raised by the hand of man, there is none that presents to the historian of the human mind a deeper interest than St. Peter's. . . . The most sublime associations that could appeal to the intellect or the religious sentiment cluster thickly around it, but an association of which none but dreamers have consecrated it, and will abide with it for ever. The most sacred relics of the Catholic faith are assembled within its walls. The genius of Michelangelo, Raffaele, Bramante, Cellini, Thorwaldsen, and Canova have adorned it. Mosses of matchless beauty reproduce the greatest triumphs of Christian painting, and mingle their varied lines with those gorgeous marbles that might have absorbed the revenues of a kingdom. Beneath that majestic dome, which stands like the emblem of eternity, and dwarts the proudest monuments below, rest the remains of those who were long deemed the greatest of the sons of men. There lie those Mediæval pontiffs who had borne aloft the lamp of knowledge in an evil and benighted age, who had guided and controlled the march of nations, and been almost worshipped as the representatives of the Almighty. . . . It is inexpressibly great as are these associations in the eyes of the theologian, the recollection of Luther and the indulgences and the Reformation will tower above them all; while to the philosophic historian St. Peter's possesses an interest of a still higher order. For it represents the conclusion of that principle, growing out of the anthropomorphic habits of an early civilisation, which had led men for so many centuries to express their religious feelings by sensuous images of grandeur, obscurity, and of terrorism. It represents the absorption of the religious by the æsthetic element, which was the sure sign that the religious architecture had terminated. The age of the cathedrals had passed. The age of the printing-press had begun."

Here, then, was once for all a complete change in the conditions of architectural progress. It

was no longer possible for a nation to work out its own stylo with that singleness of aim and unconscious freedom from external influences which rendered possible the concentrated unity of expression and steadiness of purpose which we find in the Greek and Gothic, and in a lesser degree in other styles before this date. Not only had the antique past been resuscitated, but, through the invention of printing, it was in some sense no longer the past; the ideas which had formerly been lost in the distance being thereby floated down over the sea of Time, and "brought home to men's business and bosoms." Hence arose that vacillation of style,—that tendency to copyism and consequent absence of definite expression which has characterised architecture since the fall of the Mediæval style, and has been, with good reason, so much deplored by the most thoughtful of recent architectural critics. For when a generation of men who have been at work upon their own style, isolated by the conditions of time and place from the accurate knowledge of any other style or form, and therefore unconscious of anything like a principle of selection, simply because they had nothing to select from,—when men so placed suddenly had a wealth of new ideas opened up to them, without time to mature any principles, it was inevitable that they should immediately be seized with the desire to imitate and adopt all that seemed so admirable in this new field, without much thought of its fitness for their own purposes. In process of time, indeed, some degree of selection was arrived at, in so far as some things were seen to be more worthy of imitation than others; but that clear though unconscious unity of purpose with which the Gothic architects worked is gone for ever; we can never revive it; it depended upon a condition of things which the state of modern society and education has rendered for Europe, at least, an impossibility.

The vacillation and mixture of styles consequent upon the newly acquired knowledge of the art and literature of other times, was rendered still greater by the increased inter-communication between different countries, which the advance of civilization and commerce induced and rendered possible. Yet, strangely enough, this influence of foreign travel, which for a long time fostered the multiplicity of art-fashions, by giving to different nations just sufficient intercourse to enable them to borrow one another's ideas, without the opportunity of arranging and systematising them on any concerted principle,—this very habit and facility of locomotion, when raised to the comparative perfection in which we now see it, seems likely to afford the best means of regaining that unity of art which was lost in the fifteenth century. For if the invention of printing was a triumph over time, making the past to become present with us; surely the invention of the steam-engine may be called a triumph over space, whereby distant countries are brought into comparatively close union and brotherhood. Forty years ago it was remarked by Carlyle,* that the increased means of communication seemed likely to unite Europe into one nation; and Mr. Mathew Arnold, in a recent essay,† observes "Europe tends constantly to become more and more one community, and we tend to become Europeans instead of merely English, French, Germans, or Italians. So whatever aptitude or felicity one people imparts into a spiritual work gets imitated by the others, and thus tends to become the common property of all." This is a significant sentence, and is fully borne out, I think, by fact. When we notice the incessant stream of travellers and tourists passing from end to end of civilized Europe (in which epithet I do not of course include Russia), when we remark the prevalence everywhere of the languages of the two leading nations, and observe how completely the literature of any one nation, even down to its reviews and periodicals, is the property of all literary Europe; when, looking at our own profession, we see eminent men among ourselves employed on great works in Germany and elsewhere, and eminent architects from all parts of the Continent contesting our own competitions with us; when we look at our own architectural alliance (which but for railways would have been impossible), and consider the facilities that are and may be offered for similar associations on a far more extended scale,—it is not difficult to see where all this must land us. The old barriers are breaking down, the old landmarks are being submerged, the old prejudices and

nationalities are fast fading away, and we may look forward with confidence to the development of a European style of architecture.

What turn would such a stylo probably take, and upon what basis, amid the present embarrassing wealth of materials, might it be with any firmness fixed? The styles which have shown most unity and stability hitherto have been those which most represented the spirit and feeling of their day. Reasoning from analogy, if we would have a style with any permanent life in it, it must be in accordance with the principal moving spirit of modern Europe. But what is that spirit? "Oh!" some will say, "that is easily answered; any one may see that the prevailing spirit now is the romantic—the Mediæval." Granted, just now; but how long will that last? On closer inspection, it will be seen that the present century has hitherto been, in a peculiar degree, a period of rapid oscillations of thought and feeling, of which the Mediæval mania is merely the latest phase. These changes on the surface, which usually accompany a transitional state of society, but are much accelerated by the increased interchange of thought in the present day, should make us careful lest we mistake for the great movement of the age a mere passing fashion, influencing, in fact, only a section of the community. But were I to describe in one word what seems likely to be the characteristic spirit of the present age in Europe, I should call it emphatically the age of Political Economy. It is this spirit (taking it in its widest sense as the effort to secure the greatest happiness and convenience of all men) that underlies everything else, and is viewed and studied with interest by men of all nations and parties; and it is the more likely to be a lasting influence, for some time to come, because it is yet in its infancy; we are only just becoming conscious of its mission; only, to use Mr. Mill's words, "touching with the tips of our fingers" the great social questions which it involves. "But what has Political Economy to do with Architecture?" Much every way. An age which is engaged in investigations, in all directions, for the solution of problems so important and so eminently practical as this science involves, will certainly not, in the long run, choose for its architectural expression a style characterised entirely by upward aspirations. The effort to provide suitable dwellings for the poor, which is only a branch of the subject, is already leading us to numerous experiments in planning and construction. The Wages question, again, will indirectly affect the style of construction. A great modern writer has observed, speaking of the Pyramids of Egypt, that "the mere appearance of those huge and costly buildings is a proof of the state of the nation that erected them. To raise structures so stupendous and yet so useless, there must have been tyranny on the part of the rulers, and slavery on the part of the people. No wealth, however great, could meet the expense that would have been incurred, if they had been the work of free men, who received for their labour a fair and honest reward."‡ Contrasting such a state of things with the rising power of what are called the "working classes," and the increased demands made by labour upon capital, it is evident that political economy will produce structural economy, and that a class of buildings not yielding a per-centage will necessarily be at a discount. Let the advocates of the "free-church movement" take this into consideration.

There are two other, less deep-seated perhaps, but still prominent characteristics of the present age, which must certainly influence our future style. One is the ardent desire for knowledge and light of every kind, the greatly increased faith in the progress of science, of which we have daily larger evidence. This feeling will certainly render it impossible for us to be satisfied, for any length of time, with the roughly-cut forms and nascent sculpture which have characterised the Gothic school of architecture; nor will the comparative gloom and mystery of that style be at all acceptable to an age which has shaken off all superstition, and seems inclined indeed to ignore the supernatural altogether. To such a state of feeling the carefully-studied sculpture and the cheerful

* "Miscellaneous Essays" "Gothic."

 ‡ Buckle's "History of Civilization."

aspect of the buildings of the Classic school will certainly be the most acceptable models, while the increased perception of the law and symmetry everywhere pervading the natural world will not dispose us to accept the wild irregularity of plan and outline which has been carried to such a fantastic excess in some ancient and many modern Gothic buildings. On the other hand, the seriousness of thought of which we first observed evidence in the works of the Mediæval artists, combined with a certain indescribable grasping after infinity, which is a peculiarly modern feeling, and which probably originated the present love of landscape art, and of external nature, with its lofty hills, cloud shadows, and sweeping distances,—all this tends to dissatisfy the mind with the restricted, rigidly symmetrical, and comparatively cold and colourless beauty of the pure Classic school. In short, the whole tone of modern thought, considered on all sides, seems to demand in art a blending of the artistic refinement and severe training of the Classic school with the deeper, more earnest feeling, and (in a chastened form) something of the picturesqueness and colour of the Romantic school. The two types of art have been left us, each in its unalloyed unity and completeness; our task is to aim at a higher perfection than was attained by either, by selecting the higher and enduring elements of each, and rejecting the lower and transient. This can scarcely be said to have been fairly attempted yet in architecture; but that such a union in art is possible, and with the highest results, has been fully proved in some of the most beautiful designs of Fluxman and Thorwaldsen.

It must be remembered, however, that while the influence upon architecture of national habits and tone of thought is one that changes with time, there is another powerful influence over it, which changes with place and not with time; I mean that of climate and atmosphere. And if we look into it, we shall find, I think, that while the former influence has most effect upon the general plan and design of buildings, the latter will regulate the character of the details. In an age, for instance, where the ecclesiastical spirit is predominant, and where churches are the principal buildings, a vertical style is likely to predominate. But let the samonation, in a time of advancing prosperity, become engaged in commerce as its principal object, and the result will probably be a preference for a horizontal style in its architecture, both from the more commonplace and less aspiring spirit that would be induced, and also because the increased value of land and the large accommodation required for carrying on business would necessitate buildings of several stories one over another, which, on true architectural principles, would be marked on the external design. But the atmosphere remaining the same, the style of mouldings and foliated ornaments which was effective at one period would be equally so at another. And there can be no doubt that, in our own climate, whatever dignity and symmetry of general design we may derive from the Classic principles, we shall still require the deep undercutting character of the original English style, if we are to make our buildings effective. Let any lover of Classic purity who doubts this go up into the portico of the Liverpool Free Library on a day of ordinary clearness, and thence contemplate the west flank of St. George's Hall, and contrast the admirable effect of the colonnade of square massive pillars, relieved by the deep shadows between them, with the tame and spiritless aspect of the shallow panellings over the windows, and the faintly recessed facias of the architrave round the northern portion of the building, and he will probably come down again convinced. Returning along Dale-street, he may see in the new Public Offices that details, Gothic in spirit and perfectly effective in this climate, may be applied to a "regulation" Classic building with a considerable heightening of its effect; and if he continue his walk to Old Hall-street, he may there see, in that admirable building the Albany Offices, a design perfectly horizontal in character, completely expressing the purpose intended and the high civilization which renders such buildings necessary, yet enlivened with ornament perfectly Gothic in type, and adapted to a northern atmosphere as completely as the roll mouldings and deep-cut foliage of the Mediæval artist.

If the foregoing views be in any degree correct; if there are glimpses of a progress, uncertain indeed and wavering at present, towards a possible unity of architectural principles and style; if the present vagaries of design and want

of definite aim be admitted to be highly unsatisfactory, it were well to consider for a moment what may be the causes of this state of things; what the obstacles to our arriving at the desired haven. And, first, with regard to our profession, it is much to be deplored that its present status is so low and its limits so undefined; that there is, in fact, no recognised entrance to the profession; and that any jerry-builder who has perpetrated a shop-front for a friend, may dub himself architect, and play his fantastic tricks before high heaven to his heart's content, without let or hindrance, rendering the aspects of our streets pitiable enough, and degrading the profession in the eyes of educated men. This will never be stopped until all who wish to practise as architects are subjected to the test of a compulsory examination. This is the only cure—the evil is a crying one, and half-measures are useless. And with regard to the question, what such an examination should comprise, it may be said that the education of the best section of the profession at present is too broad, and not high enough; they are expected to be conversant with a variety of subjects, such as no one man can possibly master, and many of which have no necessary connexion with architecture; while no provision is made for raising and strengthening the tone of the mind by the study of history and general literature. Yet it is only by such studies that the habit of thought and power of generalization are fostered, without which a man is at the mercy of every caprice of fashion, and for want of which many men of high talent, and possessed of every necessary capability of hand and eye, are at this moment employed in carrying out, with great industry, buildings which the next generation will infallibly regard with disgust (if it regard them at all). No doubt, power of manipulation with the pencil is indispensable, and should be acquired by every architect; but something more than this is necessary, namely, the power of thought, without which a man is not a designer, but only a draughtsman, and his dexterity with his tools may amount only to an extensive capability of doing mischief. Yet it must be admitted that in a large number of the buildings designed even by our cleverest men, there is but little evidence of anything like the requisite amount of thought having been bestowed, especially upon details. Too often there are the indubitable marks of hurry and want of time; mouldings and ornaments with no appearance of having been designed for their place, or carefully considered with reference to the total effect of the building; but having a stuck-on appearance, and encumbering instead of emphasizing the expression of the design. A great deal of the ornament of modern Gothic just at present seems to consist in cutting circles in every available place: church windows are seen composed entirely of round holes of different sizes pierced in a plate of stone; and the same feature re-appears *ad nauseam* in buttress-gables, bench ends, pulpits, &c., &c. This is a very easy way of designing. Much of the hurried appearance of modern work is owing to the fact that architects in large practice have generally more work than they can possibly attend to in person; and for this the architect himself, perhaps, is not so much to blame, as the clumsy per-centage system of payment, which makes his income depend not on the quality but the quantity of his work; whereas, if he had the power, as a painter or musician has, of raising his terms in proportion to his reputation, he would be preserved from the necessity of overtasking himself and could afford to restrict himself to such an amount of work as he could really give his whole mind to. But with the present system comes the necessary but very serious evil of working by proxy, whereby the architect, instead of being an artist and constructor, is turned into a sort of art-capitalist, and his office into a manufactory, where we might write up, "N.B. Designs in all styles turned out with neatness, finish, and despatch." Another injurious influence in modern practice is the constant desire for novelty, both on the part of the architects and the public. Copyism is wretched work, no doubt; but why, on the other hand, should a building resemble nothing that has gone before it? And why, when a man has designed a really successful ornamental detail, for instance, should he not repeat it in suitable positions? The Greek and Gothic architects did so continually. But no—this is not to be allowed; and so the design is altered, not in order to improve it, but simply for the sake of alteration,—and ten to one it is spoiled. From a similar feeling arises the de-

mand for sensational effects and preposterous skylines, to which all breadth and simplicity are too often sacrificed. It is really difficult now to find a design with sufficient breadth of wall-space and unbroken continuity of line to constitute anything like repose or dignity of effect. It is to be feared that the system of architectural competition, where every man endeavors to attract attention to his own design, has done much to foster this sensational style. If so, the inroads made by that system upon our pockets and our time are the least of the evils for which it is responsible. Some of the most instructive developments of this style are to be found in the treatment of inlaid and pierced woodwork in cabinets, organ-cases, &c. Some of these look like the productions of an enterprising Feejee islander, who had nothing better to do, rather than the work of educated European minds.

Upon the question of round arches *versus* pointed, the importance of which has been so much exaggerated, it does not seem necessary here to say much. We are all beginning to perceive that the Classical or Romantic schools of design are not necessarily dependent on either form. In a general way, it may be said that could we direct ourselves of the present prejudice in favour of the pointed arch, we should probably perceive the round one to be artistically the best form, especially on a large scale, and where dignity and grandeur of effect are sought for. The beautiful effect of the pointed arch in pure Gothic arises chiefly from its complete adaptation to the constructive necessities of the vaulted roof, to the perfect execution of which it is indispensable. But a style of roofing so expensive and so wasteful of material is not likely permanently to find favour in these days; and the principal formative influence of the pointed arch being thus removed, it does not seem consonant to sound art that the feature should be retained in the secondary parts of a building; and it seems more likely that, in high-class works of architecture, the noblest of internal features, the dome, would give the keynote of the modern style; for whatever form of construction, whether lintel, pointed arch, or round arch, be adopted in roofing a building, should, I imagine, be carried out in the minor parts of the building also: certainly much of the satisfactory effect of the Greek and Gothic temples is owing to this unity of construction. The principal use of the pointed arch, in future practice, would seem to lie in its constructive value, in all cases where weight has to be concentrated on the crown of an arch; and it is not improbable, therefore, that its future employment may lie more with the engineer than with the architect.

Lastly, if anything decisive is to be done by our profession towards advancing the art of architecture, and raising it to a higher and more satisfactory state, it is necessary not only that we should establish principles of action, and assist and encourage one another therein by mutual co-operation and criticism; but also that the public, our employers, should be awakened by every possible means to more interest in the art, and a better understanding thereof. This is the more necessary because we have now to deal with hundreds where we formerly dealt with units. With the rising of that great new power, the People, the patronage of art has been taken from the hands of a few of the influential among the upper classes (who had some opportunities of learning something about art, if they cared to do so), and is distributed among the numbers constituting what is called the middle class, for whose education in art our public schools and universities furnish no provision worth naming. And our own art seems to fare worst of all; for how often do we meet with intelligent and educated people who have a fair appreciation of a picture or a piece of music, but who, on the subject of architecture, are in Egyptian darkness,—ignorant of its first principles,—ignorant, indeed, that it has any principles at all. How are we to pierce through this gloom? In the absence of organized instruction in architecture in our schools something might be effected if those in our profession whose abilities, age, and standing, would give them some influence, would take opportunities, when possible, of lecturing publicly on the subject, and thus stirring up, if it may be, an interest in it among those to whom at present it presents no meaning or attraction. Something also is perhaps being effected by societies consisting, like our own, of professional and amateur members,—a constitution which has been found fault with lately, very unwisely, I think; for by this mingling of the amateurs with the professional architects,

the interest of the former in the subject of architecture is certainly stimulated, and they in turn may influence others who are out of our reach, all which is manifestly for our advantage; not to speak of the valuable hints which we may, and often do, receive from our amateur friends. But above all it is necessary that architects should fully realize the fact that they are bound to be the leaders of public taste, not to be led by it; that they are intrusted to themselves and their art when they consent, for the sake of pleasing a capricious and ignorant client, to build that which they know to be bad. It is no answer to say, "I must not offend my client and lose my commission." The making of money is not the business of an architect, or of any artist whatsoever. His aim should be to do the utmost, according to his talents, to advance his profession, and to carry out the work entrusted to him in the best possible manner; any payment that he may receive for it is simply the means necessary to enable him to prosecute his calling. To make money,—to produce capital,—is the legitimate object of our friends on 'Change: may they prosper therein! Our part is to help them to spend it in a useful and ornamental manner, not upon works which will be a nuisance and an eyesore to future generations; for of those who build badly it may truly be said,—

"The evil that they do lives after them;"—

and, until architects are prepared to give up a commission rather than erect an ill-planned or inartistic building, there will be little hope of a high standard of architectural taste being established among us.

Such appears to be the problem—such the principal difficulties—presented to the modern architect. To fuse into one complete and living whole the two complementary elements, as I may term them, of all past art, each of which, at its highest point of development, has been crystallized and preserved for our use; to join to the brightness and technical perfection of the Classic school the energy and passionate feeling of the Romantic; and to work out these elements with all the increased constructive knowledge and variety of material now at our command—this is surely a great task, and worthy of the highest efforts of our profession. And the present century is a peculiarly fitting time for such an attempt. To all who study history comprehensively it must be evident that there occur from time to time periods of unusual mental activity; times when a new spirit moves upon the face of society; when there is a "stirring among the dry bones," and men, as by one consent, show a common impatience of the old paths, of the worn-out forms which no longer satisfy them, and rise up with the determination to awaken a new spirit in art, or religion, or politics, and to find a new scope for their enlarged perceptions and aspirations.

"On such a full sea are we now afloat."

never, perhaps, in the history of the world has there been a time of such intellectual activity, such strenuous exertions in every department of thought and industry, as at present; and nowhere is this more conspicuous than in the great works which are employing the time and abilities of so many of our profession. It is for us to take care that we do not let this opportunity pass without making the most of it; that we leave to the generation to come after us works evidencing careful and original thought, and such as may be worthy to give the key-note for the future style of Europe. But if we would do anything towards this great work, we must turn from the trivialities in which so much time is being wasted, and direct our thoughts rather to the future than to the past. Surely it is very pitiable work to see talented men consuming their energies over church millinery,—engaged in acrimonious squabbles as to the scraping of an old cathedral, or the position of a crozier in the right or left hand of a monumental statue,—when a great European civilization is opening out before them; promising new forms of thought, increased social and artistic communion, new developments, on a greatly extended scale, of a higher and nobler art than has ever yet been practised,—

"And all that else the years will show,
The Post-forms of stronger hours,
The vast Republics that may grow,
The Federations and the Powers;
Titanic forces taking birth
In divers seasons, divers climes;
For we are Architects of the earth,
And in the morning of the times."
Tennyson's "Day-dream."

H. H. STATHAM, JUN.

DUBLIN.

GREAT excitement has of late existed in Dublin, in consequence of a leakage in the large reservoir at Verry, which is of the dimensions of a good-sized lake. The leak happened the more unfortunately that the safety-valve and conduit regulating the supply were out of working order. A cut in the by-wash was opened, thus discharging 70,000,000 gallons per day. The water continued to diminish at the rate of about 1 inch in the hour, an enormous quantity over such a great area. The leak was not altered in quantity, and every precaution was being taken against any possible accident. The contractors weighted the haul, and a large ball, with which a defective discharge-pipe was stopped up, was got out. The engineers anticipated no danger; and in the House of Commons, a day or two since, Lord Naas, in reply to a question on the subject, said that the Government had received satisfactory assurances in regard to the safety of the works.

Mr. Dargan's funeral, in Dublin, was the most numerous attended within the recollection of the citizens. The employes of the Dublin and Wicklow Railway, of which Mr. Dargan was a director, walked before the barse, and the remains were interred in the "O'Connell Circle" of the Glasnevin Cemetery. It has transpired, for the first time, that a sum of 2,000*l.*, for the purchase of pictures and other works for the National Gallery of Dublin, anonymously bestowed in 1864, through the late Irish Lord Chancellor, was a gift by Mr. Dargan to the institution.

THE PROPOSED ROAD IMPROVEMENT AT HYDE-PARK CORNER.

OUR readers will recollect of Mr. Snell's proposal in the *Builder* to convert the Park-road, from the Corner, up to Park-lane, at Stanhope-gate, into a public road, thus obviating the costly necessity of widening the Piccadilly end of Park-lane, and saving to the rate-payers nine-tenths of the 105,000*l.* which the scheme of the Metropolitan Board of Works will cost. Mr. Snell has since addressed the Vestries interested on the subject, and has also sent a detailed communication as to it to the Metropolitan Board, with coloured plans, showing both schemes and how he proposes to alter the position of the Park Gates, clear of Apsley House, so as to face Rotten-row and the other roads radiating from the Corner, together with the new Park-road to Stanhope-gate, which he proposes to form in lieu of the nearly parallel one, to be used as a public road.

The chief objection would probably come from the owner of Apsley House, though there is the general objection to alienating any part of the Park. Nevertheless, the proposal has much in its favour, and should receive careful and impartial consideration.

SPONTANEOUS COMBUSTION OF GAS.

IN the course of the inquiry into the cause of the disastrous explosion at the Oaks Colliery, a letter was read by the coroner from Mr. John Marshall, of Stewarton, Ayrshire, stating that under certain conditions coal gas became ignited spontaneously. Mr. Stewart does not give any details, but says, in conclusion, "Notwithstanding the present systems of ventilation and the use of the Davy lamp, the fire-damp in mines will sometimes explode through activity of the latent causes to which I have referred." Mr. Stewart's letter reminded us that the subject was brought before the Society of Railway Engineers of Berlin, on the 9th of January, 1866, by Herr Busse. The author called the attention of the society to a fire which took place at the goods station of the Stettin Railway Company, which broke out two hours after all the lights were extinguished. An escape of gas was, we presume, known to have taken place, and Herr Busse gave an account of a theory according to which a jet of gas is liable to spontaneous ignition. Herr Schwartzkopff mentioned a fire which took place in his own manufactory, in consequence of the ignition of a small jet of gas, which escaped notice, during the operation of trying the pipes with a lighted candle, suggesting at the same time that the fire mentioned by Herr Busse was due to the same cause. The source of our information, the *Zeitschrift für Bauwesen*, 1866, p. 473, unfortunately omits the details of Herr Busse's theory,

so that we are unable to give an opinion as to its probability. It must be remembered that coal gas is a perfectly stable compound, and is not liable to spontaneous decomposition or explosion, as some other gases are. The well-known lecture experiment, in which a mixture of chlorine and hydrogen is exploded by simple exposure to the sun's rays, will probably occur to most readers. Considering the number of lives lost annually by explosions of carburetted hydrogen, any theory explaining them, however unpromising at first sight, is worthy of examination.

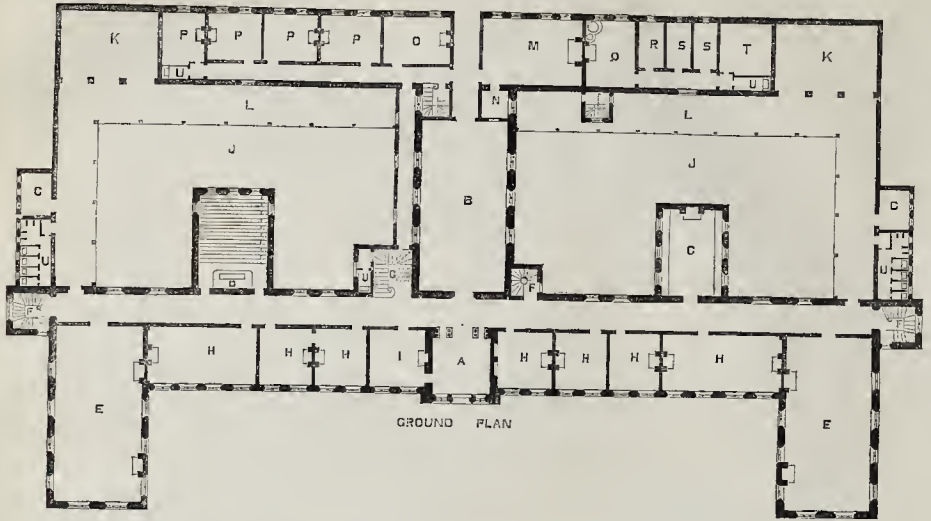

INTERNATIONAL COLLEGE, SPRING GROVE, MIDDLESEX.

THIS college, of which we give a view in our present number, is now being erected for the International Education Society, at Spring Grove, and is intended, when completed, to afford accommodation for 150 pupils, with six resident masters. The head master has a separate residence. The ground-floor contains two schoolrooms, each 51 ft. by 25 ft. 6 in., designed as wings, and two stories high; series of classrooms and masters' rooms, approached by a corridor running the whole length of the front building; and dining-hall, 49 ft. 6 in. by 25 ft., extending from centre of front to back building, which contains the offices. The lecture theatre and laboratory are thrown out from the back of the front building.

The first floor contains the secretary's rooms, committee-rooms, masters' bedrooms, and daily superintendents'. A sick ward is provided, with separate staircase and entrance in the back building. The second and third floors are devoted to the dormitories and contingent offices of the pupils. Each dormitory is distinct, and separated by a partition 7 ft. high. The staircases throughout are of stone, those for the pupils being carried up, at each end of the corridor, in towers, which form bold features.

The masters' stairs are on one side of the dining-hall, and approached from the corridor. The building will be constructed of brick with stone dressings, faced with yellow malms, with courses and diapering of red bricks. The total cost will be about 30,000*l.* The portion now being erected has been contracted for by Messrs. Holland & Hannen, of Duke-street, Bloomsbury, at a cost of about 12,000*l.*, and will accommodate eighty-four pupils. Messrs. Norton & Masey are the architects.

The idea of international education seems to be traceable to the great International Exhibition of 1851. It was then felt that it would be a great advantage to every nation to gain some knowledge of the arts and the industry of other nations, and that an honourable competition might thereby be created, which would be highly beneficial to the progress of all. The result, answered the expectations, and both the social and commercial intercourse among the civilized nations has since increased to a degree to which history furnishes no parallel. Such a state of things could not but call for some change in the system of education, at least in this country and in France, in both of which the study of foreign modern languages had not received any great encouragement in the public schools. The vastly altered circumstances began to demand that our young men—those intended for the learned professions, as well as those destined for mercantile life—should be tolerably well acquainted with the leading languages of Europe. These considerations, coupled with the extreme unwillingness of our great schools to reform themselves in such a manner as to satisfy the demands of the age, led a number of gentlemen, about two years ago, to form a society for the promotion of international education. Their aim was to establish schools or colleges in England, France, Germany, and Italy, in all of which the same system of education was to be followed; so that a pupil at any time, and without any interruption in his ordinary studies, might be transferred from one school to another, and thus acquire a practical as well as a theoretical knowledge of the language of the country in which for the time he might be residing. The Society was at first headed by the late Richard Cochen, whose noble efforts to establish amicable relations among the peoples of Europe have endeared his memory to all who are interested in the progress of humanity. The vacancy caused by his premature death is practically filled by his friend, the treasurer, Mr. A. W. Paulton, to whose indefatigable zeal and large-hearted generosity it is in great measure owing that the Society has been

GROUND PLAN

THE LONDON COLLEGE OF THE INTERNATIONAL EDUCATION SOCIETY.

able to erect the building at Spring Grove, of which we have given a representation. The building will be completed about Midsummer, but in order not to lose any time in carrying out its plans, the Society has secured a temporary house in the immediate neighbourhood, which was opened for the reception of pupils on the 1st of May, 1866, under the head mastership of Dr. L. Schmitz, late rector of the High School of Edinburgh. Negotiations are in progress for founding a similar institution in France, and Dr. A. Baskerville has recently been appointed as the Society's representative in Germany (Lindenthal House, near Cologne), where pupils receive the same kind of education, and on the same terms, as at Spring Grove, in England.

Besides the acquisition of modern languages, the object is to impart a sound knowledge of the natural sciences, which unfortunately are even more neglected in our great schools than the

modern languages. Nor should it be imagined that classical studies are pursued with less energy than in other public schools. The fact that Dr. Schmitz is the head master is a sufficient guarantee that justice is done to this department. But in the new College the study of the classical languages is not commenced until the pupils are familiar with the grammar of their mother tongue, it being held that by this mode of proceeding greater and more rapid progress is made than by boys beginning their linguistic studies in a foreign language so different from their own as the Latin.

The London College of the International Education Society, to sum up, professes to afford thorough instruction in classics on an improved and rational system, and in the subjects which are commonly too much, if not altogether, neglected,—modern languages and natural science.

That the Society's scheme is duly appreciated

by the public is evident by the number of applicants for admission, for we understand that at present there are very few vacancies remaining.

We wish the undertaking every possible success: the country is sadly in want of a better system of education than that usually enjoyed by the higher classes of society.

INTERNATIONAL COLLEGE, SPRING GROVE, MIDDLESEX.—MESSRS. NORTON & MASEY, ARCHITECTS.

THE FEMALE SCHOOL OF ART.

THE Royal Society's large room at Burlington House was filled on Saturday last, to witness the presentation of prizes to the successful students. Earl Granville, the Countess with him, officiated, and many old friends of art in general, and of this school in particular, were present. Professor Donaldson read the report, which stated that by the erection of a spacious and lofty gallery for the study of the antique, and by extensive improvements in the original building in Queen-square, such as adding other classrooms, dressing and luncheon rooms, improving the ventilation, and other alterations, the school, the committee believe, is now rendered as complete in all its various departments as is possible, both in regard to the studies of the students, as well as their personal convenience, health, and comfort. At the last competition the number of medals offered was ten gold, twenty silver, and fifty bronze; 100 schools competed, and 968 works were selected from the schools for the competition. This school had obtained one gold out of the ten, one silver, two bronze medals, and one prize of books! The report further stated that the dress and veil of Honiton lace worn by Princess Helena at her marriage were designed by a student of the school, Miss Margaretta Clarke. Miss Bryant, a former student, had designed successfully a Honiton lace lounce for Mrs. Treadwin, of Exeter, which was to appear at the forthcoming International Exhibition in Paris. Messrs. Kindon & Powell, of Old Kent-road; Messrs. Lapworth, of Old Bond-street; and Miss Bell, of Alton, had offered prizes for designs. The gratification with which the committee saw the completion of the buildings, and the general satisfactory condition of the school in other respects, was considerably tempered by the fact that they had found themselves compelled to incur a debt, which, although it might not be very large, considering the importance of the objects gained, was still heavy enough, if allowed to continue, to hamper the future operations of the school.

We can mention only a few of the recipients:—

PRIZES presented by the Committee of the School to those Students whose Works were selected for National Competition.—Alice Williams, painting of flowers from the flat; Virginia Hart, painting the figure and landscapes from flat copies; Mary Howes Dennis, painting the figure from the life; Fanny Seddon, drawing the figure from the life; Hannah Cole, drawing the figure from the cast; Emma Ellis, study of flowers from nature; Jane Chapman, sheet of proofs of wood-engraving.

THREE PRIZES for Designs for Oil-painting, presented by Messrs. Kindon & Powell, of Old Kent-road.—First, Alice Bailey; second, Mrs. Stewart; third, equally divided between Charlotte Ellis, Wheeler Smith, and Maria J. Andrews.

MEALS and Prizes presented to those Students whose Works were successful in the National Competition.—Mary Whitman Webb, a book prize for outline from the cast; Mary Julian, a bronze medal for study of flowers; Catherine Banks, a bronze medal for study of flowers; Alice Bailey, a silver medal for elementary designs; Alice Manly, a gold medal for study of grapes from nature.

The Lords of the Committee of Council on Education also presented the Second Princess of Wales's Scholarship to Alice Manly as having taken one of the two highest prizes of the year awarded to the female students, in the national competition of all the schools of art.

The Chairman then addressed the meeting in his usual agreeable manner, urging at starting the desirability of getting rid of the debt, about 1,000*l.*, when the school would, doubtless, prove self-supporting; and the worthy superintendent of the school would be able to devote the whole of her time to the care of the school itself, the development of the institution, and making known among all classes in the neighbourhood the facilities which this school affords for the study of art. After urging the value of learning to draw, believing it to be most conducive to the interests of all classes, of immense advantage to the nation at large, that the pursuit of art contributes to our material prosperity, to the elevation of our sentiments, and adds immensely to the charm of life, the Chairman continued, with respect to those who, either from want of sufficient time or from other causes, have not been successful to-day, I would say persevere. To those who feel they have no natural disposition or taste for art—if there are any such among you—I would say, notwithstanding the possible frown of your excellent superintendent, Miss Cann, or the committee, give it up and leave the school. To you, however, who feel that the instruction given has produced increased facility of conception, increased power of observation, greater accuracy of both hand and eye, I would implore you to go on in a course of study which is one of the most fruitful sources of happiness and pleasure I can

possibly conceive. To those of you who have been successful in different degrees the best advice I can offer is to beg you to persevere in the course upon which you have entered, and do not allow yourselves to be diverted from continuous labour by the great and brilliant successes you have achieved.

Mr. Boreford Hope said schools of art like that tended to break down the old pedantic barriers which formerly circumscribed and hampered in the artist, and separated him from those who were students of the variety of forms of nature and art for the purpose of making them their own, and reproducing them in various branches of manufacture. That pedantic rule would "dub" him or her an artist who would paint some picturesque old gate, or ruin, or landscape, but would refuse the name to one who produced with great care and elaboration a design for a screen or a grillo to be reproduced afterwards in metal. Miss Cann had set herself the task of breaking down that barrier, and she was engaged in fighting the battle not only for the present time, but for future generations. The great end for which this and similar schools of art were established, was to show by the works which were produced the great law of proportion, of mutual dependence of size, which must govern not merely all constitutional forms, but the very possibility and the existence of all things in this material world. True art was the essence of proportion. Art was the chemistry of form, just as much as chemistry was the art of elementary substances. Every one had his faults. Men were hard, dry, and calculating; they worked by form, rule, and numbers, and wanted the impulsive element. Women, on the other hand, were gushing and impulsive, and were not disposed to take hard matter-of-fact views of things. It was necessary, he said, to sober down the light hues, to bring into harmony those darker spots which floated before the sunlight of woman's infinite perfection.

Professor Westmacott proposed a vote of thanks to the chairman, which was seconded by the Rev. Emilus Bayley, and of course carried unanimously.

We must offer our own praises to Miss Alice Manly, Miss Julian, Miss Isabella F. Smith, Miss Cons, Miss Chapman (wood engraving), and some of the other young ladies whose works we have seen at the school.

A concert will be given by "The Wandering Minstrels," in aid of the school, on the 2nd of March, and a bazaar, with the same end in view, will be held in June next.

THE ESTIMATES.

MR. OSBORNE wanted to know, in the House of Commons, under what circumstances Messrs. Banks & Barry had been appointed Architects to the Office of Works, and how it was they had prepared designs for a new National Gallery at Burlington House, at a cost of 5,000*l.*, when the House expressly refused to remove the National Gallery to that site. For the first time they got the cost of the meeting in Hyde Park. The estimate for that was 3,372*l.* That was the cost of the meeting, though it was put down to the railings.

Lord J. Manners said, Messrs. Banks & Barry had consented to reduce their charges by 3,000*l.*, on condition of their being appointed architects to the new buildings at Burlington House. The charge for Hyde Park was an exceptional one. The money had been expended in replacing, in a temporary manner, the railings that had been pulled down; and it was obvious that this year, and not next, was the proper year to be charged with the expenditure.

Discussion ensuing as to the money that would be required for the Paris Exhibition,

The Chancellor of the Exchequer gave the following details:—"Internal fittings, 1,610*l.*; supplementary buildings in the park, 23,670*l.*; ancient and modern art, 11,050*l.*; Government departments (Admiralty, War Office, &c.), 11,490*l.*; management, watching, and lighting, 14,755*l.*; house expenses, 17,300*l.*; jurors, 12,600*l.*; royal commission, expenses, 2,750*l.*, and others, making a total of 117,650*l.*

The French Government, it appears, have thrown a larger expenditure on foreign Governments than was expended.

The sum of 45,271*l.* was voted for the purchase of the Biacas Collection, now in the British Museum. The Chancellor of the Exchequer observed that the purchase had been made

under fortunate circumstances, and on terms which for his part he should never regret. More than one State in Europe were disappointed at its being now stored in the national collection of England.

Mr. Gladstone said,—“I do not see how the wealth of the country can be beneficially employed if it be not in the acquisition of treasures of this nature, which are themselves not only a perpetual and an unfauling source of delight to multitudes of cultivated persons, but which are likewise most powerful instruments of practical education for the people.”

IRON CHURCH FOR PARIS.

A CONTRACT has been entered into by the Paris Church Committee, with Messrs. Cox & Son, of Southampton-street, Strand, the church furniture manufacturers, to supply on hire for the English church service an iron church, to hold 500 persons, to be erected close to the Exhibition building. The nave of the church will be seated with chairs, but we understand it is the intention of the firm to fit up the church handsomely, with carved oak pulpit, desk, table, stalls, and brass altar-rails, illuminated reredos, and other appropriate fittings, so as to show our foreign friends how an English church should be fitted.

RESTORATION OF ST. MARY'S CHURCH, GAINFORD, NEAR DARLINGTON, ON THE BANKS OF THE TEES.

THIS church is one of considerable interest to the archaeologist. Although Roman and Saxon buildings existed on the site, the present edifice was entirely constructed in the thirteenth century, and consisted of a west tower, supported on arches, and open to the body of the church, a nave with north and south aisles, under one immense roof, which left the aisle walls unusually low, whilst the nave was of considerable altitude: the nave roof, being continued, formed that of the chancel, so that the side walls of the chancel were very lofty compared with the aisles. In the fifteenth century alterations were made. The church was pewed at various times and ceiled; the arches of the north aisle and the tower filled with galleries, the latter being like hastings or the stage of a wild-beast show, the tracery taken out of the windows, and two large windows of tasteless design inserted on the south side. After a complete destruction of all architectural features, the church was permitted to fall into a still more deplorable condition by neglect; the eaves were allowed to drip over the walls, the earth to accumulate round about them, and dampness and decay with its accompanying mustiness (the floor in some places being broken up with rat-holes), made the church thoroughly disgusting. The west arch below the tower and the south aisle wall showed signs of giving way, large cracks being observable in many directions. The bells consisted of three, one of which was cracked, and there was an old clock greatly out of repair. Asphalts and other obnoxious materials were close to the main entrance of the churchyard, and in the churchyard. Such was the state of the church in April, 1864, when the restoration commenced; Mr. J. A. Cory being the architect. The south wall and tower were taken down; the old stones rebuilt so as to preserve their original character. A new roof has been put on the nave and chancel of the original pitch; the whole of the church fitted with solid open seats of oak, and carved pulpit and desk of the same wood; the chancel has been laid with encaustic tiles, and stalls and communion-rails, also of carved oak, have been placed in it. Two arches have been opened, one into the chancel (north side), the other into the east end of the north aisle, and a chamber built, in which is placed a beautifully toned organ of considerable power, having twenty-eight stops and four couplers, and every recent improvement. Below the organ chamber is a cellar for the hot-water apparatus, which successfully warms the church.

In making the alterations a great number of curious stones were discovered—five evidently of Roman workmanship, two of which are inscribed (see *Gentleman's Magazine*, Sept. 1866), one with part of a Saxon inscription,—and remains of several large upright Saxon crosses, slight remnants of Norman work and tombstones, or coffin lids, of all later periods. The whole of these have been carefully preserved; such as

have only one side sculptured (including some which were found in rebuilding the vicarage kitchen wing) are ranged in a new north porch, and the others are intended to be placed in a sort of cloister, where they can be inspected by the antiquary and preserved from injury. Several coins of Alfred the Great were found.

An excellent clock and a fine peal of six bells have been placed in the tower, under the directions of Mr. E. B. Denison. Provision for the more decent interment of the parishioners has been made by enclosing half an acre of land and adding it to the churchyard, and new gates and boundary wall have been erected.

The restoration has cost 2,000*l.*, including 398*l.* for the chancel, which sum was found by Trinity College, Cambridge, the patron and owner of the great tithes. It is almost inconceivable that the church of a living in the gift of that noble foundation should have been suffered to fall into such a state; but allowances must be made for its distance from Cambridge, a consideration, however, which the easy access to the place by railway now puts out of the question for the future. The organ and bells cost about 1,000*l.*; the clock about 120*l.*

PROPOSED ALTERATIONS IN CONTRACTS.

BRISTOL ARCHITECTURAL SOCIETY.

A MEETING of the professional committee of this society was held on the 15th inst., to which all the architects in Bath and Bristol, not members, were also invited. The chair was taken by Mr. Hansom, one of the vice-presidents. The hon. secretary, Mr. C. J. Phipps, read letters from the Architectural Associations of London, Liverpool, Birmingham, Newcastle, Nottingham, Manchester, and Glasgow, and from a number of architects who could not attend, but who sent their opinions in writing upon the subject for which the meeting was called, viz., "To discuss a circular issued by the General Builders' Association, addressed to the architects of Great Britain upon the subject of building contracts." The circular was signed by the representatives of fifty-two builders' associations in England (including those of Bristol and Bath); but it was a matter of remark that none of the London builders had signed it. The gist of the circular is, that the builders suggest the following alterations in contracts:—

1. To omit all indefinite clauses.
2. To make the bills of quantities a part of the contract, subject, in case of inaccuracy, to the measurement of the work during progress or at completion, with provision for arbitration.
3. Allowance for time in case of lock-outs or strikes.
4. Provision for settling all disputes during the progress of the works (hitherto in every case referred to the architect) by arbitration.

A long discussion ensued, during which a form of contract, suggested by Mr. Plevins, of Birmingham (and published in our pages), was read, it having been drawn up specially with a view of setting the matter upon a proper footing. It was felt that, in these days of low estimating, it was absolutely necessary for the architect to have considerable power in dealing with builders, but no architect of any standing or position would use that power in an arbitrary way; if so, builders could refuse to tender under him; and it appeared unfair to urge conditions upon architects as a body which were only applicable to persons calling themselves architects, with no pretensions to the honours or responsibilities of the properly-qualified practitioner. Eventually the following resolutions were unanimously agreed to:—

"That a building contract being an engagement between an employer and contractor, it being open to one or the other to make special conditions to meet the special requirements which arise in nearly every case, it being also open to contractors to decline any contract where the conditions are not such as they can accede to, it is the opinion of this meeting that the conference between a committee of architects and the General Builders' Association, as suggested by the latter, would be perfectly useless, and lead to no satisfactory result.

The system of quantities being taken up by architects for their own buildings is deprecated by the rules of the Royal Institute of British Architects, and it is considered by this meeting objectionable to make the quantities a part of the contract, but it suggests that the plan adopted in Government works, and by a large section of the profession, should be generally adopted, viz., to allow the builder whose tender is accepted sufficient time to prove the accuracy of the quantities as representing the measurement of work contained in the drawings and specifications, after which no question as to their accuracy to be raised."

The form of arbitration suggested by clause 4 of the Builders' Circular was considered objec-

tionable in the highest degree, as opening the way for endless disputes and complications, it being generally agreed that, as heretofore, the architect during the progress of the works should be the sole referee upon all questions of payments due, quality of materials, and workmanship,—in fact, the carrying into effect the designs; and that the arbitration clause should be confined to all matters arising after the completion of the contract as to any amount due to the contractor, &c., according to clauses 15 and 16 in Mr. Plevins's suggested contract. As regards clauses 1 and 3 in the Builders' Circular, no objection could be raised.

WHITE LEAD.

At the last meeting of the British Association, a paper by Mr. P. Spence, "On a New Process in the Manufacture of White Lead," was read in the Chemical Section. It runs thus:—White lead is one of the staple chemical products, of almost first necessity. It has long been in use as the basis of nearly all the pigments employed in oil painting, few, if any, of the colouring bodies being the qualities that are required for painting in oil; and although, from its insensibility to discoloration on the slightest contact with sulphuretted hydrogen, and also from its poisonous character, substitutes for it have been eagerly sought after, as yet nothing has been found to supersede it. Anhydrous oxide of zinc has, to a certain extent, been introduced, but does not appear to make any way. It has not an equal covering quality with carbonate of lead; but its chief defect is its want of permanency. White lead forms an almost indestructible compound with the oil, while oxide of zinc forms only a mixture. The various modes that have more or less been adopted in the manufacture of white lead are historically known to those interested in chemical manufactures. Almost all of these processes are based on the action of acetic acid upon lead or lead oxide, with the exception of the process patented by Pattinson in 1841, which is founded on the decomposition of galena by hydrochloric acid, the formation of chloride of lead, and the decomposition of the chloride by alkalies, or by alkaline earths, such as lime or magnesia. Practically, this process is now confined to the production of oxycarbonate of lead, which seems to act with oil to a great extent like white lead. The oldest, most successful, and most generally practised mode of producing white lead, is that called the Dutch process: by this mode the object is accomplished by placing castings of pure lead of a suitable form one over another in stoneware pots, in the bottoms of which acetic acid or vinegar is poured; the pots are then loosely covered and piled in masses, the whole being then covered over with spent tan or some other slowly fermenting body, which will generate a small degree of heat for a considerable period. This evaporates the acetic acid, which acts on the lead, oxidising it and partially carbonating the oxide, and in about eight weeks the greater part of the lead is corroded and converted into oxide and carbonate of lead, the acetic acid is spent, and the crude lumps of white lead are ground, any metallic lead left being picked out, and after washing, the article is ready for use. Nearly all the white lead now made in this country is by this mode. The German and Austrian process is the same in principle as the Dutch, but differs in detail. A good many attempts at the manufacture of white lead have been founded on the fact that acetate of lead in solution has the property of dissolving lead oxide, forming a basic compound.

My reasons for presenting to the Chemical Section of the British Association a process which may at first sight appear only as one of the many futile attempts to improve upon the established mode of producing white lead are two:—First, that the process is new, being in altogether a different direction from any attempt that I can find recorded, and although based upon a known law, yet that law never having been seen to point to this process, it is technologically a discovery. My second reason is, that a very important feature of the process as distinguished from all others is, that by it white lead can be manufactured from materials now useless. All other modes deal either with the purest metallic lead or equally pure oxide of lead. Pattinson's process must deal either with the purest galena, free from iron or copper, or the chloride of lead must subsequently be freed

from contamination by these metals or others, before it is used for the precipitating of oxycarbonate. By the process I shall now describe, any ore or mineral that contains eight or ten ounces of lead can be used for the production of white lead, and it is of no consequence what other metal the mineral contains; the process separates the lead directly without touching the other constituents of the mineral, and the white lead is perfectly pure. This being so, practically, I expect that all the white lead required may be made from ores or minerals now consigned to the rubbish heap as being too poor to work; and I know of large quantities of minerals useless as lead ores which will be economically adapted for the production of white lead. The process is based on the fact that oxide and carbonate of lead are soluble in solutions of caustic soda or potash, and are insoluble in the carbonates of these alkalies: the process, therefore, is effected by taking any mineral that contains oxide or carbonate of lead, or lead in any form that can be calcination or otherwise be converted into oxide or carbonate of lead, and by either macerating or boiling the mineral in a caustic solution all the lead is dissolved and extracted in a limpid and colourless solution. If the mineral contains oxide of iron, copper, or zinc, the caustic solution does not touch any of those oxides, and only attacks the lead. The lead solution is now passed into it carbonic acid gas, by which the alkali being carbonated, the lead is instantly precipitated as oxide and carbonate. The alkaline solution is now causticised by quick lime, and is ready for a second action on mineral containing lead oxide. The precipitated white lead has only to be washed to separate the solution of carbonated alkali, and then dried for use. It has been tried for painting, and is said by the painter, who had it used in various ways by his workmen, to be equal to any white lead he could procure. It has also been tried as a glaze in the potteries, and declared to be equal to any white lead the firm had in stock.

STONES AND TREES OF BRISTOL.

SPRINGING from the label-moulding of a window in the tower of St. Mary Redcliff Church, is a tree more than fifty years old. It is a specimen of the well-known magic witcher or royan tree,—the mountain ash (*Pyrus ascetica*). The tree naturally delights in mountainous districts, and the seed of this specimen was probably inserted by one of the birds known to dearly love the orange-coloured fruit. As might be expected, the tree is small, hard, and wiry, and old inhabitants can remember it for more than fifty years past. Its occurrence is not, however, so remarkable as the many young trees to be seen growing on Pencoy Church, Herefordshire, where the penetrating roots of a number of the young trees have actually displaced the stonework.

On the top of the tower is another fruit-bearing tree, a specimen of our common blackberry (*Rubus fruticosus*), that annually displays its white rose-like flowers, and produces its sweet tiny black fruit. (By the way, the blackberry was recently referred to, with amusing ignorance, by a reviewer, as the original of our garden-raspberry!) On other parts of the church may be seen the fern known as *Asplenium Ruta muraria*, the rue-leaved spleenwort or wall rue; the stone-crop (*Sedum acre*), ivy, and a good many grasses and plants of lesser note.

The roof of the south porch and some of the tower staircases are littered with twigs and small branches, brought to the church for building purposes by the loquacious and whimsical jackdaws. These birds find an irresistible attraction to the church in the many ancient wall-holes that go right through the thick walls into the belfry and tower staircases. Owls are not to be seen there, but pigeons and other birds frequent the church in company with the water-living wagtail.

Near Bristol, and just over the Suspension Bridge, are the rocky precipitous Leigh Woods, where may be seen a good number of well-grown trees, principally oak and ash: many of the old ash trunks present an appearance seldom met with to such an extent as may be observed in these woods. The trunks of several of these trees are studded and bossed from top to bottom with hard, woody, jet black, polished, bemispherical projections, ranging in size from the diameter of

a walnut to that of a large orange. The hard knobs sometimes in place of being polished are covered with a sooty down, which really consists of millions of the black seeds or spores of this woody parasite, which is a hard fungus (*Hypozoylion concentricum*), quite peculiar to the ash.

The old oak trunks are overgrown with two other fungous parasites—the exclusive property of the oak—both jet black, shapeless, wick-like-looking, and gelatinous; the first, *Bulgaria inquinans*; the second, *Exidia glandulosa*. The latter is very tremulous and gelatinous, covered with small black papillae, and may be immediately known by the touch and appearance of the under side, which feels and looks exactly like black crape.

A day in January is not the time to observe living nature; had our visit been on one of the beautiful humid days of a wet October these notes might have been extended ten-fold.

W. G. S.

FAIR PLAY FOR THE NEW LAW COURTS.

SIR,—I have reason to believe you prefer speaking to person, and are not afraid of speaking plainly when necessary. I ask you, therefore, and have little doubt as to your compliance, to let me tell the Secretary of the Commission for the New Law Courts, Mr. Edwin Field, that he is acting neither wisely nor well. His partisanship is the object of general remark on the part of all who have had occasion to frequent the building containing the designs: and I could tell instances by the score, and will, publicly and by affidavit, if this note should have no effect, of his endeavours to bias persons in favour of one particular set of designs, and to prejudice them against others. In fact, it is going on all day. My chief object in writing is to express a hope that the report of the Architectural Clerk and his assistants will be forwarded to the judges independently of the secretary. All the costly arrangements of the commissioners to ensure the fullest and fairest consideration for every competitor in this arduous undertaking will go for nothing in the public mind if the present system of tooting and depreciating, obvious to all, be not put an end to.

ONE ON THE SPOT.

SIR,—I was at the exhibition of the designs yesterday, and noticed a gentleman actively engaged in pointing out and explaining to persons round him,—myself for one,—the plans and arrangements of one particular designer. I thought no more of it, considering, of course, it was some one appointed from the architect's own office, and was surprised, when informed this morning, that it was the Secretary to the Commission. Would you kindly inform me if it is usual in competitions for the Secretary to the Commissioners to attend and explain to visitors one particular set of drawings. A CLERK OF WORKS.

"A Chancery Barrister," and "An Architect's Clerk" write to the same effect. We are quite ready to attribute the proceedings complained of to excess of zeal, and have no doubt the hint here given will lead to greater moderation in the exercise of it. It is greatly to be desired, in fact absolutely necessary, that two professional architects should be added to the judges, and that they should be chosen by the competitors themselves.—Ed.

THE CONSTANT SUPPLY OF WATER FOR LONDON AND FROZEN PIPES.

In the report of Mr. Bateman's valuable lecture on the above, given in your pages, it is stated that when the constant supply of water to London is introduced, "very much of the annoyance and inconvenience arising from frozen cisterns and burst pipes, which are the common attendants of the winter season, will be avoided."

Agreeing, as I do, in the main with Mr. Bateman's lecture, and with the principles laid down, in which, probably, most engineers, having experience in the construction and management of water-works, have long since, for the most part, concurred; yet, with the statement I have quoted respecting frozen cisterns and burst pipes, I must say my experience is not in unison.

Frozen cisterns, so far as cisterns may be abolished, of course, would cease; but with respect to burst pipes, I have known 70 to 80 per cent., or more, of the consumers of large districts, supplied from impounding reservoirs by gravity, even on the system of constant supply—for instance, the town of Ashton-under-Lyne, in Lancashire—to have their service-pipes frozen and burst in time of very severe frost.

When any town or district is supplied by river-water, or from surface water collected in open impounding reservoirs, or by means of

water led through long distances, in open aqueducts, the water, in cold, frosty, and snowy seasons, necessarily passes into the mains and service-pipes at a temperature only a few degrees above freezing. For instance, the average temperature of the water in the Thames, for a whole month, in a cold winter, is frequently as low as 35 or 36 degrees Fahr.

Water of such a cold temperature can hardly fail to get frozen, and in freezing to burst the tenants' service-pipes in houses as usually constructed, especially those of the middle and poorer class, whether supplied on the constant or any other system.

My experience teaches me that, in order to remedy the great inconvenience and loss arising from water freezing in cold weather in service-pipes, and thus bursting them, it is necessary that the water should be supplied into the mains and distributing pipes of waterworks, not at a temperature of 35° or 36° Fahr., but at a temperature of 50° to 52° Fahr., which is the normal temperature (summer and winter) of spring water about London; and that care should be taken to lay the service and distributing pipes at a sufficient depth below the surface of the ground, say the top of the pipe 3 ft. to 4 ft. below the surface of the ground, in order to prevent the water being unduly cooled down before it reaches the consumers.

When water of the normal temperature of 52° Fahr. is conveyed, without exposure to the air, direct from its source into properly covered reservoirs, and is distributed through mains and pipes laid at a sufficient depth below the surface of the ground into the houses of the consumers, and care is taken to place the draw-taps indoors, say in a scullery or wash-house, so that the tap in the cold weather may be slightly opened to permit a small quantity of water to drip from it without inconvenience; then, owing to the well-known great specific heat of water, the comparatively warm water from the mains slowly passing through the draw-taps and service-pipes keeps the water in the service-pipes from freezing, and thus from bursting the pipes and taps used to supply the consumers.

In confirmation of the above I may state, that although the Caterham Spring-water Works have been in operation for more than five years past, and are situated on a high hill, at an altitude of 700 ft. above the sea, and supply a district of country varying in altitude from 700 ft. to 400 ft., yet such a thing as a water-pipe bursting, from being frozen, is rarely known. Still, it must be borne in mind, that should a water-pipe burst, say at night, or in an empty house, without being at once attended to, a greater, rather than a less, flooding would be the result of constant supply.

The water, in the case of Caterham, is derived from a deep well in the chalk; the water is pumped direct from the well into a covered reservoir, and the mains and service-pipes are laid below the surface of the ground, to the depth hereinbefore named; and, I may add, the water is supplied on the system of constant supply. The Kent Water Company supply 33,000 houses with spring-water, from wells sunk in the chalk, of the normal temperature of about 52° Fahr.; and water of this normal temperature is supplied to the towns of Brighton, Croydon, Hail, and very many others.

With water of such a normal temperature, frozen and burst pipes, on the system of constant supply, with proper care, may be prevented; but when water, already nearly at the freezing point, is distributed from water-works deriving their supply from rivers or open reservoirs, or from long open ducts, I must say that I have never found that the water could be prevented, at least in ordinary houses, from freezing in very cold weather, and thus bursting the service-pipes, even when distributed on the system of constant supply.

SAMUEL COLLETT HOMERSHAM.

THE STREETS AND HOUSES OF THE METROPOLIS.

SIR,—It must be acknowledged that the plan for the renaming and renumbering of the streets of London has proved, so far as it has been carried out, a great success, to the convenience of the public in general, and the rapid delivery of the post in particular. The thing to be regretted is, that the system has been only partially adopted; the Act of Parliament, in a certain sense, being only permissive, that is, the Metropolitan Board of Works has no power to order alterations of names, &c., except on the previous request of parishes or individuals; and we know what slow coaches vestry boarders, and at the present rate of progress it may well take fifty years be-

fore the metropolis is reduced in its numerous Johns, Thomases, Williams, Gloucesters, Carltons, Clarendons, and other favourite names in every quarter of London. There is a new Building Act expected to pass through the House of Commons this session,—would it not be well to give to the Metropolitan Board the power to take the initiative in these matters? Live in the district of St. John's Wood and Edgware-road, and we have two Carlton-roads, two Canterbury-roads, two Clifton-roads, two Blenheim-roads, and a number of short streets rejoicing in three or four names. Would it not be well to simplify matters, and get rid of subsidiary names, &c., &c. And as to the Edgware-road, in particular, it should be divided into three names,—Edgware-road, Maids-vale, Kilburn-road; at present nobody knows where the Edgware-road ends or where it begins; and so of many other parts of London. I submit the building trade is much interested in this apparently trifling matter. A. B. C.

THE NATIONAL GALLERY COMPETITION.

We have reason to believe that our few words last week about the National Gallery Designs have not been without effect, and that the injustice meditated will not be fully carried out, though the report may still be unsatisfactory.

THE DESIGNS FOR THE NATIONAL GALLERY.

SIR,—I am one of many who think that the designs for the National Gallery have not met with fair play at the hands of the critics. With some exceptions they seem to me highly creditable, and much of the criticism bestowed upon them might more fairly have been directed against the agencies of the conditions, and the strange difference of opinion which exists among artists as to what constitutes a good picture-gallery. It also seems to me that the designs labour under a great disadvantage by reason of the place where they are exposed, for I cannot say seen. It is almost impossible, even on a light day, to make a careful examination of the drawings. At Lincoln's Inn all is light and cheerful, and each design is well exhibited and easily seen. At the Royal Gallery the effect is dull, dark, and dispiriting, and it is most difficult to examine the designs.

I cannot believe, however, that the First Commissioner of Works will allow the gross injustice hinted at in your last number to be carried out; as, if so, there must, as it seems to me, be an end for the future of Government competitions. A SPECTATOR.

BLACK BRICKS.

SIR,—Will some of your readers kindly inform me of a well-tried and permanent black stain or dye for fancy brickwork? I am aware that black bricks are made, and they are undoubtedly the best; but it frequently happens that the readiest and least expensive method is to black the bricks after they are built in. B. A.

POTASSIUM AND LEAD PIPES.

SIR,—With regard to the inquiry suggested by your correspondent, "P. Squire," February 9th, as to the effect of Dr. Schwartz's discovery, I navigated it myself, not knowing how to prepare a "hot solution of the sulphide of potassium," and entertaining the opinion that this singular coating, if not soluble itself by the same water which solves the oxide of lead, and thereby renders the pipes poisonous, would be at all events so liable to erosion and abrasion from the numerous curvatures and joints which the pipes have to undergo in the process of laying or fitting, that it would turn out, even if theoretically correct, to be practically useless.

The only safe means I know of to render leaden pipes innocuous is to give them a thick coating of tin on the internal surface; and for this process there are at least two patents existing. M.

THE LINE OF FRONT.

At the Hammersmith Police Court, Mr. E. H. Corbould, the arrier, was summoned for erecting a building beyond the general line of frontage, as determined by the Superintending Architect of the Metropolitan Board of Works.

Mr. Raymond, on behalf of the Kensington vestry, who were the complainants, gave an outline of the case, from which it appeared that the defendant's house was situated at the corner of the Victoria and Eldon Roads, with a frontage in the former road. A studio, with a conservatory, &c., in the Eldon-road, had been taken down, and a new and larger building erected. The general line of other buildings in the Eldon-road was considerably behind the line of the new building. He said the summons was taken out under the 75th section of the Metropolitan Local Management Act Amendment Act, but the 74th section also applied, and he argued that both sections should be read together. The 74th section of the 26th and 26th Vict., cap. 102, stated that in case any building which shall in any part project beyond the general line of the street in which the same may be situated, or beyond the front of the building, wall, or railing on either side thereof, shall at any time be taken down to an extent exceeding one-half of the building, it shall be lawful for the Board to require the same to be set back into such a line and in such a manner for the improvement of any street as the Board shall direct, provided that the said Board shall make compensation. The 75th section stated, "That no building, structure, or erection shall, without the consent in writing of the Metropolitan Board of Works, be erected beyond the general line of buildings in an street."

Mr. M'Leod, for the defendant, said the case was of considerable importance to Mr. Corbould, who had expended 1,100*l.* upon the building. He (Mr. M'Leod) argued that the 7th section was inapplicable to the case, inasmuch as the defendant only pulled down a portion of his premises, upon which a larger studio was constructed. The house and studio were all one premises, having an internal communication, and therefore did not come within the meaning of the section. He also contended that the 7th section was not applicable, because one-half of the building had not been pulled down. If it had, then the Board might proceed to set it back, and pay the defendant compensation.

Mr. Raymond, in reply, referred to the other words in the section, "structure or erection," being used.

Mr. Ingham decided against him, as he thought the premises were one whole thing. He also thought that the 7th section was inapplicable, as it applied to new buildings.

Mr. Raymond intimated an intention to submit a case for one of the superior courts.

Mr. Ingham then dismissed the summons, and ordered the vestry to pay five guineas costs.

Without giving any opinion as to the suvance caused to neighbours, or otherwise, by rebuilding the studio of large size than it was previously, we have no hesitation in saying that there was no case under the sections quoted to take there to the magistrate.

COMPETITIONS.

New Town-hall, Grantham.—The Town Council of Grantham are about building a new town-hall and goal for prisoners, and for this purpose invited designs. Twenty-seven were sent in, and on Friday last the first premium was awarded to Mr. Watkin, of Lincoln, the gentleman to whom the Corporation of Doncaster lately awarded the first premium for their Corn Exchange and market extensions.

LONDON AND COUNTY BANK.

SOME shareholders of the bank ask us to point attention to the advertisement in our last, showing the declaration of a dividend, making the dividend of the whole year 25 per cent. We willingly do so. There is the fact, and it will doubtless have its weight. But when they go on to say the balance-sheet *proves* this and *proves* that, then we demur. The balance-sheet *proves* nothing. It is utterly valueless, and one item will establish the truth of what we say,—the item that shows the "Discounted bills and advances to customers" to be 114 millions and more. Of what value, in comparison with this, are all the other items of the statement? Absolutely none. Everything depends on the nature of the securities on which these advances are made. They may be worth 11½ millions, and doubtless are; but they may be worth nothing. To talk of a banking company's balance-sheet proving anything, is simple nonsense. Without the guarantee of impartial and able examiners that these advances are made on sound securities, it would be nonsense to talk of proof: everything must be taken on trust. All the other items are absolutely of no consequence at all in the face of this one entry, concerning which nothing is known. It will be readily understood that we are not seeking to cast the remotest slight on the successful and respectable banking company which has afforded us an example. Our observation applies to a system.

WATER SUPPLY AND DRAINAGE.

Doncaster.—The town council have resolved to advise with Mr. Rawlinson, C.E., as to the best means of obtaining an adequate supply of pure water, and of disposing of the town sewage.

Stockport.—A Bill is now before Parliament applying for powers to supply this borough with water, and also to purchase the present works of the District Water Company. The corporation are the promoters of the Bill. Their water supply committee offered 130,000*l.* for the works, payable by mortgages redeemable at seven, fourteen, and twenty-one years, with interest in the meantime at 4 per cent., being nearly twenty-two years' purchase upon the present rental of 7,500*l.* Mr. Bateman, C.E., chairman of the District Water Company, stated in reply, that the offer was not one which the shareholders would accept, and that the question should be determined by arbitration. The committee have also agreed to petition Parliament against the Manchester Water Bill so far as it affects Stockport.

Maryport.—At a meeting of the Waterworks and Sewerage Committee held to confer with Mr. Lawson, C.E., on the subject of his Parlia-

mentary estimate, and to ascertain from him how far it could be reduced so as still to give a sufficient supply to Maryport, Mr. Lawson's explanations of the various items were held to be, upon the whole, very satisfactory. The reductions, he thought, might safely be put down at from 5,000*l.* to 6,000*l.*, and the entire cost might be brought within 20,000*l.* Detailed particulars of his reduced estimate he promised to furnish to the trustees.

CHURCH-BUILDING NEWS.

Rumboldswyke (near Chichester).—The church has been re-opened after repair and restoration. Mr. Gordon M. Hills was the architect, and Messrs. Bushby & Son, of Littlehampton, the builders, by whom the changes have been effected. The church consisted of a nave and chancel; the oldest feature being the chancel arch, which probably is Saxon work. The door and the windows were of the thirteenth century, inserted in the older walls. In the progress of the restoration some mural paintings were discovered in the chancel. These were of different dates (from 1200 to 1700), painted one over the other. The walls were found to be largely built of Roman brick near the arch mentioned. There are two piscinas—one in the south wall of the nave, and the other in the chancel.

Redcar.—In addition to the improvements in the heating apparatus in St. Peter's Church, and the new organ recently erected by Messrs. Forster & Andrews of Hull, the turret clock shown at the York Industrial Exhibition has just been fixed in the tower. An addition has been made since the clock left the exhibition of striking apparatus and two bells for the quarters. The cost is about 200*l.* The incumbent has now turned his attention to the windows, which he proposes should be filled with patent cathedral glass, instead of the common glass by which the church is at present lighted (except at the east end).

Ystradgynedy.—The parish church of this village has been re-opened by the Bishop of Llandaff. The edifice has been considerably altered, under the superintendence of Mr. Backeridge, of Oxford, architect. Little has been done to the exterior, but the windows, which in the former building were very low and square, are now large, and oblong, with arrow-headed arches. The two windows at the east and west ends of the church especially denote the change. The building is entered by a porch opening to the north. The lath-and-plaster ceiling has been removed, and the roof thrown open. The roof, which forms a pointed arch, is held up by five supports, which, in uniformity with the roof, rest on carved stone brackets. The chancel is divided from the body of the church by a Gothic arch, which rests on two dwarf columns, with foliated bases and capitals. The chancel is paved with glazed encaustic tiles in colours, put in by Mr. Harding, of Hereford. Over the altar-table a sculptured red marble cross is inserted in the wall. The interior walls of the building are not defaced with plaster or stucco, but the open brickwork is presented. Fire-bricks have been employed, relieved by alternate lines of red bricks; while the red brickwork is also brought into service in the formation of the arches over the windows, doors, &c. As there are no means of lighting the place with gas, paraffine-oil has been used, and a chandelier, containing four full-sized lamps, depends from the roof, in the centre of the chancel, while ranged along each side of the church are brackets attached to the wall, holding each a light. The pulpit is formed of white sandstone, chiselled into a circular shape. The pews are new. The building is warmed by means of a hot-air apparatus. Mr. James Price, of Cardiff, was the contractor employed.

Books Received.

Up and Down the London Streets. By MARK LEMON. London: Chapman & Hall. 1867.

On the first hearing of these sketches, in the shape of lectures, at the Gallery of Illustration, in Regent-street, and afterwards as they appeared in the pages of "London Society," they received our commendation; and this, now that they are gathered together in a handsome volume, with various copies of old prints to illus-

trate them, we gladly repeat. Mr. Mark Lemon, to whom as much as to any man living all are indebted for wholesome amusement, has not pretended to write a new book about the metropolis, or to set himself up as a fresh authority on the subject; but he brings the old stories together cleverly, and tells them pleasantly and well; and his book will greatly increase for many the pleasure of future walks "up and down the London streets."

VARIORUM.

THE current number of the *Fine Arts Quarterly Review* (Day & Son) contains, amongst other papers, a very interesting account, by Mr. George Scharf, of the Westminster Portrait of Richard II., illustrated by Mr. Scharf's correct pencil. Success appears to have rewarded the very bold and risky steps taken by Mr. Henry Merritt, under the direction of Mr. G. Richmond, R.A., to get rid of the over-paint. If it had not done so, we know very well what would have been said of those steps. Mr. Scharf bears strong testimony to the skill with which the work has been done. The number altogether is a good one.—"Journal of the Transactions of the Victoria Institute or Philosophical Society of Great Britain." 1867. Hardwicke, Piccadilly.

This volume contains some able papers and discussions, preluded by an Introductory Address by the Rev. Walter Mitchell, M.A., one of the vice-presidents, in which he dissects pretty sharply some portions of Mr. Grove's address to the British Association. The paper by Professor J. R. Young, "On the Language of Gestulation and the Origin of Speech," is a very interesting and able one, no less ably controverted in the discussion which followed the reading of it. Much suggestive matter also occurs in the paper on Miracles, by the Rev. W. W. English, and the discussion on it; and another paper on the same subject, by Mr. E. B. Pether, adds to the interest of the subject. A paper on Geological Formations, by Mr. Evan Hopkins, also merits notice.—"Phases in the Developmental History of Infusorial Animal Life," by James Hogg, F.R.S., is a reprint on a curious subject from the *Intellectual Observer*. Mr. Hogg is the senior assistant surgeon to the Royal Westminster Ophthalmic Hospital, and author of various scientific treatises, especially on the microscope. The elucidation of the mystery which surrounds the beginnings of organic life and the discovery of the living principles which exert so powerful an influence on all animated creation, are noble subjects for study, notwithstanding the fear of timid and superstitious minds that such study is an encroachment on forbidden ground. Mr. Hogg treats the subject in a philosophic and interesting manner.—"Destitution in Poplar: a Letter to the Earl of Derby, with practical Suggestions." By T. Lond, Honorary Secretary to the Relief Committee, Poplar, Tweedie, Strand. Mr. Lond suggests that Government might order the construction of some ships, on which the ship-building trades at the east end might be employed; and he deprecates the "foolish and wicked" conduct of those who, in the face of such distress as has of late existed at the east end of London, preferred throwing themselves entirely out of work, to enabling their employers to undertake new contracts at a lower rate than usual, by submitting to a reduction of 6*d.* a day from 7*s.*, as the workmen's share of the relative loss. Mr. Hogg explains, however, that the great weight of the distress has had nothing to do with this transaction, in which only a comparatively few out of the "30,000 men who are at the present moment in the most abject state of utter destitution and wretchedness" took part. There are hundreds of shipwrights out of employment, he says, who would be thankful to work for 6*s.* 6*d.* a day if there were work for them to do, and no tradesman to prevent their doing it. Mr. Lond admits that "the effect of this refusal on the part of the shipwrights has been to close the hearts and purses of thousands against the necessities of the starving mechanics?"—the more is the pity that a minority of misguided men should have made the majority so to suffer by their folly. Mr. Lond suggests that the

• Even as we write we observe from the Thames Police reports, in the daily papers, that a new strike has taken place amongst the iron-shipwrights, and that intimidation is being used against those who have remained at work. It is full time something were done for the protection of workmen against the stupid and merciless conduct towards them of their own idly-juiced fellow-workmen.

workhouse regulations ought to be relaxed in the present instance, as they certainly ought ere now to have been. Lord Derby, in reply, reminds Mr. Lond that the distress in Poplar is nothing but the cotton famine in extent, which is rather a little too much in the Job's comforters' style of consolation, in a case where the depth of distress may be no less severe, though not so extensive as that of the cotton famine. His lordship declines to order ships to be built "which are not required for the public service," and as to the relations between capital and labour which Mr. Lond suggested should be taken into consideration by the Legislature for the curbing and protection of both labour and capital, Mr. Lond is indirectly referred to her Majesty's speech.—Keith Johnston's Royal Atlas: Africa and Prussia. Blackwood & Sons, Edinburgh. These two new maps, engraved for Dr. Keith Johnston's Royal Atlas, comprise the explorations of recent travellers in Africa, and the marvellous transformations effected by the seven weeks' war and subsequent negotiations in Prussia and neighbouring states. The proprietors appear resolved that no exertion shall be wanting to make this atlas a perfect one of its kind.

Miscellaneous.

FALL OF A FLOOR.—A sad accident has just happened at Monte Rocca Dona, in Sardinia. The mayor, Pietro Masala, who was highly esteemed, died, and the people wishing to testify their respect hastened to visit the mortuary chamber. About a hundred persons were assembled in the room when suddenly the flooring gave way, and the whole of them, as well as the corpse, were precipitated to the lower story. The neighbours hastened to their assistance, and after some hours' labour they were extricated, but one woman was found dead and several other persons were more or less injured.

THE LIABILITY OF PUBLIC BODIES FOR THE NEGLIGENCE OF THEIR SERVANTS.—An important decision was given in the Court of Exchequer (sitting in Banco) affecting the liability of public bodies for the results of negligence on the part of their servants. The vestry of Bermondsey were making a sewer in Blue Anchor-road, when a Mr. Juniper stumbled, in the dark, over a heap of dirt left by the workmen, which caused his death. Mrs. Juniper then brought an action, and obtained a verdict, with 875*l.* damages, which the vestry appealed against, and now moved for a rule to set aside. In giving judgment, the Lord Chief Baron said that recent decisions had finally settled the principles of the law as applicable to cases of this nature; and it was authoritatively settled that the members of a public body, created for public purposes, although having only public duties to perform, receiving no salaries, and having no funds out of which to pay damages, were liable for the damages caused by the negligent performance of their duties. The rule was refused, and the verdict therefore stands.

ROMAN VILLA ON LANSDOWN.—The Rev. Prebendary Scarth has read a paper to the Bath Natural History Society, entitled "A Notice of a Roman Villa which stood on the old Harbour Farm, in the Parish of Wick, near the ancient Cromlech, and which was excavated in the years 1865-6 by the Bath Field Club." The building consisted of fourteen chambers, with the remains of two suspended floors and their hypocausts and heating apparatus. The lecturer went into the probable nature of the walls of Roman villas, and considered them to have been constructed of timber and earth or clay, and upon a foundation of stone, probably about 4 ft. high from the foundation. He gave instances in support of this conjecture, from the wall-plaster in other villas having been found to contain upon it impressions of straw-bands, which revealed the construction of the interior of the wall. The cob-walls of Devonshire, and the walls of some of the barns and out-buildings in other counties, seemed still to perpetuate this kind of building. This mode of construction, he suggested, may have been introduced by the Romans, though many considered it to be much older than Roman times, as it is a mode very generally followed in the East, and in Africa among the Moors, and may have owed its origin to Phœnician settlements. If the walls of Roman houses were so constructed, it would account for the great mass of earth that now covers the site of Roman towns and villas.

A "HALL OF JUSTICE," FOR BRIGHTON.—The town council have resolved "that, as it is desirable that all the buildings for the administration of justice should be contiguous and erected on public property, the Pavilion Committee be instructed to bring up a report, with plans, showing what portion of the Pavilion property is available for such purposes."

THEATRES.—In the House of Commons, Mr. O'Beirne asked the Secretary of State for the Home Department whether it was his intention to introduce any measure this session for the better regulation of theatres and places of public amusement in Great Britain. Mr. Walpole said that he hoped to be able to bring in a Bill on the subject involved in the hon. gentleman's question, and that Bill would embody several of the recommendations of the committee.

LIMITED LIABILITY COMPANIES.—On Wednesday morning was issued a return to Parliament of the number of companies registered under the Limited Liability Act during the years 1864, 1865, and 1866, with the amount of capital proposed to be raised in shares. The summary of the return is as follows:—1864: 992 companies were registered, with a proposed capital of 237,437,083*l.* 14*s.*; 5 companies were registered without nominal capital—total, 997. 1865: 1,013 companies were registered, with a proposed capital of 205,391,818*l.*; 20 companies were registered without nominal capital—total, 1,033. 1866: 768 companies were registered, with a proposed capital of 76,599,823*l.*; 10 companies were registered without nominal capital—total, 768.

RATING OF GAS-WORKS.—Certain gas-works were rated to the poor in respect of the occupation of land by the Company's pipes. The Company claimed deductions in respect of their meters, retorts, purifiers, steam-engines, boilers, and gas-holders. The meters were supplied by the Company to each consumer on his premises, and were their property. The other articles were commonly used in gas-works, and such as a tenant carrying on such works would have to take to and find capital for working. It was held by the Court of Queen's Bench that all of them, except the meters, should be considered as forming, if not part of the freehold, at least so far connected with it as intended to be permanently attached thereto, and therefore should be taken into account in determining the rateable value of the land so occupied by the pipes. This was the case of the *Queen v. The Inhabitants of Lee*.

INDUSTRIAL DWELLINGS COMPANY.—Several members of Parliament and other gentlemen who take an interest in the question of providing house accommodation for the poor, were present at the half-yearly meeting of the Improved Industrial Dwellings Company, at which Mr. Alderman Waterlow presided. The chairman, in moving the adoption of the report, said he thought Government should give some assistance to the object. Mr. Samuel Morley said it was quite a mistake to suppose that the investment of money in improved dwellings did not pay, for 3,000*l.* he had invested in such undertakings was now increased to 5,000*l.* The Right Hon. G. J. Goschen, M.P., in moving that a dividend of 5 per cent. per annum be declared upon the paid-up capital of the company, said he saw that it would pay commercially to invest money in such undertakings. The company had proved that it was possible to pull down dens and build good houses in their place at a profit instead of a loss; the reason being that they could choose their own sites, and escape the expenses of arbitration. Thus by a selection of economical sites good business might be done. The direction was entirely honorary; all the expenses were cut down to the very lowest point; and he hoped that a large amount of capital would be attracted to the work. The 50,000*l.* or 60,000*l.* expected to be obtained from Government would help the company very much; and that afternoon he intended to ask the Secretary of the Treasury why the grant had not been made sooner. It was true that these new dwellings did not house the extremely poor, but the enhanced rates were cheerfully paid, and hundreds of tenants try to get into any vacant rooms when they are to let. The rents vary from 4*s.* 6*d.* to 7*s.* 6*d.* per two rooms, averaging 2*s.* 5*d.* per room. The shareholders would be glad to learn the fact that each block of buildings erected by the company yielded by itself a profitable revenue. He knew of no reason why the company should not always realize good dividends.

WRITING ON GLASS.—We hear of the preparation of an ink with hydrofluoric acid, and hydrochloric acid, properly thickened, with which, using any pen, ineffaceable characters can be traced on glass.

THE COST OF CASTING THE NELSON LIONS.—Public disapprobation is increasing of the asserted fact that Baron Marchetti is to receive 11,000*l.* for supplying the metal and making the castings of the lions in Trafalgar-square. About 6,500*l.*, it is stated, would be a full price. Moreover, was not some of the metal given by the Government?

OTHER FOUR LIONS.—The four Lions are now being placed in front of the Leeds Town-hall. Two of the four have been uncovered, in the presence of a large number of spectators, including the sitting magistrates; the architect, Mr. Erodick; and Mr. Wm. Day Keyworth, jun., of London, the sculptor selected to execute the statues. The two placed animals, though similar in size and general effect, their height being 5 ft. 6 in. and length 11 ft., differ in expression, countenance, and position of head. The lions are in a superior kind of Portland stone. The manes are disposed in large bold masses, the surfaces of each lock of hair being tooled, to convey the impression of smaller locks. The less covered parts display the large anatomy of the king of beasts, and the suppleness of the limbs.

FALL OF THE HOE PILLAR AT WOKING.—This old beacon has fallen into a complete ruin during a recent gale. The traveller by the South Western Railway, when passing the Dramatic College, may have noticed a slender shaft, octagonal in form, rising to the height of 60 ft., or upwards, amid the group of elms by which it was surrounded. This was the Hoe Pillar, of Woking. Within memory, it was surmounted by a wooden cupola open on all sides, which served as a Belvedere by day, and a lantern by night. This being neglected by its owner, the Earl of Onslow, was blown off some fifteen years since, and then the work of destruction began, which weather and the sunbail plough have since completed. The Hoe Tower, or tower on the height, as the Saxon name denotes, was built to light benighted wayfarers across the trackless heath, or to show the way to the royal hunting parties overtaken by darkness. Though of no great altitude, it could throw its light into Middlesex, Hampshire, and Berkshire. Some years after the death of the Duchess of Cleveland, which did not occur till 1707, the property passed into the family of the present owner. The tower, like that of Pisa, had long inclined on one side, but without any other signs of decay, and would have stood two centuries more had a few pounds been bestowed on its repair. Nothing now remains but the fuel chamber at the base, and a few old elm trees near the spot.

ST. LUKE'S NEW VESTRY-HALL.—The old work-house of St. Luke's, a part of which has so long been used for vestry offices, is now superseded by a building, in the Italian style, of simple design, at a cost of 6,400*l.* The dressings to the windows and doors are of Portland stone, and the front of Suffolk bricks. The main front towards the City-road is divided into two stories above the basement. The entrance porch is of Portland stone, with carved capitals to the piers, and leads to a vestibule protected by an enclosure. On the ground-floor are offices for the vestry clerks and their assistants, the surveyor, the headle, and a waiting-room. A corridor separates these offices from the vestry-hall and ante-rooms in the rear. The vestry-hall is about 50 ft. long, 25 ft. wide, and 25 ft. high; it has an elliptical coved ceiling, containing eight lights, and springing from an ornamental bracketed entablature, which is supported by Corinthian pilasters of polished Parian; it is intended to have records of the several charities placed between the pilasters. A stone staircase leads to the first-floor, on which are a large board-room, committee-room, and waiting-room. Another corridor corresponding with the one on the ground-floor, runs from end to end, giving access to all the rooms. The basement story contains kitchen and waiting-rooms, munition-room, bread-rooms, &c. Mr. Christie, the surveyor to the vestry, arranged for the rooms of the several officers, but had not time for the completion of the drawings and superintendence of the works. The vestry, therefore, applied to Mr. F. Warburton Stent, of Westminster, to complete the designs and superintend the works. Mr. Sawyer, of Dulwich, was the contractor.

NEW LIGHTHOUSE AT BOMBAY.—The chief stone of the new lighthouse on Kenney was laid on the 19th of January, by Sir Bartle Frere.

LEAD-POISONING.—M. Marmise points out a novel source of lead-poisoning, viz.—the painted woodwork obtained from the demolition of old houses, and which being used for fuel gives off smoke charged with lead, that may be disseminated and taken in with the breath. According to the *Lancet*, five out of ten dealers in old panelings in the city of Bordeaux have suffered more or less from lead colic, and in some instances the metal has been found deposited in the chimneys of those fireplaces in which old woodwork has been burnt. It is also said that the handling of freshly-printed journals, inasmuch as the ink contains litharge, may also account for the existence of symptoms clearly referable to the injurious influence of lead.

METROPOLITAN COMMON POOR FUND.—The following charges are, by Mr. Hardy's Bill, to be paid out of the Common Poor Fund, in addition to the relief of the houseless poor already charged upon it.—The expense of the maintenance of lunatics in asylums, registered hospitals, and licensed houses, and of insane poor in asylums under this Bill, except such expenses as are chargeable on the county-rate; the maintenance of patients in any asylum specially provided under this Bill for patients suffering from fever or small-pox; medicine and medical and surgical appliances for the poor in receipt of relief; maintenance of pauper children in district, separate, certified, and licensed schools; salaries of clerk to guardians, chaplain, medical officer, relieving officer, master, matron, nurse, and porter of workhouse, and of the dispensers in the proposed dispensaries; compensation to any medical officer affected by the determination or variation by the Poor-Law Board of a contract for medical relief in the workhouse; fees for registration of births and deaths; and fees and expenses of vaccination.

THE AMALGAMATED ENGINEERS.—"We stated in a paragraph, some months ago," says *Engineering*, "that the authorities of the Amalgamated Engineers had determined, if possible, to put an end to piecework, and that the cost of many varieties of work was regularly sent in by foremen, workmen, &c. These statements were at once denied by the secretary of the union, but we have since had further evidence of their truth. Unless masters can bring sufficient pressure upon the men, the whole system of piecework is doomed, and the slow and slovenly workman will be placed upon the same footing as the most active and efficient. We know superior workmen who have earned 2l. 10s. to 3l. a week at locomotive factories and repair shops, by taking piecework at low prices, and we know that they are marked men, with all the grudges and jealousy of inferior workmen,—the latter leagued together in a powerful body,—upon their shoulders. It is impossible to say to what a depth of inferiority the overthrow of the piecework system would sink most kinds of mechanical labour." We may here note that we observe the Great Eastern Railway Company are purchasing French locomotives, and that they obtain them 200l. below their former prices.

LONGITUDE BY THE ATLANTIC CABLE.—The difference of longitude between England and America has, hitherto, rested upon the chronometric expeditions instituted by the Coast Survey during 1849-51 and 1855. Fifty chronometers were transported three times in each direction across the Atlantic. The probable error of the result of these expeditions was estimated at 19-100ths of a second. When the success of the cable provided telegraph transatlantic connexion with England, parties of the Coast Survey were formed, under the direction of Dr. B. A. Gould, to take advantage of these means of obtaining a result still more precise. The probable error of the resulting longitude is now estimated at about 4-100ths of a second. A distance of about 1,900 miles has thus been measured, and the measure is considered to be probably not more than 40 ft. from the exact truth. The time required for a signal to pass through the cable has been discovered with still greater precision to be 31-100ths of a second, which is regarded as being probably not in error by 1-100th of a second. This is equivalent to a velocity of 6,020 miles a second, and is notably less than the velocity of the electric force upon land lines, which numerous observations have shown to average 16,000 miles a second.

CHARING-CROSS HOTEL COMPANY.—A dividend for the half-year has been declared at the rate of 10 per cent. per annum.

NEW LIGHTHOUSE AT GUERNSEY.—The structure which has been for some time in course of erection on the eastern extremity of the Castle Breakwater, at the southern entrance of the outer harbour, is now all but completed. The edifice, to the point of the vane, stands 56 ft. above high-water mark, the masonry being 41 ft. 4 in. The light will be furnished with a third-class dioptric lens, and will show 43 ft. above high-water springs, and 59 ft. above mean-tide level. The lantern and lens are supplied by Messrs. Chance, Brothers, of Birmingham.

BARRIERS ACROSS STREETS.—At the last meeting of the Metropolitan Board of Works, the Works and General Purposes Committee brought up a report, recommending that a petition be presented by the Board to Parliament, to repeal any authority given to private individuals to erect gates or barriers across streets or thoroughfares so as to obstruct the traffic therein, in cases where the lighting, cleansing, and paving of such streets or thoroughfares is paid for out of the public rates. The committee had taken counsel's opinion on the matter, with the view of advising the Board. The report was agreed to.

DANGEROUS PAPER.—There is a great difference in the combustibility of common paper. Enamelled card paper, on account of its compact body and the presence of mineral matter, white-lead or barytes, is quite disinclined to burn; in fact, some kinds are practically fireproof. White writing and printing paper can seldom be lighted by a spark, and when ignited by a flame it requires dexterity to keep it burning. On the other hand, there is a common reddish yellow paper, which, in some circumstances, according to the *Paper Trade Review*, is as dangerous as gunpowder. It takes fire by the smallest spark, and burns like tinder. When once lighted, if left alone, it is sure to be consumed completely. All the yellow and buff paper, out of which envelopes are made, partakes more or less of the same character. There is no doubt that such paper has been the occasion of some of the fires in paper warehouses and offices of professional men.

BOILER EXPLOSIONS.—The report for the past year of Mr. H. Hiller, the chief engineer of the National Boiler Insurance Company, Limited, has been printed. It states that the business of the company is making satisfactory progress: no explosion had occurred to any boiler under the company's inspection, while in other cases throughout the country nearly six explosions had taken place in 1865 and seventy-four in 1866, in the latter instances causing seventy-seven deaths and injury to 152 other persons. Over-pressuro caused twelve out of the seventy-four explosions, external corrosion nine, deficiency of water eight, and weakness of internal flue tubes eight. Of the exploded boilers, twenty-two were one- or two-lined, and externally fired, and twelve plain cylindrical ones, externally fired. The boilers exploded by over-pressure were two small vertical ones with internal furnace, two Cornish one-lined, two portable (locomotive type), two marine, one Galloway, one plain cylindrical, and one balloon. The report contains much useful information on the subject of steam boilers.

LABOURING CLASSES' DWELLINGS.—In the Commons recently Mr. Goschen asked whether any applications for loans had been made under the Act of last session "for enabling the Public Works Loan Commissioners to make advances towards the erection of dwellings for the labouring classes," and how any such applications had been dealt with. Mr. Hunt replied that there had been ten applications for loans under the Act. No money was to be advanced unless the Board of Works certified that the buildings were suitable for dwellings for the labouring classes. Of the ten applications sent in, six did not give sufficient information to justify the plans being sent to the Board of Works, and they had been referred back for further particulars. By-laws had been agreed upon within the last few days, under which the remaining applications were to be dealt with, and one of the plans had received the sanction of the Board of Works, and been referred back to the commissioners to ascertain what sum should be advanced. Another of these plans was under consideration; and as to another, it was expected that a loan of 20,000l. would be asked for.

TENDERS

For building Fire Brigade Station, for the Board of Works, Sheppard's-lane, Brixton. Quantities by Mr. Young:—

Johnson	£2,220 0 0
Beaser	2,220 0 0
Taylor	2,130 0 0
Easton & Shaw	2,080 0 0
Keastace	2,040 0 0
Sahy	2,040 0 0
Piper & Wheeler	2,042 0 0
Oliver & Co.	1,987 0 0
Nutt & Co.	1,867 0 0
Webb & Son	1,884 0 0
Wigmore	1,880 0 0
Mudley & Rogers	1,948 0 0
Eaton & Chapman	1,884 0 0
Fish	1,890 0 0
M'Laclan	1,873 0 0
Nightingale	1,843 0 0
Marsland & Sons	1,835 0 0
Sawyer	1,789 0 0
Elby	1,714 0 0
Mann	1,687 0 0
Cooper	1,687 0 0

For villa residence, at Blackheath, for Mr. A. W. Gibbs. Mr. C. W. Courtney, architect. Quantities by Mr. Hart:—

Hart	£1,695 0 0
Welby	1,994 0 0
Prince	1,963 0 0
Webb & Sons	1,880 0 0
Green	1,874 0 0
Bland	1,834 0 0

For villa residences, at Loughton. Messrs. Lander & Bedells, architects:—

Manley & Rogers	£1,475 0 0
Williams & Co.	1,469 0 0
Dobbs	1,443 0 0
Dove, Brothers	1,365 0 0
Webb & Sons	1,283 0 0
Green	1,275 0 0
Mann	1,219 0 0
Egan	1,201 0 0

For new Congregational Church, Tympoth, Northumberland, exclusive of foundations, which are already in. Mr. Thomas Oliver, architect. Quantities supplied by the architect:—

Hutcheon	£4,470 0 0
Scott	4,363 0 0
Welton	4,345 0 0
Elliot	4,137 0 0
Robinson	3,900 0 0
Robinson (accepted)	3,880 0 0
Hardwick (tender incomplete)	3,769 0 0

For five villa residences, at Hornsey, for Mr. T. Lawes. Messrs. Bacon & Ball, architects. Quantities by Mr. James Gandy:—

Emery & Co.	£7,601 7 6
Robinson & Sons	7,325 0 0
Kilby	7,280 0 0
Francis	7,143 0 0
Auley	6,961 0 0
Perrett, Jun.	6,965 0 0
Spearing & Condy's	4,600 0 0

For erecting new relief offices and dispensary, for Southampton Incorporation. Mr. F. A. Skilton, architect. Quantities supplied by Mr. H. H. Pether:—

Stevens	£1,298	£76
Conway	1,230	90
Martin	1,230	150
Sander	1,198	150
Adams	1,178	150
Gambling	1,128	150
Phillips	1,080	220
Bull (accepted)	1,115	236

For alterations to the Crown and Shears public-house, Minories, E. Messrs. Humphrey & Son, architects:—

Stephens & Watson	£275 0 0
Sparks	739 0 0
Scrivenor & White	738 0 0
King & Sons	688 0 0
Emor (accepted)	613 0 0

For new warehouses, Ost-lane, City, for Mr. Charles Beckwith. Mr. George Elkington, architect:—

Gannon & Sons	£2,738 0 0
Brown & Robinson	2,705 0 0
Kilby & Co.	2,631 0 0
Brace & Co.	2,464 0 0
Piper & Wheeler	2,368 0 0
Coleman	2,378 0 0
Hitchcock	2,348 0 0
Wells (accepted)	2,285 0 0

For public-house, at Acton, for Mr. J. J. Sterne. Mr. M. W. Hors, architect. Quantities supplied by Mr. Sidney Young:—

Butt	£1,725 0 0
Langmead & Way	1,697 0 0
Robson	1,607 0 0
Mann	1,645 0 0
Salter	1,550 0 0
Nightingale	1,480 0 0
Eborall	1,488 0 0

For works, at Cambridge House, Ladbrooke-grove, Kensington Park, for Mr. J. T. Thomas. Mr. C. E. Davis, architect:—

Jenkins	£1,082 0 0
Piper & Wheeler	1,063 0 0
Colley	1,064 0 0

Johnson	808 0 0
Butt	808 0 0
Nightingale	808 0 0
Neal	783 0 0
Eborall (accepted)	748 0 0
Norton, Brothers	598 0 0

For building three villa residences, for the Walton Tenth Company, at Walton-Thames. Mr. R. Kimball, architect. Quantities supplied:—

Curtilage	£4,785 0 0
Horstages	4,427 0 0
Johnson	4,400 0 0
Stevenson	4,206 0 0
Neale	4,030 0 0
Warne & Co.	3,875 0 0
Nightingale	3,070 0 0
Harris	3,689 0 0
Hunt	3,964 0 0

For new warehouse, Southwark-New-street, for Mr. Bates. Mr. E. Bates, architect. Quantities supplied by the architect:—

Hart (accepted)

TO CORRESPONDENTS.

O. E. B. A. (we cannot allude to it without particulars)—Luz must look back for himself.—A. D. (yes. Look to the Building Act).—A. Wanderer (in type)—G. E. A.—A. & Co.—W. W. L.—C. O.—H. D.—E. W. S.—Messrs. H. & Sons.—J. A. P.—Constant Reader.—Messrs. G.—H. D.—E. R. K.—S.—E.—W. R.—J. D.—T.—A. B.—P.—C.—J. H. S.—W. S.—J. D. P.—C.—J. P.—R.—S.—J. R. M.—J. H.—W. M. G.

We are compelled to decline printing out books and grating designs. All statements of facts, lists of tenders, &c., must be accompanied by name and address of the sender, not necessarily for publication. None.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

Advertisements cannot be received for the current week's issue later than **THREE O'CLOCK P.M. ON THURSDAY.**

The Publisher cannot be responsible for ORIGINAL TESTIMONIALS left at the Office in reply to Advertisements, and strongly recommends that COPIES ONLY should be sent.

TO SUBSCRIBERS.

NOW READY. The TWENTY-FOURTH VOLUME of "THE BUILDER" (bound), for the year 1866, Price One Guinea.

CLOTH CASES for binding the Numbers, price Two Shillings and Ninpence.
COLOURED TITLE-PAGE, Gratis.
SUBSCRIBERS' VOLUMES will be bound on being sent to the Office, at a cost of Three Shillings and Sixpence each.

[ADVERTISEMENT.]

C HURCH, TURRET, and STABLE CLOCKS. W. BENSON, having erected steam-power and improved machinery for clock-making, at the manufactory, Ludgate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machine, especially cathedral and public clocks, chiming tunes on any number of bells. A descriptive pamphlet on Church clocks post free for one stamp. Watch and clock Maker by Warrant of Appointment to H.R.H. the Prince of Wales, and maker of the great clock for the Exhibition, 1862. 25, Old Moor-street, and 33 & 34, Ludgate-hill, E.C. established 1749.

ADVERTISEMENTS.

NEWSPAPERS and MAGAZINES.—Messrs. WYMAN & SON, Printers of "THE BUILDER" and other First-class Publications, beg to call the attention of Proprietors of Newspapers and Periodicals to the unusual facilities they can afford for the production of the above class of Work in the regular and in the best style.—Lancet's Iron Steam Printing Works, 74-75, Great Queen-street, W.C.

SCIENTIFIC BOOKS, published by ATCHLEY & Co., 106, Great Russell-street, Bedford-square, London. WORKS ON ENGINEERING, ARCHITECTURE, SURVEYING, MILITARY CIVIL, and MECHANICAL DRAWING, MONUMENTS and ORNAMENTAL DESIGN.—A new list sent free. If amount of books remitted, postage paid.

NEW COURTS of LAW DESIGNS.—An important Descriptive and Critical Article upon these subjects, by a eminent Writer on Architecture, will appear in the MARCH number of "BRICKLAYER" a London Magazine, conducted by M. H. B. Ready February 21. Price One Shilling. Office, Warwick-house, Palace-street-row.

MANUAL of HYDROLOGY. By N. BARNARD, Esq., F.R.S. Part I.—Hydraulic and other Tables for computing the flow of Water, Gas, and other fluids through pipes; with descriptive notes. Part II.—On Rivers and Volume of Water; on Percolation; on Falls and Springs; on the Flow in Sewers, and Water Supply. With plans of tidal canals, sections of rivers, &c. Part III.—On the hydraulic character of their hydraulic conduits. Part IV.—On Tides, Tidal Rivers, and Estuaries; showing the motion assumed by them where there is the bore, and where the tide wave variable; on the Effect of Improvements in Tidal Rivers, in the shape of tidal canals, sections of rivers, &c. Part V.—On Rainfall and Evaporation—containing Tables of rainfall at every elevation throughout the British Isles, Prussia, Germany, Italy, Russia, North America, Australia, and India, with best experiments on evaporation in various climates. Price 6s. Part VI.—On the hydraulic character of the tidal rivers price of 2s. Bound by WATERLORD & SONS, 43, Pall-mall-east, West-london; and may be had of SWEENEY & Co., WEALES, F.R.S. 28, GOSWELL; or the SOLEMAN, or through any Bookseller.

To Architects, Civil Engineers, Builders, &c.

THE NEWEST DESIGNS FOR LAMP POSTS, Dwarf Gas Pillars, Brackets, Lamps, Gates, Railings, Balcony Panels, Stable Fittings, Columns, &c. &c.

will, upon receipt of particulars, be forwarded free, on application to TURNER & ALLEN, Ironfounders, Engineers, &c. 201, Upper Thames-street, E.C.

SCHOOLS and SCHOOL HOUSES, Parochial and National, in the Gothic, Old English, Tudor, and Elizabethan styles, illustrated by a Series of Plans, Elevation, and perspective Views, with Estimates, and Descriptive Letter-press. By H. E. KENDALL, Jun. M. Litt. A. F. S. A. Twenty-four beautiful lithographic Plates. Small 6s. half-bound morocco. Published at 22, 12b. 6d. offower at 11.8v. by BRADLEY T. BATESFOR, Architectural and Engineering Bookseller, 69, 52, Regent-street, London, W.C. N.B.—A very few copies for sale at this price. Post-office orders payable at the Holborn Office.

ARCHITECTURAL and ENGINEERING BOOKS.—A large COLLECTION of New and Second-hand English and Foreign BOOKS, relative to Architecture, Building and Decoration, Civil and Mechanical Engineering, &c. etc. at the lowest prices, will constantly be found at BRADLEY T. BATESFOR, Architectural and Engineering Book Dealer, 69, 52, Regent-street, London, W.C. N.B.—A Catalogue forwarded gratis and post-free on application as above.

ROYAL POLYTECHNIC.—The Head of the Deplacated Spawning, and the Editors, in Professor PEPPER'S Scientific Entertainment, daily, at half past 5 and last night at 7. "ART" in a beautiful Star (constructed by Messrs. De Laing), appears to float in the Air. The Christmas Carol, by the kind permission of Charles Dickens, sent, with three Effects, given by F. DAVENPORT, Esq. daily, at 4.15 and 5.15. The Story of WHITE LETTER and his Cat, told by J. L. KING, Esq. Weekly, Miss Bianchi Reeves.—Open from 12 to 6 and 7 to 10.—Admission 1d.

CHILDREN'S SOCIETY, King's Arms, 69, Pall-mall-east, London, W.C. DECORATIVE PAINTERS.—GILBERT, experienced in every branch of the trade, may be ENGAGED at the above Society House. Postal communication immediately attended to. J. TUNGATE, Secretary.

SEWER VENTILATION.—DETAIL DRAWINGS and particulars of the most effectual system of SEWER VENTILATION will be supplied to Engineers and Architects, on application to EDWARD GEORGE, Field House Fire Clay and Sanitary Tube Works, Huddersfield.

PERFECTION in BOOK-KEEPING.—A Builder desiring a ready and systematic plan to have a list of Models for Builders' Books by Double Entry, in which was awarded the Prize offered in "The Builder" of last September, and which has been adopted by many large firms. Also a modern arrangement, by Single Entry, suitable for small Builders.—Address, R. A. 4, St. George-road, Regent's Park.

THE SHIRLEY LOCAL BOARD OF HEALTH, Southampton.—WANTED, a steady, honest, and thoroughly competent FOREMAN, or other subordinate, for the Shirley Drainage Works.—Application, giving references to previous engagements, and stating salary required, to be made in person to J. G. POOLIE, Architect and Surveyor, 21, Portland-street, Southampton. February 20th, 1867.

DRAINAGE, DEODORIZING, and SINKING MANTIE WORKS, WATER SUPPLY, &c.—An Engineer of experience is prepared to furnish PLANS and ESTIMATES of the above, either approximate or in detail, on the most moderate terms.—Address for enquiry, ALFRED SWEENEY, Stone and House, Kensington-green, London, S.

ENGINEERS and CONTRACTORS assisted in Monthly Measurements and Taking out Quantities, Levels given, Railway Curves or Trigonometrical Lines set out. Orders and Iron-work designed. Plans of Sewer-walling and Gridding on a new and approved principle.

PARTNER WANTED.—The Advertiser has been established as a DECORATOR and BUILDER in the West of London eight years, and is desirous to extend the Building Branch, for which he requires a PARTNER, with at least £1,000 of command. Active or otherwise.—Address, 455, Office of "The Builder".

PARTNERSHIP.—TO ARCHITECTS and ENGINEERS.—A moderate premium will be paid by a Gentleman, who is a good person for an architect or draughtsman, for a suitable PARTNERSHIP in town or country.—Address, by letter only, with particulars, 231A, 23, Portico-road, Fiddington, W.

TO CAPITALISTS.—WANTED, a Sleepy PARTNER, with from £1,000, to £2,000, to join the Advertiser in carrying on a Brickfield, situated in the centre of a good building neighbourhood, where the bricks can be sold on the ground. The field is good working order.—For full particulars apply to first instance, by letter, to H. J. H. 30, Basinghall-street, City, E.C.

A RESPECTABLE LAD WANTED, as an APPRENTICE to the Painting, Graining, and Whiting. A premium offered.—Address, 71, Bedford-square, Abney-road, St. John's Wood.

CITY OF LONDON.—SANITARY INSPECTOR.—The Commissioners of Sewers of the City of London will meet in the Guildhall on the 21st of FEBRUARY, at 10 o'clock, for the purpose of electing a TWELVE MONTHS SANITARY INSPECTOR. Candidates must be practically acquainted with building, surveying, and related to their application, and send in their full particulars as to past employment, &c. with certificates of age, &c. addressed to the undersigned, and before MONDAY, the 26th MARCH next, and will have to attend a Committee for examination on a day which will then be communicated to them. The person elected must give up his whole time to the duties of the office, particulars of which may be had on application to the undersigned, EDWARD GEORGE, 59, 52, Regent-street, W. Principal Clerk. Sewers Office, Guildhall, 19th February, 1867.

WANTED, a competent Man, who thoroughly understands PLUMBER'S BRASS WORK, and the general business of a Plumber's Brass-work Establishment.—Address, 59, Office of "The Builder".

TO BRICKLAYERS. WANTED, an experienced Man as WORKING FOREMAN at JOBSING or BUILDING, for about Ten Bricklayers. Must be steady and of regular habits.—Apply to Mr. B. PARHAM, Builder, 20, Upper Martin-terrace, Regent-street.

WANTED, in a Country Builder's and Surveyor's Office, a useful, practical, and experienced CLERK, well up in accounts, accustomed to superintend and measure up works taking out quantities, estimating, and the usual routine of an Office—Apply, stating terms and references, to SUPERVISOR, Post-office, Andover.

WANTED, in an Architect's Office, a competent ASSISTANT—Apply to Mr. ELKINGTON, Architect and Surveyor, 95, Cannon-street, City.

TO SLATERS. WANTED, for a Permanency, a GOOD WORKMAN. One who can fill up his time at Flushing or Bricksetting.—Apply to SMITH, Brothers, Northampton.

WANTED, by a BUILDER, &c. an energetic and competent CLERK—Must be good at putting out, estimating, measuring, &c.—Address, stating age, salary required, and particulars, to Mr. B. Powell, 5, Shepherd-street, May Fair, W.

TO THE TIMBER TRADE. WANTED, an experienced TOWN FOREMAN.—Apply to Mr. DUKTON, 15, George-street, Manon House, City.

WANTED, a PLUMBER and GAS-FITTER.—Apply, by letter, at 35, Chancery-street, Croydon.

TO PLUMBERS and GAS-FITTERS. WANTED, a steady Man—a thorough workman. A married man preferred.—Apply, stating age, salary, and references, to WILLIAM GREENE, Plumber, 85, Saffron Walken, Essex.

WANTED, TO MARBLE CARVERS, &c. MARBLE WORKS. Must be good draughtsmen, and able to carve, Wags, &c. a week, and house free.—Apply to ALEX. COLLIER, Kilkenny, Ireland.

WANTED, for a Constancy (if suitable), in the neighbourhood of Barnham, Wiltshire, an energetic WORKING FOREMAN of CARPENTERS.—Address, stating age, wages required, &c. to 415, Office of "The Builder".

WANTED, in a West-end House of Business, a CLERK of active business habits, well acquainted with book-keeping and measuring, and accustomed to the management of lands in the Building trade.—Good references required.—Address, G. W. 15, Great Castle-street, W.

TO ARCHITECTS. WANTED, a RE-ENGAGEMENT, in the Office of a London Architect, as ASSISTANT. Several years' low experience, and first-class references.—Address, H. 10, Lavender-via, Battersea.

TO ARCHITECTS, &c. WANTED, a Permanent or Temporary ENGAGEMENT, by a DRAUGHTSMAN of considerable experience. Is able to prepare and finish drawings from rough sketches. Classic style. Salary moderate.—Address, J. M. C. 20, Mableton-place, Euston-road.

TO ARCHITECTS and CONTRACTORS. WANTED, by a practical Man, of many years' experience, a RE-ENGAGEMENT as CLERK of WORKS or GENERAL FOREMAN. Good draughtsman and surveyor. Well up in all branches of the building trade. Good testimonials. Town, country, or abroad.—Address, D. W. care of Mr. Fatee, Stationer, Exeter-street, Sloane-street, S.W.

TO ARCHITECTS, &c. WANTED, an ENGAGEMENT, by a competent CLERK of WORKS, who has just completed a Church at West-end and good references.—Address, A. D. Z. 19, Chichester-street, Piccadilly, S.W.

TO PLUMBERS and CONTRACTORS. WANTED, by a respectable Young Man, a permanent situation as PLUMBER and GAS-FITTER, casting, Glazing and Painting if required. Wages not less than 7s. per hour. Good references.—Address, Mr. WOODMAN, Stonehouse, 4, Humer-road, Hackney Wick.

TO PLUMBERS and BUILDERS. WANTED, by a Young Man, who is a first-class Plumber, a SITUATION as PLUMBER at Three-bunch Hand. First-class references if required.—Address, J. W. 5, Crowland-road, St. Pancras, N.W.

TO MASTER PLUMBERS, &c. WANTED, a JOB, by an experienced Plumber, aged 30.—Address, F. L. Plumber, 7, Bury-street, Bloomsbury, W.C.

TO ARCHITECTS and BUILDERS. WANTED, a SITUATION, as CLERK of WORKS or FOREMAN, to take charge of a job. The Advertiser is a thoroughly efficient Joiner, with a knowledge of drawing, &c. Upwards of seven years' unquestionable reference from present employer.—Address, E. A. 57, Queen Margaret's-grove Millenary Park, Kingston, Surrey.

TO BUILDERS. WANTED, by the Advertiser, aged 20, an ENGAGEMENT in a Builder's office in London. Can square dimensions, copy and trace drawings, and understand the practical part of the trade. Good references.—Address, A. H. 8, Frost-office, Little-Brittain.

TO COUNTRY PAINTERS. WANTED, by a steady Man, a constant situation as PAINTER, GLAZIER, PAPERHANGER, and DISTEMPERER, generally useful.—Address, T. WIDGESS, 5, Portland-place, Wainsworth-road.

TO PAINTERS. WANTED, by a steady Young Man, a constant situation as PAINTER and GLAZIER; generally useful. Wages not less than 10s. per week.—Address, G. COLLINS, 5, Portland-place, Wainsworth-road.

TO CARPENTERS and BUILDERS. WANTED, by a Young Man, aged 21, with three years' experience in carpentry and joinery, a SITUATION as EMPLOYER.—Address, T. E. Post-office, Park-street, Sovery.

TO BUILDERS. WANTED, by a thoroughly practical Man, a RE-ENGAGEMENT as SHOP FOREMAN of JOINERS, Good references. Town or country.—Address, &c. care of Mr. Audit, No. 9, Skinner-street, Clerkenwell, E.C.

The Builder.

VOL. XXV.—No. 1256.

How Not to Invest.

EW subjects have attracted more constant attention than prognostication of weather. Rules

of more or less exactitude are given us to enable us to ascertain what the morrow will, in this respect, bring forth, by authors of every grade. We find them in the Georgics of Virgil, and we find them in the almanacs of Zadkiel and of

Old Moore. Weather forecasts were but the other day published by the aid of the English Government. One only drawback has been found to attend the efforts of the astrologer, the naturalist, the man of sciences. The rules, no doubt, are right enough, but the weather will not go by the rules; so, after all, we are reduced to the simple and cumbersome precaution of carrying an umbrella on all occasions as the only absolute weather wisdom in the latitude of London.

There is, however, one sort of observation as to the weather that possesses a positive value. When we know what is the state of the barometer at different points of Europe at the same time, we then form a very tolerable guess at what is coming. When barometers are high in the northern countries and low on the Atlantic and Mediterranean coasts, the resulting north wind is pretty sure to bring cold weather. In this case we do not so much predict as infer, from the action that is indicated as taking place, the natural results that will follow. We do not prophesy, we observe.

In the unusually depressed state of that which, to so many of us, has for some time been a more serious matter of observation than the weather, namely, the public confidence, the barometer of Lombard-street has been long and anxiously watched for symptoms of change. Nothing has been read for many a month but the doleful counsel, "Expect much rain about this time." At last the constant fall has ceased, out no gentle and steady rise, so grateful to the expectant of fine weather, has succeeded. The financial atmosphere has remained in the most capricious state of unstable equilibrium. Thunder-storms there have been; but they have not cleared the air, and the oldest observer cannot remember such a period of prolonged gloom.

That the time of change must come, experience forbids us to doubt. It may be rapid when it sets in; it may be gentle and steady. That can be only prognosticated as a guess. But when we find indications of the variation of pressure, or of the return of a more buoyant state at other stations, it is natural to expect that the change will, before very long, affect our own shores.

One of these indications has just reached us. While the City barometer still remains with unaltered index, we hear of a rising of the mercury on the Continent. "The German loan-markets," we are informed by a very competent authority, "have rarely been so buoyant as at present." What does that buoyancy promise?

A period of great activity in our own public works has been succeeded by a period of stagnation. It is not because all such enterprises as

contain within themselves the elements of success are accomplished. Far from it. On every side, at home and abroad, a careful examination will detect much that requires to be done,—much that, if properly executed and managed, would amply repay those who undertook the work. The returns on our railways are slowly overtaking the rates of dividends that was thrown away in 1845. In spite of a profuse and lavish expenditure,—in spite of the sums wasted in Parliamentary conflicts,—most of the old lines are steadily increasing the dividends on their swollen capital. The effect of the application of science to the service of man is becoming daily more apparent, and that in spite of the reckless manner in which the promises of increased wealth has been so often disappointed. The commerce of Great Britain was never so extended as at the present time. The condition of the revenue and of the expenditure of the empire was never so satisfactory. At no period of our history did there seem such a fair field open for legitimate enterprises, and no period has there been less apparent probability of its resumption.

The cause of this apparent contradiction is not far to seek. In every quarter you will hear the same cry. There is a want of confidence. Money is not only plentiful, but is becoming more than plentiful—it is lying idle. Men prefer to let it lie idle rather than risk it. The dog has been so badly burned that it dreads not only the fire, but anything which can convey the sensation of warmth. We are balancing a period of extreme and baseless confidence by one of equally groundless and equally injurious mistrust.

This general feeling is by no means confined to the enterprises regulated by the engineering and architectural professions. It is not merely commercial, not exclusively even financial; neither is it confined to our own country. Everywhere man seems to look with suspicion on his neighbour; and the worst of this is, that it is at the same time an impractical and a destructive suspicion. It is the case of the patient who will neither take the advice of his doctor, nor bestir himself to recover health by any exertion of his own.

We have instances of this morbid state of feeling on the largest scale. They seem present in the bosom of more than one of those deliberative assemblies on which the hopes of so many repose. Any effort to grapple with the great questions of the day is met with a chorus of depreciation. The general condemnation of every attempt at progress cannot be called criticism, for criticism involves a knowledge of the subject. It rather results from that state of suspicious and ignorant incredulity which is the most formidable barrier to any kind of improvement. Ahuss may defeat its own object, direct attack may be turned upon the assailant; but a shrug and a sneer are as unanswerable as they are often fatal.

There are some features in our own social condition that indicate the probability that this general and hopeless state of distrust may have the result of throwing on the executive government responsibilities which each person is so anxious to shift from his own shoulders. Our chronic fear of undue governmental influence is swallowed up by our acute fear of being unable to watch our own interests. A nation which in three years, or, rather, in two years and a half, found a sufficient number of subscribers to the new form of limited companies to register capital to the amount of 519,428,724*l.*, is now leaving its spare cash unemployed for fear of being taken in. What more likely than that the next feature in our anæmia will be a rash to invest in such securities as bear the sanction of Public Law. All must go wrong if a Government ceases to pay. Foreign Governments, as a rule, have paid with exemplary regularity the interest on their loans. It is, therefore, by no means an

unlikely supposition that the buoyancy of the German loan-market may indicate a coming buoyancy in the English market for foreign loans.

Why not? Why should people be content with 2½ per cent. when they may receive 5 per cent? 1,000*l.* invested in English Consols will only return 34*l.* 6*s.* 8*d.* per annum. Why not invest in French *Rentes*, and receive 43*l.* 5*s.* for your interest? Why not, even more eagerly, invest in Italian Stock, and find your income raised to 92*l.* 10*s.*? What is the reason that what we may call, to coin an appropriate name, the Penecimeter, stands at such a different height at London, at Paris, and at Florence?

Something, of course, goes for convenience. It is worth something to have your dividends paid in sterling at the bank, instead of in francs or lire, which have to be remitted to you through a foreign banker. But difficulties of this nature are moderators in their amount, and, if they were all, would rapidly evaporate before a profit of nearly three to one. There remains, then, the ugly certainty that, after all, the investor has more confidence in the English than in the French or the Italian funds,—much more confidence,—confidence that, represented by a pecuniary measure, is in the extreme difference nearly as three to one.

Now, when the foreign loan-market becomes buoyant, this nervous want of confidence disappears. That is the meaning of buoyancy. People are not afraid to buy. It is true that they may not buy with the view of a permanent investment. They may buy in the hope of a rise, and with the intention to sell at a profit. So long as such investments are not the fashion, a man has to rely on the dividends alone. He may have no good reason for anticipating any hesitation as to their payment, but his property will not be readily convertible. Convertibility is, with many, as important a desideratum as good return. A rate of dividend, therefore, that will not attract the *bonâ fide* investor, when alone, will attract with magnetic force when the investors count by tens instead of by units. It will cause a notable rise in price when the tens amount to hundreds.

And after all, in nine cases out of ten, what other guide has the would-be investor than the rash of his fellows? Who among us has the time, or the means of information, or the patience, to sit down and make a calculation for himself? Thus might he reason. If I purchased at the present rate, I shall have 6 per cent. for my money beyond the return which I should have for an investment in Consols. If such-and-such a Government, then, satisfies its creditors for twelve years, I shall have recouped my principal, and my stock will, by that time, have cost me nothing. Whatever it is then worth will be so much to the good. How long, therefore, can I count with tolerable certitude on the stability of the Foreign Government, and on the maintenance of its good faith?

An investigation of this nature, sound as it may be in its principle, is not to be expected from the generality of men who are seeking to invest their money. They do so on the ground that A, who ought to know, says it is a good thing, or that prices have gone up ¼ per cent. while they have been making up their minds. Unfortunately A, who ought to know, cares more to be sure that B, C, and D will follow his example, or, as the case may be, his advice, than to make the more troublesome inquiry on his own behalf. So when, by some of those impulses which never fail when the season is propitious, the movement commences, it continues with increasing momentum, and takes its rank in that great decennial wave of flow and ebb which has brought ruin to so many firesides since 1825.

We can offer a little light to B, C, and D. But a rushlight, it may be; but still enough to make

them see the propriety of working out, each for himself, the simple formula we have stated. We can tell him how much our foreign friends will have to borrow,—of us if we will let them, of somebody at all events,—in the next ten years. We can tell them this, not as matter of prediction or prognostication, but as matter of deduction from well-ascertained data. We cannot even say that the effort will be crowned with success, but we can tell the alternative. Three ways, as usual, lie before us. We think that a careful study of the map will deter any traveller, not hopelessly urged on his journey, from following either path.

There was a well-known English nobleman who was ultimately distinguished, even more than by his exalted rank, historic name, and princely seat, by his gigantic embarrassments, and by results thereof unusual to men of his order. This nobleman had a peculiarity which, according to the testimony of those who should know best, cost him something disproportionate to the luxury of his indulgence. He never would be without a certain sum of money—1,000,000, or so—in his possession in notes or gold. He made a point of it. In the state of the ducal revenue this sum was only to be obtained by the expensive process of borrowing; and the loan had, of course, to be negotiated, not in the City, but at the West-end, where the Bank minimum does not rule the rate of the day—or rules it only when multiplied by ten. So long as there is something hard upon certificate of ultimate payment, loans are always to be had on these terms (or were at the time we refer to) in the parishes of St. James and St. George. The upshot was, that his Grace always had his money; that he often made no use of it—that is, of this habitual reserve; so that when the three months' promissory-note on which it was advanced came due, the identical bank-notes which he had furnished were handed back to the lender, with, say a tenth more for the three months' interest. The plan had this radical defect, that if the nobleman could have made up his mind to do without this reserve of unused cash in hand for the short period of two years and a half, he would have saved the full amount by the mere delay.

Now those who would borrow the money of John Bull are in even a worse predicament than the nobleman to whom we have referred. They cannot afford to wait. They do not, indeed, borrow at 40 per cent.—at least, not as yet. But borrow they must, or else they must cease to pay for that which they have already borrowed. How much they will need between this and 1876 we may tell with some accuracy from totting up how much they have borrowed between this and 1856.

We must just make a very honourable exception. If Myrlheer wants our money we cannot do better than accommodate him: but then he does not want it. Alone in the world the Dutch government has, within the last ten years, paid off 16 per cent. of its national debt. All honor to the Dutchman!

Belgium and Great Britain must also be spoken of with respect. Omitting to notice some of the smaller and more prudent German powers, because no one is yet in a position to say what will be the effect of the war of 1866 on their financial position, Belgium and Great Britain alone, of European states, have paid the dividends of the last ten years out of revenue. The debt of Belgium, and the united debt of Great Britain and of India, have, during the last ten years only increased respectively by 4 and by 3½ per cent. For nine years out of ten these countries, therefore, have faithfully satisfied the public creditor out of their revenues. In doing so they stand alone.

It requires no great effort of the imagination to impersonate the remaining powers of Europe as visitors to the well-stored bank of John Bull. The Spaniard stalks by, with the corner of his cloak thrown over his shoulder, and casts side-long glances at the cash-box. He does not beg,—not that he is ashamed, but that he knows it would be needless,—but he cannot resist the fascination of the jungle of counted gold. Most Southern people seem to feel that the very aspect and neighbourhood of money have something of the nature of sunlight; they like to get as near to it as they can. The Greek and the Italian are more hopeful than their experienced and repudiating cousin. They draw nigh with intent glances and agreeable smiles, and with a very consistent and dramatic story ready, so soon as they find a moment in which to tell it. The German looks on with a frown, a contribution

cigar in his mouth, and the needle-rifle in his grasp. He, too, thinks the moment inopportune. It is the Frenchman who, with an easy air, takes the pas to which he is no doubt entitled. "Mon cher Boule," says he, "I have no want of you. My own countrymen will supply my need. The discovery of the day is to go to the millions for your loans, not to the individuals. I find the idea to answer. During the last ten years I have borrowed 150,000,000 of what you call sterling. I pay 10,000,000 sterling a year in taxes more than you do. I spend 30,000,000 a year more than I did when I adopted the Imperial régime. My income will soon equal my expenditure,—next year, or in 1868 at farthest. Meantime the milliard that I mean to spend in public works will be forthcoming if I lift my finger. It would be only out of neighbourly feeling if I let you subscribe for ever so small a part of it. I shall only require two or three other milliards between this and 1876 to do as I have done for the last ten years, and I shall thus readily pay the interest on my *rente*. I am in a proud and enviable position, and am happy to give you a lesson. It is not every one who can increase his funded capital at the rate of 16,000,000,000 a year for ten years running. I can, and I mean to go on. Some of my neighbours you can make a good thing by helping. My friend here, who has only increased the amount of his *rente* by 57 per cent. during the last ten years, will require 100,000,000 sterling to make a railway to Siberia. My Hungarian neighbour would be glad of a similar sum in order to resume specie payments. My Italian friend and *protégé* will require nearly twice as much in order to make both ends meet, while he is trying how to *fare da se*. These are the chief investments which offer themselves at present. I am not particular for a month or two, or even for a year or two; but, if you will take the matter *en bloc*, you will find that nine or ten of us have borrowed, rather more than 700,000,000,000 sterling since 1856; and that, to pry a regular interest on this, and on what we borrowed before, we must have at least an equal sum before 1876, or the consequences will be unpleasant. In fact, as I am not in the market, I do not mind saying that we have had to borrow all the *rente* we have paid for the last ten years. To do without this assistance we should have to raise our taxes all round 30 per cent. People cannot stand that, so, when you cease to lend, we,—very reluctantly,—shall be obliged to cease to pay! You see it is to your interest to go on."

It is possible that our neighbour might not be so frank. The outline of the case, indeed, is thus correctly stated, but it might be thought prudent rather to rely on questions of detail. So much goes to the thorough examination of a matter! Every man of the world acknowledges the duty of putting the best foot foremost. Thus the Frenchman may tell you with truth that his annual expenditure, per head, of the population, is 5s. less than that of England; that the actual commerce of France is greater than that of Great Britain; that her area is nearly double, and her population eight millions more numerous; so that her national debt amounts to only 16s. per head, instead of the 30s. per head owed by the Englishman. All that is true. But it may be regarded in another light. The area and the population of France are much larger than our own, but the density of her population, that sure gauge of prosperity in an old country, is as 38 to 51. Her commerce is larger in total amount, but, taken per head, it is only as 11 to 17 compared with that of Great Britain. Her debt is less in amount and less per head, but it has increased nominally cent. per cent., and virtually 58 per cent. during the last ten years, so that every son paid to the public creditor with one hand has been borrowed from him with the other. That is the view of the same case with the other leg put forward.

We hope, therefore, when the great reservoir of unemployed money that is weekly swelling more and more within its dykes shall at last overflow, as it assuredly must do, that the diversion of the fertilising stream will not be turned to rendering buoyant foreign loans. If we see further indications of such a tendency, we shall gladly strengthen the dykes by the rude statistical facts of which we have above indicated some of the results. Better take the debentures of the A, B, and C railway, which, if they represent neither capital nor interest, at least have a credit on the bank of hope, than invest savings, or hope for profit, in the never satiated quicksands of foreign loans.

THE MAGIC OF MASONRY.

Of late years our discarded superstitions have come into vogue again for a new purpose. It is supposed that some of our old household stories, sayings, spells, and beliefs in fairies, goblins, hobgoblins, and other varieties of supernatural beings, are fragments of some old mythology that obtained among men in pre-historic times; that the deeds of the giants, dwarfs, imps, and elves to which we used to listen breathlessly were, possibly, articles of faith to the men of the iron, bronze, and stone ages, and, certainly, accepted facts with thousands in the Middle Ages; and that by gathering these together, piecing them, contrasting them with the forms the same legends have taken in other countries, we may recover some long lost lore. As we have said, it is only recently that the idea of considering these old wives' tales in the light of traditions handed down orally from Cælo to pre-Celtic people has taken root. Bishop Percy and Sir Walter Scott, the revivers of popular interest in Mediæval literature, put in no claim for so remote an origin for the "great thoughts of heart" they collected. But when we consider the tenacity with which man clings to ancient customs, especially when undisturbed by much contact with other peoples, something may be said for those who suppose that the lip-lore in question has the antiquity now assigned to it. The sacrifice of animals to avert some threatened calamity is not unknown among us at the present day, and yet science and theology have been equally opposed to such a proceeding for centuries. Yet the custom is clung to by some minds. Mr. Henderson, Durham, records that less than fifteen years ago one of a herd was so slaughtered in the county of Moray when threatened with the murrain; and, going farther back, but not beyond the bounds of the enlightenment of modern civilization, in the records of the Presbytery at Dingwall there are entries that show that the sacrificing of bulls and pouring libations of milk on mountains was practised at the island of Innis Maree, in Loch Maree, down to A.D. 1678; especially, that several members of the Mackenzie family were cited before the Presbytery "for sacrificing a bull in a heathenish manner, on the island of Saint Rufus, commonly called Eilan Moury, in Lochev, for the recovery of the health of Cristane Mackenzie, who was formerly sick and valentudinair." Now, if the tradition of this Druidical custom remained in details vivid enough to court a trial of the efficacy of the cure, how can we deny the same vitality to some of the legends of the same period? And, when we find curious legends full of uncouth power in the possession of country people, especially among those living in out-lying, hilly, and secluded places, in which the incidents as related are alike as default to scientific facts as to common sense, and could have only originated in minds that were totally unfettered by the exigencies of probabilities and possibilities, and yet were bold, plastic, and fanciful, we may suppose that we have the thread of some old story in our hand that was woven before our primeval forests were felled.

Among this quaint lip-lore there are a few statements relating to masonry, which we give as we have met with them. In the instances in which supernatural beings have endeavoured to prevent building on certain spots, we should probably not be wrong in assigning an Oriental origin for the main facts of the legends. The abandoned tower of Babel, still standing in the likeness of a mighty mound of ruin, as described by Mr. Layard, would not be without influence or celebrity; and tribes moving westwards would bring its wondrous story with them. A general belief that supernatural beings occasionally interfered to prevent the progress of building would find fresh expression in particular instances; and is, probably, the root of the particular traditions we are about to mention. In various parts of the country it is stated by the local residents that a certain house in the neighbourhood, generally the hall or castle, was attempted to be built on a different site; and after every commencement the work was always found overthrown next morning till the site was altered, when the building was allowed to proceed. A story is current to this effect concerning Callaley Castle. The edifice is seated on low-lying ground at the base of a lofty hill, about five miles north of Rothbury, in Northumberland, which is clothed with wood, ferns, and heather to its summit. From the hill a lovely prospect is gained. The rich vale of Whittingham on one side,

and the low country watered by the Coquet on the other, the one hemmed in by the Cheviot Hills in the distance, and the other bounded by the green and grey hills around Rothbury, are spread out at the feet of those that climb the towering crag; and it is at this elevation that it is believed the first builders endeavoured to plant the castle. The oldest portion of the present edifice appears to be of Edwardian antiquity. Whether it is this early portion of the stronghold or some previous work now lost sight of, that is supposed to have been interfered with by the fairies, does not appear; but the story goes, that three attempts to build upon the hill were as many times defeated; upon which it was decided to try the plain at the foot of it, where no further opposition took place. Callaley Castle was granted by Gilbert de Callaley, in the reign of Henry III., to Robert Fitz-Roger, whose son was surnamed Clavering, by King John. This son left no male issue, but his daughter's history and that of her descendants have made Callaley a centre of interest for the historian and antiquary. She had four husbands; by the second of whom, Ralph Nevill, of Raby Castle, she had two sons. In the space of six generations Lady Eva Clavering numbered among her descendants a king of England, a queen of England, a duchess of York (who in her turn was mother of two monarchs of the house of York and grandmother of a third), a duchess of Clarence, a duke of Bedford, a marquis of Montacute, an earl of Northumberland, Westmoreland, Salisbury, Kent, the Earl of Warwick, besides several other personages whose deeds are part of the history of the country. The castle has remained in the occupation of the descendants of the first Clavering down to the present day.*

We take our second example of supposed supernatural interference in the progress of buildings from a Devonshire story. It may be referred to in the appendix of Household Stories affixed to a new work on Folk-lore, by Mr. Henderson, which we have before mentioned. It will be found to the following effect:—When Sir Francis Drake, the Elizabethan navigator, proposed to build himself a house at Buckland Monachorum, he brought workmen from Plymouth, Exeter, and Tavistock, who worked with so much goodwill, some squaring the stones, others setting them, that they reached a height of six feet from the foundation the first day. Next morning, when they meant to resume their task, they found every stone removed to a great distance. This occurred twice. On the completion of the same height for the third time, Sir Francis hid himself in a tree and watched till midnight, when he perceived a multitude of little devils step out of the earth, with much laughing and talking, began to carry the stones away again till cockcrow, when they vanished, leaving the masons' work again demolished. Nothing daunted, the walls were rebuilt for the fourth time, when as evening approached, Sir Francis dressed himself in white, and hid himself again in the tree. At midnight the little devils appeared once more upon the scene, and were about to commence their mischievous operations when the great sea-captain flapped his arms and cried out with a loud voice, "Kikkeriki." They took the great white figure in the tree for a bird which had come to announce the end of the world; and dropping the stones they were removing, disappeared, screaming with fright. We must add that this incident in the life of Drake does not appear in Dr. Johnson's account of the navigator, although he goes into various details, including his burial at sea in a leaden coffin. Hitherto it has been folklore only. Mr. Baring-Gould is doubtless right in deeming it only a fragment of a household tale that has suffered anthropomorphism. There are many other instances of the application of this kind of magic to masonry in various parts of the country. We content ourselves with calling attention to the fact and to these examples of it.

Great building powers are attributed to his Satanic Majesty. The number of Devil's causeways, Devil's dykes, Devil's gaps is curious. Near Wooler, at East Libburn, there was formerly a large heap of stones which Satan was accredited with having brought there. It was called his "Apronful of stones." When it was determined

* The popular local rhyme in which this supposed interference is recorded is as follows:—

"Callaley Castle built on the height,
Up in the day and down in the night;
Built down in the shepherd's shaw,
It shall stand for aye and never fail."

to make use of this huge cairn-like heap of material for repairing the roads, the base and fragments of a cross, raised on a platform four steps high, were found in it. This confusion between things that are sacred and things that are supposed to be accursed, is puzzling. It crops out again in the belief that the first person who enters a new church is the property of the devil. This is a German fancy. And here we may quote Mr. Baring-Gould again. "At Aix-la-Chapelle is shown a rent in the door, which is thus accounted for:—The church was ready for consecration, and before any one entered it a dog was driven in. The devil, in a rage, seized the dog, and flew away with it, shivering the door. In various parts of Germany, and in Norway, a dog or pig was harnessed in the churchyard as an offering to the devil. He is thus outwitted, and receives a beast instead of a man as his tribute." In connexion with the last subject, Mr. Henderson mentions, in the interesting work we have before referred to, that a clergyman of the Church of Scotland informed him that there was a great difficulty in bringing his new churchyard into use, for no one liked to bury their dead there, as it was thought the first body interred would be a *teind* to the evil one. This feeling was only cast aside after a poor tramp was found dead on the road and buried in it. Mr. Henderson relates, of his own knowledge, that a similar dread existed with reference to the churchyard round St. John's Church, in the parish of Bovey Tracey, South Devon, which was long unused, the country people averring that the devil would seize any body laid in it; and that interments did not take place till a stranger, the servant of a visitor in the parish, was buried in it. In Aberdeenshire the workmen employed to pull down an old church on the completion of a new one, manifested some reluctance to take out the first stone of it for the purpose of pulling it down; but this difficulty was overcome when the agent for the estate pulled it out, as the second stone did not seem to involve the same terrible consequence. It was alleged that whoever pulled out the first was liable to a violent death. It is deemed just as unlucky to begin to build on a Friday as it is to commence any other task, except that of a journey through life; for, curiously, in some parts of the country, Friday is thought well of as a birthday, as witness the saying,—

"Friday's child is loving and giving;
Saturday's child must work for his living."

The ruined residence of a giant was pointed out, not many years ago, at Charlton (West), on the North Tyne. This encompassed an acre of ground, with strong walls built of large ashlar stones, 4 ft. thick. Its size, strength, and antiquity, in the absence of any exact knowledge of its history, impressed the minds of the country-people in the vicinity that it had been the habitation of some mighty giant in the days of old. This ready belief in the potency of unknown beings and unknown powers is an easy way people used to have of accounting for many things connected with building and the arts. Most of the Roman relics found on the great Roman wall were mutilated in the Middle Ages to dispossess them of any power with which their heathenish proprietors might have invested them; and many of the objects of Roman art found in the Thames seem to have been purposely mutilated for the same object. Unknown evil spirits lurked in ruins, ghosts promenaded in churchyards, shades of various degrees haunted hundreds of houses. People used continually to see these things and to hear them: yet, where are they? Judges and juries sat upon witchcraft cases, and frequently adjudicated death, with a fearless inconsistency, to aged people who, if they had been able to practise any occult arts, would surely have turned their most evil eye upon them for their verdict and sentence.

We have two other short stories connected with the magic of masonry to tell. The first we must call the magic of gallantry. At Heidelberg the cicero shows strangers a handsome stately gateway leading from the castle grounds into a fair garden overlooking the windings of the river in the plain below and the academical town at the foot of the hill on which the mighty castle stands. It was here that Elizabeth, daughter of James I., was brought on her marriage to the Prince Palatine. At that time there was no gateway between the castle grounds and the garden. One day the princess said to her husband, "I wish there was a gateway here," and behold! next morning there it stood as we see

it now. He called a little army of workmen together, and built it in one night. The second gives something of the character of a fulfilled prophecy to the Britannia Bridge, between Carnarvonshire and Anglesea. Hundreds of years ago a Welsh poet prophesied that the island of Anglesea would some day be joined to the opposite shore; and, as we know, unlikely as this seemed, it has come to pass. There was a particular spot near Porthaeth-hwy where a natural jetty of small rocks appeared, as though it had once stretched across the channel, till the sea had washed away some support which caused the greater part of it to give way and tumble into the bottom of the channel, the rocks shivering and splintering as they fell. Perhaps the Welsh poet, wandering along the shore and noting the hollows and cavernous interstices formed by the masses of these fallen rocks, and seeing and hearing the sea eddying and boiling in the deep pools it formed, was plighted by the grandeur of the scene, and so moved to prophecy. If all fact as this is, it is a link between minds of a very different order over an interval of centuries. Our folk-lore, however, is supposed to have had no such interval, though extending over as many centuries, and possibly many more. From lip to ear, and from ear to lip, it has been handed down from generation to generation from we know not what remote time. When and where, for instance, originated the belief that it is a sign of good luck to the occupiers of a house for swallows to build under the eaves? This is the general impression of the whole Germanic race. Was the coming of the swallow a sign of the approach of summer to the hardy Scandinavians, and so of open seas, with fresh sea exploits and plunder, and a season of things they enjoyed? or was the confidence of the bird an assurance of a genial climate and generous soil to tribes wearied with wandering thousands of years before this?

GENERAL EXHIBITION OF WATER-COLOURS.

The sales at the "General Exhibition of Water-colour Drawings," at the Egyptian Hall, have been very good up to this time. They amount, we understand, to 2,700l. The collection, consisting of 678 frames, is an interesting one. Observers must be struck with the similarity of manner and feeling observable in the majority of the works exhibited; so much so, in fact, that many of the artists might be thought to be pupils of one master. This of course results from the proclivities of the hanging committee, who had an enormous number to select from. The number submitted, indeed, was so great, that many of the drawings could scarcely be looked at. Last year, the majority of female heads exhibited had the "I'm a weary" and "He will not come" expression; and the same aspect, in a somewhat less degree, will be observable in the present collection. We mention this, by the way, not in disparagement, by any means, but as indicating the school. Amongst the most finished and complete works will be noticed "Jack o' Lantern" (63), H. S. Marks, 166, by J. D. Linton.

"Moss that softens on the spirit lies,
Than tired eyelids upon tired eyes."

"Myrtle Blossoms" (177), by Simeon Solomon; "Moonshine" (196), by Adelaide Claxton (an improvement on her Ghost Scene at the Academy); "Cordelia's Portion" (249), by F. Madox Brown; "Holmby Hill" (274), a brilliant landscape, by Vicat Cole; and "The Island of Graves, Skye" (291), by Walter H. Paton. Mr. Raymond Tucker's "Boat" (27) is well floated; and Mr. A. B. Donaldson, "Tobias and the Archangel" (91), emulates oil painting. The works of Mr. Halfiday, Mr. Thomas Danby, Mr. Poynter, Mr. Waite, and others, would have comment if our notice were more extended. There are nearly fifty-nine ladies amongst the exhibitors.

VANDALISM AT TENBY.—The town council of Tenby have doomed to destruction one of the ancient gateways of their town. Few like to remain. Are there no common-sense men in Tenby (we say artistic hearts) who will move to prevent this wanton and irreparable injury to the place. To destroy a point of interest in such a town as Tenby is an act of suicide.

THE DESIGNS FOR THE LAW COURTS.

The designs are no longer so freely on view as they were.* The public interest in them appeared undiminished to the last. Day after day, although admission was limited to those who had procured tickets of permission, through after through lounged before those clever prospects which but a short time ago were but sparkling, or anxious, or despairing, or brilliant thoughts, in the brains of the men whose pencils have made them more apparent. Here and there a wiggled and gowned barrister was to be seen among the constantly changing groups that were passing all day long from drawing to drawing and from court to court; and there was no lack of fair spectatrices of the architectural tourney. Now the stream was arrested, as it were, before the fine vision of Mr. Burges. Eager gazers took in its wealth of towers and turrets, and refreshed themselves in a dreamy sense of power. In another compartmental aisle there were as many eyes wondering at the pencilled thoughts of Mr. Seddon; and into one after another were to be seen groups melting away or concreting as the case might be. There was no particular preference exhibited for either of the works displayed, if we may take the dissolution and concretions of the public into groups as a guide to popular sympathies, like there is for the works of particular artists at the exhibition of the Royal Academy. Perhaps at a first visit we might have remarked a larger throng than elsewhere in Mr. Scott's court, attracted by his lavish of sculptured decorations, bassi relievi, and wall paintings, but, at a second look round, this state of things was reversed, and we found his corridors and halls, with their cunning finds of story, comparatively deserted, and the same eyes equally absorbed before the shadowy, suggestive water-view of Mr. Waterhouse's odd beaklike towers. Men's eyes and women's eyes were slow to turn from this mystic piece, showing the rising site, the slow waters, the pile darkening in the gloom thrown upon it by the cloudy dying day, and its tall towers with their corbelled parapets standing out against the sky as only towers have hitherto been seen to do on the grape-bearing banks of the Italian and German rivers. But turn they did at last; for we might see the same spectators arrested but a few minutes afterwards, by Mr. Raphael Brandon's eclectic witcheries, or by Mr. Street's picturesque and powerful strokes. "See what can be done with only three strokes," we heard above the faint hum and rustle. At another time it was impossible to get sight of Mr. Barry's capital plan or his dome, recalling St. Peter's to those who know Rome, and St. Paul's to those who do not. Again, Mr. Deane's group of separate buildings for separate purposes had its admirers; and Mr. Abraham's utilitarianism; Mr. Lockwood's quiet, reticent manner, as though he had but to let his pencil free and a hundred towers would spring up where he now keeps them down; and Mr. Garling's versatility, had their due share of admiration. The matter will now go into the hands of the judges. We entreat the fullest consideration for all.

The actual site of the proposed courts is fast becoming a scene of utter desolation, though in the heart of the heart of London. The wide courts, the narrow courts, the fine old mansions, with their Renaissance plaster ceilings, chimney-pieces, oaken staircases with carved balustrades, and carved oak wainscottings, window-shutters, and doors; the smaller houses with their less ample doorways and plainer panellings, are putting on the most forlorn appearance, as one after another is dismantled and deserted preparatory to demolition. Shut-up shops, broken windows, unswart footways, inclosed doorsteps, dirt and rubbish drifting into every one of the many nooks and corners, denote that the destroyer is at hand. Though most of the houses and shops, too, were dingy in the extreme, there were, and will be for a few weeks, among them some specimens of interiors of the days of William and Mary and Queen Anne that are well worth more than a passing glance. Antiquarian and archaeological societies should take steps to learn what may be worth recording, if preservation be out of the question.

We propose to publish views illustrating the external aspect of three or four of the designs

* We are asked to say that the Designs will, after this present month and until further notice, be open to the Public on Thursdays only, and to Members of both Houses of Parliament, and other Special Visitors on Saturdays only; the remaining days being required for the work of the Commission.

which seem to present the strongest claims for consideration on the part of those who are to make the selection. In our present number we give a view of the Strand or south front of the design by Mr. Waterhouse.* A block plan of the arrangement, and some descriptive particulars, will be found in a previous number.† The main entrance to the courts and central hall is nearly in the middle of the front, and would be approached by a private carriage-way, separated from the Strand by a parapet wall, and passing under the great porch, so as to set down persons thus arriving under cover. The Temple Bar Bridge, on the right of the view, has an archway for this road. The Tower are seen on the same side. Into this Smoke Tower it is proposed to carry the smoke from all the open fireplaces, brought in the first instance downwards through vertical flues under the streets, and opening into the Smoke Tower at the foot, or 300 ft. below the top of the shaft, where it would finally escape. The chimney stacks seen in the view, instead of being used to emit smoke, are intended for the supply of fresh air to the various rooms. The enormous system of artificial ventilation shadowed forth seems to us one of the weak points of the plan. The Will Towers are at the west end of the pile, and do not come into the picture. The gateway at the extreme left of the view admits to a roadway through Clement's Inn. The archway between this and the great porch gives entrance to what the designer terms Common Law-street, shown on the block plan. There is another entrance to the same street at the foot of Temple-bar Bridge. The style adopted is, generally speaking, the Gothic of the thirteenth century. Portland stone is recommended as the material for the exterior, with red brick, perhaps, in combination with it.

We understand that our suggestion as to the appointment of a certain number of architects to assist the judges has been taken up by the competitors. They have such confidence in Mr. Shaw and Mr. Pownall that they ask that these gentlemen should be placed on the list of the judges with equal votes, and that the competitors should name a third architect to rank with the others. It is sincerely to be hoped that this request will be complied with.

DEBATE AS TO THE NEW COURTS OF JUSTICE.

On the motion for going into Committee of Supply in the House of Commons, Mr. Bentinck called attention to the estimates for the designs of the new Courts of Justice, and, after some remarks, made the following motion:—

"That, in the opinion of this House, it is expedient that all arrangements respecting the building of the New Courts of Justice should be effected under the sole responsibility of her Majesty's Government."

Mr. Beresford Hope, in reference to the remarks, said he was sorry his hon. and learned friend had prejudiced his case by giving an opinion which lent a colour to the supposition that some artistic or personal objection to the designs underlay it. Admitting, as he did, in the fullest manner, the legal eminence of the commissioners, he must contend that the First Commissioner of Works ought not to be relieved from his responsibility in the construction of the new Law Courts. As the representative of the architectural profession, he had presented a memorial to the Government asking them to amend the tribunal. The answer he received from the Treasury was—"You are too late;" but it did not say one word in answer to the claim. He could not go with his hon. friend in his objections to a larger expenditure than 750,000*l.* That was originally set down as the price, but then there were further requirements; and when the architects were ordered to carry these out, it was not fair to blame them for exceeding the estimate. In the instructions to the architects not one word was said about style. His hon. friend said that if the matter had been left in the hands of the Government the architecture would have been that of modern times. He presumed that the architecture of Harley-street and Baker-street, and that he would have had the Courts of Law a repetition, on a large scale, of No. 73, Upper Baker-street. He hoped that his hon. friend would not press his motion to a division. Parliament would not, he thought, wish to refer this subject to any

* See p. 161.

† See p. 68, ante.

others than the eleven distinguished architects who had sent in so magnificent a series of designs, and he trusted there would be no variation in the intention that this edifice should be of English architecture.

Mr. Cowper said he wished to assure his hon. friend that there was no question at issue as to relieving the Government from responsibility with respect to the erection of the buildings to which the resolution related. The Commission had been appointed simply to consider and report on the subject. On that Commission all branches of the legal profession, including several judges, were represented. The estimate of 750,000*l.* was, he still maintained, quite adequate to secure the amount of space it was then intended to provide. The Commission were, however, of opinion that it would be a pity to lose the opportunity thus afforded of going beyond the immediate wants of the hour. As to the question whether the Government or the House were committed to the carrying out of those views of the Commissioners, his answer was that neither was bound to adopt them unless they chose. As to the designs themselves, it would, he thought, he admitted they were admirable by almost every one, except the hon. member for Whitehaven, who, although very fond of talking about art, and possessed of great taste and ability, had shown himself on all occasions to be quite incapable of seeing any merit in the Gothic style.

Lord J. Manners said that as the appointment of the Commission had been decided upon before the present Government came into office, he thought it right to allow a member of the late Administration to explain the circumstances of the case before he ventured to speak on the subject. Having heard from the right hon. gentleman who had just sat down that explanation, he had no wish to add to it a single word. Of course, everything would be done with a view of keeping the expenditure within reasonable bounds, but he must say that any notion which at the present moment would intercept altogether the action of the Commission would be a great misfortune.

Mr. Bentinck then withdrew his motion.

THE CONDITION OF ARCHITECTURE AND ARCHITECTURAL EDUCATION IN THE UNITED STATES.

At a recent meeting of the Royal Institute of British Architects, Mr. W. R. Ware, of Boston, United States, member of the American Institute of Architects, gave an address on this subject.

Seeking, as we have long done, to connect in our sphere the two countries, we gladly welcome Mr. Ware amongst us, and print the pick of his observations, not alone because they will interest our readers, but in the hope that the publicity thus given may serve to aid the objects he has specially in view.

Mr. Ware said: The invitation I received a fortnight ago, to tell you something of the condition of architecture and of architectural education in the United States, came with the force of a command. The wishes of our benefactors are imperative, and I have enjoyed too many favours at the hands of this Institute and its individual members not to be glad to do anything that would even seem to repay them. It is some months since, at the instance of my kind friend Professor Donaldson, your honorary secretary for foreign correspondence, favoured me with a circular letter of introduction, which has obtained for me in every part of England and in Scotland courtesies and kindnesses from the Fellows and Associates of this Society for which I cannot sufficiently express my obligations, and which I am glad to be able thus publicly to acknowledge.

But I am particularly willing to make the use you have indicated of the time put at my disposal, because I may perhaps thus best serve the two institutions whose minister I am, the American Institute of Architects,—a society constituted in most respects like your own, and whose seat is in New York,—and the Massachusetts Institute of Technology, established within a few years in Boston, the educational institution with which I am myself especially connected. In saying what I wish to say of their history and prospects, I shall perhaps best cover the ground you have staked out for me. The condition of the profession on the other side of the water may perhaps be most distinctly set forth in relating what the Institute is trying to do for its improvement, and our modes of build-

ing, in explaining the structures shown in the photographs, with which you have done us the honour to cover your walls. The condition of architectural education may best be shown in speaking of the only institution of learning which, so far as I know, has taken up this work in earnest.

Up to a very recent period,—indeed I may say up to this time,—the condition of architecture in the United States was very similar to that which it held in England twenty or thirty years ago, previous to the establishment of this Institute, or of the architectural periodicals which have done so much for its improvement. Building, in general, was to a small extent only in the hands of professional architects, and was, for the most part, carried on by builders and contractors. The professional architects of most of the large cities of the United States might be counted on the fingers of one hand, and their works were almost entirely confined to the more important public buildings, such as state-houses, churches, custom-houses, and banks, the great bulk of the general work being done by masons, carpenters, and contractors, of one sort and another, in which the interests of art were left to take care of themselves.

In the last century this state of things perhaps did not do so much harm. At that time the respectable practice obtained of following the rules of Vignola; and the consequence was, though there were no architects engaged in the work, the carpenters and mechanics following those rules covered the country with houses, not very novel indeed, but comely and decent. Amongst the photographs on the wall will be found illustrations of the works that were done under that régime,—cathedral buildings with classical cornices and details, a repetition in wood of the sort of buildings erected in England during the last century, monuments of what the song calls the "good old colony times when we lived under the King;" these were the dwellings of the squires and local aristocracy, and the smaller houses were, in their degree, like unto them. The neighbourhood around Boston are full of them, dating from before the American Revolution, and some have attached to them a good deal of historical and local interest. One of the best of these old houses, of more than ordinary pretensions, is standing on the outskirts of Cambridge, being the house which was occupied by General Washington during the siege of Boston, and now acquiring a new title to fame as the residence of the poet Longfellow.

This state of things has long been overthrown, and a succession of styles has since prevailed, faint admimations of the phenomena which European architecture has meantime exhibited. The influence of Stuart and Revett, and of Pugin, of the Italian school, of the German school, and of the French school, of the rage for cottages, and of the rage for castles, may easily be traced, together with any number of styles which native enterprise has concocted out of these various elements, making the confusion worse by confounding everything. This enterprise would have lacked its most obvious and characteristic manifestation, and the chaos would have remained incomplete, if its agents had not everywhere assumed the title and degree of architect. Under this dispensation the rules of professional procedure became corrupted and lost, artistic work pretty much unknown, and even the traditions of professional etiquette and the old-fashioned way of doing business, so far as we had ever inherited them from the mother country, fell into abeyance and were forgotten. Such changes were, of course, natural to a society which, from being part of an old nation, had come to be a part of a new one: they were the phenomena of a state of transition, of which other things as well as the arts of building felt the influence.

But a state of transition is an uncomfortable one, as those architects found who, in spite of everything, endeavoured to conform to their own practice to an ideal standard. It is hard for isolated individuals to stand against the current, and vain for them to try and turn it. Feeling that it was only by acting together that they could do anything to affect public opinion, that it was only by helping each other that they could themselves advance, a few architects in New York, eminent alike for professional attainments and for professional zeal, combined to establish a society, professedly modelled upon your own, its objects being, as its constitution declares, "to promote the artistic, scientific, and practical perfection of its members; to facilitate their intercourse and good fellowship; to elevate the standing of the profession; and to combine the

efforts of those engaged in the practice of architecture for the general advancement of the art."

In these objects it has succeeded to the extent of promoting good will and confidence among its members, and establishing among them a considerable uniformity of professional procedure. It has also, by admitting them to its privileges as Associates, been of great service to young men, mostly the pupils of the older members, who have thus enjoyed the society and counsel of the most distinguished men of the profession. It has also, as I have said, by extending its fellowship to architects of other cities, been the means of producing an intercourse which has been of the greatest advantage to those who have shared it. They have not as yet attempted to enlist within their ranks the members of the profession at large, wisely preferring to try their experiment on a small scale at first; but they are now enlarging their operations, and rapidly extending their numbers and usefulness. I had the pleasure of handing to one of your honorary secretaries at the last meeting one of the printed papers of our Institute, in which it has been attempted to establish amongst the members of the Institute, and thus in the profession at large, fixed rules of procedure in their business, similar in its general character to that which has been issued by this Institute. Within these last few months it has been proposed to establish, under the direction of the Institute, an architectural journal, which shall at the same time benefit the profession and interest the public in architectural matters. From the circular issued by a committee of the Institute I will read a single paragraph, which fully explains its objects and character:—

"It is proposed that the journal shall contain illustrations; so much of the minutes of the Institute as would be of interest to the public; papers on the principles of design and general art criticism; discussions of problems of construction; correspondence from members, at home or abroad, both professional and honorary; notes of travel by architectural tourists; extracts and translations from foreign architectural and scientific periodicals; test cases of architectural litigation; prices current of building materials at the principal business centres; and other items of interest to the architect, or instructive to the public."

Nothing decisive has yet been done upon this scheme, and this circular was only issued to the members of the Institute in order to elicit their counsel and advice. Still it shows, as far as it goes, the direction in which the Institution is moving, and the field of usefulness which it proposes to occupy.

It may be interesting to you to hear something of the men by whom this Institute was originated, and of their works; to make, as it were, the personal acquaintance of your friends over the water. To this end I will give a brief account of the architects of the American Institute, beginning with those who have been bred as well as born in the United States. They were not in all cases the persons who have the largest professional practice; the largest share of work still falls into the hands of men who look upon architecture not as a profession, but only as a business, and who naturally possess the confidence and sympathy of a business community. Yet we are not without men of great and deserved repute; and of these the most eminent, and one whose eminence is illustrated by the photographs before you, is Mr. Thomas U. Walter, one of the vice-presidents of our society, the architect of the famous Girard College in Philadelphia, and of the extension of the Capitol at Washington.

The English architects belonging to our society are Mr. Withers, a name familiar in this place, and Mr. Diaper, still one of your members. Mr. Vaux, well known in this country by his publications, was formerly associated with Mr. Downing in the introduction into the United States of the English system of landscape gardening; and of late years, since the sudden and lamented death of Mr. Downing, he has largely devoted his attention to this branch of art, not, however, abandoning the practice of his profession, as these photographs attest. The bridges and other architectural embellishments of the Central Park, in the city of New York, have been erected chiefly from his designs.

Another Englishman, Mr. J. W. Mondé—once, I believe, a pupil of Mr. Owen Jones, and a coadjutor with Mr. Vaux in the Central Park—was one of our earliest members, an architect whose works, though not numerous, show great vigour and fertility of mind, besides exhibiting the characteristics, rare on our side of the water, of the school in which he was trained. These circumstances have given him an influence, and an influence for good, as marked and extensive,

perhaps, as that of any one of our number. The best qualities of his work are but inadequately exhibited in the photographs contributed to this collection.

The influence, however, of Mr. Upjohn, our beloved and venerable president, has been for thirty years far greater and more salutary than that of any other man in his own line of work. He was the first person in the United States to practise with thoroughness and fidelity the classical Gothic, if such a combination of terms is allowable in this audience. Well versed in the different English precedents, he set himself to build well-advised and defensible examples of the different styles in which he worked, and his first work of magnitude, Trinity Church, in New York—standing at the lower part of Broadway, at the head of Wall-street—was and still is the most conspicuous and most extensive Gothic structure, perhaps, in the United States. The erection of this church, between 1840, I think, and 1845, was an era in the architectural history of the country.*

Mr. Ware, after speaking in more detail of these and other architects and their works, especially of Mr. Eidlitz and Mr. Lienau, who represented the German and French influence, of Mr. Wight, the architect of the new Academy of Design, and of Mr. Richard Hunt, the most eminent of the Americans educated abroad, and describing severally the illustrations of their work furnished by the photographs, which, as members of the American Institute, they had presented to this society through his hands, explained that the incompleteness of the collection was due to the haste in which it had been gathered together, these gentlemen having emptied their portfolios and stripped their walls rather than let him come without this mark of their respect and goodwill. He then proceeded to speak of the peculiarities of construction these buildings exhibited, especially in the methods of building in iron and in wood. The new dome of the Capitol, 100 ft. in diameter, and 255 ft. high, was the most important example of the first, built entirely of cast-iron, inside and out, for the upper 216 ft., and braced and framed with iron trusses, as was shown in the photograph of the section taken from Mr. Walter's drawing. This structure was quite unique, but cast iron had been used a good deal for façades, instead of stone walls, both alone and in conjunction with brick. In design these iron fronts vary from the perfectly simple forms adapted to warehouses and workshops, to elaborate imitations of Venetian Renaissance palaces, sometimes backed up with brick, sometimes lined with only a lath and plaster partition.

The extent to which wooden buildings prevail, he continued, and their excellent quality, seems not to be understood in England. In the towns the buildings are of brick, the fronts often faced with stone. But in the country almost everywhere wood is the universal material, and the houses and churches built of it are perfectly firm, tight, and warm. They only differ from stone or brick houses in the outer walls, the partitions within being, of course, of the ordinary construction, vertical studding, faced on each side with laths and plaster. The outside walls are built in the same way, lathed and plastered on the inside, but covered on the outside with two sets of horizontal boarding. That next the studs is common rough boarding, 1 in. thick, on which is nailed a peculiar board, called clap-boards, from 4 ft. to 6 ft. long, 6 in. or 8 in. wide, laid lapping so as to expose a weather face of from 4 in. to 4½ in., and of a wedge-shaped section, about half an inch thick at the lower edge, and tapering off to a feather edge where it is covered. They are planed on the outer surface, to shed rain more easily, but left rough underneath to make a tighter joint.

The frame into which this outer studding is fitted consists of sills, posts, girts, plates, and braces, which are all tenoned and pinned together. The sills lie horizontally at the bottom of the wall all round, and the plates at the top, just like any wall plate. Between the sill and the plate are the vertical posts which stand at the corners of the building, and at convenient intervals along the sides. If, as is usually the case, there are two stories, beams called girts run between the posts at the level of the upper floor, those parallel with the floor joists being on a level with them, and those which cross their ends and support them being sunk to receive them. The lower floor joists are cut into

* Mr. Upjohn has been elected Honorary and Corresponding Member of the Institute of British Architects.—Ed.

the sills, so as to come flush at the top, and those of the third floor rest either on the plate at the top of the wall, or upon plank balved into the upright joists at a somewhat lower level. The junctions of the posts with sills, girts, and plates are strengthened by braces, about 6 ft. long, tenoned and pinned, as are all the other articulations, with oak pins. The timber is generally spruce or pine, but the sill, as being exposed to rot from the dampness of the ground, must be of pine. In the north a cellar is dug, and the stone wall carried above the surface of the ground to receive the sill. In the south, where there are no cellars, the sill is supported by posts driven into the ground. The roofs are like all roofs, but covered either with slate, or with shingles of pine or cedar, sawn or split. The sawn lie closest and are warmest, but decay soonest. The split cedar, shaved, are the best. In all cases the rafters are covered with a close boarding, to keep out snow and wind. We have no tiles.

The construction of the inside partitions presents no peculiarity, except, perhaps, this, that we avoid the use of large beams at the floors, to save shrinkage, putting only a 2-in. strip of southern pine or chestnut at the top of the sills below, as a partition head, and resting the floor joists and studs of the story above directly upon it, taking care to bring their bearings as nearly over the studs below as possible.

Walls or outside partitions, such as I have described, with only the clap-boards, the rough boarding, and a coat of lath and plaster between the air within and the wind without, though generally thought sufficient, are rather thin and cold, and a variety of things are done in the better class of houses to improve them. A layer of tarred paper or felt between the clap-boards and the under boarding is the most common and most effectual device. The under boarding is itself often tongued and grooved. Sometimes bricks laid in mortar, either flatwise or on edge, are built up between the joists, but this is not so much done as formerly. It was at one time the fashion to fillet the studs and cut in laths between them, so as to give what was called hack-plastering; but the best opinion at present is rather in favour of covering the entire inner surface with a second coat of lath and plaster, separated from the first by inch battens. Any one or any two of these measures—and it is not often that more than two are employed—makes a wall impervious to wind, rain, cold, or heat. The thickness of the walls is altogether between 6 in. and 8 in.

In this way are constructed the "shingle palaces," which Washington Irving celebrates, light, cheap, dry, and warm. They are not exposed to any agency that will not equally injure a stone or brick building, except the decay of the sills. This makes very old houses crooked and shaky. But against this we now take precautions, and by giving the sills plenty of air and letting no water get to them, hope to save the buildings of the present generation from decrepitude in their old age. As to fire, isolated houses never catch fire from without, and the wooden house is no more likely to catch fire within than any other. When it does burn, it burns up clean, which is rather an advantage.

It is hardly worth while to go more into these details, which it is difficult to explain without diagrams. The photographs show how the window frames and caps, the cornices, strings, and bases, and the corners of the buildings, are finished with joiner's work. They also show how we are trying to introduce, influenced remotely by German or Swiss example, a form of building and a kind of finish, more suited to the material in hand than the classical details employed by our ancestors.

The newer parts of the country are full of extensive and costly buildings, but they do not, so far as I know, present any unusual features, except, indeed, the gigantic warehouses for corn erected in the western cities. But these can hardly be explained without drawings.

The lateness of the hour prevents my going, as I could wish, into the second branch of my subject—the condition of Architectural Education in the United States, past, present, and future. So far as the present is concerned, indeed, the chapter need be no longer than the famous chapter on the snakes of Iceland. We have at present no system of professional education, young men educating themselves, and picking up in offices what they may, some as pupils and some as draughtsmen, of whom the latter are rather the best off, as it is important to their employers that they should know some-

thing, while the pupils, who sometimes pay fees and sometimes not, are left pretty much to their own devices. Any system of regular apprenticeship is quite unknown to this generation, so far as my information extends, except that Mr. George Snell, an Honorary and Corresponding Member of this Institute, and personally known to many of you, has made an effort to introduce in Boston the English usage in this respect, in his own practice, and with valuable results.

The only scheme of education which has existed within my own experience, other than this desultory work in offices, was established by Mr. Richard Hunt, whose name I have mentioned, and who, after his return from Paris, opened in New York an *atelier*, upon the French system, and for four or five years had a small class of students, who enthusiastically pursued, under his electric influence, the study of architectural drawing and composition. A mere private establishment of this sort, dependent upon the energy and devotion of one man, suffered, of course, from the lack of the regulating and sustaining influence which the Ecole des Beaux Arts exerts upon the *ateliers* which supplement it; and Mr. Hunt's *élèves* were, of course, utterly without the systematic instruction by lectures in history, science, and construction, which, to a certain extent, supply in Paris the deficiencies of mere *atelier* education. But he was able to breathe into it what was more important than all this,—the atmosphere of the Paris school; and his studio, while it lasted, was a real bome of art, a real fountain of inspiration. From this school were recruited many of the younger members of the Institute, who, joining it as Associates, sat at the feet of their elders during their novitiate, and have since ascended to the upper seats.

Some years later than this, finding a good deal of difficulty in obtaining assistance of the sort I needed, I attempted to repeat this experiment in Boston, on a smaller scale and chiefly for my own behoof. Beginning by myself, I soon afterwards enjoyed the powerful co-operation of Mr. Van Brunt, who had been a fellow pupil with me at Mr. Hunt's, and who has, since 1863, been associated with me in my business. Following, in general, the same course that had been followed with us, we endeavoured, so far as other avocations allowed, to add some practical information to this purely theoretical course, and achieved a very satisfactory success, perfectly answering our own immediate purpose, of obtaining a valuable company of auxiliaries, and we accumulated a capital portfolio of drawings made by them during their pupillage, which was quite a show among our friends. It was this success that attracted the attention of the managers of the Massachusetts Institute of Technology, and led to their inviting my co-operation in the Architectural Department of their School, and to the organization of that department, so far as it has been organized at all, in the form it now presents.

I will say but a single word of the nature of this organization and of the character of the work in hand. The architectural classes are a part of a general school of applied science—the only part which touches the domain of fine art; though drawing, as a useful accomplishment and a natural language, is taught in all the departments. In the exercises of these departments the architectural students may learn what they require of mathematics, physics, chemistry, engineering, construction, mechanics, and the modern languages. All this work is taken off our hands. Whatever we need for our students can here be supplied. Our own work thus relates only to our own profession and our own art.

In the performance of this work we propose to do nothing that can be dispensed with, leaving matters that can be learned in offices to be learned there, and not encumbering the student with useless and irrelevant lore. At the same time we recognise the fact that many practical matters whose details may best be learned by office work, need a systematic and theoretical discussion for their proper comprehension, and this discussion we propose to afford. We also recognise the architect's need of a liberal culture in his art and extensive learning, at least to the extent of having explored the field it covers, and knowing where to find detailed information. Nor do we consider either needless or irrelevant, but regard a practical knowledge of what are called the industrial arts, so far as it can be obtained, as being even more serviceable than a technical knowledge of the fine arts, in developing and disciplining the ideas of proportion, harmony, and æsthetic expression, by means of subordin-

tion and contrast, upon which architectural composition depends. In historical research and in the study of construction and professional procedure, we propose to treat our classes rather as students than as pupils, leading them, under the necessary guidance and control, to pursue a course of independent study and individual investigation, each contributing to the common stock the result of his labours. The Class of Construction in the Architectural Association, a society which, if I may say so, seems to be doing more for professional education than any agency now at work in the Kingdom, affords an example of the application of this co-operative system, which I have observed with the greatest interest and satisfaction. Its continued success will afford to our own undertakings the greatest encouragement.

The constant practice of design, which, when the topics chosen and the data given are suited to the student's state of development, seems to be the most efficient and wholesome, as it is undoubtedly the most stimulating method of study, we propose to employ with great freedom, not only as an exercise in modern architectural composition, but as an auxiliary to the study of the history of the art, just as boys compose in Greek and Latin to perfect their acquaintance with those tongues. In these exercises, competition rather than co-operation comes naturally into play, and we propose to establish real or nominal prizes, as circumstances may determine, as an incentive. The occasional delivery of special lectures on special subjects, by persons specially qualified to treat of them, is the only remaining feature of the plan that need be mentioned. By these lectures, as well as by our collections, and by the accumulation in the course of time of much valuable information, we hope to be of service not only to our own classes, but to the profession at large and to the general public.

Of the personal material with which we have to deal, I will only say, in conclusion, that besides drawing in the pupils and draughtsmen and assistants already at work in offices, we shall have students devoting their time exclusively to the school, and pursuing a stated curriculum within it. The increasing number of young men of liberal training and culture, who of late years have turned their attention to architecture (a band that would have been much larger than it is, there is reason to believe, had any satisfactory means of education been open to them), gives cause for the most satisfactory anticipations in this regard.

I have laid upon your table a copy of a pamphlet, explaining in somewhat greater detail the ground this school proposes to cover, and the principles by whose guidance we propose to fashion our educational structure. A portion of this paper Mr. Godwin has done me the honour to re-print, in the last June part of the *Builder*. To collect the materials for this structure, the photographs, casts, prints, books, business documents, drawings, and sketches, which must form our educational apparatus,—or to learn where they can be got, to perfect our plans by the study of European schools of art, and to chasten our judgments and correct our aims by the counsel of men whose insight or experience fits them to be our counsellors,—this is the quest which brings me to your shores, and has directed my footsteps to your door. We need the best advice and information, as well as good apparatus, to enable us to set out upon our path with confidence, and pursue it with a reasonable assurance of success. For the valuable suggestions and sagacious counsel I have already enjoyed, I cannot too strongly express my obligations.

Sir Walter James said he had listened with great gratification to Mr. Ware's address. He thought it worthy of note that gentleman should have come over to this country to take notes here, and to elicit information as to the state of the architectural education in this metropolis. He felt that a great compliment was paid to this Institute and to the architects of England by the circumstance, and he considered whatever instruction they were able to give Mr. Ware would in the course of a short time be amply repaid to them by the reflected light which would be returned to them from that new continent, where, to use this gentleman's own phrase, architects have, perhaps, rather a freer swing than was the case in this country.

Mr. T. L. Donaldson, Fellow, said that, but for the lateness of the hour, he would have wished to have stated to that gentleman should have come over to this country to take notes here, and to elicit information as to the state of the architectural education in this metropolis. He felt that a great compliment was paid to this Institute and to the architects of England by the circumstance, and he considered whatever instruction they were able to give Mr. Ware would in the course of a short time be amply repaid to them by the reflected light which would be returned to them from that new continent, where, to use this gentleman's own phrase, architects have, perhaps, rather a freer swing than was the case in this country.

indebted to America for many notions. Possessing in a large degree the genius of invention, that nation had, perhaps, shown greater aptitude in the improvement of the inventions of others, as well as great intelligence in the application of them to the necessities and purposes of life. It was not, therefore, surprising that architecture did not appear as yet to have been cultivated as they deserved in America, because the first necessities of a people had to be supplied before attention could be paid to the higher refinements of the human mind; but it was now found that their American brethren were coming forward in this respect, and there were numbers of their fellow-countrymen studying in Italy, particularly as sculptors, and those who have lately returned have distinguished themselves by their productions exhibited in this country, for which we had given them all honour. They must all be gratified at seeing the energetic movement now being made with reference to the architectural education of the young men who would hereafter enter into the profession. There was no question that elementary principles were necessary, but it seemed, as if in Europe so in America, there was a great notion of having genius to itself, untrammelled by the theories of a by-gone age. America possessed many fine architectural monuments, and he trusted they would improve themselves by an adherence to those rules of previous centuries which had produced the buildings of which this country and Europe generally boasted. He was sure they had all been greatly interested by the communication Mr. Ware had made to them, and that simple and unaffected way, as well as gratified by the warm interest he had manifested in the proceedings of this Institute. He begged, therefore, to propose a cordial vote of thanks to Mr. Ware for his highly interesting communication.

Mr. M. Digby Wyatt, Fellow, said it was with feelings of great pleasure he rose to second the motion. They had all been greatly interested in what he said in America, American art, and the early struggles of that art, which had been laid before them; and they could not fail to have been struck with the technical dexterity which the Americans had shown in the architectural use of iron, steel, iron, and stone. It was from that cause, as well as from the educational course which Mr. Ware was endeavouring to bring forward, that he signed a successful letter for America, and he was glad to hear that the country which that country possessed in a great degree, and must lead to genius,—urgent requirements on the one hand, and on the other enormous wealth and unbounded resources. These were incentives to good art, and he would constantly manifest themselves in a more powerful form. If we were to look upon America in future as a great commercial head, we must also look to her, like Florence of old, for the development of her art, which she possessed. What might have been even more interesting, he thought, than the narrative of these early struggles, would have been some definite account of the way in which the great master necessity in America was supplied. He would have liked to have seen the plans of the great hotels of the country, and an explanation of their working and administration; as also of the great stores and warehouses which Mr. Ware had spoken of, the details of construction of the floors, &c., and the extent to which the fire-proof system was adopted. Those buildings in Cincinnati and Philadelphia were carried out upon an enormous scale, and far surpassed those of London. He would have liked to have heard how they had met difficulties which must assuredly have been encountered with ingenuity. He hoped Mr. Ware was favoured when by appearing before the Institute again he would come prepared with information on these interesting points. At the same time he (Mr. Wyatt) felt very grateful to that gentleman for his communication, and he was delighted to hold out the hand of fellowship to him and other brethren of the profession who might arrive here from that country.

Professor T. H. Lewis said, having had the pleasure of seeing the portrait of Mr. Ware since his arrival in England, he would bear witness to the assiduity with which that gentleman had prosecuted the objects he had in view; and he (Professor Lewis) was satisfied, from what he had seen of the views and opinions which he had carried with him to America, pleasing recollections of his sojourn in this country. The point on which, if time had permitted, he should particularly like to have heard a more detailed explanation, was to the extent of the architectural education proposed to be adopted by the different institutions, more especially that with which Mr. Ware was personally associated. He could only unite most cordially with the remarks of the gentleman who had preceded him, and join most heartily in the thanks accorded to Mr. Ware.

Mr. George Godwin, Fellow, said it was his privilege to make the first address of Mr. Ware known to English readers, he was glad to be called on to add his humble tribute of thanks to that gentleman for his straightforward and interesting statement. The names he had mentioned had, no doubt, recalled many interesting circumstances to the minds of those present. It was gratifying to find that men known to them a few years ago were now acting so good a part in America. The portrait of Mr. Ware which Mr. Ware had brought with him particularly interested him, because he had had the pleasure of that gentleman's personal acquaintance during his visit to England years ago, soon after he had completed the erection of the Grand College. He had had the satisfaction of considerable correspondence with another gentleman mentioned—Mr. Downing, at the time of the publication of his work on Landscape Gardening—a book which had done great good in America. Mr. Vaux, too, had been his correspondent. He concurred to the fullest extent in the hope expressed by Mr. Wyatt that Mr. Ware would, in some form or other, be connected with the Institute, and the modes of construction adopted in the buildings of America.

Mr. C. F. Hayward (Hon. Sec.) would say one word with respect to the Institute with which Mr. Ware was connected, the first object of the Institute at Rome. One great feature in the course of instruction in that Institute was, that while a four years' course was required, the first two years were devoted rather to general than to technical instruction, but from the third year not only mechanical but free-hand drawing was made a necessity. An institution which embodied that among its general requirements was, he thought, deserving of particular notice, because of the reasons of the instructions of the present day sufficiently recognised the importance of drawing as a branch of education.

The President (Mr. Beresford Hope, M.P.) said he would say a few words, but from the remarks which he was sure Mr. Ware would take in good part. They had listened with great interest to Mr. Ware's narrative of the gradual development of architecture in America, and the recognition of its professors; they had also heard with pleasure how the landed art of landscape-gardening had been fostered there, and fostered as the President always con-

sidered it should be, as a branch of and connected with architecture, a thing which in England they had too much lost sight of. He would invite Mr. Ware's attention to one point, and would ask him whether there was much to be done in the way of architecture here at home? The ravelling plan, of which Washington was a distinguished instance, did not exist, he believed, in any other city north or south; which were, like New Orleans and the new parts of New York and Boston, laid out uniformly on the rectangular plan. That system of planning towns was most distasteful and disadvantageous to the proper appearance of the public buildings of these towns; and he was sure if the American Institutes, with the intimate knowledge they possessed of the susceptibilities and tendencies of their country, would direct attention to the advantages of the radiating plan, so as to make the great public edifices the principal objects, it would give a great impetus to the growth of architecture, of which they had already seen such vigorous young shoots.

Mr. Ware, acknowledging the vote of thanks, said, with regard to the points raised by the President he would say, he felt that architecture and landscape-gardening, in connexion with each, were more likely to have way than had hitherto been the case, and with respect to the planning of towns, although Washington was built upon the radiating plan, it was considered one of the most inconvenient cities in the United States, in regard to strangers finding their way about. Of late, architecture in connexion with landscape-gardening had been called in aid, in laying out not new towns, but new parts of towns. With regard to fire-proof construction in America, the plan was that which was familiar in this country, of wrought-iron girders and brick arches. With regard to the remarks that fell from Mr. Hayward and Professor Lewis, he assured them it was at the sacrifice of personal feeling that he had put the Institute with which he was more intimately connected in the background, and had placed the American Institute of Architects in the more prominent position. He thought, coming here as he had done, it was best to touch upon those subjects which were likely to be of most interest to them, rather than advance any personal views of his own, or the objects he had most at heart.

ART AND ARCHÆOLOGY IN ROME.

ONE of the studios of Rome still open to the public, and still called by the great artist's name, who is no more,—that of Gibson,—may now excite a peculiar and mournful interest. Many of its contents, both casts and marbles, are packed in boxes ready to be sent to England; but many others, and among them the finest of those produced within recent years, are still on view. With renewed pleasure must we now consider the sculptor's last work, the "Thesens slaying the Robber Chief," to which he was about to apply himself at the very moment the mortal stroke first rendered him helpless, and which those responsible have judiciously caused to be cast from the unfinished model, without any attempt to complete in the clay what had been left as we now see it,—an imperfect but noble work, wanting much of anatomical detail, especially as observed at the back of both figures, but still so far elaborated as to present in impressive truthfulness the entire conception and feeling. Nothing could be finer than the indignant but calm energy with which Thesens stands over the prostrate robber, about to slay him with the sword held aloft, and in an action that throws out the finest attributes of the heroic beautiful in form. This group had been sketched in the clay about thirty years ago, and in that state seen by Thorwaldsen, who expressed approval; and the idea of completing it had frequently occurred to the artist, who at last applied himself to the long-postponed work with some feeling of presentiment (to infer from what his assistants tell us) that it might be his last, or that he might not live to finish it.

At Benzon's studio, the principal work lately produced, and just completed in marble, is the group, above life-size, of the "Flight from Pompeii," or Diomed assisting the mother with her infant at the dread catastrophe, as described in the well-known romance; and whatever we may think of the inappropriateness of such a subject for sculpture, we must admire this wonderful example of difficulties overcome in a scene of utmost agitation and terror, hurried movement and confusion, presented with pathos that at once touches the heart, whilst conforming to the ideal standard of the sculptor's sphere; the noblest quality being the predominance of the moral feeling, in the generous humanity of Diomed, and the motherly tenderness of the female, over the selfishness of fear as over the physical horrors of the situation. In the accessories, ornaments, vessels, &c., strewn on the ground, are exact copies from Pompeian antiquities; and this striking group is to be placed by its purchaser, a Mr. Stephens, of New York, in the centre of a hall fitted up and decorated so as exactly to reproduce one of the aristocratic interiors in the lava-buried city. We hear that Tenerani, now a septuagenarian, has commis-

sions on his hands sufficient for ten years' labour, but has dismissed several of his workmen, yielding to the irritation in his mind (such, at least, is the report) at the generally unfavourable criticism passed on his monument to Pius VIII., when that colossal work was first exposed at St. Peter's, about a year ago. In that criticism on the Papal monument rare merits have been overlooked, even granting, as we may, that the figures be less impressive when grouped together than as seen in the studio. No new work of importance has been undertaken within the last year by Tenerani. Mr. Rogers, one of the most successful and constantly engaged of the American sculptors in Rome, has received a commission for one of the many monuments to be raised in the cities of the United States to the President Lincoln.

Much decorative and restoring work has been in progress in Rome's churches, and much is still continuing, begun in the last or in previous years. Our general impression is of splendour, lavish use of rich material, marbles, gilding, bronzes, &c., sometimes in suitable accord between the new adornment and the architectural character viewed as a whole, but not of any exalted merit or feeling in sacred art, still less of any intelligent appreciation for the Christian antiquities thus too often marred or tastelessly altered in the intent to embellish. The restorations and paintings, by Cognetti and others of his school, at S. Maria in Trastevere (in its oldest parts a church of the twelfth century), are still progressing, and, we are told, are to involve the outlay of 200,000 scudi, half given by Government, half by the capitial clergy. Along the high attics have been executed large fresco figures of sixteen male and female martyrs, divided by pilasters with gilt capitals; and above the chief portals have been opened three round-arched windows, with glass paintings, large size, of Cornelius, Calixtus, and Julius I., sainted pontiffs who contributed to the building or restoring of this church. The fine Mediaeval pavement of inlaid marbles has been taken up, but will, we are told, be replaced in similar style, and with the same materials. S. Maria in Aquiro, better known as the Church of the Orphan Asylum, a modern edifice of indifferent architecture, has been renewed interiorly with much magnificence,—colossal fresco paintings, coloured marble incrustations, stucco reliefs, and gilding. Along the flat spaces of the heavy piers between nave and aisles, large figures of Greek and Latin fathers, executed with a certain breadth and boldness, in which we recognise the student of Michelangelo; on the wagon-vault roof the four Evangelists with their emblems, angels; and along a frieze below scenes from the life of the Virgin Mary; in two ample lunettes at the end walls, the Visitation and the Assumption of Mary, with a group of saints and Pope Paul III., patron of this orphanage; in the cupola, Moses, Jeremiah, David, and Isaiah, associated with four sibyls; and on the pendentives below, Joachim, Joseph, Zechariah, and St. John Baptist, here admitted as personages connected with the Virgin in life,—all by Cesare Mariani, a professor of the St. Luke Academy, now in high repute among Roman artists, and certainly entitled to a high place in this local school. The restorations of the same church, modern Italian in style, are by the architect Gustavo Morichini. More noticeable for historic importance is the lately-completed renovation of S. Niccolo in Carcere, a church that had been shent, on account of these repairs, for nearly twenty years, and which stands above the ruins of three temples, partly preserved within its structure, to Hope, Piety, and Juno Sospita, a subterranean beneath being the supposed site of the story of the "Roman Daughter," not, however, according to archaeological authorities. Entering this church, which is of the basilica type, we are struck by the splendour of the renewed interior, as contrasted with the insignificant front. Along its attics we see the frescoes, in ten scenes, illustrating the life of St. Nicholas of Myra (patron saint of Bari), by Guidi; and in the apex two larger scenes, one from the same biography, the other representing a vision of the Saviour and the Virgin in glory, by Pasqualoni—two artists not yet very well known, nor hitherto (we believe) engaged to adorn any other public buildings; their works here being, if not of the worst, certainly not among the best, lately admitted into Roman churches. Over the high altar we notice a superb canopy of bronze and gilt woodwork, resting on four columns of Oriental alabaster. Another ancient and historic church, renovated by recent labours, is

S. Bartolomeo, on the Tiber Island, founded by the Emperor Otto III., A.D. 1000, on the site of the Temple of Æsculapius, frequently restored, but still of the same basilica type, and now rich in newly-placed marbles and gilding, also adorned with frescoes by Fra Bonaventura, one of the Franciscans of the adjoining convent, who has painted along its attic and coffered ceiling scenes in the life of Mary and beads of apostles. At S. Agostino (a church long in part closed to allow of extensive repairs), Gagliardi is still engaged on a series, begun several years ago, of frescoes along walls and vaults, illustrating the lives of St. Augustine and other saints of his order, besides numerous figures of apostles, patriarchs, martyrs; and at the grand old basilica of S. Lorenzo (the late restoration of which we must protest against), an artist of new-born renown, Fracassini, is now employed in fresco-painting. The works at St. Paul's are still carried on with activity, all the windows along the minor aisles being now painted with large figures (too large, it strikes us, for their location), and the mosaics on the facade advancing to completion, though in no part yet visible. At two of the less prominent churches, S. Maria in Monticelli, and S. Lucia, the above-named Signor Martini has either nearly or entirely finished other paintings, spoken of highly in the Roman journals.

At the last meeting of the British Archaeologic Society, at the English Consulate, was read by Mr. Shakspeare Wood, secretary, a translated paper by Visconti, on antique Roman construction and modes of building, explained with much learning and fulness of detail, by the Italian writer. But most of all did this lecture derive interest and importance from the many illustrations in coloured drawings by Mr. Charles Cooper Wood, brother to the above-named secretary of the society; these drawings, of spirited execution and admirable effect, representing their subjects, chosen among Rome's classic ruin-piles, were on the same scale as the originals, and with exact transcript of the details peculiar to successive periods. For such treatment of the theme of the day's studies as was thus provided, addressed to eye and mind, thanks were due, and with like emphasis, to the learned writer of the paper, and to the artist of the illustrations. Since that occasion the society has twice assembled in the open air, to visit, under Mr. J. H. Parker's guidance, the most interesting remains of aqueducts, both within the city walls and on the Campagna, at certain distances. At the last meeting of the society's committee, it was reported that members, up to that day, were 66 in number, associates 172. The Archaeologic library is developing, thanks to many donations, and the catalogue has just been printed.

The diggings in Trastevere have further brought to light the remains of what is inferred to be a station of the Vigiles, where several *gruffiti* have been found, besides other antique objects of some value. Much interest is excited by the announcement of a discovery, through works directed by Visconti, of a buried city near Albano, assumed to be more ancient than Rome; a paper referring to the ruins on the site of which was lately read by that gentleman to the Roman Archaeologic Academy.

COAL SUPPLY.

The question started some time since as to the length of time our coal was likely to last has led to inquiries by our Government as to the coal supply of other countries, and the result must be very reassuring to those (if there be any such) who fear that the world will be short of coals some three or four thousand years hence. The information appears in the form of a blue-book, containing reports which have been received from secretaries to various British Embassies and Legations respecting the prospects of a supply of coal, if used by, from abroad. The return includes reports from Austria, Baden, Bavaria, Belgium, Brazil, France, Prussia, Russia, Spain, the United States, and the Zollverein. France, in 1865, produced 11,297,052 tons, and imported 7,108,286 tons, of which 1,455,206 tons were imported from Great Britain. Every year shows an increase of coal consumption in that country. Prussia is rich in mineral fuel, especially in very good coals. The working of the coal-pits is rapidly and continuously increasing. No coal is exported from Russia, which is supplied in a great degree from other countries, prominently Great Britain. During

1863, the latest date from which statistics are supplied, the coal produce of Spain amounted to 401,297 tons. No coal is exported from that kingdom. Austria, Bavaria, Belgium, and other continental countries all seem to have well stocked coal-cellars to fall back upon.

In the year ending June 30th, 1866, the produce of the United States was 20,553,350 tons, being an increase of 3,447,043 tons as compared with the previous year. It has been estimated that the capacity of the Pennsylvania mines alone is fully equal to 20,000,000 tons a year. In nine counties of the State of Missouri there are about 3,500 miles of coal lands, which average a mean thickness of 11 ft. Professor Sealow's computation makes out 35,000,000,000 tons of coal in these nine counties alone. In forty counties of the same State there is said to be sufficient coal to last 3,000 years of 300 working days each, if an average of 100,000 tons were mined every day. Professor Rogers has estimated that the Illinois coal-fields are six times as extensive as those of Great Britain, and that it would take 100,000 years to exhaust them. South America, too, has abundance of coal.

British Columbia, Falkland Islands, Mauritius, Newfoundland, New South Wales, and New Zealand are all reported on in an Appendix. In none of these, however, is there coal in any quantity, with the exception of New South Wales, where this valuable mineral is described as abounding. The exports of coal from the colony are extensive, and are rapidly increasing. Coal, too, has been discovered in Natal, so that the notion prevalent among men of science in England that there is "not an inch of coal in Africa" requires qualification. The coal of Natal is of good quality and large quantity, forming a huge watershed, draining a very large area into one natural outlet, the channel of the Tugela river. The coal occurs in seams over 6 ft. thick, which alternate with beds of shale, and it may be seen running directly into the face of the hills. It is richly bituminous, burns readily, makes excellent fires, and cokes well. It is already in almost universal use among the blacksmiths of the colony. There are no engineering difficulties between the coal-field and the sea which would prevent the speedy construction of a railway, and the coal could thus be sold at the port for about 11. sterling per ton. Steam-vessels of large burden could be made to perform profitable voyages of six and seven thousand miles, with a speed of twenty miles an hour, if they could obtain coal at this price, and Natal is less than 7,000 miles from England, and much less from India.

So much for the world's coal supply, and for our own position even were we to run short of coals at home.

FROM MELBOURNE, AUSTRALIA.

The old Olympic Theatre, in Lonsdale-street, has been totally destroyed by fire. The foundation stone of this building was laid by the late G. V. Brooke, in 1855, and within six weeks the theatre was opened. The building at the time was facetiously termed the "Iron Pot" in reference to its having been constructed of iron, with the exception of its foundation, which was of brick. Since then improvements have from time to time been effected, the iron walls having given place to brick. When more commodious theatres had been erected, the tide of fortune deserted the Olympic; and, after remaining closed for some time, part of it was used for Turkish baths, and the theatre and front offices passed into the hands of the German Association, who had possession, as tenants, of it at the time of the fire. The amount of damage is estimated at over 3,000l., the loss falling on several insurance companies. The German Association are heavy losers, having lost a quantity of valuable music, and all the fittings of their gymnasium.

At a recent meeting of the Melbourne press, held at the London Tavern, it was resolved that steps should be taken to erect a memorial to the late Mr. G. V. Brooke, and a committee was appointed to consider and report on the form that memorial should take.

A new tea-house, or temple, has been erected at Emerald Hill for the Chinese residents, and was recently devoted to its purpose. It stands near the southern extremity of Clarendon-street, and is partly European and partly Chinese in its style of architecture. The erection consists of a central hall and two wings; the central hall being the main place of worship, the door of which opens directly into the *sanctum* of the

Buddhist rites. The main entrance opens on a lobby, or, by its peculiar construction, a portion of the hall, as it may be. A few feet from the door are two pillars, with doors so attached as to be capable of making a partition or not, as may be desired. There are pillars ranging right across the hall, and dividing it into three parts, the centre being devoted to the priests, the outside to the worshippers, who, at the opening, might be seen standing in respectful and silent attitudes, fully intent, to all appearance, on the object for which they were assembled,—the acquisition of bliss, through the rites and ceremonies, all appealing to the wandering mind and aiming at the captivation of the soul by sensational effects. These rites and ceremonies, accompanied by strange music, gunpowder explosions, and other no doubt Chinese soul-stirring accompaniments, were renewed at short intervals throughout the day.

The Exhibition is regarded as a success. One would scarcely expect to find a Medæval Court in an exhibition of the products of a new colony; but such a court there is, illustrative of ecclesiastical architecture; and it constitutes, perhaps, the most pictorially effective part of the whole building. Messrs. Ferguson, Urie, & Lyon, glass-stainers, Melbourne, exhibit a decorated chancel, the ceiling of which has for a centrepiece the *Agnus Dei*, surrounded with Scriptural texts and Gothic clouds. The other portion of the ceiling is divided into twelve compartments, having the emblems of the twelve Apostles. The walls are diapered with a simple pattern. It is lighted with five stained-glass windows, the subjects of which are, the Nativity, Passion, Crucifixion, Resurrection, and Ascension. These windows are made for the chancel of the church at Casterton. At the altar are two illuminated tablets of the Commandments, Lord's Prayer, and Creed; also an illuminated painting of the Last Supper. A considerable quantity of stained glass is exhibited, in ecclesiastical and domestic styles; also, numerous samples of stained and embossed borders and small subjects. On the right-hand side of the court is a carved baptismal font, in Caen stone, designed and executed by Mr. John Young, contractor, Melbourne. It is all colonial workmanship. The upper portion is octagonal, representing the Four Evangelists. The base represents evil spirits, in the form of dragons, emblematical of the sacrament of baptism casting them down. The lid of the font is of carved colonial blackwood, polished, ornamented with wrought-iron. In this department are also some ornate water-fonts, sculptured by Mr. F. Utyco; a number of figures carved in wood, for the internal decoration of St. Patrick's Cathedral; an altar and fittings, some hand-rails, and several statues of saints. The *Australian News*, a spirited colonial illustrated newspaper, gives a good engraving of the Medæval Court.

The arbitrators in the metropolitan lunatic asylum case have decided in the plaintiff, Mr. Young's, favour, to the extent of 10,887l.—that is, 7,000l. for profit, 450l. for work done, and the balance for the plant on the ground when the contract was stopped.

The Committee of the West Melbourne Literary Institute have accepted a tender for the erection of the front portion of their new institute. The building is to be erected on a site at the south-east corner of William and Little Lonsdale streets, granted by the Government for the purpose, and is to be constructed of bluestone and brick, with cement dressings. The cost, when completed, will be about 2,200l., but it is intended to finish the front portion only at present, the contract for which is 637l. 10s.

Strenuous exertions are being made to obtain sufficient funds wherewith to erect another hospital in or near to Melbourne. The site on which the present hospital stands is considered unsuitable. It is understood that over 3,000l. have been subscribed for the new building.

Messrs. Greenwood & Co. are now making good progress with their contract at the Malmesbury waterworks. They have been engaging men as fast as they offer themselves. The pug mills are at work, and 200 men are now employed at the aqueduct. It is intended to carry on this work as far as the Expedition Pass, by means of day labour. At the Pass, and at Stony Creek, near Geelong, the works are also reported to be satisfactorily progressing.

The building trades in Kyneton are fully employed. A local paper observes:—"We were informed yesterday by a master builder that he found it necessary to send to Castlemaine for men to complete works on hand. Prices for

labour have not advanced, but the abundance of employment and cheapness of food must be beneficial to the working men, and betoken a cheerful Christmas."

A movement is on foot to induce the Government to place an import duty of 15 or 20 per cent. upon all manufactured ironwork imported into the colony. A mistake.

A meeting of the timber merchants of Melbourne and suburbs has been held, for the purpose of obtaining redress for losses suffered at the hands of importers of timber. After some discussion, it was resolved "That the American timber was incorrectly marked, and that the meeting should not bid for it; that undressed timber should not be bought by superficial but by actual measurement; that should a deficiency of one per cent. occur in dressed timber, full measure should be required, as well as the immediate delivery of at least half of each auction purchase."

It is understood that the Government has accepted a tender in the sum of \$5,000, for the erection of industrial schools for the Ballarat district, the site for which is designed to be rising ground some distance to the north-west of the Botanic Reserve. It appears that about two hundred acres of land will be appropriated to the uses of the institution; and, as this tract has to be placed under cultivation and irrigation, the Government desires to arrive at some arrangement with the Ballarat water supply committee as to a supply of water.

THE SEWAGE QUESTION.

Birmingham.—The Public Works Committee of the Town Council have now submitted a definite plan for the disposal of the Birmingham sewage. They have procured the offer of land, on lease, adjoining the sewage outlet at Sitley, and suitable for irrigation. Mr. Addley's agent has again reminded the council that the pollution of the Tame continues unabated, notwithstanding the order of the Court of Chancery, and hints at the possibility of a more peremptory edict being procured from that tribunal.

Oxford.—The drainage question has advanced a stage by the report of Mr. Bateman having been laid before the local Board, and ordered to be printed. The original idea of Sir Wm. Cubitt was to convey the sewage and water of Oxford to Sandford, in sewers 6 ft. in diameter. The plan was approved by Mr. Bazalgette; but the surveyor strongly urged the desirability of separating the storm-water, and so reducing the dimensions of the main sewer to 4 ft. 6 in. The Board determined to send the rainfall to the river—the sewage to the soil; and Mr. Galpin has been co-operating with the eminent water-engineer first mentioned to secure the result. All previous plans have included the carrying of the sewerage system beneath the bed of the river, to reach the Berkshire shore; and it was formerly intended to discharge the sewage of about 30,000 persons into the stream at Sandford. Mr. Bateman proposes to provide for 45,000 inhabitants, on the principle of applying the sewage to land. He agrees with Mr. Galpin as to the separation of water and sewage, as well as the lines the sewers should generally take. He, however, departs from all previous proposals by taking the sewage under the river, by inverted siphons. It appears that a similar *modus operandi* has been adopted successfully in the city of Hamburg, and is also being applied at Barking Creek. By this means all the difficulties of sewerage beneath the river would be avoided. Under the head of "sewers" Mr. Bateman estimates a cost of 57,000. The land to which the sewage is applied must not be water-logged, but of a friable absorbent nature, and the quantity must be strictly regulated to the limits of fertilization, in order to ensure the greatest possible utilization of the sewage. High ground, near Oxford, must be selected; that near Bagley Wood was accessible and in every way suitable; if more were required, the system could be extended to Littlemore. The cost of pumping the sewage would be 35,000. The quantity of sewage on which Mr. Bateman's figures depend is several million gallons a day. In Edinburgh and London, the sewage is undiluted, and there 600 acres of ground would be the limits which that quantity would fertilize. In Oxford, with a smaller fall, and the necessary flushing required, it would be diluted, and more land would be required, but he could not say exactly how much. Authority is not agreed

as to the proportion of sewage per acre; but the balance of testimony being in favour of 5,000 tons, for a four-fold increase of crops, he has his calculations on that amount. For an outlay of about 100,000l., Mr. Bateman thinks the irrigation scheme may be carried out with pecuniary advantage. At a low estimate of its value, even below that of Mr. Morton, the sewage would be worth 3d. per ton for sale to the farmers. The quantity in Oxford will be, say 4,000,000 gallons a day, but being diluted with water for flushing, its value is reckoned at 2,500,000 gallons of the rich fertilizing elements when not diluted. This will realise 8,488l. 10s. per annum, showing a surplus of 4,000l., after paying interest and working expenses, should the co-operation of the agriculturists be secured. If the Corporation have to apply the sewage themselves, and income, as it were, their own farmers, there will be a further outlay; but the sewage may then be made, it is said, worth 1d. per ton, or 16,972l. per annum, when, of course, the profit would be double.

Tunbridge Wells.—Mr. Bazalgette has just made a report to the Local Board of this town, in which he states that, after a personal examination of the northern (or Tunbridge) and southern (or Groombridge) valleys, he concurs in the views expressed by Mr. Lawson (the engineer whom the Board had previously consulted), that the lands in the southern valley are best suited for irrigation with sewage. He suggests that, before designing works for such distribution of sewage, it would, of course, be prudent to treat for suitable lands for its reception. The lands which are available and can be irrigated by gravitation are known to the Board, and whether they should purchase and lease such lands and farm them themselves, or sub-let them, or lease the sewage to any of the present occupiers after conveying it to them, could be best determined by the Board, upon negotiations instituted by some land surveyor on their behalf. In selecting the position of such lands, it might be roughly estimated that the cost of conveying the sewage to a distance in a covered channel would possibly be at a rate of about 5,000l. per mile. Mr. Bazalgette agrees with Mr. Lawson that about 200 acres will be required, and says that when available lands have been selected, the plans and estimates of the cost of conveying the sewage thither can be more definitely determined.

THE PICTURE OF GUILDHALL.

The Court of Common Council, at their last meeting, determined not to purchase the picture painted by Mr. and Mrs. Melville, representing the interior of Guildhall on the occasion of presenting the Freedom of the City to His Royal Highness the Prince of Wales, though the City Lands Committee had recommended it should be bought, at a price not exceeding 5,000l. It is a very large picture, includes a great number of portraits, and has occupied the artists three years continuously. The result must be something like ruin; and if, as is asserted, they were misled to believe that the picture would certainly be purchased, the case is a very hard one. The painting has considerable merits, though when we saw it much work was wanting to bring it together as a whole. Many of the portraits are good, but, by the arrangement of the picture, the important personages are in the background; and, concerning the majority of the gentlemen and ladies represented in the foreground, though doubtless very eminent and beloved in their respective circles, posterity probably will not much interest itself. Justice, however, is justice; and if Mr. and Mrs. Melville have been led by members of the Corporation to this devotion of their time and abilities, they are bound to prevent the sacrifice of the artists. The price named was preposterous, and probably contributed to bring about the decision of the Court.

THE TRADES MOVEMENT.

Termination of the Masons' Strike, Newcastle. After long dispute, the question at length narrowed itself to that of the men accepting 1l. 10s. for working ten hours a day, or 5½ hours a week; or the masters should concede to the men the nine hours per day, or 50½ hours a week, at the old wages of 1l. 7s. per week. Mr. A. Carse made a suggestion through the press that a meeting of the employers and the em-

ployed should be held in the Lecture-room, and the question finally settled by the ballot. This was at once accepted by both sides, and the meeting was held in the Lecture-room, Nelson-street, Newcastle. Each person entitled to vote was provided with a perforated slip of paper, on one side of the perforation of which was printed "9 hours," and on the other "30 shillings," so that when the proper time came the holder could easily divide the piece of paper, and put the piece which represented his particular view of the case into a large glass jar provided for the purpose. After a statement on the part of the masters had been read and the men had replied, voting commenced. At the close, the Chairman said that 422 had voted, and of these 401 had voted for the nine hours and 21 for the 30s. a week. The result was received with loud and prolonged cheering.

Trades' Unions.—At the invitation of the Amalgamated Society of Engineers, a number of members of trades' unions met at Exeter-hall, on the 21st ult., to consider the recent decision of the Court of Queen's Bench as to the legality of trades' unions, and also the issuing of a royal commission to inquire into the law relating to these bodies. Mr. Wm. Newton, engineer, presided. The hall was full. After an able address by the chairman, the following resolutions were unanimously adopted:—

"That in the opinion of this meeting the recent decision of the Court of Queen's Bench in the case of *Hornby v. Close* virtually destroys the protection which trade societies have enjoyed since the passing of the Friendly Societies Act, and takes from them the privilege the Legislature intended to give in the passing of that measure. It therefore calls upon all trade societies to support the following resolution to the Home Secretary in favour of Mr. Nestlé's Bill.

"That in the opinion of this meeting no commission of inquiry into the doings of trade societies can give satisfaction to the working classes unless they be represented on the commission by members of their own order; and that, as the royal commission appointed to inquire into the organizations of trades' unions contains no such direct representation, we feel bound to express our disappointment and regret that the commission has not been more equitably composed."

Mr. Walpole's Bill has been printed. It gives to the Royal Commission power to enforce the attendance of witnesses and the production of documents, and gives to any witness, not being the actual perpetrator of any act of outrage or crime, and making a full and true disclosure, a certificate of indemnity against any civil or criminal proceeding in respect of any matter touching which he has been examined; but no person is to be compelled to answer questions tending to criminate himself as such actual perpetrator. No evidence taken under this Bill is to be admissible against any person in any civil or criminal proceeding whatever.

Bradford.—The plasterers of Bradford are taking a most arbitrary and unjustifiable course of action. Among other regulations they insist that no plasterer shall be allowed to work in Bradford unless he is a member of the society, or to serve "any firm consisting of more than two masters, unless every partner's name is publicly stated in full." They even go so far as to dictate what work shall be done and what work shall not. They demand that no employer shall, under penalty of a strike, be allowed to dismiss any plasterer unless the rest choose, or to employ more than one apprentice to every five journeymen, each boy being under fifteen years when he joins the trade. In one case the men struck because a master plasterer had some of his sons working under him who were not members of the society.—*Albion.*

Masters and Workmen.—Lord St. Leonards has written a letter to a gentleman in the north with regard to his Masters and Operatives Bill. He says,—

"You have probably seen that I introduced my Masters and Operatives Bill into the House of Lords last evening. The only alteration which I have made is to extend the authority of the arbitrators to future wages for a period not exceeding twelve months. Both masters and operatives have asked me to extend the Bill to future wages generally, and I have declined. I have reason to be satisfied that the operatives generally are willing to accept the Bill. The masters, who were once strongly in favour of it, appear now to think that it will be of no use to them. This, I think, is a mistake. The Bill, you will observe, is simply permissive. The Government intends to inquire into strikes. I told Lord Derby that, although I approved the step, it would be found very difficult to carry with trades' unions. They have become national, and they have attempted an international union, and they are now joining the Reform League. Their organization is surprising, and their power very great. . . . I told Lord Derby in the House last evening that I wished to co-operate with the Government, and I would therefore either read my Bill a second time and take the sense of the House upon it, or let it be referred to his committee on strikes, and he is to read the Bill and let me know his views."

Birmingham.—A special general meeting of the Master Builders' Association has been held

to receive a report of the results of the recent conferences with the trade delegates with reference to the proposed alterations in the local trade rules. Mr. W. Webb presided, and there was a very good attendance. The alterations in the masters' proposed code of rules were unanimously adopted by the meeting, and ordered to be circulated amongst the master builders of Birmingham, and sent to the various branches of operatives in the town. It was also decided that the rules should be signed by the Association if they were agreed to by the men. Should the operatives refuse to agree to these rules, the masters were prepared to meet the operatives at a public meeting, when delegates should be appointed on both sides, and the question decided by arbitration.

Wolverhampton.—As the operatives in nearly every branch of the building trade have given notice for an advance of wages and other privileges, the delegates of the master builders and of the operative carpenters and joiners and the plasterers have met and discussed the claims, under the presidency of Mr. R. Kettle, the umpire. The questions were fully and fairly argued with the best spirit on both sides, and the decision rests with Mr. Kettle, who has taken time to consider the grounds relied upon by the respective sides. The operative carpenters and joiners have resolved, at a recent meeting, that it would be desirable, at a recent meeting, that it would be desirable for them to form a co-operative building association on the limited liability principle, and have appointed a committee for the furtherance of the end in view.

South Wales.—The notice of a reduction in wages at the South Wales Ironworks has expired at the majority of the establishments, and the men have unreservedly accepted the drop of 10 per cent. Owing to the activity in the coal trade, the wages of the colliers have not been interfered with, and they continue on the old scale.

ANTIQUARIAN DISCOVERIES AT HOLME CULTRAM.

A MONUMENTAL slab of one of the abbots of Holme Cultram has been discovered. The inscription runs thus:—"Hic jacet WILLEMS. RY-KAR, Abbas xx. de Holme Cultram, cains aie propicietur Tens. Amen." The letters between y and k in the surname are unfortunately broken out. A correspondent of the *Carlisle Journal* says,—"The late character of the work would lead one to suppose it of about the same date as that of the west porch, A.D. 1507, and probably the work of the same abbot, Abbot Chambers. William de Redekar was abbot in 1431 (see 'Dugdale's Monasticon,' vol. v. p. 593), and was the immediate predecessor of Abbot Chambers; so that this monument is undoubtedly to the memory of William de Redekar, or Rydekar, and probably erected by Abbot Chambers." The material is red sandstone, 4½ in. thick. Interesting as this discovery is, there are now lying in the churchyard the remains of a monument surpassing it in interest,—that of Abbot Chambers himself. The fragments are sculptured in high relief. The abbot, the central figure, is represented in his robes, mitred, with the staff in his left hand.

DRAYTON BEAUGHAMP, HERTS.

The church has been restored, in memory of "the judicious Hooker," formerly rector of the parish. It is a small church, but has many points of interest about it. The plan is, a nave, with aisles, chancel, west tower, and north porch. The chancel is of four bays, of simple bold First Pointed work. The rest of the church is of late Third Pointed date, with clear-stories and insertions of very debased work. The font is a fine Norman one, with small sunk arches round the bowl. At the east end of the aisle is a beautiful Third Pointed reredos, formed by quatrefoil and other shaped panels, bearing traces of their original painting. There are several brasses of the Cheyne family, who lived here as early as Richard II.; and in the chancel is a great tomb of the same family. The east window, before the restorations commenced, was filled with stained glass, taken from other windows (it is said). It was greatly injured, but there remained the figures of the Virgin Mary and some of the Apostles, with armorial bearings below, chiefly relating to the Cheyne family. The whole has been re-arranged and repaired by

HOUSE ARCHITECTURE, BARBICAN.—MR. ROBERT WALKER, ARCHITECT.

Messrs. Clayton & Bell. The structural works undertaken have been, repairing the ancient flat-pitched oak roof of the nave and aisles, a new oak roof to the chancel, new battlemented parapets to nave aisles and chancel, the old parapets having been entirely destroyed; rebuilding the chancel aisle, and reseating the whole area with new oak seats following the old seats, which have been retained in their former positions. During the progress of the works a number of ancient tiles were discovered; these, together, with others previously in the chancel, have been reproduced by Minton, and the chancel has been laid with them, in patterns, divided by borders. The pulpit is of oak, on a stone base, octagonal in plan, and on each face of it is an angel, 2 ft. 6 in. high, bearing an emblem, and with its outspread wings covering the whole side. A new carved pyramidal font-cover, of oak, has been placed on the ancient font; this, together with the pulpit and the carving of the chancel-seats, has been executed by Mr. Forsyth. The external facing, of flints and stone, in cloggers, has been restored, having been covered over with rough cast and cement. The tower still remains to be done.

The works have been carried out, under the architects, Messrs. Slater & Carpenter, by Mr. Chappell, of Tring, Mr. W. Thompson being clerk of works.

A brass plate has been let into the pulpit, with an inscription.

CITY HORSE REPOSITORY, BARBICAN.

CONSIDERABLE alterations are in progress at the Royal City Horse and Carriage Repository, Barbican, of which Mr. J. S. Gover is the proprietor. The stabling and yards have been increased by the purchase of a large freehold site at the back of the Clarence Hotel in Aldersgate-street, where an additional entrance has been formed, nearly opposite the new station of the Metropolitan Railway.

The portion of the property facing Barbican has been pulled down and a new building erected, as shown in the above engraving. It the Repository, with foreman's residence over, and a warehouse on the right-hand side; a series of loose boxes on the right-hand side; a new range of stabling, with offices and buildings over, will be shortly commenced.

In consequence of the heavy traffic to the premises great care has been taken to round all the external angles of the buildings, and for the same reason the columns supporting the front are of cast-iron, weighing about 1½ ton each, and resting on granite bases. The arches and entablature over are in Portland stone, and the rest of the dressings in Portland cement.

The first portion of the contract is being executed by Mr. Andrew Kilby, of Limehouse. Mr. Robert Walker, of London, is the architect.

DESIGN FOR PROPOSED LAW COURTS.—By Mr. ARTHUR WAREHOUSE, ARCHITECT.—View in the Strand.

[See p. 14, ante.]

THE HEMEL HEMPSTEAD WATERWORKS, BATHS, AND WASH-HOUSES.

The contract for the erection of these works was taken by Messrs. Atkins, gas and water engineers, London, who erected similar works at Berkhamstead last year. A piece of land was purchased for a site opposite Marlow's Chapel. The buildings are of considerable extent. There are two entrances to the baths, with arches supported on stone pillars with carved capitals. Between the two entrances is the pay-office, and on the left are the private rooms of the managers of the works. There are six baths in each department, four first-class and two second. The bath-house is heated by steam pipes, and ventilated. Waiting-rooms are provided for the bathers. The second-class baths are but little inferior to those of the first-class. The washing processes are carried on by the company themselves.

A single steam engine supplies the town with water, and impels all the machinery in this establishment. The superfluous steam from the boiler, passing by pipes through a tank of water, is condensed into water again, and the water in the tank is thus heated, the boiler replenished, and the baths and laundry supplied with hot water.

The company obtain their supply of water from an artesian well, 212 ft. deep, in a chalk and flint formation. From this well the water is pumped, by steam power, into a covered reservoir, in Chapel-street. A continuous high-pressure supply is given from the reservoir to the consumers' houses, and storage tanks are rendered unnecessary. The company state that their pumping apparatus enables them to deliver water to the highest elevation in the district. Mains are laid on in all the principal thoroughfares; and fire-plugs and stand-pipes are placed at different parts for watering the streets, extinguishing fires, and for other purposes. The charge for a supply of water for domestic use, supplied by meter, is 1s. 6d. the 1,000 gallons. The engine and pumps were designed by Mr. Atkins, and made by Messrs. Tidcombe & Son, of Watford. The boiler is a Cornish one, 6 ft. in length and 21 ft. in diameter. It was manufactured by Mr. William Wilson, of Glasgow.

THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held at the House in Conduit-street on Friday evening (the 15th ultimo), Mr. R. W. Edis in the chair.

Mr. Turner brought under notice the desirability of increasing the library, either by voluntary donations from members or others, or by assistance from the funds of the Association.

Mr. Armstrong suggested that the better course to adopt would be to raise a fund of 100l. or 150l. in the first instance, either as a gift from individual members, or by way of loan, to be repaid in future years by crediting the annual subscriptions with a portion of the money lent. If it were known that the Association possessed a really good library, he believed it would be the means of attracting many additional subscriptions, because there was no other architectural library in the metropolis which allowed the members to bring the books to their own homes.

After conversation, Mr. J. D. Mathews (hon. secretary) said the committee could not see their way to devoting their funds in the proportion mentioned, even to so valuable an object as the formation of a better library; and he for one would object to setting aside a portion of the annual subscriptions in the manner suggested. His own opinion was that, if it were more generally known that the Association wanted a better library than it now possessed, the senior members of the profession would come forward and help them. In fact, many gentlemen had volunteered subscriptions to the Association, but, as their rules prevented them from accepting such offers, all he could do was to suggest that the volunteers should become members of the Association, and in that way many senior members of the profession had joined them. He believed that, if the members would invite their professional friends to assist them in making the library more useful, assistance would not be refused.

* The following gentlemen were elected members of the Association:—Mr. A. J. Hewitt, Mr. Wall, Mr. F. T. Döman, Mr. Fitzpatrick, Mr. Taring, Mr. Collier, and Mr. John Seet.

Mr. R. Plimbe thought the great want of the Association was a large room for the use of the members, and for its general business.

Mr. T. Roger Smith inquired whether any surplus books had been received from the Institute lately.

Mr. Mathews replied that none had been received for two years.

Mr. Smith said that in that case he would place in the hands of the Secretary a letter he had received from Mr. Beresford-Hope on the subject, and that he would recommend them to agitate a little until they got what they wanted. He suggested whether, without seriously trenching upon the funds of the Association, a small percentage of the subscriptions might not be applied to the extension of the library. Good books were the most valuable agents which the student of architecture could have in acquiring a knowledge of his profession; but he thought it would be more desirable to accumulate them in the library than to take large premises, as the library being a lending one, the books could be taken home. He was not aware that the senior members of the profession had been asked for assistance.

Ultimately the subject was referred to the Committee.

The Chairman drew attention to a letter which he had received from the Secretary to the Architectural Museum Society inviting assistance towards their new building near Westminster Abbey. The subject had, he said, been brought under the notice of the Committee, who had arrived at the conclusion that they would not be justified in voting any of the Association funds to the Museum unless they got something in the way of an equivalent. Under these circumstances, they had asked for fifty tickets, but they had not yet received any answer. Should their proposal be favourably entertained, the Committee would subscribe. He understood that the new buildings in Westminster would be convenient and comfortable for art students.

Mr. T. Wells then read a paper on "The Influence of Eastern and Western Art, and more especially on that influence as exhibited through the medium of Constantinople." These influences he considered under five principal heads—first, in Greece and Rome before the transfer of the seat of empire from Rome to Constantinople; secondly, in the effects of the political, commercial, and artistic relations between Europe on the one side, and Constantinople and her dependent cities in the Levant on the other; thirdly, in the effects of the occupation by the Saracens of Spain, of Sicily, of much of the shores of the Adriatic, as well as of the European coast of the Mediterranean; fourthly, in the results of the Crusades; and, fifthly, in the art of Modern Europe. To the explanation of the second of these manifestations Mr. Wells chiefly applied himself, contending that the arts of Europe were in past times greatly indebted for their excellence to the graceful and fertile imagination of the East. In his opinion much of the inferiority of the art of modern Europe was due to the lack of that stimulus of emulation once provided by the compulsory existence of a powerful, cultivated, and, in Mahomedan times at least, a rival condition of society in the Levant. This emulation was excited and continually renewed by the fame of edifices, of admirable invention and beauty, rising in never-ending succession in all her famous cities, by a familiar acquaintance with the examples of her art in all classes and degrees of excellence, which she day by day sent forth (whether under the regis of Constantinople or other sovereign cities) to pass freely as articles of commerce from hand to hand throughout the length and breadth of Christendom.

A short discussion ensued.

ARCHITECTURAL EXHIBITION SOCIETY.

The report of the Council shows that the current expenses of last session were fairly met by the receipts, though the amount paid by the public for admission was very small. This, of course, means that the exhibitors had a much smaller public than it is desirable should be gained for them. The council have put themselves in communication with the committee of the Architectural Museum, and the lectures of the two societies will be made to form one list. The council are striving to render the next exhibition a good one. Drawings must be sent in by the 6th of April next.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

At the meeting on the 27th of February, Mr. H. Syer Cuning, V.P., in the chair, Mr. E. Roberts, F.S.A., exhibited the known portrait, by Zincke, of Shakespeare, denounced in pp. 22, 23, in Wivell's Supplement, for the examination of the Society, as few persons of the present day are acquainted with it. Mr. Bailey exhibited an enormous tooth of a Seal, found in London-wall in December last, at a great depth. It was discovered in the usual black soil, but as it appears to be the only known example found in England, information was requested. Mr. Irvine exhibited drawings of Roman antiquities in Cirencester Museum. As regards an assumed sacred monogram, I. H. S., on some pottery, it was hoped the specimens themselves would be sent up, as doubts were entertained, firstly, of the accuracy of the sketch; and, secondly, of the meaning attributed to it.

Mr. Cato exhibited a very beautiful and perfect Roman glass bottle, having a globular-shaped body indented on four sides, and a long, narrow neck, found in Dover-street, in December last. Mr. Cuning stated that it is of a very rare type. Mr. Gunston exhibited some of the most recent home forgeries.

These and numerous other exhibitions caused discussions, which left little time for the consideration of the paper by the chairman, on the "Cross Tau of St. Anthony," giving an account of this early emblem; its being found in the hands of Egyptian divinites; having been worn by Pharaoh's subjects; used by the Druids; used as charms in Gnostic, Hebrew, and Knights Templars' times; and subsequently known as the emblem of St. Anthony.

In the brief discussion which ensued, Mr. Roberts, followed by the Rev. W. S. Simpson, threw out the suggestion that this emblem, like the triangle, always was applied to a triumph of almighty powers.

THE PROPOSED ROAD IMPROVEMENT AT HYDE PARK CORNER.

Str.—In the notice you have done me the honour to take of the improvements at Hyde Park-corner suggested in the *Builder* of the 15th December ult., you state that the proposition to alienate part of the Park is likely to be objected to.

Permit me to draw the attention of those likely to make such an objection to the fact that the proposal is nothing more than a repetition of what has already been done in St. James's Park by the formation of Birdcage-walk; for this roadway was originally part of the Park; and then let me ask them to look at the question in the following manner.

Imagine Birdcage-walk roadway not to exist, and the question now to arise for the first time, what is the best way of providing for the passage of traffic between George-street, Westminster, and Buckingham-gate? Imagine, further, that the Board of Works answer the question by a proposal for carrying the traffic round Victoria-street, and that a counter proposal is started for the formation of the present Birdcage-walk roadway. They have then a case analogous to the one now before the public for the improvement of the roadway between Stanhope-gate and Grosvenor-place, and with the same probable public objections thereto: that such public objections have not prevailed against the formation of the Birdcage-walk roadway is a sufficient reason that they should not be allowed to militate against my proposal, especially when it is evident that the benefits resulting to the public from the adoption of my plan would be more than treble those afforded by the Birdcage-walk scheme.

But who can read your interesting article last week on the Grosvenor-place and Piccadilly Improvements without regretting that what you call "a main artery from Grosvenor Hotel to Hyde-park Corner" should be stopped short in its course at Piccadilly, while an opportunity is offered for, and a saving of 94,000l. is to be effected by, continuing that grand thoroughfare in an almost direct line to Oxford-street.

The direction of and want for this "main artery" now being constructed by the Marquis of Westminster, is caused by the erection of the Victoria and Paddington Railway Stations, and the consequent increase of traffic between these two points; clearly, therefore, a plan having for its object the continuation of this enormous

stream of traffic in a direct course to its destination, is better than one which would make that stream stop short in the middle of its course, turn sharply off at an acute angle, and then, after a passage of 300 yards, make another turn at a still more acute angle, before it could again assume the direction in which it was ultimately tending. And this, sir, you will see on reference to the two plans is really the difference between the scheme of the Metropolitan Board of Works and my own.

You truly state that "the chief objection to my plan would come from the owner of Apeley House." His Grace will, however, have learned from the result of the opposition by another high personage to the formation of the Thames Embankment, how impossible it is for an individual to successfully oppose a public improvement.

HENRY SAXON SNELL.

THINGS NOT GENERALLY KNOWN.

WHEN the sinking of the caissons for pier No. 3 (the second from the Middlesex side) of New Blackfriars-bridge is to be commenced.

When the new Meat-market is to give us meat.

When the Circus at the corner of Cornhill, Gracechurch-street, &c., is to be made.

When the circus is to be formed at the bottom of Ludgate-hill.

When the railway-bridge over Ludgate-hill is to have its side staircases opened.

When the widening of the road at the top of Ludgate-hill is to take place.

When Contract No. 1 for Northern Thames Embankment (Westminster-bridge to Somerset House) is to be finished.

When Contract No. 3 for Northern Thames Embankment (Temple to Blackfriars) is to be commenced!

When the Chelsea Thames Embankment (Chelsea Hospital to Battersea Bridge) is to be begun.

When the part of the Southern Embankment which reaches from Ferry-street Dock, Lambeth Bridge, to Gnn Horse-alley, Vauxhall Bridge, is to be completed.

When Albert Bridge, Chelsea, is to be finished.

When Wandsworth Bridge is to be commenced.

When Southwark Park is to exist!

When Finsbury Park is to be.

When Park-lane is to be widened.

When Middle-row is to be removed!

When St. Clement's Church, Strand, and St. Mary's Church, Strand, are to be removed; and the wretched "Strand Middle-row," which forms the south side of Holywell-street, is to be taken down, and the Strand made of a decent width as an approach to the new Law Courts.

When the sixty or seventy houses which now form a barrier to a straight road from the Strand to Hampstead, by way of Newcastle-street, Lincoln's-inn-fields, Gate-street, and Southampton-row, are to be removed.

When the opening from Whitechapel to Commercial-road is to be commenced.

When the Pneumatic Railway (Whitehall to Waterloo) is to be in operation.

When the Metropolitan District Railway is to begin to run trains.

When the East London Railway will commence tunnelling under the East Dock of the London Docks.

When the side streets running from Victoria-street (the Blessed) are to have their names put up.

When Phillips-street, Victoria-street (the street which runs behind the noble new distillery), is, after twelve years' of unfinishedness, to be proceeded with and opened.

When the Metropolitan Railway will reach its destination, the Crescent, Minorities.

When the carriage road in front of the Metropolitan Board of Works Office, Spring Gardens, will be thrown open to the public.

When Waterloo, Charing Cross, Lambeth, Vauxhall, Chelsea, Putney, and Hammersmith bridges are to be free bridges.

When the bridge from the Tower to Bernondsey is to be built.

When Old and New Bond-street are to be renumbered, and form one street,—Bond-street.

When Wood-street and Cripplegate-buildings are to be renumbered, and form one street,—Wood-street.

When the wilderness of ground on three sides of Battersea Park is to be built upon and civilized.

When Dowgate-hill, Cannon-street, is to be cleared; and Walbrook to be widened.

When the Metropolitan Board of Works will acquire all the property needed for New Earl-street.

When the notches in Newgate-street are to be filed off.

When the Westminster Bridge-road is to be made of the same width as Westminster Bridge.

When the Tottenham and Hampstead Junction Railway is to be completed.

When the new Blackwall Railway Bridge is to be built over Leman-street, Whitechapel; and when the widening of Royal Mint-street is to be completed.

When San Tavern-gap (a delicious spot), Ratcliff Highway, is to be made a carriage thoroughfare.

[There was to have been inserted here,—

"When Victoria-street is to be completed," but it has been suggested that that is a thing generally known. The answer being,— "Never." This, therefore, is omitted.]

When the press is again going to report to the world the monthly money progress of the Southern Thames Embankment, commenced September 21, 1865, and last reported by the press, September 29, 1866; when 67,000*l.* had been done in plant, materials, and labour, about 5,600*l.* a month.

When the Thames is to be embanked from the Victoria Tower to Lambeth Bridge.

When buildings which are to last for many ages are to be so planned as to allow of easy alteration to admit of new improvements and inventions, and not be open to the objections which Sir A. Clifford recently most righteously brought forward against the New Houses of Parliament.

When architects will learn that steps at the street-doors of buildings, whether churches, Strand Music-halls, shops, or any other buildings, are almost necessarily a nuisance and a defacement,—a relic of the times when, there being no pavements, a man was compelled to build his house high to keep himself free from floods.

When the electric telegraphs of the country are to be placed under one management, and a very small uniform charge made for messages.

When Tower-hill, and all round the Tower, are to be lighted and properly paved.

When a proper system of public urinals, lavatories, &c., is to be established in London, with directions at the corners of the streets as to where they may be found.

When notice-boards on church doors are to cease to be shabby with old partially-defaced bills.

When travelling in London is to be (as it might be) half its present price, with double its present convenience.

A WANDERER AND A WONDERER.

BELLS FOR PUBLIC CLOCKS.

CERTAIN well-known dictionaries and cyclo-pædias tell us, that a bell is "a vessel or hollow body of cast metal, formed to make a noise by the act of some instrument striking against it."

And the fact must be admitted that numerous bells, of various kinds, are "formed to make a noise"—in too many instances a dreadful one—and nothing more. Nevertheless, I maintain that a bell, properly so called, is "a musical instrument of percussion;" and that no "vessel or hollow body," the tone of which is offensive to a good ear, ought ever to be introduced for a public clock, or, indeed, for any other purpose.

Moreover, knowing that the sound of a really good bell is often marred in effect by that of its neighbor, I have long entertained the opinion that when a tower or a turret contains a clock with a fine-toned and truly efficient bell, no other bell, the note of which is not in accord or harmony with that of the former, should be put up for any other public clock within a reasonable distance from such tower or turret. Accordingly, when I consulted some years ago respecting a clock bell for a new edifice standing near an old church tower containing a powerful hour-bell, being the tenor of a peal in the key of E, I proposed to design one to emit the dominant note of that key. So that whether the two clocks happened to strike simultaneously or otherwise, no disagreeable effect would be produced.

A word on the composition and form of bells, for notwithstanding the statements of our highest authorities, based upon the experience of the

best founders in the world, we find year after year, the following "vulgar errors" reproduced:—1. "The finest old hells had silver in their composition, which accounts for their sweetness of tone." 2. "Bells for turret clocks should be made in the hemispherical form."

Now, with regard to the first point, I may say, that in fragments of some old bells that have been subjected to analysis, a very small proportion of other metals, such as zinc, silver, &c., has been detected, in addition to the usual alloy of copper and tin. But experiments have been made, the result of which clearly shows that the notion that bells would be improved by silver is a delusion. It rather injures their sound.

As to form, everybody knows, that for house-clocks, &c., bells of the hemispherical form are very properly used. Nevertheless, if you want a bell for a tower or turret, to produce a good volume of sound, and a fine quality of tone that shall be heard at a reasonable distance, it must be made of the long-established shape and proportion of our best church-bells. And we know the reason why. Bells of the hemispherical form weighing about 4 cwt. may answer for cemeteries for obvious reasons. But the sound of heavier bells of that form is generally *tubby*, extremely doleful, and offensive.

THOMAS WALESBY.

FAIR PLAY FOR THE LAW COURTS COMPETITION.

SIR,—You have given good help. The letters which you published last week,—but especially your own remarks appended to them,—in which the matter was put so kindly, and yet only fairly, as every one must admit who knows the secretary's genuine integrity, had a very good effect; but the help must be continued, or the competition will end in disgrace yet to every one. There are pretty decided indications that the hatteries are only "masked" for the present.

I enclose a printed paper, which will show what I mean. It was handed to the Solicitors' Committee,—of whom I am one,—and the Bar Committee,—for whose guidance it had been prepared,—and one or two of us who had examined the designs saw that it was substituting a new test for the only one which the architects could accept, viz., the book of "Instructions;" and, worse still, that the new test was constructed on the basis of one design, that of Mr. Waterhouse; so that while it might admit one or two other designs on some minor points, it would admit the first-named design *alone*, on those points which the paper declares to be vital!

The Bar Committee refused to look at the paper. We, the Solicitors, received it, but had it reprinted as "confidential." It is being worked upon: so, you see, means are still being adopted to force the one favoured design into the first place. I could name several, but I content myself with one more instance which has come to my knowledge in a curious way.

Dr. Percy was invited to report on the various schemes as to *capability* of ventilation, as well as on the systems proposed. He wrote a private note to say that he must warn Mr. Field that he was greatly prepossessed in favour of Mr. Waterhouse. Most persons would have thought that the writer, by this candid and very proper intimation, proved capacity. No such thing. It is understood that he has now accepted the duty, and it remains to be seen if his first note will be laid before the Commission. Pray continue to keep a vigilant eye on the whole business.

A MEMBER OF THE SOLICITORS' COMMITTEE.

AS TO THE PROPOSED LAW COURTS.

SIR,—I have read with much interest the description in the *Builder*, of the plans now being exhibited for the new courts, intended to be erected near Temple-bar; and having had considerable experience of courts of justice, my vocations having caused me to attend them for many years, I may be allowed to have acquired some knowledge of what is required, although not an architect.

I am a Londoner, and know the site in question, and observe that it is called the Strand, but I will call it Pickett-place, which I believe to be more correct. The ground rises gently

from Pickett-place to Carey-street. I am against a central hall, and suggest an inner court-yard, the Law Courts forming four sides of a square, the chief entrance to be from Pickett-place, through an archway, protected by gates; and after the judges have alighted from their carriages, the egress to be through an archway into Carey-street, with a porter's lodge at each gateway.

You will perceive from the above that I mean the judges to ascend to the judgment-seats of their respective courts by entrances from the courtyard.

I propose that there should be eight distinct blocks of buildings, separated from each other by a passage-way, with a side entrance for the barristers and attorneys, and a front entrance on the four sides for witnesses; with a staircase leading to a gallery for the public, with three law courts in each block: this would allow of a fourth part of the block for a consulting-room for the barristers and attorneys, the arrangement being one court on the ground-floor, and two courts on the first floor, with rooms above for any purpose deemed necessary. This plan would meet the wish of the authorities, and prevent idlers from passing from court to court, unless they left one building before they entered another.

The judge's bench in each court to have the windows of the room on the right and left of the judge, which will give him a good light, and preserve a current of air, from side to side, by allowing the window sashes to be slightly raised in very warm weather. The judge's benches to be parallel to each other, with a room between the two walls, having two doors, one on each bench, behind the chairs of the respective judges, to which room they can retire for consultation or other purposes.

Over the front gateway a clock-tower to be erected, with fire-proof chambers for the records. Over the Carey-street gateway, apartments for the hall-keeper and other attendants.

In the centre of the inner court-yard an octagon building, with rooms for harristers, robing, and other purposes.

It will be seen that by this arrangement of the building twenty-four law courts are secured,—which, it will beacknowledged, are as many as will be required,—and numerous rooms on the second floor for the officials attending on the judges, &c. From studying the matter, I think an inner court-yard would be a great advantage, particularly as it would give the judges an easy and convenient entrance to their courts, and obtain good light and air, a very important consideration. MENTOR.

PUBLIC AND PRIVATE BATHS.

THE bath prevailed to such an extent amongst the ancient Greeks and Romans, that at last its use came to be looked upon more in the light of a necessity than a luxury, and it was even customary for the host, immediately on the arrival of his guest, to offer him the refreshment of levation, with all the concomitants of costly perfumes and rich garments. This practice still obtains, in a certain degree, with the higher order of Orientals, who have their bath-rooms fitted up in the most superb style, and replete with every convenience to increase the exhilaration of the process. In striking contrast to all this is the disregard which the majority of Englishmen appear to pay to the hygienic and other beneficial effects derivable from a free use of the bath. Unquestionably, in the case of public baths, this indifference and apathy is partly to be attributed to the laches of parochial authorities, in not taking proper steps to introduce them into the districts over which they exercise surveillance. For instance, in the parish where the writer resides (Chelsea), with a population of about 60,000, there does not exist a single public bathing establishment, and those of the inhabitants who during the summer months wish to indulge in the healthful and delicious recreation of natation can only do so by making a journey to Pimlico or Lambeth. This state of things naturally reflects discredit upon those in power, more especially as there are generally plenty of people ready to invest capital in any enterprise likely to be remunerative; and no reason is deducible why the erection of public baths and wash-houses should not prove as profitable as a vast number of other investments, if regulated and maintained in a proper spirit. If it is really desired to eradicate some of those infectious diseases that make such terrible havoc

amongst us from time to time, and which are indubitably in a certain measure due to want of cleanliness on the part of the poorer classes of the community, some action should be immediately taken in the matter, so that, at least this reproach would be removed from our doors. Supposing the purification of the Thames, owing to the improved system of drainage, continues to progress in an even ratio to the present, it is not Utopian to promise that some day we shall find baths floating upon its pellucid surface similar to those of the Seine, Rhine, and Danube. The only objection to this mode is that the water cannot be made tepid in proportion to the coolness of the weather; but bathers will put up with almost any discomfort rather than total deprivation, and the plan seems to answer exceedingly well on the rivers just referred to.

The importance of some such realization is considerably intensified at this moment by reason of the observations which the calamity in Regent's Park has called forth. Many persons hold the opinion that had more of the unfortunate sufferers been able to swim the terrible results of the disaster would have been greatly mitigated. Such sentiments are not entirely without foundation, for two or three of the survivors affirm that they owe their lives to a knowledge of this art, although at first sight the excessive frigidity of the water certainly appears to militate against such a possibility. However, be that as it may, the fact nevertheless remains patent that the chances of escape must have preponderated immeasurably in favour of swimmers, as in all probability they would have continued comparatively tranquil until succour arrived, and not exhausted their strength in vain and ineffectual struggles, as unfortunately too often happens.

Concerning baths in private dwellings. From the frequency of accidents lately through the failure of certain details of the apparatus arranged to produce hot-water, it might be surmised that there are difficulties in the way of obtaining suitable means for this purpose. But it is not so. The principal solution of the problem is the fact that men are engaged who have scarcely any idea of the *modus operandi*, and much less of the laws which govern the circulation of water, and the expansion and contraction of metals: consequently, the whole concern gets fixed in a most confused and unsatisfactory manner, totally irrespective of the influence exerted by these laws. The only sure remedy is to employ none but those who are experienced; this being, as in almost everything else, the unfailing insurance of competency.

The practice in vogue in order to secure a constant supply of hot-water for the bath is generally to locate the boiler at the back of the kitchen-range in such a manner as to be in direct and immediate contact with the fire, and subject to its full effect, or to pose it somewhere low down in the chimney, exposed to the influence of the hot gases arising from the combustion of the carbon beneath. A great drawback to the first arrangement, however, is the inaccessibility of the boiler, when after some time, in spite of the circulation of the water, incrustation supervenes. The sediment has to be removed by means of a scraping tool inserted through a plug-hole into the boiler, or the latter must be disconnected from the range, which requires to be drawn out for that purpose, operations consuming time, and always accompanied with trouble, and inconvenience. Therefore the plan which places the boiler above the fire is preferable, as an aperture panelled on ordinary occasions can be formed in the chimney-breast to admit of inspection or extraction, as the case may be. Again, to diminish the chances of mishap from frost, supposing the fire to become by any means extinguished, the pipes and cisterns are invariably situated within doors, and the former, where convenient, are ranged in close conjunction to those intended to supply cold water to the upper chambers, thereby preserving them likewise from the same all-powerful action. Extra precautions are also taken by fixing a small lever or spring safety-valve to the "return" pipe, and placed in a wooden box provided with an overflow tube to carry off the waste water. The surface line of the water in the cold cistern is shown through the instrumentality of a glass gauge similar in many respects to those ordinarily seen on steam boilers.

In instances where a magazine of hot-water is not imperatively demanded, a periodical supply is efficaciously attained by affixing a gas furnace to the bath itself, with the usual adjuncts of flow and return pipes; these are naturally much

shortened, and expensive fittings almost entirely dispensed with. Moreover this furnace is capable of receiving sundry appliances for warming linen and other domestic articles, no mean consideration to matrons of schools, and establishments, &c. It is true that the time needed to convey sufficient caloric to the cold water is rather extended, but then compensation is afforded by freedom from danger and decreased cost of erection and maintenance.

S. W. WORSSAM, JUN.

CONDENSED WATER FROM GIRDERS.

SIR,—I have lately been concerned in the erection of a school-room for the use of the working-classes. The room is frequently used in an evening for lectures, and occasionally for social meetings, and is generally crowded. The roof is sustained by seven iron beams of a semi-circular form, about 12 yards in diameter. These beams are cased in wood, with the exception of a hand about 2½ inches wide. When the room is full, the warm air condenses on this iron band, and a constant dripping of water takes place, to the great annoyance of bald-headed men and gaily-dressed women. "There is nothing new under the sun," we are told; and if so, this inconvenience is not new, and probably you or some of your readers may be able to suggest a remedy. I shall be grateful for any practical suggestions that may cure the evil.

AIRQUIS.

. The obvious remedy is to cover with absorbent material the exposed part of the girder, though efficient ventilation might render this unnecessary.—Ed.

THE REMOVAL OF TEMPLE BAR.

IT having been proposed to fix the old landmark as one of the entrances to the Temple in Fleet-street, I beg leave to move as an amendment, that it be placed at the entrance to Temple Gardens, where it would be better seen in an ornamental point of view than if crowded in among the houses in the street, to say nothing of the ground it would occupy,—at least enough for five or six houses, which, at a rough calculation, would produce 3,000l. a year: rather too expensive a lodging for our old friend. The entrance to the ornamental inclosure, opposite the Horse Guards, would be a better place than the Temple, but I suppose there is an objection to its leaving the City. GEORGE ELLIS.

ODOURS FROM NEWSPAPERS.

SIR,—Can you, or any of the readers of your journal, explain how it is that such a horrible smell proceeds from some newspapers,—particularly when held, as they often are, between the reader and a hot fire? It cannot be the paper, I should think; if not, then it must be the ink; but whatever it may be, I assure you I have often been not merely disgusted, but sickened by it. On one occasion I had accumulated a pile of newspapers and magazines in a closet of my bedroom, and the smell resembling rotten cheese, which I ultimately traced to its true source, was such as to render the apartment almost uninhabitable. As you are a sanitary authority, and as the *Builder* never smells had (whatever places it describes may do), I thought me of writing to you on the subject. I have not the least doubt others have suffered from the same cause. C. B.

FOLKESTONE COMPETITION.

SIR,—Has any one heard if the South Eastern Railway Directors have arrived at any decision on the plans submitted in this competition at Christmas last? A COMPETITOR.

HEALTH IN LEEDS.

SANITARY matters here seem in a ludicrous condition. The town-council appointed an officer of health; and, poor innocent man, he actually began his work, uprooting nuisances and foul abuses militating against public health. All Bumbledom was rampant, and in public meetings he was recommended to "go to the place from whence he came, for Leeds didn't want him." Ominous hints were given to him that those who paid his salary might possibly withdraw it, if he insisted too much on new-fangled notions of there being any virtue in cleanliness. The West Riding motto—and Leeds *par excel-*

lence is the West Riding—is, "Where there's muck there's money," and he must be conservative of muck, or there might be lack of money, to his account especially. And so the poor officer is simply extinguished. Nothing has been heard of him for months.

The Society for the Prevention of Cruelty to Animals has, in conjunction with private persons in the town, appointed a resident officer in Leeds, Inspector Temperly, and week by week we see the result, in cruel human brutes being fined at the police courts for illtreating brute animals. But not so with the sacred privileges of landlords. The people pay for the officer of health, but seldom hear of his earning his salary, when the sufferers he is appointed to protect are mere human beings.

RAILWAY MATTERS.

A NEW station has just been opened at Crews which has been built by Messrs. Parnell, Son, & Bennett, of Rugby, at a cost of about 36,000. A deviation line, about a mile long, is also being made north of the station for the Chester line which at present passes through the Crews Works. Extensive shopping is being added to the already great pile, in which the manufacture of steel rails, locomotives, carriages, &c., is conducted at this rapidly growing railway town.

A project has been proposed to the North-east Railway Company of Switzerland to cross the Lake of Constance by floating the trains over. A train of fourteen to sixteen carriages is to be placed upon a steam-vessel, which will be furnished with rails for the purpose. The boat or raft, will be propelled by an engine of 200-horse power.

The Prussian Government has given the Berg-Märkisch Railway Company permission to build a bridge across the Rhine at Hemm, just above Düsseldorf, on condition that the piers are constructed in such a manner as to admit of being blown up at any moment below the water, and so effectually as to make its repair a work of time. The company is also required to build sufficiently strong works for the protection of the bridge against a *coup-de-main*, to secure the power of destroying it before it can be forced by the enemy.

COMPETITIONS.

Wath Cemetery.—The design submitted by Mr. J. D. Webster, of Sheffield, architect, has been unanimously adopted by the Burial Board, and the buildings will be commenced forthwith. The cost will be about 1,300.

INSTITUTION OF CIVIL ENGINEERS IN IRELAND.

A GENERAL meeting of members has been held in the Museum Buildings, Trinity College, Dublin. The chair was taken by Professor Downing. Colonel Meadows Taylor read a paper on "Tank Irrigation in Southern India, with the native construction of Dams, Sluices, and Escape Weirs." The paper, which was of a practical kind, commenced with a brief description of the various soils, and the means of irrigation by use of tanks and reservoirs in the south of India, touching on the various historical events by which these inventions were brought about, resulting in the most noble hydraulic works in the world, which had existed and would continue to exist for centuries. He gave lengthened and minute descriptions of several of the principal reservoirs visited by him in India, and great credit to the native skill by which they were constructed. He also described waterworks he had constructed while holding an official position in India. The lecture was illustrated by diagrams, and lasted nearly two hours.

Mr. W. E. Bateman, C.E., remarked on the difference between the construction of such works in India and in this country, arising from different surrounding circumstances and materials available in each case. There were not the difficulties to contend with in India that there were in England and Ireland in constructing water-tight embankments, especially as regarded the foundations on which they were laid. Here the engineers had to contend with broken strata and unfavourable soil generally, as well as want of proper material in sufficient quantities for the

pudding, and which abounded in India, where the surface of the ground was essentially water-tight, and where they had clay without broken sandstone. He described the various methods of constructing reservoirs in England, and stated that it did not follow that because there was a leakage in an embankment there was necessarily any danger, or that there need be any apprehension of a disaster to the works; and he also illustrated, by means of a large diagram, the cause of the catastrophe which occurred at the Bradford reservoir some few years ago. The chief cause of that unhappy occurrence was the portion of the bank which gave way being laid on a slippery foundation of sloping rock.

COMPENSATION.

Recess and Turner v. The Royal Commissioners of the New Lane Courts.—His claim, heard by the High Bailiff of Westminster, exceeded 6,000, on leasehold premises, No. 238, Strand, adjoining Temple-bar, and the consequent on removal. The claimants, as book-yearly increasing. They could not procure other premises, and anticipated that they should sustain a loss, and have to be sold by auction. The value of property in the Strand had greatly increased, and the present rental value of the house in question was estimated at 4200 a-year. An instance was given of the rise of property, in the fact that Mr. Archer, a tobacconist at Westminster Broadway, whose premises had been demolished by the Metropolitan District Railway, had taken a place in the Strand, at the corner of Grey-street, and had to pay a premium 5000, and to expend 8000, on new premises, and then to pay a rental of 3500, which would make his house about 7200 a-year. Mr. Lloyd (with whom was Mr. Kenaly), for the claimants, regarded the case as one of peculiar hardship. They had established a business, and were patronized by the legal profession, and by their removal would suffer a great loss. Mr. Hawkins, Q.C. (with whom was Mr. M. Mason), for the Commissioners, called no witnesses, but complained of the claim made. The High Bailiff having briefly pointed out to the jury the nature of the evidence, they retired, and on their return gave a verdict for 2,600.

BUILDERS' LIABILITIES.

In the Court of Common Pleas (Sittings at Nisi Prius, in London, before Lord Chief Justice Bovill and a special jury), the case Buck v. Brass has been decided, and the defendant (a builder) was employed to erect some buildings on the site of the East-India Warehouse, and the footpath was placed in a covered way. There was an opening across this covered way for carts to pass to and from the building, and the plaintiff was about passing over some scaffold-poles which lay beside the road, when he was suddenly and rapidly raised, and before he could get out of the way he was lifted off his feet, and afterwards fell heavily to the ground. His left arm was broken near the elbow, and the arm was very severely bruised. The joint was permanently injured.

For the defence it was said that the defendant did not hear of the accident until a month after it had happened. The investigation which had, however, been then set on foot led to these conclusions:—That the building was at least 10 feet high, and that it was not wanted to raise any scaffold-poles. None were raised, and in fact the building, and the policemen on the beat were called, until after the communication from the plaintiff, and it was suggested that, in the pain and confusion, the plaintiff must have made some mistake as to where the accident occurred, and that probably it happened at some other building in the same street.

The jury, however, found a verdict for the plaintiff; damages 150.

THE PEABODY FUND.

ACCORDING to the "Statement" of the trustees for 1866, four blocks of buildings, accommodating 195 families, have just been completed at Shadwell, and named, like those at Islington, Posbody-square. These when filled, together with the others now occupied, will contain above 400 families, numbering about 2,000 persons. The amount of capital invested in the land and buildings at Islington is 40,397. 2s. 1d., the gross rents from which for the year amounted to 1,171. 16s. 9d., and after deducting 543. 16s. 4d. for taxes, working expenses, and charges for repairs, alterations, and improvements, there remains a net return of 1,174. 0s. 5d. The investment in land and buildings at Spitalfields is 27,251. 11s. 3d., and the amount of rents for the year, 1,019. 6s. 6d. Deducting 376. 6s. 4d. for taxes, working expenses, and charges for repairs, alterations and improvements, there remains a net return of 641. 2s. 2d. The cost of the general management of the trust during the year, including printing, stationery, salaries, and small sundries, was 317. 11s. The trustees have laid out 4,632. 11s. on land at Chelsea, and 4,891. 11s. at Bermondsey. The cost of land and buildings at Shadwell to the present time is

40,982. This statement relates altogether to the original gift of 150,000. The subsequent gift of 100,000. is in Hudson's Bay Company's Stock, and is to accumulate till 1869. Freehold sites may be purchased in any locality within ten miles of the Royal Exchange, accessible by railways.

EQUALIZATION OF METROPOLITAN POOR-RATES.

A CONFERENCE at the instance of the Tower Hamlets Association for the Equalization of Metropolitan Poor-Rates, has been held at the London Tavern, for the purpose of considering whether any, and what, action is necessary with respect to Mr. Gatliford Hardy's Bill. The chair was taken by Mr. Locke, M.P. The Rev. H. G. M'Gill, after referring to the desirableness of having Mr. Hardy's Bill passed into law, especially as it recognised the principle that the poor parishes of the metropolis ought not to be called on to support all the poor in these parishes, but that the burden should be equally distributed over the metropolis, moved the following resolution:—

"That this meeting, while cordially approving of the general principles of Mr. Hardy's Bill, is of opinion that the charges proposed to be placed upon the common fund of the metropolis should be extended, so as to include, if not the whole expenses of the indigent sick, at least all cases of cancer, paralysis, and other acute and easily curable diseases, as also the whole of the expenses of building under the Act; and that a provision should be made for levying a rate in aid in event of any special emergency pressing upon any particular district."

The Rev. G. T. Driffield seconded the motion. Mr. Ayrton, M.P., thought there was very little use in arriving at any specific resolutions on the question, or offering any public opposition to it, as it was certain to be for years the subject of amendment Bills, and to involve the loss of 100,000. If they attempted to criticise the Bill he did not know where they could stop, as the Bill was obviously defective. He thought it best for a deputation to wait on Mr. Hardy with reference to the question. The Rev. Mr. M'Gill adopted the suggestion, and embodied it in his resolution, which he moved in its amended form. Sir T. Fowell Buxton, M.P., seconded the resolution, which was then carried.

THE ALKALI ACT.

In a recent article on this subject, we mentioned that the evidence of the inspector was often of the greatest value to manufacturers in cases of actions brought against them by individuals for injury to their crops or goods. The inspector was able to come into court and say that the system of condensation was so perfect that the quantity of hydrochloric acid sent into the atmosphere was too small to be estimated. Several actions have, in fact, been decided for the defendants on the impartial evidence of the inspector, and that they were at last free from the harassing and vexatious law-suits, to say nothing of heavy damages, to which they were continually subjected. A recent decision in the Birmingham County Court entirely upsets this view. An action was brought against Messrs. Chance, the well-known glass manufacturers, by a draper, for damage to his goods caused by noxious emanations from the defendant's alkali works at Oldbury. In spite of the evidence of Dr. Angus Smith, and the other Government inspectors, and of some local chemists, as to the perfection of the condensing arrangements, the court gave judgment for the plaintiff. The amount claimed was small, only 40, but the principle involved in the decision is a very important one. It was admitted by Dr. Smith, that a condenser had worked so well as to allow only 7-10ths per cent. to escape, had suddenly been found to give out nearly 7 per cent. of acid.

STAINED GLASS.

St. Ann's, Brighton.—A stained-glass window by Messrs. O'Connor, has been erected in this church. The window consists of a central six-floiled circle, surrounded by eight smaller circles. In the central circle is placed a figure of the ascending Saviour, surrounded with a glory, and having the globe beneath its feet. Four of the outer circles contain the signs of the Evangelists.

In the remaining four the triumph of the Cross is indicated by crowns in the two upper quadrants, over crosses in the two lower. By an ingenious treatment of the colouring the four quadrants at the principal points are made to form the outlines of a large cross, running through the length and breadth of the window. A special effect has been produced by rendering the face and upraised arms of the Saviour in glass of delicate hue, on which a halo of light is reflected from a small portion of pale green glass in the outer part of the window.

St. Matthew's, Edgely.—Mr. Bailey has erected a stained-glass window in the south aisle of St. Matthew's Church, Edgely, in memory of his late daughter, Mrs. J. Smith, and her children. The subject selected is the raising of Jairus's daughter. The window was by Messrs. Hardman, of Birmingham.

Books Received.

The Analysis, Technical Valuation, Purification, and Use of Coal Gas. By the Rev. W. R. Bowditch, M.A., F.C.S., Incumbent of St. Andrew's, Wakefield. With numerous illustrations. London: Spon, Bickersley, 1867.

Of the Rev. Mr. Bowditch's long-continued, and we hope to himself profitable, efforts to improve our gas-light, we have more than once spoken favourably in the *Builder*. He appears to have mastered the subject in all its bearings, and the present learned and useful volume is the result. It is somewhat curious in which the author incidentally exposes the ignorance of some of his quondam detractors, who ought to know better while sneering at one who evidently does know more of their own subject than they themselves do.

On the nature and mode of carburetting or sulphurizing gas we shall quote a passage or two for the purpose of showing how the author deals with his subject.

"The following is Professor Dunsen's statement ('Gasometry,' p. 113).

ANALYSIS OF MANCHESTER GAS. IN 100 PARTS.

Non-illuminating heat-producers	Hydrogen	46.69
	Methane gas	34.90
	Carbonic oxide	6.84
Heat-producers	Nitrogen	1.62
	Hydrogen	2.35
	Carbonic acid	3.67
	100.00	

This is canal gas. In common gas, such as that of London—which has little more than half the illuminating power of Manchester gas—the proportion of illuminants is smaller, and of non-illuminating heat-producers is larger. The mean result obtained by many chemists shows that common London gas does not contain more than 4 per cent. of illuminating constituents, the other 96 per cent. being non-illuminating heat-producing compounds; that 54 ft. in 100 cubic feet of gas yield 100 cubic feet of canal gas, we obtain and use only 61 ft. of useful illuminants, and are obliged to take 37 ft. of gases (which do not furnish any heat) to get the 100 ft. of heat. It means extra cost, and extra gas that we buy and burn. Can we do better? And if it be, is it necessary? Cannot the illuminants be made and sold without the heat-producers? This is impossible. Gas cannot be made without its bulk being non-illuminating. But still something can be done to increase the proportion of illuminants, and this is called sulphurizing or carburetting. We find by experiment, if we pass gas over the highly carburetted substances called sulphur, that every foot of gas carries away with its vapour a part of the sulphur; that the naphtha vapour burns with the gas; and that the light-giving power of the gas increases with the quantity of sulphur used. We can measure the amount of sulphur the gas, weigh the naphtha removed, determine the increase of light obtained, and thus ascertain exactly the illuminating value of each grain of naphtha burnt with the gas. The naphtha, thus added to gas, does not burn with a red flame, which gives off much smoke, as it does when burnt alone; but it gives a bright, white, smokeless flame. This result is due to the non-illuminating but heat-producing compounds of the gas. The naphtha contains so much carbon and so little heat-producing hydrogen, that when it is set on fire alone the carbon is not heated sufficiently to burn it, still less to render it highly luminous; whereas the light is feeble, and much of the carbon is deposited as soot. But when it is burnt with gas the heat-producers in the gas raise the carbon of the naphtha to a sufficient temperature to enable it to set off a brilliant light, and to burn without smoke. Thus the heat-producers are rendered directly useful. They raise the carbon to the temperature required for illumination and combustion. The naphtha, by the other hand, supplies the way to the luminosity in the gas by adding to it much carbon, in which it is deficient, and but little hydrogen, in which the gas itself abounds. Experience shows this to be a mistake, and proves that the illuminating power of a gas of naphtha depends upon the relation which it bears to the bulk of gas with which it is burnt, and that, within certain limits, its illuminating value varies greatly. The apparatus for carburetting consists of a gas-tight metallic vessel to hold the hydrocarbons, from which depends a gas-pipe carrying one or more burners. The hydrocarbon vessel is provided with a screw-plug for convenience of filling, and with an inlet for gas, by which it

can be attached to ordinary fittings. The hydrocarbon vessel is placed above the gas-flame, so that it may be heated thereby to the temperature required to enable the gas in its passage to combine with and carry forward a suitable quantity of hydrocarbon vapour. Seven inches between the burner and the hydrocarbon vessel are found in practice to be the most suitable distance to secure enough, but not too much, vapour. When the gas is first lighted it gives but little light, owing to the fineness of the burners through which it passes; but as its heat warms the hydrocarbons, their vapour passes with the gas which sweeps over their surface, and the light gradually improves until the full illuminating power is attained. This happens soon as the hydrocarbons have obtained their normal temperature. The vapour of these hydrocarbons is more than four times the density of air, and consequently their tendency is to descend. Their specific heat is so small that they condense very readily, and the union between them and the gas is dependent upon the maintenance of high temperatures; wherefore I place the pipe which carries the burners below the hydrocarbon vessel, that the flow of heavy vapour may be facilitated by gravity. This pipe, moreover, is so placed as to be heated considerably, so as to prevent condensation, and thus is secured an illumination which cannot be procured otherwise. The light is so placed in reference to the pipes as to be shadowless. In some situations this form of apparatus is unsuitable, and I have therefore adopted a modified form suitable for chandeliers, &c., but still retaining the principle of heating the hydrocarbons, and passing them and the gas through heated tubes. In gasoliers the hydrocarbon vessel is heated to the proper temperature by a small subsidiary jet of gas, and the arms which carry the burners extend from the vessel but a very short distance, so that they may be kept hot enough to prevent condensation. . . . The superiority of carburetted over uncarburetted gas-light is shown—1. By the steadiness of the former as compared with the latter; and 2. By the carburetted light enabling us to distinguish colours with almost the same distinctness and accuracy as we distinguish them by day-light. The imperfection of ordinary gas-light in the latter particular is well known."

Photographs of Old English Cathedrals. Mason & Co., Old Bond-street.

The second part of this work consists of five views of Ely, with a brief account and list of bishops. In the view of the west end the lines are scarcely so upright as might be desired; the details, however, are presented with great fidelity. An excellent view is given of the choir, with the fine reredos and other modern work.

VARIORUM.

The current number of "Nature and Art" concludes an interesting account of Holbein in Germany, with copies of portraits of himself and his wife, the latter coarse enough to almost explain why he remained in England without her. Mr. Aaron Penley's hints on Sketching from Nature are continued. — Black's "Guide to Paris International Exhibition of 1867," at 6d., is a misnomer. It is a guide to Paris, not to the Exhibition; and though, of course, only an outline, is compendious, and will be found very useful for the pocket. It is edited by Mr. D. T. Austed, and has maps. — "Debrett's Illustrated Peerage" is very convenient as to size. We find in the 1867 edition, the addition of clubs, seats, and residences, the biographies of the younger sons and married daughters of peers; the name of the eldest son (if any) of the heir apparent or presumptive of every peer; full account of the colonial bishops; and biographies of very new peer and bishop up to the date of publication. — "Debrett's 'Baronetage'" matches the "Peerage," and appears carefully brought up to the latest moment before publication. It claims to be the oldest publication of its class. — Lockwood's "Builder" and Contractor's Price Book for 1867 has been revised by the editor, Mr. G. R. Burwell, to meet the present state of the trade of building. — "The Engineer's, Architect's, and Contractor's Pocket Book" (for 1867) contains its usual large amount of valuable information. Its interest does not end with the year.

Miscellanea.

EXPLOSION OF GAS AT WHITEHAVEN.—For some time past there had been an escape of gas from a pipe connected with the shop of Mr. Robert Douglas, draper, King-street, and the gas so escaping had made its way into the shop of another Mr. Douglas, also a draper, who occupies the shop adjoining, thereby causing him considerable annoyance. He procured a ladder, and, with a lighted candle in his hand, mounted it for the purpose of inspecting the pipe communicating with the lamp which hangs in front of his neighbour's shop. A loud report took place, and the sign bearing the name of his neighbour was blown across the street, and deposited in front of a shop opposite. Beyond this, however, no damage was done.

THE GRADIC.—At the next meeting, to be held on the 13th inst., ladies will be admitted.

STATE SUPERINTENDENCE OF THE TELEGRAPHS. In reply to a question in the Commons, Sir S. Northcote states that Government have the question of bringing in a Bill for placing the telegraph lines in the kingdom under the superintendence of the state under consideration.

THE NEW CLUB HOUSE, LINCOLN.—The directors of the Lincoln Club Company (Limited) have accepted Mr. Huddleston's tender to erect their new club-house for 2,656*l.* The building, which has been designed by Mr. Drury, architect, will be four stories high, and 63 ft. long, occupying the site of the present club premises and the stone-yard adjoining. The material is to be red brick with stone dressings.

A PHOTOMAGNETIC COMPASS.—An ingenious contrivance has been recently invented by a naval engineer, M. Corridi, for ascertaining a ship's course during a voyage. On the dial of the compass, instead of the star which indicates the north, a circular opening is made, furnished with a small lens. The light shining upon the compass penetrates through the lens, and traces a black mark or line on a sheet of sensitive paper underneath, which is made to move at a certain speed by means of clockwork. The sensitized paper turns with the ship, and as the needle remains perfectly steady, every deviation or alteration of the course is photographed on the paper.

DISCOVERY OF THE SITE OF A LOST VILLAGE. The site of one of the Domesday villages in Yorkshire, to which the traditional name of Thorndale has attached, has been brought to light. Mr. R. Mortimer, of Pimber, has examined the place now known as Thorndale, and has found the traces of numerous foundations of the lost village. This examination was made consequent on the finding of an ancient well in one of the fields. The well to some depth is walled, and it is 43 yards deep, and has at the present time 16 yards' depth of pure water. The discovery in a country so badly watered as the wolds will prove of very great value, independent of its antiquarian interest.

EVENING OPENING OF MUSEUMS.—A public meeting has been held in Peckham, to promote the opening of museums on week-day evenings, as recommended by a Parliamentary committee which sat in 1860. The following resolution was carried:—"That owing to the great success which has attended the early closing and Saturday half-holiday movements, the great majority of the working classes could occasionally or habitually visit the museums on week-day evenings, as proved by the large attendance in the evenings at the South Kensington Museum and the industrial exhibitions held in various parts of London, and that the petition to Parliament should be adopted." Mr. Hill, who seconded the resolution, remarked that 2,210,000 persons had visited the South Kensington Museum in the evenings since it had been opened three nights per week, and at the recent Industrial Exhibition held at Islington more than 500,000 persons paid for admission in ten weeks, the great mass of whom were of the working class, who attended in the evenings.

WIRE-ROLLING FOR THE PARIS EXHIBITION.—Messrs. Johnson & Nephew, of Bradford Iron-works, near Manchester, the wire manufacturers, have rolled, in their serial wire-mill, a telegraph wire rod, of No. 3 gauge, 251 lb. weight, and 530 yards long, without a weld or joint in any part. This extraordinary length of wire, says the *Engineer*, was made from one bloom, and rolled into a 1½-square billet 60 ft. long. This at the same time was bent into a serpentine form, that it might be more readily placed in the heating furnace, which is of gigantic dimensions, heated by gas on Siemens's latest improved regenerative principle, at the mouth of which is placed Mr. G. Bodson's patent serial wire-rolling mill. The billet is placed in the furnace at the opposite end, and in a few minutes is sufficiently heated to enter the rolls, and is gradually drawn out of the furnace by the mill itself. During this operation one portion of the billet is leaving the furnace, whilst the other end is being coiled finished wire, about ¼ inch in diameter. The time occupied in heating the billet was only seven minutes, and in three minutes more it was passed through the mill complete. The rolling speed and present capability of production in the mill are upwards of 100 tons per week.

LITERARY FUND ANNIVERSARY.—The Very Rev. Dean Milman will preside at the ensuing dinner.

"GREAT EASTERN" STEAMSHIP.—47½ per cent. dividend last year, and 10 per cent. for the recent half-year, with better prospects for the present! What do the old shareholders say about this and the clever fellows who managed the sale of the vessel?

GALLERY OF ILLUSTRATION. MR. AND MRS. GERMAN REED'S ENTERTAINMENT.—"The Family Legend" will be withdrawn at the end of this week, when the gallery will be closed for a few days, in order to prepare a new entertainment, by Mr. F. W. Robertson, the author of "Onra." It is a Venetian story. The scenery is by Mr. W. Tolhin and Mr. John O'Connor, and promises well.

CHANDELIERS AND FOOT-LIGHTS.—The Messrs. Defries, of Houndsditch, have been exhibiting a "Crystal Candelabrum," manufactured for the Nizam of the Deccan, and a model of their Patent Float or Footlights. The Candelabrum is a fine thing of its kind. As to the footlights, experience must decide their value. We are bound to mention that the accounts which we reached us from the new theatre in Liverpool, where they are used, were not, in the first instance, wholly satisfactory, and that some alterations were then about to be made. We have long urged the want of improvement in this item of the stage, and shall be very glad to hear that the objections which were found to attend at first the arrangement made by Messrs. Defries have been successfully overcome.

INDIAN GUARANTEES.—On the general subject of Indian railways, or any particular points connected with it, no man is listened to with more respect than Mr. W. P. Andrew. We are glad, therefore, to see him come frankly forward to vindicate the Indian Government, with respect to the good faith which it had always observed in the matter of its guarantees. "I have been a party to no less than four contracts with the Secretary of State for India in Council conferring the advantages of the guarantee of the Government of India on the several undertakings with which I am connected, and in no instance has there been for a moment the slightest cavil as to the amount of interest due from Government, or a day's delay in the payment of the amount." This is no more than ought to be said about the good faith of the Indian Government; but it is well that it should be said on high authority.

ARTISTIC FURNITURE.—We have seen some very elegant pieces of furniture manufactured by Mr. Leonard Collmann, of Grosvenor-street, and intended for the Paris Exhibition; notably a piano-forte of satin wood and amboyna wood, and a cabinet to match. The metal work and the carving are exceedingly well executed, the heads of the mnes appear in the frieze of the piano-forte, and their Greek names are found amongst the foliage below. The great merit of the furniture, however, is that there is no extra size,—that there are no extra and awkward projections, for the mere sake of ornament. Like some other good things, its merits are discoverable rather than protruded. Mr. Collmann, who has the advantage of being himself a good draughtsman, supplements his exhibition with some capital views of apartments in the British Museum that were decorated by him, and a very rich ceiling executed by him in Lancashire.

WATER SUPPLY, DRAINAGE, AND VENTILATION. A practical and useful lecture was lately given in connexion with the Hastings Mechanics' Institution by Mr. John Banks, of Beak House, the subject being "Water Supply, Drainage, and Ventilation," as affecting the public health. In the course of his lecture Mr. Banks spoke of the plans adopted at Croydon and Worthing for the utilization of the sewage, and in continuing said there is no doubt that legislation is much wanted in the matters of water supply and drainage. There is no reason why Local Boards should not have powers over watersheds, or catchment basins. Why should a town, situated at the upper part of a valley, have the power of damaging water which runs towards the lower part? To look nearer home, why should not the governing body of Hastings have power to prevent pollution of any kind taking place in the valley in which it is situated? That it would come to this he had no doubt. The lecturer then offered some remarks upon the various points connected with the subject of ventilation, pointing out the way in which it is neglected, and giving some useful hints in regard to it.

GYMNASIUM, NEWCASTLE-ON-TYNE.—It is proposed to erect a gymnasium on a site in Bath-lane, in this town. Mr. Thomas Oliver is the architect.

THE HULL TOWN HALL.—At a meeting of the Town-hall committee, Alderman Bannister (the chairman) stated that the pulling down of the old Mansion-house, the erection of the new Town-hall, the extension of the building, and the whole of the furnishing, together with architects' charges, amounted to 21,665*l.* 8*s.* 10*d.*

GAS.—The Liverpool Gaslight Company have declared their usual dividend of 5 per cent. for the past half-year.—The Malvern Link Gas Company have declared a dividend of 6 per cent. for the last year.—The Stafford Gas Company have declared dividends at the rate of 10 per cent. per annum on their old shares, and 8 per cent. on new for the last half-year.—The Ipswich Gaslight Company have declared a dividend of 10 per cent. on original shares and 7½ on new, free of income-tax, for the last year, over and above a balance of 227*l.* carried forward to next year.

THE DISTRESS IN EAST LONDON.—The manager of the Millwall Ironworks suggested, that as on the 1st of April in each year the War Department order from 9,000 to 10,000 tons of iron to be manufactured for guns and gun-carriages, if it could be so arranged that a portion of that order, say 1,000 or 2,000 tons, could be given out immediately, the company with which he was connected would at once take on about 800 workmen, equivalent to the relief of 3,000 people. This suggestion was very favourably received by Lord Derby, who promised to lay it before General Peel and Sir John Pakington as the heads of the War and Naval Departments. The result has been favourable. Last week the Millwall Ironworks Company received an order from Her Majesty's Treasury for 1,000 tons of iron, in addition to the quantity the company were already under engagement to supply for the use of the manufacturing departments of the army. The company at once took on 400 additional workmen. It is stated that, with the concurrence of his colleagues, Sir John Pakington is about to give out several contracts for ironclad vessels without waiting for the passing of the navy estimates.

ISWICH PUBLIC AND MUSIC HALL.—A site for the proposed hall has been secured in Westgate-street. The hall itself will be built away from the noise of the street, the frontage to Westgate-street being appropriated to the erection of two or three shops and as many private houses. The length of the hall (including the orchestra), will be 125 ft., the width 53 ft., and the height 50 ft. There will be accommodation on the floor for 1,000 persons, the orchestra will accommodate 250, the first gallery, at the upper end of the hall, 370, and the second gallery 210, so that in all the hall will seat 1,800 persons. There will be two entrances: one from Westgate-street (which it is proposed should be 20 ft. wide) will lead to the second-class seats and galleries, and the other from Museum-street to the reserved seats. Provision will be made by the way of ante and retiring rooms, and from the Museum-street entrance a covered way will lead to a porch, which will lead to a large room, 56 ft. by 25 ft., to be used as an ante-room to the large hall, and also available for public dinners and other meetings. From this room broad flights of steps are to lead to the great hall. In the basement there will be a kitchen for public diners and tea-meetings, and with a lift to a refreshment-room in immediate communication with the halls. The architect is Mr. F. Barnes. The promoters anticipate an income of five per cent. on the money invested, and calculate that the total cost will be 11,000*l.*, made up as follows:—Cost of site, 3,000*l.*, of the front buildings, 2,000*l.* (after allowing 500*l.* as the value of the old materials), of the hall, 4,200*l.*, of furniture, 800*l.*, and for extras, a margin of 1,000*l.* is allowed. About 350 shares have already been applied for.

For building a new church at Cassop-cum-Quarrington, Durham. Mr. Withers, architect:—
Bell £2,350 0 0
Readshaw 1,610 0 0
Loves 1,572 0 0
Simpson & Co. (accepted) 1,450 0 0

For alterations at Longdon Vicarage, Worcestershire. Mr. Withers, architect:—
Bell and George £468 0 0
Griffiths 475 0 0
Bell 475 0 0
Osborn & Co. 418 0 0
Meadings (accepted) 398 15 0

For building a new church at Corthoe, Durham. Withers, architect:—
Bell £2,926 0 0
Foster 2,550 0 0
Gradon 2,448 0 0
Robson & Son 2,298 0 0
Loves 2,270 0 0
Spencer & Co. 1,890 0 0
Simpson & Co. (accepted) 1,785 0 0

For house and shop at Snaresbrook, Essex, for Mr. Bodger. Mr. Marshall, architect:—
Lose £675 0 0
Mundy & Hutchinson (accepted) 650 0 0

For the erection of a new Station Hotel, Asselt, Messrs. Langton, Burrows, & Co. Messrs. Wm. & J. Brown, architects:—
Bell £1,400 0 0
Fether (accepted) 1,190 0 0

For the erection of an earthenware manufactory Hanley, for Mr. Thomas Worthington. Messrs. R. Scriven & Son, architects. Quantities supplied:—
Woodridge £3,250 0 0
Bailey 3,234 0 0
Giles & Hudson 3,215 0 0
Steele 3,167 0 0
Mathews (accepted) 2,997 0 0

For completing Convent Church, Madresladen-road, Leonard-on-Sea, Sussex, for the Rev. Superioress. M. G. Goldie, architect. Quantities supplied by Mr. Jam. Schofield:—
Contract A. Contract B.
Hunt £4,100 £1,191
Nightingale 4,100 1,043
Simms & Martin 3,785 996
Roberts 3,205 823
King & Son 3,232 891
Fitcher 3,099 807
Simpson 2,982 713

For building four houses for Mr. Allen, at Newwood. Mr. A. Bridgman, architect:—
Wallis £1,720 0 0
Wallis 1,243 0 0
Johnson 1,120 0 0
Nightingale 1,103 0 0

For building two houses for Mr. Nightingale. Mr. A. Bridgman, architect:—
Wallis £900 0 0
Wallis 880 0 0
Johnson 890 0 0
Nightingale 813 0 0

For eight houses at Barking, Essex, for Mr. Hawes. Mr. J. W. Denison, architect:—
Anshole £1,367 0 0
Brett 880 0 0
Stokes 1,713 0 0
Withers (accepted) 1,360 0 0

For sixty-eight cottages at Wilneote, Warwickshire. Mr. J. W. Denison, architect:—
Claron £5,000 0 0

For building additions and making alterations and new shop-fronts to 21, 22, and 23, Victoria-road, Epsom, for Mr. F. Gorringe. Messrs. Walford & Doukin, architects. Quantities supplied by Mr. Doughtney:—
Lawrance & Sons £4,315 0 0
Turre & Sons 3,942 0 0
G. H. & A. Bywater 3,771 0 0
Ramsey 3,786 0 0
Newman & Mann (accepted) 3,494 0 0

Accepted for improvements on Crown property in Oxford-street, for Mr. T. Holloway. Mr. J. Dale, architect:—

Stone Front.
Carter & Son £1,678 0 0

Fittings of Ground Floor and Library.
Carter & Son 1,987 0 0

Plastering Work.
Parsons 750 0 0

Ornamental Ceiling.
Jackson 260 0 0

Joist.
Johnson 70 0 0

For works per schedule of prices. The following trades were accepted:—
Iron Shutters.—Clarke & Co.
Decorations.—Cowntan & Co.
Senghola.—Dopson & Son.
Engineering and Copper Works.—Fontflex & Wood.
General Fittings.—Aulton.

For the erection of two new houses and shops, Shepherd-street, Mayfair, for Mr. W. H. Whitehouse. Mr. Joseph S. Mope, architect. Quantities supplied:—
Stoner £1,837 0 0
Sapwell 1,794 0 0
Walton 1,582 0 0

For plastering at Sandly Hall, near Harrow. Mr. John Dale, architect:—
Eastlake £233 0 0
Ford (accepted) 233 0 0
Dowling 240 14 0
Harvey 245 0 0
Andrews 215 0 0
Horne 198 10 0

TENDERS

For the erection of two cottages at Reading, for Mr. R. Attenborough. Messrs. Wm. & J. T. Brown, architects:—
Betcher (accepted) £460 0 0

For two houses and shops at Snaresbrook, for Mr. Wilkinson. Mr. Marshall, architect:—
Rivett £1,383 0 0
Mundy & Hutchinson (accepted) 1,325 0 0

The Builder.

VOL. XXV.—No. 1257.

On the Principles of Proportion as Common to both Gothic and Classic Architecture.

IN general principles it would appear to be fairly assumable that the Gothic and the Classic styles, being both architectural, must have common dependence up to a certain point upon identical principles common to all architecture; and if this is the case both styles should prove susceptible of common furtherance as these principles become better understood, their applications and developments subjected to more masterly control. Upon this ground, so far as its just range extends, neither one school nor the other can arrogate an exclusive nor even a prior right. Here both alike are in a stage of pupillage, and it is at a subsequent stage that the privileges of independent option, and even of individual caprices, may be said to have begun to accrue. There are certain conditions of propriety and dignity in a door or window which must be acknowledged in the instance whether the head be pointed or horizontal. Such common conditions are not indeed, but therefore it is that they are so universal; and therefore it is, that they stand the earliest as well as most unremitting recognition. After the common constructive obligations, it is in allegiance to Proportion, that the architectural styles most importantly inculcate. The peculiarity of proportion no doubt that style becomes so strongly contrasted with other, but this is no more than an extreme of the same principle of modulation, by which all but limitless variety is developed by varied proportions within the conditions of the style.

The subject of Proportion as an element of art has occupied more or less of the attention of all the important writers on architecture, and those who have devoted to it the fewest pages have marked emphatically their sense of its influence it exercises,—the dignity of its applications; of those who have treated of these more fully, it may, perhaps, be said that the most successful have been the readiest to admit the completeness of their results, whether relative to ideal theory, or even to the fund of principles which seem to have been within the grasp of architects who have left no works other than architectural.

One of the best introductions to remarks upon this subject in itself, may be a critical survey of the conclusions of a recent writer, and we choose the article on Proportion in the Dictionary of Architecture, by M. Viollet-le-Duc. If the refutation of an erroneous system were not the establishment of a true, how many controversies would have long ago sunk to rest! But, as systems may conflict, and yet neither be destroyed, just as vessels may come into collision, and both be sunk. There is good service to be done nevertheless, in buoying the wrecks, and ensuring a happier voyage for future adventures.

travers. We freely concede, therefore, to the writer that M. Quatremère de Quincy cannot be safely followed in his view, that a true system of proportion would establish such an absolute reciprocal dependence of principal parts, of subordinate and of the smallest subdivisions, that given a particular instance of relation, the proportions not only of the parts but of the whole would at once be deducible. Beauty is not thus to be produced by receipt, and the enigma of sublimity is not to be solved by overhearing a catch-word.

Doubtless when we contemplate a truly harmonious work we recognise an affinity between all members, and even parts of members, and the whole; the foot of Hercules affects us with a sense of congruity in its forms with the hand of the hero, and both with the general musculature of body and limbs. It is even possible that by careful study we may work our way to some leading principle by which the congruity was brought about, or a special application of such a principle; but the genius of the artist invented the principle as well as effected its application. A key-note governs a symphony,—its harmonic relations may be as well known to us as to the composer,—but neither the key-note nor the very theme itself would ever have helped any but the gifted musician to his symphony.

The setting of a palette is no unimportant part of a painter's day; but, after it is set, it will be of little avail for any pencil but his own. It were but a weak retort that if the theory of proportion is not useful to the extent of enabling us to evolve beautifully proportioned structures, it may at once be set aside as worthless of study. Not on such view proceeds the melodist as he applies laboriously to the recondite mathematics of his art,—not so the executant who practises unwearied scales,—not so the painter observant and experimentative without ceasing of the effects of colours upon each other in every variety of mixture, and purity, and tone.

It is always a nice question how nearly theory may be pressed forward upon practice, and the relation of proportion to architecture is no exception. Up to a certain point, the development may be said to be purely scientific and remarkably precise; beyond that line there is little more to be established than a limited code of general maxims,—limited, indeed, and general, and yet the grand results of the intellectual inquiry. The next function is for inventive imagination to devise for ever-variable contingencies, those combinations of elementary principles in subordination to the general, that constitute happy and beautiful solutions.

When we come to analyse a complete and successful work, it is of the utmost importance to recognise the distinction indicated;—it is much the same that obtains in grammar between etymology and syntax. We may easily mistake what is but scaffolding for the building if we are content but to note by aid of what lines and centres work was set out, and fail to observe the broad contrasts to which those details were subservient. There is, therefore, indeed, a preliminary inquiry as to what scale the artist employed; and even this we are at liberty to criticise as possibly but a makeshift; but let it have what excellence it may, the far more important question arises afterwards as to the principle and the success of his application of it.

Natural taste is sometimes ahead of scientific culture, and snatches a grace that it would not have ventured to justify, knowing not that it was justifiable; and at other times it pays the penalty exacted from ignorance by missing, in its awe of the established rule, a hearty fairly within grasp.

An exacter analysis of the design of Classic architecture has brought out the result that the Greek architect set great value upon his dimensions being simple in their relative proportions, and those executed with the nicest exactness;

and it has, moreover, appeared that the lines which he held of most importance to be brought into proportional dependence, were the vertical and the horizontal; that is to say, to the apprehension of the Greek the architectural eye was inevitably disposed to appreciate heights upon the plumb-line, with reference to the several breadths most intimately connected with them, and vice versa. The influences that predispose to such dominant comparisons lie deep in nature, and are within us and around us at every moment. Every movement we make strengthens our personal experience of the dependence of stability and equilibrium or balance upon the lateral distribution of mass with reference to the vertical, and the satisfaction of the sense of security in these respects is the primary condition of architectural effect. Again, the convenience of every distribution of plan or opening, and the requirements that they make upon us for movement or use are naturally estimated by dimensions taken upon the vertical and horizontal lines, and to extent of divergence upon lines at right angles to each other.

When we look at the proprieties of the case thus broadly, it would seem that up to this point architectural principle is—

"Whole as the marble, solid as the rock,
As broad and general as the casing air;"—

and that to this primary rule architecture, as architecture, must render allegiance until such time as it shall be called upon to satisfy tastes and habits in a new condition, where the all-regulating plumb-line ceases to be at right angles to the horizontal. Every diversity of classic style, between early Doric and latest Corinthian, recognised the obligation and the guidance of the principle; nor does it appear how any other style, however contrasted, Byzantine, or Moorish, or Indian, or Gothic, can emancipate itself from a rule at once so stringent and, in truth, so advantageous.

That in truth they cannot, whether so ill advised as to wish it or no, is apparent from the universality in all architecture of any pretension to fine art, of that symmetry which is in fact one of the most important consequences of our principle.

A Gothic cathedral is to the full as symmetrical a building as a Greek temple; the prevalent supposition that it is not so, is either the mistake, or a concession to the mistake, of those who do not distinguish between original design and alterations, and semi-restorations and patch-work; who feel bound to take pleasure in the varied styles of Canterbury Cathedral, and think that the nave and choir of Gloucester happily illustrate the flexibility of their favourite Gothic.

And whether the ceiling of a nave or a cella be arched,—be semicircular or pointed or flat,—it will ever be estimated as low or lofty in effect by an appreciated proportion between its height and breadth,—it will be broad or narrow by corresponding mental comparison of its breadth taken at right angles to its length.

Tros Tyriusæ.—Gothic or Greek: from these spontaneous acts of indissoluble association there is no escape, and the corollary appears to be, that in Gothic design, as in Greek, heights are bound to be proportioned upon the vertical in relation to the horizontal; and the further presumption is as little to be overlooked that exact execution of proportionate dimensions will be as valuable in one style as in the other.

This last, however, is a last refinement, and highly as it may enhance the last effect,—admirable effects, though not the most admirable, are probably not inconsistent with somewhat negligent observation of it, especially when very large and varied dimensions are in question.

It would follow from these premises that, if the Gothic architects,—whatever the details and the general proportions of their predilection,—did not make these comparisons the basis of their design, they must have worked upon a faulty

and defective plan. Inventive imagination and corrective taste may, it is true, in favourable cases, compensate for false theory and bad technical aids and instruments, and with such saving qualifications the Mediaevals must be largely indeed credited. In fact, if we are to assent,—as it seems we must,—to the expositions of their system by Viollet-le-Duc and others, it is only so that we can account for their practical success, in despite of the disadvantage at which they were placed by their theory.

This is a matter that becomes of importance if Gothic is a style that is to live on; it can only really live, like any other organism, so long as it continues to grow; and growth is dependent on healthy roots and free circulation of air, and resolute cutting away of whatever is dead, whatever is stunted, and rigorous control of whatever, vigorous though it be, is tending to deformity.

Let us follow out then, to a certain extent, the theoretical system upon which a Gothic work was set out, and satisfy ourselves whether it really had much to do with the best beauty that was realized,—whether it was not constantly inapplicable to very important problems, and had not to be departed from,—did not very frequently stand in the way of a better rule,—frequently induce distributions that had been better dispensed with. This is a very heavy bill of indictment, and the greater the honour to the architects who in their self-assumed fetters could still vindicate their native artistic power. With all our respect for them, we owe it to the common art to bring their schemes of harmonizing proportion to the test; and the great test of all is, whether in a given instance, where it was certainly applied, beauty was really achieved, and, when achieved, was really due to the employment of it,—or came by the neglect of it on all critical points, and so, in fact, was conquered in its very despot.

It appears satisfactorily made out that the architects of the Middle Ages adopted triangles, and of these a certain set as generators of proportion.

The first was the rectangular isosceles triangle; that is, a half square set on the diameter of the square as its base, and with right angle at apex.

Secondly, the so-called Egyptian isosceles,—having a base proportioned to vertical as 8 : 5.

Thirdly, the equilateral triangle.

For an example it is shown, among others, that, in the Sainte Chapelle at Paris, not only was the clear of the pointed window-arch formed on an equilateral triangle, but that the full height of the windows was determined by the prolongations of the sides of these triangles; the window-sill being made coincident with the line of their third intersections. The beauty of this chapel may well commend to our favourable consideration a system which manifestly had an influence upon the design. Whether this was the technical system employed exclusively,—whether it is based on true principle, and, if not, how its defects declare themselves in the work, or how it was that they were effectively counter-acted, are further questions. Certainly the scientific justification of the system as set forth seems to demand emendation.

The proportions of architecture are based, we are truly told, in the first instance, on stability, and the laws of stability are dependent on geometry; and we may further admit that a triangle may give a very satisfactory expression of stability if appropriately applied—but scarcely that, as a general fact, it gives the most satisfactory: apart from solid pyramids that are their own abutment, inclined forms, by the very force of geometrical stability appealed to, are suggestive of sliding and collapse.

Still less does it appear why design should be restricted to three particular forms of the triangle. Marvellous variety and beauty were certainly evolved from combinations of the specified three, but this only awakens enterprise to experiment upon those that have been passed over. Doubtless, the selected forms present themselves as most easily managed; the rectangle in the semicircle,—the triangle of which the apex is given by the intersection of arcs struck with the same radius, and the triangle which can be set out by the whole numbers, 3, 4, 5, applied to half-base, vertical and inclined side,—a form which, however, shares its advantage with others, though less known. As regards the first form, it has no special Gothic application, being equivalent, even in the cited example of the Cathedral of Bourges, to the system of equal squares, which is the common property of mechanical design in all times and countries,

The most complete example of a systematic application of theory in the design of a great Gothic work is, probably, Cologne Cathedral, as elaborately analyzed by Boisserée. The favorite equilateral triangle regulates dimensions in one form or another throughout, and the result that, at least, was not avoided, stands thus on record:—"At Cologne, the artist has vigorously adhered to his geometrical data; his composition is a formula which makes no allowance for perspective effect, nor of the apparent alterations of curves resulting from the height at which they are placed. Thus the choir of Cologne is rather surprising than delightful; the geometrician has overpowered the artist." So Viollet-le-Duc. Fergusson marks still more distinctly that it is precisely in the aesthetic effect of proportion that the building is defective. "Looking at Cologne in any light, no one can fail to perceive that its principal defect is its relative shortness: now that the whole of the interior is finished these defects of proportion are become more apparent than they were before,—the height of the nave is nearly four times the width, a proportion intolerable in architecture, &c."

Viollet-le-Duc, while stanchly asserting the employment by the Goths of a harmonic theory, makes claim for the French architects—especially at Beauvais—that they avoided the rigid practice that failed at Cologne; "the artist is ever present at the side of the geometrician, and knows in case of need how to make formulas give way" (*faire fléchir les formules*).

If this can be approved, it is excellently said; but a still stancher theorist of harmony is justified in saying that frequent and important suppressions of formulas prove by their very success either that the formulas were wrong, or, at least, the system incomplete, and so he gains a *locus standi* for the exposition of a more developed theory, that will render an account both when subordinate rules must be observed and when they either must or may be departed from.

We will take the very cited example of Beauvais,—the choir, as figured and commented upon in vol. vii, p. 551, of the Dictionary of French Architecture. It is shown that the spacing of the piers both of nave and aisles is determined by the division of the plan into systems of equilateral triangles. Thus the axis of the nave being laid down and its width from centre to centre of pier adopted, the axial lines of the nave piers are also obtained; their longitudinal spacing upon these is then determined by an equilateral triangle, having one angle on the nave axis and each of the others on the centre of a pier; that is to say, the diagonals of the four piers of a bay intersect the axis of the nave at an angle of 60 degrees. The oblong plan of a bay thus obtained has the proportion of the side of an equilateral triangle to double its vertex, or 4 : 6.928. These numbers may seem tolerably near to the ratio of whole numbers 4 : 7, but the error in exactness upon a plan of 46 ft. amounts to more feet—2.6—than a Greek would have tolerated tenths of inches.

In general result, the spacing of the side openings is rather more than half the width of the nave, which may possibly be effective; but the advantage of such a distribution of difference would have been as easily obtained by direct comparison of lengths and breadths—a system which would also have provided a large variety for free selection.

To proceed: the prolongations of the sides of the equilateral triangles give intersections deciding the line of aisle piers or shafts, which are placed upon them accurately; and then still further prolonged, the line of the external wall,—the outer line.

The interior aisle has still the advantage, whatever it is worth, of corresponding with an equilateral triangle in the form that it is transversely as the vertex and longitudinally as the side,—or 1 : 1.732; but in the outer aisle this fails from the thickness of the wall being deducted from the vertex. There is thus introduced a difference of width between the aisles which may have all the general value claimed for it, but which is only gained by the sacrifice of the system,—and might have been so gained under no system at all,—under a more rational system it might have been effected consistently.

Again, the width of the bay next to the piers of the crossing is diminished from just regard to the responsibility of extra thrust, but the degree of diminution is again not in any way deducible from the triangles. Credit is taken for the architect's superiority to formulas in neglecting here the centre of his triangulated plan; but it is

again no slight impeachment of a theory of proportion that it breaks down and has to be deserted precisely where its aid should be most valuable,—on the verge of an inevitable modulation.

The incommensurableness of the plan as propagated to the vaulting, as the span of the transverse arch has the same broken ratio to that of the diagonal again as the vertical to the side of an equilateral triangle; in the arches themselves, where alone the triangular form is real salient, the assumed governing triangle of the design is set aside, and exercises no appointing power over its successor. The transverse,—the more important arch,—is proportioned as in span to 3 in height, or very considerably flatter; and to the height thus determined the diagonal has to accommodate itself; but it does not appear that the particular height was selected from any common principle.

The same system is pursued not much more satisfactorily into the elevation of the interior. The interval from centre to centre of piers taken as the side of an equilateral triangle from which others are raised, forming a vertical series of lozenges, of which the limits should define the architectural divisions. But already at the springing of the arches the scheme fails, and a new commencement has to be assumed, and again above the triforium still another commencement, and of different span. It is only in the arch of the window that the equilateral triangle re-appears beyond all question, or indeed is effective, apparent at all.

Such a faltering application then of the equilateral triangle as a guiding instrument of design seems to illustrate little else than its inefficiency, if the result at last was beauty compatible with these diversifications and obscurities. In any case it only promises to condense into a very thicket of incommensurables that try upon the principle of strict proportion at every step.

But even if the coincidences had been more frequent and exact than they prove to be to what would they amount? In what manner do they, as set forth, touch or pretend to touch those determining lines on which the ultimate impression of appropriate and expressive proportion depends? The expositor, at least, does not pretend to furnish us with a norm for the full height relatively to breadth, either of a bay of the nave transversely,—still less of length of the choir relatively to height; and yet these are the combinations that appeal directly and overpoweringly to our sensibilities; these are the terms between which, if anywhere, harmony must preside, and assert itself in its prerogative.

We must not, however, sacrifice the architect to his interpreter; from the original error of adopting units of transverse dimensions that are incommensurable, he is not to be absolved, nor from its consequences; but the diagrams supplied seem to establish, or at least allow the assumption of, a more simple process of development than has been set forth.

The height from the proper level of the pavement to the upper string-course of the triforium will be found to equal very exactly the width of the nave and two side-aisles, taken from the centre of the nave-pier to the wall. The width of the nave measures the pier from the floor up to the capital of the side-arch, and the extent from this point to the string-course at the base of the triforium equals the breadth of the first aisle, and the triforium itself equals that of the outer aisle, which is diminished by the thickness of the external wall. The difference, however, here lost is thrown into the dimension from the top of the triforium to the springing of the nave-arch, and makes up its height with one width of the aisle. In this way the height of the bay, from floor to springing, becomes proportioned to the width of the nave as 5 to 2, a very lofty proportion; the added height of the nave arch brings out the still loftier of 6 to 2—3 : 1.

The height of the nave, like its breadth, is made up of verticals of the normal equilateral triangle, and has this to thank for its commonness; but the bay, having its spacing determined by the side of the triangle, does not participate in the advantage.

In the repetition, as a vertical whole, of a dimension that is very decided, but still broken into more marked divisions, horizontally, the Gothic architect employed a stratagem of cover-commensurableness that the Greek had practised before him, and that would be an available furtherance of repose in any style of architecture, but the operation by the equilateral triangle

convicts itself in every case where it does not become virtually inoperative. In detail it leads to the confusion of proportion, and as regards any pretensions it may have for saving general effect, let us hear the independent judgment of an architect well affected to the deservings, if any, of the style.

"No building of its dimensions and beauty of detail can well be so unsatisfactory as the choir at Beauvais."—i. 12. The architects "determined to carry the clearstory to the unprecedented height of 150 ft., or about three times the width, measuring from the centre of one pier to that of the next (opposite). This, with a very long nave, a very acute vault, wide pier-spaces, and bold massive supports, might have been not only tolerable but sublime; but as this cathedral wants all these qualities, the effect now is only, &c."—*Fergusson, Arch.*, vol. ii, p. 494.

We should only be travelling over the same ground to the same results by developing in detail the relation of the beauty of the Sainte Chapelle to the technical theory of regulation that there also was so lightly held in hand.

The most glorious culmination of art is arrived at in those rare and happy instances where genius is in full possession of all traditional, technical, academical aids and instruments, and still can assert its supremacy in unfettered mastery. The workman then has the best tools, but is master of his tools no less than of his materials; the artist is neither cramped by a rule that is wrong, nor forced to break through it,—laudably, no doubt, but as at random so ever precariously. The qualification of the style of Bolingbroke by Pope,—

"Correct with spirit, elegant with ease,"—

exactly expresses that marvellous combination of regularity and inspiration that gives effect to the works of the Greeks in poetry, and oratory, and sculpture—and in architecture perhaps more of all. The genius of the Mediæval never quite attained—so it seems to the writer—the last term of accomplishment. What genius could do with imperfect instruments he grandly did; but, as the instrument was advancing to perfection, his chances and his age were past, and theory alone was then unable to do more than turn correctness into coldness, and regularity into restraint, while the free daring of true genius degenerated into extravagance or subsided in timidity.

Two great masters, but in other arts, came just in time to show the world what the Mediæval spirit was capable of when combined with the cultured sense of proportion which is the world's heritage from Greece. Only in the sacred pictures of Raffaele did the most divine inspirations of Mediæval painting attain to the fullest and most harmonized development; and only in the plays of Shakspeare, which reflect in every act the influences, however indirectly received, of the antique drama, did the dramatic genius that pervaded the Middle Ages break fully into bloom.

In either case, the proper Renaissance in its disparaging sense,—the revival which would revive the exhausted,—that would accept imitation for a new birth, came later,—or so far as was contemporary, ran on in parallel stream, but on a lower level. A Gothic Renaissance is as readily as much to be deprecated as ever was Classicism in such a sense as this; in a better sense it is worth striking for; he will be at least the right opening who, in the spirit of our Mediæval fathers themselves, shall be confident to purpose not to imitate but to surpass them as they ever did their best to overpass their promoters. There is still a large field open for the adjustment of new forms to new requirements, and especially for the enhancement of the best Gothic effects, by harmony of well-understood and exactly-realized proportion.

GAS-HEATED BOILERS.—An engine and boiler have been erected in the warehouse, No. 50, Cannon-street, City, worked by steam generated by gas-beat, under the patent of Mr. Arthur Jackson. The fire-offices, it is said, have admitted a system to be adopted without any increase of premium, and thus in all warehouses or other establishments where cranes, hoists, or other apparatus requiring power are in use, steam can be supplied, without stoker, smoke, ashes, or dirt, in any description. No brickwork or chimney is necessary. The space occupied is very small, and the furnace is fully kindled in a few seconds, and extinguished instantly.

THE HEALTH OF LONDON IN 1866.

THE Registrar-General's annual summary of the Weekly returns of births and deaths in London is at all times full of interest, and the fact of its appearance so promptly after the close of the year with which it deals, gives it a value, of which too many of our official publications are bereft through such delay in their issue, that the facts to which they refer have been previously dismissed from the public mind. The annual summary of the births and deaths in London during the year 1866 is, moreover, invested with an additional interest from its containing the first complete *resumé* of the effects of the cholera epidemic in the various portions of the metropolis for the whole year.

The meteorological conditions of the year 1866, as far as they present any variations from an average of previous years, would appear to have been favourable to the public health. The mean temperature of the air was, at the Royal Observatory, Greenwich, 49.8°, or only half a degree above the average of 25 years, and whereas in the first and last quarters of the year the temperature was above the average, the summer was cooler; thus neither intense cold in winter, nor excessive heat in summer, tended to raise the mortality. The 30½ inches of rain which fell during the year, was an inch above the average of 51 years; and the average daily amount of horizontal movement in the air was 274 miles, or considerably higher than it has been since 1848; there was, therefore, no deficiency of rain, or of movement in the air, both elements of considerable importance to the health of the inhabitants of crowded and ill-drained towns. The effect of these apparently favourable conditions was more than counterbalanced by the visitation of a cholera epidemic, which raised the rate of mortality in 1866 considerably above the average, and higher than in any years since 1840, excepting only the influenza year 1847, the cholera years of 1849 and 1854, and 1864 when diseases of the respiratory organs were unusually fatal.

The population of London, estimated to the middle of 1866, was 3,037,991. During the year 107,992 births and 80,129 deaths were registered in this population, thus showing, in spite of the excess of deaths, a natural increase during the year by the balance of births over deaths of 27,863; the excess in the previous year had been 33,262. The numbers of both births and deaths exceeded those recorded in any previous year. The 80,129 deaths give a rate of mortality for the year equal to 26.5 per 1,000 persons estimated to be living; or higher than the rates in any of the last 27 years, excepting the four above mentioned, when they were respectively 27.0, 30.1, 29.4, and 26.5. The average annual rate of mortality in London during the ten years 1856-65 was 23.6; and the death-rate in 1866 from all causes, other than cholera, was 24.6; the rate being raised by an increased mortality from diarrhoea in the autumn, in addition to the actual deaths from cholera. The death-rates in most of our large towns have been steadily increasing during the past few years; and this undeniable fact has only recently attracted the attention which its importance should command. The cause of this general increase of mortality is now beginning to be understood, and there is, therefore, ground for hope that before long a re-action may take place. The growth of London in recent years has been unexampled in previous periods, and yet the buildings have not kept pace with the increase of population. The dwellings of the labouring classes have been undergoing a steady process of demolition for many years to make room for railways, warehouses, or other erections, which bear a higher commercial value than the poor class of houses which have been removed. The evicted tenants, unable and unwilling, to seek their homes at a great distance from their daily occupations, have crowded into the remaining houses of their neighbourhoods, regardless of the consequences to health, and as a natural result, fevers and other epidemic diseases have increased in fatality, and the death-rate generally has been higher. In the five years, 1855-60, the death-rate in London, averaged 22.7 per 1,000, while in the years 1861-5, it had increased to 24.5. The experiments upon a large scale, which have been made by the trustees of Mr. Peabody's gift, and by many of the donors of his company, have set at rest many of the doubts which have been so often expressed as to the practicability of erecting model dwellings for the poor, which should at once be attractive to the classes for which they are intended, and prove a safe 5 per cent. investment for capital.

If the attention of architects and builders were seriously given to the subject, the examples of which we speak would soon be further improved upon; it is also to be expected that the public, convinced that this is a matter of life and death to the labouring classes, and also that such erections on freehold land afford good security for the capital employed, will, ere long, support this movement with at least a portion of the confidence which, has recently been bestowed upon the long succession of "foreign loans."

Of the 80,129 deaths registered in London during 1866, 23,680 resulted from diseases of the zymotic class. Cholera alone caused 5,577 of these deaths; and, before passing on to notice a few of the other principal causes of death, it will be interesting, while the recent epidemic is fresh in our minds, to recall a few of the facts connected with its outbreak, duration, and results. Up to the end of June, throughout the metropolis only 29 deaths had in the six months been referred to cholera, mostly of a sporadic character; but, during the week ending the 7th of July, 14 fatal cases were recorded, and in the following week these had increased to 32, of which a large proportion were of the worst Asiatic type, and occurred in Stepney, Mile-end Old Town, Poplar, and Bermondsey, the very districts that afterwards suffered so terribly. The deaths from cholera now rose rapidly, until, in the week ending 4th of August, 1,053 cases were registered. From this date the numbers declined almost as rapidly as they had risen to about 200 per week at the beginning of September; but from this point the disappearance of the epidemic was very gradual. Even in the week ending 17th of November, 32 cases were recorded; but by the end of the month the disease as an epidemic may be said to have died out. Only in the eastern districts of London did the epidemic ever assume alarming proportions. In those eastern districts comprising the unions of Shoreditch, Bethnal Green, Whitechapel, St. George-in-the-East, Stepney, Mile-end Old Town, and Poplar, occurred 3,931 of the 5,577 deaths from cholera in the whole of London. In Shoreditch, the death-rate from this disease for the whole year did not exceed 1.07 per 1,000 persons living, but in Stepney it was 10.76; in Poplar, 9.08; and in St. George-in-the-East, 8.79. The southern districts suffered next most severely, showing a total of 712 deaths; but the disease in a severe form was almost confined to Greenwich and Woolwich, where the death-rate per 1,000 from this cause was 2.07 and 1.69. In the northern districts, including Marylebone, Pancras, Islington, and Hackney, 417 deaths occurred; the rates per 1,000 were, 1.06 in Hackney, .6 in Pancras, .43 in Islington, and only .3 in Marylebone. St. Giles, Strand, Holborn, Clerkenwell, St. Luke, and the City, comprising the Central districts, contributed 320 deaths, the highest rates being 1.57, and 1.18 in the east and west portions of the City. Cholera was scarcely epidemic in any of the west districts of London, the total deaths in the year being 188; the heaviest death-rate per 1,000 from this disease being .84 in Fulham, whereas in Paddington, Kensington, and Chelsea it did not exceed .25, .21, and .33, and in St. George, Hanover-square, it was only .17. The fact of the first serious appearance of cholera, and of by far its most terrible ravages having occurred in the area supplied by the East London Water Company, is beyond all dispute; but whether this company's water either caused the outbreak, or rendered it more fatal, seems to be beyond the possibility of conclusive demonstration; the accumulated evidence of preceding epidemics is, however, sufficiently impressive to enforce conviction upon the most incredulous that purity of water supply is an element of the first value in securing comparative immunity during a cholera epidemic.

Other diseases of an epidemic character besides cholera contributed to the high death-rate in London last year. Small-pox, to which in 1864 and 1865 only 537 and 646 deaths were referred, was fatal last year in 1,388 cases. The unsatisfactory working of the present legislation upon vaccination will, it is to be hoped, be remedied during the present session. Measles also increased from 1,302 deaths in 1865 to 2,259 last year; on the contrary, deaths from scarlatina and typhus each showed a decrease. The year 1866 was remarkably fatal to persons suffering from phthisis, the more than average amount of wind may in part account for this; in the three previous years, the deaths from this disease had been successively 7,991, 8,559, and 8,710, but last year they increased to 9,277; the rapid increase in the fatality of this disease has

a very close bearing upon the overcrowding in dwellings in so many parts of the town, which is not only dangerous in times of epidemics, but is continually sowing the seeds of untimely death in numerous and varied diseases.

Space will not allow us to enter more into detail regarding the causes of death in London last year, or even to touch upon many subjects of interest discussed in the pages of the Registrar General's Annual Summary. The result of the cholera epidemic in London is from one point of view satisfactory, its ravages were less extended and less severe than in either of the former visitations of 1849 or 1854; in 1849 the deaths from cholera in the Metropolis were 14,137, in 1854 10,738, and last year only 5,577; but we, inhabitants of the largest city in the world, have a heavy task before us if we would feel secure against future visitations, and seriously undertake to reduce our death-rate more nearly to the established healthy standard of 17 per 1,000 persons living.

A RAMBLE AMONG THE RUINED AQUEDUCTS AND FOUNTAINS OF ROME.

We have already briefly alluded to the visit lately paid by the British Archaeological Society of Rome to the most remarkable ruins of the antique aqueducts. The object was, under the guidance of Mr. Parker, to trace in ruin and identify by historic records the earliest monuments of the uses of water for public benefit or more refined luxury by the Romans, and to illustrate all ascertainable sites and buildings mentioned by classic authors in connexion with the sacred fountain, the public thermae, the private bathing-house, and the aqueducts of republican or imperial origin.

For the first walking expedition the rendezvous was before S. Anastasia, near the north-western base of the Palatine hill. At a few paces thence is seen, westward from that church, through a cavity opened in the pavement, the subterranean course of a hot spring, identifiable as the *Fons Julverna*, which flows at the depth of about 20 ft. below the modern street-level, and emerges to view near the mouth of the Cloaca Maxima. Leaving S. Anastasia, the party first visited the arch of Janus Quadrifrons, to observe where the ancient city's level is obviously left to this day unaltered, at the base of the great *mur* supporting that quadruple arch ascribed to the time of Septimius Severus. The ruins covering the northern slopes of the Palatine, not far distant hence, present examples of construction various in date,—that of the kings of Sylla and the emperors; and near an extent of buttress walls, in massive peperino blocks, that, if not positively referable to the city of Romulus, must certainly pertain to the very oldest fortifications built on this hill, we enter a conduit followed in the living rock, lofty, winding, and sufficiently spacious to be explored for the distance of several feet, that may have served for the supply of water to gardens, or the citizens in general. Mr. Parker observed the similarity between this conduit and that of Alba Longa, which yawns on the rock-side, close to the picturesque convent of Palazzuola, above the Alban lake. Ascending the same hill, and bearing in south-eastern direction, along the grounds where excavations are now being carried on by Government, we reach several imposing and, in many parts, well-preserved remains of imperial building, whose long suites of chambers, still vaulted, gloomy, irregular, and labyrinthine, present a solemn effect of dark interiors, in which have been found many valuable marbles, sculptured and architectural fragments. Some of these have the appearance of being baths, several halls having distinctly traceable divisions for bathing purposes, and may be supposed among the works of Nero. Descending the Palatine, on the side of the Circus Maximus, we visit, below the height occupied by S. Balbina, known as the Pacudo-Aventine, south of the loftier hill so called, an extensive brickwork ruin, now divested of all architectural character on the outside, but with interior divided into parallel vaulted chambers, in the greater part entire—no other than the *Thermae Publicae*, or great reservoir, where were centred the waters of the Appian and Trajan aqueduct, now extant in but few remains; the exterior masonry, perhaps, of that last emperor's time, while the interior may be supposed republican. Following the Appian and quitting that highway, near the church of S. Sisto, to enter into private grounds,

we visit the recognisable site of the valley of Egrina, below the western slopes of the Caelian, undoubtedly comprised within the actual walls, and not far from the vanished Porta Capena, its proximity to which may be proved by the well-known passage in Juvenal's satire,—*In vallem Egrivæ descendimus et speluncam*, &c. Ascending the Caelian, we see, on a terrace ground, near the villa Mattei, and behind the church of S. Maria, a castellum (or great reservoir) of the Neronian aqueduct, that brought water from the Claudian along this hill to the Palatine, and a magnificent specimen of its kind is this lofty structure, the lower part built of large travertine blocks, the upper of finest brickwork. Near its base we look down, at considerable depth, into a channel through which the waters passed in one direction below the level we stand on. The pleasant gardens of the Volkonski villa, near the Lateran, next site of antiquarian interest, comprise a part of the Ager of Sorvius Tullius, and a majestic extent of the Neronian arcades now clothed with ivy, along whose lofty summits we distinguish, here and there, the leaden pipes and the *spiragli* (respiratories), conical in form, of the modern *Acqua Felice*, or Sixtus the Fifth's aqueduct, for which many ancient structures were made available; in some parts, indeed, unscrupulously destroyed. Entering another estate near the S. Croce basilica, now traversed by the railway, we find many remarkable ruins; among others a suite of vaulted chambers (now partly serving as a garden-house) which Mr. Parker identifies as a castellum of the Alexandrine aqueduct,—that of Alexander Severus. Near this stands the still beautiful decagonal ruin, with the remnant of an ample cupola, commonly called the "Temple of Minerva Medica," but recognised on better authority as the great hall (like another Pantheon) of Alexander's Thermae, supplied with water from the same aqueduct,—an appropriation further shown by a pentagonal reservoir that opens centrally to its area. On the same estate is a spacious castellum of the Marcian aqueduct, with lofty vaulted chambers, partly subterranean, and of fine brickwork, into which we may descend by a ruinous staircase; also a nymphaeum of the Alexandrine aqueduct, now used as a wine-cellar, and containing a cistern filled with water; its antique vaulting of very ample span, now so completely blackened, that a most gloomy scene is presented by its interior.

The less generally known aqueduct ruins on the Campagna, south of Rome, formed the object of the very interesting excursion on which we set out from the Porta Maggiore on the next day. After proceeding about two miles along the Via Laticiana, we struck into a highway that runs to the right immediately below the arcades of the Sixtine aqueduct, following which structures the first noticeable antique is a series of the Marcian aqueduct arches restored in brickwork of the second century, and almost buried below the ground on the left of the road. At a short distance farther on, leaving the highway, we see a massive remnant of the Claudian aqueduct, near to where it meets that of Pope Sixtus at a right angle in a solitary field—offering occasion to contrast the grand style of the antique with the paltriness of the modern building. Here we see how (as, indeed, elsewhere) the Claudian arches have been partly filled up by brickwork of the time of Nerva or Trajan. In the midst of an unenclosed level ground, not far thence, stand the moldering substrucures of a great quadrangular brick building, with rows of niches on the arcades that seem to have served only as buttresses, the masonry in most parts laterial, in others *opus reticulatum*, and this Mr. Parker well establishes to be a nymphaeum built by Augustus for the enjoyment and use of salubrious waters on this solitary spot. Next is reached one of the most finely picturesque groups of ruins that even Rome's Campagna presents to us—the parallel arcades of the united Marcian, Tepulan, and Julian aqueducts, and those of the more conspicuous Claudian that approach within a slight distance, here divided from each other by a gently sloping ground bestrewn with underwood, and watered by the *Acqua Crabra* (the antique *Mamma*), here running within a stone channel. The Marcian arcades are of regular and massive stonework; the rest of the structure above them, of concrete; and more modern brickwork (some imperial addition) fills up the interstices of many arches; while ivy, of the most luxuriant growth, in great part conceals this noble structure, adverse to the studies of the archaeologist, but

contributing to the effect of melancholy beauty in this impressive ruin-scene, little known or visited, amidst silent solitude. Not far from this spot we find the Marcian and Claudian aqueducts changing sides, so that the former rises to the left, the latter to the right, as we follow the road in our approach to the modern arch (*Arco Furbia*) that stands in the midst of the long lines of partly antique partly modern arcades, thrown over the road to Frascati. Near a modern fountain and beside this arch, the Marcian and Claudian are seen to join, becoming for some extent instead of two a single aqueduct. About half a mile hence we reach the Torre Fiscale, a very high square tower of the fifteenth century, that rises one of the most far-seen among such Medieval piles on the Campagna, from the aqueduct arcades that support it. And the interior of this tower is well worth a visit; for here we see the junction of several *specus*, distinctly discernible as we gaze up the quadrangular building of the Anio Novus, Claudian, Marcian, Tepulan, and Julian aqueducts,—no fewer, indeed, than five *specus* uniting at one centre within this same tower, Torre Fiscale, the name given to it because here those baronial brigands of the Rome of later ages used to levy black mail on all who passed as price of their safe journey to or from the city. On some elevated ground near a solitary *osteria*, not far from that tower, we again find the arcades of the Marcian aqueduct, but here rising to no considerable height, and we can penetrate the *specus*, permeable for a few hundred feet, till choked up by soil or ruin. From this channel it may be assumed that about one-tenth of the water-supply of Rome reached its destination in the Imperial period. We have not to walk far from this spot to find once more the loftier Claudian arcades; and pursuing our way under their shadow, we come upon a sluice of the Julian aqueduct, similar in method to the locks of our modern canals, but the channel is here narrow, of diminutive scale; and it may be concluded that the great villa of Commodus, whose ruins still stand imposingly near the Appian Way, had its water-supply from this branch of the same aqueduct. On the same level ground we may be startled by suddenly seeing a wide round orifice yawning at our feet, fenced by railings, through which we look down into a mysterious and dark abyss, known to be the *piscina* of the Marcian aqueduct; and Mr. Parker assures his auditors, on reliable authority that we here stood above a stupendous subterranean dome, equal in diameter to that of St. Peter's and with vault, of concrete, about 20 ft. in thickness, overhanging the vast reservoir that extended far in invisible depth below. The engineer of the Roman Government, Signor Morandi, had lately the courage to descend and explore this extraordinary excavation. At a short distance on a line with that orifice, rises a steep isolated mound, that might seem of nature, isolated as it is associated to be the centre shell of a similar, and not less enormous dome, pertaining to a *piscina* of the Claudian aqueduct. From its summit is enjoyed a view of great extent and so grandly characterized, so striking in its features both of ruin and landscape that one might, in contemplating it, forget all specific antiquarian studies under the spells of feeling and association. Another similar, but less lofty mound, at a short distance, is identified as connected with the Anio Novus *piscina*, whose swelling dome rises above the Campagna surface like the afore-mentioned; and on its slope we observe remnants of some building, perhaps of a later imperial period, constructed upon its summit, or absorbing it. At this point, about eight miles distant from Rome, our day's excursion had its term. In the course of this and the previous day's studies, Mr. Parker had not failed to point out all that is remarkable in the more commonly-visited aqueduct ruins on our route—the majestic castellum of the Claudian and Anio Novus, with the inscriptions of Claudius, Vespasian, and Titus on its high attic, now forming the Porta Maggiore in the line of Honorian walls; the castellum of the Neronian, under which the road passes between the Lateran and S. Croce basilicas, and the now half-buried arch of the Julian, Tepulan, and Marcian, connected, in the same later fortifications, with the Porta S. Lorenzo, and bearing inscriptions of Augustus, Titus, and Antoninus Caracalla. Along the outer line of these Honorian walls, between the above-named gateways, are to be observed also several remains of aqueduct structures absorbed into the cincture; the triple *specus*, superimposed of the Marcian, Tepulan, and Julian, with

massive pilaster of stonework below; a massive portion, in peperino stone, of the Anio Vetus, brought to the city A.U.C. 481, by Curius Dentatus and Lucius Papirius, the censors; and another species probably belonging to a castellum of the Julian, near a curtain wall of the best brickwork, with windows and modillions, the style of which seems to indicate an edifice of the Neronian period.

Different, indeed, is it to follow on the familiar range of antiquities described in all guide-books, pointed out by all *ciceroni*, and to quit that beaten path for explanation based on knowledge, or for verifying theories drawn from the study of ancient writers, such as is the principle that guides archeological researches like these; the energetic pursuit of which may lead to the discovery of more, among the hidden treasures of Rome's monuments, than has yet been made known.

PROFESSIONAL SKILL IN HIGH LIFE.

To the honour of the British aristocracy he it said, that it numbers in its ranks many who are not afraid of work. In the natural course of things we do not expect a persistence in work and a rent-roll of 30,000*l.* a year to go together. The reason, of course, is that the rich man is under no actual necessity to labour. It is otherwise with the poor man, who has no choice but to live by the sweat of his brow. Hard labour, and continuous exertion of one kind or another, are his only resource. It will be observed that we speak merely of the necessity of the thing. There is a higher sense in which none can claim exemption from work, since work is the universal duty, and the great law of life. But while the obligation to labour is equally binding upon all, it is only the poor and dependent who are under the actual necessity of adopting work as a profession for support. The rich, as the saying is, can afford not to work. Your peer may toil,—your peasant must. The dignity and sacredness of labour fully admitted, titles, wealth, and the leisure which wealth brings with it, it must also be admitted, are formidable temptations to idleness, and strongly induce *vis inertia* on the part of the possessor of them, when correct principles and proper motives fail to govern the actions of life. A desire for fame, though a very strong incitement to exertion with mankind generally, is perhaps less so with the lord than the commoner, because the former feels in some measure at least, satisfied with the honours and distinctions that necessarily attach to his exalted position. If he is not entirely devoid of intellect,—if only he be able to “put in an appearance” in the House of Lords, the English peer is to a certain extent a public character, the holder of considerable influence, and the recipient of many privileges,—in the eyes of the multitude a very enviable being. Many of the aristocracy are, no doubt, satisfied with such distinction,—that of birth—and are indifferent to true greatness, which is neither born with a man, nor thrust upon him, but is attained by personal achievement. But there have been, and still are, many brilliant exceptions. There are not a few of the “upper ten thousand” who have shown that they love labour for its own sake. On the whole the British aristocracy will compare favourably in this, as in every essential respect, with the aristocracy of any other country. They are not all “wise as serpents and harmless as doves;” they are possibly not what they might be; but still many great men have sprung from them, and, as a class, they have immensely improved in mind, in manners, and in morals even since the days of the Regency. Scandal in high life has not yet entirely died out, but it certainly does not flourish as it once did. Vice, openly and gloriously indulged in, is no longer fashionable.

There is no need to point out that some of the ablest statesmen, some of the most renowned soldiers, eminent lawyers, and distinguished scholars that this country has ever seen, have sprung from the aristocracy. Names might be adduced by the score. In other departments of professional life the nobility have done real service. The labours of some in science and art, for instance, have materially aided the cause of civilization throughout the world; others have shown mechanical skill and inventive talent in less ambitious ways, though with really beneficial results. Walpole gave us an account of royal and noble authors,—a history of royal and noble workers in other fields of labour, as in the field of mechanical invention and discovery,

would prove not uninteresting. And we think it might be shown that the desire and faculty for labour in this and other directions are being largely developed in high places in the present day. It is particularly gratifying to observe that so many of our younger nobles are busying themselves in hard, earnest work of various kinds. We have, for example, Viscount Amberley, a hardworking Member of Parliament, and an able writer, at a very early age. The Marquis of Lorne, who only very recently attained his majority, has already pronounced with judgment on public questions; and we observe the announcement of his first work, “A Trip to the Tropics.” The other day the youthful Marquis of Bute, in a long letter in the *Times*, gave an account of a recent visit to the Mosque of Hebron, describing that interesting place with a facility of expression and an amount of architectural knowledge certainly altogether unexpected from a peer in his teens. Other noblemen, like Lord Milton, set out for wild and unfrequented countries, and endure all manner of hardships in order that they may earn the rewards of the scientific traveller. All this is only in accordance with the earnest and practical character of the age in which we live.

Let us see what our nobility have done in the field of discovery and invention. To go back a little in our history, the first prominent name that suggests itself is that of Baron Napier, of Merchiston, the greatest mathematician his country ever produced, and who was regarded by Kepler as one of the greatest men of his age. Napier's well-known invention of logarithms, published in 1614; his “Rods,” designed to facilitate the division and multiplication of large numbers; and his improvements in spherical trigonometry, have conferred great benefits on mankind, and earned for their inventor a world-wide reputation. The first actual steam-engine was constructed by a nobleman whose life forms one of the most romantic chapters of English history—Edward Somerset, Earl of Clamorgan and Marquis of Worcester. He accomplished what everybody before him had failed in,—he provided means to make the action of the steam-engine continuous; and although his invention was ultimately superseded by the condensing engine, and by more perfect inventions since, it was unquestionably a triumph of genius, and served its purpose. The discoveries in experimental philosophy of the Hon. Robert Boyle, son of the Earl of Cork, belong to the same period. The Stanhope printing-press is of purely aristocratic origin, being the work of the eccentric and clever earl of that name,—the “minority of one,”—and brother-in-law of Pitt, Stanhope. Until the introduction of the Columbian and the Albion presses, the Stanhope press was the best thing of its kind, and a most important invention. Though still in use, it is only in a small way, the steam-printing machine having immeasurably out-distanced all its rivals. But Earl Stanhope's inventive faculty did not end with securing buildings from fire, to two calculating-machines, one of which performed addition and subtraction, the other multiplication and division, as also a monochord for tuning musical instruments, a vessel to sail against wind and tide, and an improved method of stereotyping. We may add that the Stanhope family have in addition given us a new style of coat, and a new carriage. Lord Camelford who, in 1804, was shot in a duel with Captain Beatty, was not only a young man of great literary taste, but also a very clever chemist. The Duke of Bridgewater's name deserves mention as being inseparably connected with Brindley and canal engineering; while Lord Rosse will always be remembered with honour for his invention of the great telescope which bears his name. Architecture and building have had several distinguished disciples in the peerage. It is almost unnecessary to refer to the Earl of Burlington, who planned and designed the well-known mansion in Piccadilly, about which so much has been said of late. The colonnade of this edifice is justly admired for the beauty of its proportions. The famous villa of Chiswick was also built from designs by this nobleman. The late Prince Consort, besides being a good architect, was an excellent turner in wood, and an efficient amateur photographer. It is singular, we may here remark, what a fascination photography has for royalty, and how many princes have become extremely proficient in the art. The latest name added to the roll of royal amateurs is that of the Grand Duke of Tuscany, who has produced, it is said, some magnificent specimens

of scenery. For architectural ability the present Earl Lovelace is perhaps the most eminent of his class of the day. We might point to his own mansion at Ripley, Surrey, as well as to the new school and the inn of the village, as examples of his lordship's skill as an architect. The earl's eldest son (Byron's grandson), the late Lord Ockham, inherited his father's notions of the dignity of labour, and carried them much further. Dropping his title, he entered the ship-building yard of Mr. Scott Russell as a common artisan. This young man carried his zeal almost to a monomania. He wanted, he said, to found a great firm—“Lord Ockham & Company, Shipbuilders, Millwall.” Unhappily his career was cut short before he attained the object of his ambition. Another peer, the Earl of Caithness, has turned his practical knowledge of engineering to good account on different occasions. When the Princess Alexandra arrived in London, the Earl was honoured with the direction and personal guidance of the royal train from Paddington to Windsor. In his own country he has transformed his carriage into a locomotive, and travels the turnpike by steam. Several young noblemen, including the Duke of Sutherland and Earl Crosvenor, have gone in heartily for the fire brigade,—following the example of Lord Craven, of Charles II.'s time, who was a constant attendant at fires. Craven used always to have a horse ready saddled in the stable, and rewarded the first that gave him notice of such an accident. He usually rode a white horse, well known to the London mob, which got the credit of being able to smother the fire from afar off. On these occasions Craven is said to have been an active and efficient volunteer. His Royal Highness the Prince of Wales has not disdained the helmet and the hose; and, after all, there may be worse ways of spending time than assisting at a fire. By the way, the Duke of Sutherland's mother, the Dowager Duchess, has exhibited decided taste as the designer of carpet patterns, and we believe that her Grace is not the only clever milliner to be found among our aristocratic dames. Rumour states that the Princess of Wales herself might instruct some of the Court milliners in the mysteries of their own craft. The Hon. Mrs. Damer is probably the only instance of a lady in her sphere attaining eminence as a sculptor; it is pretty generally known however, that many ladies of rank of the present day excel as amateur painters, modellers, musical composers, &c., and their claims in the field of literature are universally acknowledged. With the late Lord Sefton cookery was a fine art. He showed decided talent in the preparation of simple dishes, while the taste which the late Lord Poltimore displayed in laying out a table, earned for himself a name among his contemporaries. Earl Granville and Lord Torrington—the former especially—excel as dairy farmers, Lord Radnor as a breeder of pigs, and the Earl of Essex as a sanitary reformer. Did not Beau Brummell confess with something like remorse, that he once ate a pea? What would the exquisite George have thought could he have received an invitation from the Earl of Essex to inspect one of his lordship's favourite sewers? or had Lord Radnor asked him to examine some of his prize porkers? He must have fainted at the idea. Brummell belonged to the class of which George IV., Lord Petersham, and Colonel Kelly, were leading ornaments, and representative types—men who had skill in cutting out coats, and originality sufficient to invent blacking, but who had no souls above buttons. It must be regarded as a wholesome sign of the time that the mere dandy and idler is dying out, and that work has become the order of the day in the castle as well as in the cottage. We deem it a good social tendency that members of the aristocracy should leave their own circles, and take part with other classes in the common affairs of every-day life. Besides offering an opportunity for individual distinction in a new field, it helps to remove the barriers of exclusiveness, and to increase habits of social intercourse between class and class. In ancient times it was the fashion for each handicraft to have its patron saint. Why should not each handicraft now have its patron peer to maintain its real dignity and right to estimation, as well as to vindicate its utility and value?

HEMEL HEMPSTEAD WATER-WORKS.—The dimensions of boiler given in our notice last week should be reversed: the boiler is 21 ft. long and 6 ft. in diameter.

NEW STAINED GLASS WINDOW IN
ST. PAUL'S CATHEDRAL.

Our readers may remember that as long ago as 1861 the committee for the completion of St. Paul's accepted the offer of painted windows from Mr. Thomas Brown and the Drapers' Company, giving the former as a site the west window and the latter the central east window. The means that were then taken to obtain a good result were elaborate and remarkable, and deserve to be recorded. As a first step, the late Mr. Charles Winston was invited to join the committee. By his advice Mr. Penrose, the Cathedral surveyor, examined the Munich glass recently put up in Glasgow Cathedral. This led him to report favourably of its fitness for St. Paul's; and the committee agreed that negotiations should be commenced with Herr Aimmiller relative to the intended works. In the ensuing summer Mr. Penrose, after going to Belgium, proceeded to Munich to confer personally with Aimmiller. In the first instance there was a difficulty as to the artist who should be employed for the designs. Baron Hesse, who was first invited, declined on account of age and occupations, and some other difficulties presented themselves at Munich; so that Mr. Penrose thought it best to go to Dresden to consult Professor Schnorr, as to the artist who should be employed. From him he obtained much information, and also an indication that the professor himself might possibly not be indisposed to undertake the designs. The committee fully recognized the importance of engaging an artist of such high reputation, and Professor Schnorr was invited to make the designs. The subjects for all the windows contemplated were arranged and approved by the Dean and Chapter; and the surveyor, in concert with Mr. Winston and the Rev. J. L. Petit, prepared instructions for the general distribution and scale of the figures and designs for the architectural accessories. During this period of the work Mr. Winston and the surveyor went to Glasgow that they might prepare their instructions with the Munich glass in view, and also have the assistance of Mr. C. H. Wilson, without whose antecedent trust in preparing the Munich glass-painters to work to mosaic glass-painting, and dispense with more uncertain. Professor Schnorr then met the surveyor at Brussels, that the matter might be talked over in sight of the windows of St. Gudule, when he so fully realized the effect of those master works that he spontaneously put together aside studies on which he had already devoted much labour, and made other designs. On the receipt of these they were drawn on glass and studied in respect of scale, chiaroscuro, and colour, on the large model of St. Paul's recently exhibited in the Royal Academy, and many modifications, in detail, were proposed and accepted by Schnorr. Various improvements in the architectural accessories also suggested themselves, which were then embodied in the enlarged drawings prepared by the surveyor for this part of the work. In addition to the above-mentioned elaboration of the designs, Mr. Winston was busily engaged in preparing Herr Aimmiller for the use of a better material than he had employed at Glasgow, and the effect of his instructions seems to be apparent in the window now set up. Aimmiller, too, we must add, had been invited to an interview with the surveyor at Brussels, at which Mr. Winston was also able to be present, after which some of the finest cinque-cento works in France were visited. The window now set up is at a great height from the ground, and when seen from the nave nearly one-third of it is cut off by a projecting gallery. To provide for this, the design is in two stories, the lower at the bottom, a colonnade of three openings (with figures in them) carrying a sort of attic at such a height that the upper picture is seen complete from most situations. This represents the Conversion of Paul, who lies prostrate in the foreground. On the left of the spectator a Roman soldier, bearing a flag, heads over him alarmed, and on the right two other figures, one of them very vigorously drawn, restrain the horse from which Paul has been thrown. Above him is a figure of Christ, with hand raised, as at the moment of entering the well-known adoration. The Saviour stands on clouds, with a kneeling cherub on each side of Him, and under the centre opening of a tripartite triumphal arch, with Corinthian columns and pediment, the entablature breaking round the capitals of the columns, and the tympanum adorned with an eagle. The side openings of the structure

have straight heads; these are hung with green garlands, and on each stands a cherub with flag. The design, as a whole, reminds one a little too strongly of some eighteenth-century title-pages, the likeness not being lessened by the staring letters V and R under crowns in the upper corners. The large ugly iron window bars left in do not improve it. There is much dignity in the figure of Christ, and excellent drawing in parts, though we cannot let this praise apply to the legs of the soldier with the flag. The colour is much more solid than in many of the Glasgow windows: the most brilliant piece will be found, — at any rate in the afternoon, — in the centre group of the lower picture.

With every willingness to congratulate the authorities of the cathedral on their acquisition, if we be asked if it were necessary to go out of England for it, we should unhesitatingly answer no. If one of our best artists had been called in to prepare the drawing, as was done in Germany, and the same elaborate pains taken in other respects, the result, we are much disposed to believe, would have been a better window. Whether by this process the cost of the English window would have been made greater than that of the German one we have yet to learn.

Another spandrel under the cupola of the cathedral is being filled in with a mosaic picture.

THE SANITARY ACT, 1866.*

An edition of the Sanitary Act has just been issued, dedicated to members of municipal and local bodies who are charged with the administration of the laws relating to public health in England. It is profusely supplemented with both legal and sanitary information by Mr. R. C. Austin and Dr. Hardwicke. The Act is divided into four parts, which contain sixty-nine sections, out of which our authors pick those which refer to provisions of a novel and interesting character. Mr. Austin at the foot of each page gives notes, which contain references to other Acts bearing upon the subject, and other legal information. And Dr. Hardwicke's contribution follows the Act in a series of short chapters on the subjects enumerated on the title-page. The latter suggests the formation of a code of sanitary law, which is to consist of a revision, amendment, and consolidation of the whole of the laws already passed, the Public Health Act of 1848, the Local Government Act of 1855, and the Metropolis Local Management Act of 1855 forming the basis upon which they are to be organised, this being a similar scheme to that recommended by the standing committee of the health department of the Social Science Department, assembled at Manchester in October. He further calls for centralization of powers, and a new appointment of the duties which are now divided between the National Registration Office, the Ordnance Survey, the departments under the Secretary of State, the Board of Trade, the Poor-law Board, the Local Government Office, and the Privy Council. He advises that Parliamentary blue-books should be circulated among officials engaged in local duties in remote places, for, as they are now printed exclusively for members of the senate, their contents would be unknown except in their circle if it were not for occasional mention by the press. He then proceeds to state his conviction of what the duties of each department should be. The Local Government Board he would entrust with the management of all matters relating to drainage, sewerage, water-supply, gas-works, public roads, parks, and gardens, baths and wash-houses, and cemeteries; and he commends the French example of assistance given to local bodies by the collection of information and plans relating to public works. District Boards of Works he would entrust with much extra power of jurisdiction in the administration of works connected with drainage, of rivers, swamps, and lowlands, the construction and maintenance of bridges, canals, and public roads. The members of such Boards, he wisely advocates, should be chosen from substantial and intelligent classes, and assisted by a suitable staff of officers. He considers the Metropolitan Board of Works a

* The Sanitary Act, 1866, with notes, statutes, &c. By Robert Cecil Austin, of Gray's Inn, Barrister-at-Law. Together with copious notes and commentaries on Public Health and the Sanitary Laws of England, containing chapters on Public Health and Sanitary Legislation, and Suggestions for a new Code of Sanitary Law. By William Hardwicke, M.D., Deputy Coroner for Central Middlesex. London: Nichols, Brothers, Frederick-street, W.C. 1867.

good sample of a Board whose operations are spread over a large area, and that its usefulness would be still further increased, but for the jealousy of vestries and other small bodies, which still claim power to drain, pave, light, water, and cleanse the highways; if it were not for this want of united action it would be a model of efficiency. Local Boards or corporations would still have to manage the poor, schools, hospitals, water, gas, public baths, highways, markets, and fairs. Concerning specially qualified officers for the administration of sanitary laws, he proposes that the Government should institute an examination, under the auspices of the Privy Council, or Civil Service Commissioners, or entrust the universities and medical schools with powers to confer a degree or other certificate of proficiency for employment by the State. Throughout the work the doctor strenuously urges the importance of the science and practice of preventive medicine, and advocates various other essentials so often, by us, insisted upon.

The chief merit of this edition of the Act lies in its special adaptation to the classes entrusted with the responsibility of making provisions for the public health. To such we recommend it as a condensation of much of the general information now current upon this subject. We will say that it is proposed to establish a village, or town, or temporary hospital. Dr. Hardwicke informs those concerned what are the essentials they must strive after, where they will find the best additional information upon the subject in hand, and the importance of architectural skill and experience in the erection of the necessary building. He urges that national or district hospitals have as just a claim upon the county in which they are situated as prisons and asylums. About 3,000,000 persons are among us in a sick or dying state, who are too poor to provide medicine and attendance for themselves, and he rightly contends that the cost of ministering to these should be equitably equalised over the kingdom, and not made local charges. One or more large hospitals, in suitable districts, he would organize, where the poor could at all times receive medical, surgical, and midwifery assistance, and to these he would add small village hospitals for convalescent, paralytic, and incurable persons. No less than sixty of the latter, built after the model of those at Crawley and East Grinstead, were erected during the last year, and were filled with patients, some of whom were supported by their friends or by sick-clubs, and others by the guardians of neighbouring unions, at a charge of from 3s. 6d. to 10s. weekly. The doctor would have such institutions provided with flower-gardens, shady walks, and resting-places for the old and infirm, and in every way made as sanitary, cosy, and attractive as it is possible their associations would permit. If we read aright, he would procure for the poor in every county a staff of physicians and surgeons, on which should be enrolled the ablest men in the provinces, and supplement this incalculable boon with a system of nursing based upon the generous, passionate enthusiasm with which ladies take up works of charity. May his shadow never be less!

Lord Shaftesbury once said, the poor-rates might be reduced at least 2,000,000l. per annum by placing our large towns under sanitary conditions. How much more might be saved, and how many lives might be spared, should all the dominions of her Majesty enjoy the same blessing, would require a long calculation.

ARCHITECTURE IN THE ROYAL
SCOTTISH ACADEMY.

The exhibitions of the Royal Scottish Academy, occurring as they do at a season of the year when the sun strives to gain the ascendancy over the keen north-east winds which prevail, are a source of great interest to the inhabitants of Edinburgh. The galleries are, indeed, the fashionable lounge and rendezvous, and are only deserted when Sol obtains the mastery over Boreas. The present exhibition, which opened on the 16th ult., is generally considered one of the best that has occurred for some years past, and there are more pictures of importance than usual. As is invariably the case, many of the pictures are familiar to the London public, having appeared at the last Royal Academy Exhibition; amongst these are works by Landseer, Phillip, Grant, Faed, Millais, Ballantyne, and others; and several productions of foreign artists still further enhance the interest of the display.

Reversing the usual order adopted in classifying works of art, the catalogue begins with the architectural works. We must premise that there is nothing remarkable in these, either as regards originality or peculiarity of design.

No. 1, "Suggestion for the Improvement of Edinburgh," J. D. Peddie, is a large and beautiful drawing, in which it is attempted to show what may be done, within practicable limits, to improve the view eastward from the Mound, and to heighten its classical expression, at present seriously lessened by the Scott Monument only. The drawing represents the fountain about to be erected in the Prince's-street Gardens; markets on the site of the present station for the north trains; railway-station buildings of the height sanctioned by the recent Act of Parliament; a railway hotel on the site of the present Queen's Hotel; the National Monument completed, and monuments in the form of Greek temples, and statues on suitable sites on the Calton Hill, which is thus made to assume the appearance of a Greek Acropolis. No. 22, "Manston-house for Wm. Laing, Esq.," by J. A. Hamilton, might rather be designated as a villa, for such it is, and not a very large one either. It is in the Scottish domestic style, treated in a free and lively manner. Mr. Frederick T. Pilkington is never commonplace, though frequently wild and eccentric. No. 48, "Presbyterian Church, Cardiff," however, has nothing in excess. The spire is well proportioned, light, and graceful, and the body of the church possesses only so much of Mr. Pilkington's peculiarities as to make it recognizable as one of his productions. No. 29, Pilkington & Bell, is a pleasing example of the modern style of Gothic as applied to domestic purposes; abundance of light is given, and variety is secured without violent contrast. 47, "North-west View of Castlehill, Dumfriesshire, the seat of Robert Jardine, esq., M.P., now in course of erection," by David Bryce, R.S.A., is a mansion in the Scottish baronial style, and is by no means one of Mr. Bryce's happiest efforts: the general effect is dull and heavy without being picturesque, and it abounds in detail which is manifestly false and extraneous. Mr. Bryce also exhibits "Sketch of a Monument to the late Miss Catherine Sinclair" (No. 63). It is in the form of an Eleanor's Cross. 65, "Selected Design for proposed Cathedral Church of St. Andrew, St. Andrew's, from the South-East," Robert Anderson. This design has none of the crudeness displayed in those exhibited by Mr. Anderson last year; he has now discovered that truthfulness and moderation are quite compatible with elegance and grace. The style is thirteenth-century French, upon an English foundation.

98, "Perspective of a House designed on an angle of 45 deg., cubic proportion." 230, Ditto, at an angle of 60 deg., James Gowans. Mr. Gowans seems to have an idea that all designs should be founded on mathematical principles. For himself he built a large and very peculiar house, upon the 2-feet square principle. Apart altogether from theory, the designs exhibited are pleasing enough, and should they ever be realized in stone, we doubt if any one, unapprised of the architect's purpose, would discover the subtilty underlying the outward semblance.

89, "Exterior View of Church, Compiègne;" 167, "Exterior View of the same," R. Thornton Shiells. The English visitor to Compiègne can hardly fail to see that this church is not the work of a French architect. The style is purely Early English, and the arrangements are such as are usual in small parish churches. A well-proportioned design is somewhat marred by the undue prominence given to a coat of arms over the doorway in the spire. Mr. Shiells also exhibits "Design for the United Methodist Free Church, to be erected at Park-place." This design is of the Early German type. It has a slated brooch spire in the centre of the main gable, with gablet lights in the angles. The side elevation is tame and flat; but from the position the church will occupy, it will not be much seen. The principal front, however, is effective.

117, "View of Craigmount House," and 193, "Design for the Roseburn Free Church," Robert E. Raeburn. Mr. Raeburn's studies have evidently not gone further than "Bathy-Langley;" the house has pepper-box turrets perched on the highest angles of a tower, and the church is one of those productions which figured thirty or forty years ago as being built after the Gothic manner.

118, "Lanark Parish Church, Dumfriesshire;" and 144, "Lanark Parish Church," by John Star-

forth, are good specimens of pure English Decorated. The spires have a family likeness, are well proportioned, and set to the main structure. There is a slight weakness observable in the doorways, however.

127, "New Magdalene Asylum, Dalry," James W. Smith. Justice has not been done by the draughtsman to a very meritorious building in the style of the country.

162, "Netherby, in course of erection for Mr. Wm. Roberts," by James C. Walker, is weak and ineffective, having more of the appearance of an old house patched up, than of an entirely new one. The detail is of a heavy Renaissance sort, used in the later French chateau.

182, "Design for proposed Churches," John Honeyman, jun. We believe it is proposed to erect this group of churches in the city of Perth. Mr. Honeyman has made them assume the outward semblance of a cathedral, and as such his design is good; but how far the fundamental conception of making several small churches assume this guise is correct is another matter. 195, "Design for English Church, Campbellton," Campbell Douglas. A simple, severe, and unaffected piece in thirteenth-century style, consisting of west tower transepts with double gable and chancel. 229, "The General Hospital, Toronto," William Hay, is a large square Gothic structure, with a tower in the centre of the principal façade, and smaller towers at the angles. The building assumes importance from its size, but there is nothing worthy of commendation or of censure in the design.

There are many designs to which we have made no reference: they are mostly "skayed" so that we cannot examine the detail, and many of them are very washy in colour and ineffective as drawings.

SANDERSON'S "GRAPHICE," 1658.

There is a thin folio of the year 1658, "London, Printed for Robert Crofts, at the signe of the Crown in Chancery-lane, under Serjeants' Inne," with this attractive title: "Graphice. The use of the Pen and Pencil. Or, The Most Excellent Art of Painting. In Two Parts. By William Sanderson, Esq." The book is scarce, and is too often found without "the Picture of the Author," (as is the case with my copy) a marvellous head of the author, by Faithorne, after Soest.

I have something new and suggestive to communicate about this thin folio.

The volume was a favourite with Horace Walpole, who in print, speaks of it thus:—

"Sanderson, an intelligent writer on Art,—his 'Graphice,' though in tortured phrase, contains both sense and instruction."—*Walpole's Works*, iv., 34.

"Sanderson in his 'Graphice,' an affected but sensible book."—*The same*, ii., 231.

Some account of Sir William Sanderson may be found in Granger's Portrait Biographical History. He published several "Historices"—now in little esteem,—and in his prime was secretary to the first Duke of Buckingham of the Villiers family. In this capacity we may fairly assume that he had a hand in the formation of the far-famed gallery of pictures collected by the duke.

His wife, Dame Bridget Sanderson, was "Mother of the Maids,"—i. e., superintendent of the Maids of Honour attached to the court of Catherine of Braganza, queen of Charles II.,—an office demanding great discretion and great control of temper. To my thinking, Dame Bridget must have looked not unlike the Duenna in Leslie's famous picture of "Sancho and the Duchess."

Now for what I have to tell. Among the Harleian MSS. in the British Museum (No. 6,000, 43 f.) is a thin folio with the following title:—

"An Exact and Compendious Discourse concerning the Art of Miniature or Limning, the Names, Nature, and Properties of the Colours,—the Orders to be observed in preparing and using them both for Picture by the Life, Landscape, and Historiyes."

The compilers of the Harleian catalogue do not give us the name of the writer; but my opinion (long since arrived at, and now all but confirmed) is, that it is in a great degree the original of Sanderson's affected but sensible "Graphice."

Here are a few extracts, and in the writer's own spelling:—

1. The experience whereof I saw both in the Vatican Library at Rome and in the villa of Cardinal Burghese (1st).
2. And this was the manner of our late excellent Mr. Nicholas Hilliard in making his enins (2nd).
3. Insinuated in the epitaph of your late countryman and my dear cozen Mr. Isack Oliver (3rd).
4. An ordinary playing card (4th).
5. The best abortive parchment (5th).
6. The rude and homespun apparel of my npland language (6th).
7. And the ground behind the picture it is comonly blew or crimson, somewhat like a satten or reidi velvet curtayne (much in request w^{ch} our Mr. Hilliard) (7th).
8. In the gallery of my most noble Lord the Earle of Arundell, Erie Marshall (8th).
9. The working hereof I shall tell you being taught me by our Mr. Hilliard (9th).
10. And this secret of making liquid silver I had from Mr. Hilliard (9th).
11. In a word the most general and absolute rule, and universally to be observed in landscape, was taught me in the most excellent m^r in this kinde now dwelling in Rome, Paolo Brill, whose delightfull works are many of them extante in print, and graven by Raphael and John Sadler, besides many other very rare pieces of his owne hand, w^{ch} I have seene in fresco and in oyle both in the Palesa Montolio by Sr^a Maria Maggiore, Cardinal Bentinagio on Monte Canallo, and in the church of Sr^a Cecilia Transteverca (10th).
12. His [P. Brill's] observation was only this.—Only remember that both in your leaves and trees, rivers, and all aerall morbidezza, as Paolo Brill caules it, or delicate softness, w^{ch} is the next remarkable grace and ornament to your works (11th).
13. Those greacie and fearful rocks wherein Momper,* of Antwerpe, soe pleases himself as noe piece passes his hand without them (11th).

Sir William Sanderson died *ingestate* (I am sorry to say) in the year 1676, aged 86, and was buried in the north transept of Westminster Abbey, where his grave-stone is still to be seen; and where, on the north wall, is a clever bust of the quaint old writer,—the sculptor's name unfortunately unknown.

Prefixed to the "Graphice" are two copies of verses, by Flatman,—a poor poet but imitable miniature-painter; and a head of the author, aged 68, by Faithorne, after Soest, in Faithorne's very finest style. A copy of the "Graphice," with the portrait, is a rarity that commands a high price.

One more extract from the MS. and I have done. The following passage in the MS. may be collated with p. 73 of the printed volume. That the MS. is by Sanderson, or had been seen by Sanderson, I have no doubt whatever:—

"But that which is (*frater omnium*) a History of the Barrell of o' Saucio Jesus Christ, done upon a large table of fine abortive boards, I think of pear-tree. It is now in the hands of my very worthy cozen, Mr. Peter Oliver, by whose incomparable father, Mr. Isak Oliver, it was begun and almost finished. It was a piece of the greatest benvy and perfection (soe much as is finished) that I think Europe or the world cannot produce, and I believe if Carlo Van Mander, in his 'Duch History of the famous Paynters,' had seene this picture or the inventor, his books of quartle would have growne into a tome with the description."—*Earl. MS.* 6,000 fol. (43 f.), (11th).

And now for a query. Through what genealogical tree of flesh and blood were Peter Oliver and Sir William Sanderson cousins?

PETER CUNNINGHAM.

THE NATIONAL GALLERY COMPETITION.

THE Committee of Selection, before reporting upon the drawings, in the first instance called in Mr. W. Gardiner, of Montagu-street, to examine them, to see if the instructions had been followed. They had several meetings afterwards, and came to the opinion that there was not one set of designs that could be recommended to be carried out, although in all cases possessing very considerable merit as scholastic drawings. Their report is now in the hands of the printer, together with correspondence between the late and present First Commissioner and Lord Hardinge (their chairman) upon the subject of recommending one of the competing architects to be the architect for the new building. The committee have also submitted suggestions as to the required arrangements for a new National Gallery, which, together with the report, will, we expect, be published in a few days. They have named Mr. Edward M. Barry's design as being upon the whole the most architecturally meritorious for a new building, and Mr. Murray's for an alteration of the present building.

* Of Judoocus de Momper there is a very fine specimen at Kedleston Hall (Lord Scarsdale's). See Wasgen, iii., 382.

† The following references to Sanderson's "Graphice" may be found in Worsnold's edition of "Walpole's Anecdotes":—Pp. 84, 173, 176, 880, 912.

ALTAR RAILS.

At the annual meeting of the Norfolk and Norwich Archaeological Society, the Rev. G. W. Minns read a paper, by Mr. L'Estrange, upon the subject of altar-rails. The paper commenced by calling attention to the direction given by Archbishop Laud, in 1634, "that the altars were to be railed in and that the floor at the east end of the chancel should be somewhat raised." Details were given of the opposition against this by the Puritans throughout the country, especially in the diocese of Norwich; and the paper went on to say that "In 1704, three churches in Norwich were without rails before the communion-table; but it was principally in remote parishes that they had not been erected. In Taverham deanery, out of sixteen churches, there were only two—Frettenham and Hainford—and in Blifield deanery, out of thirty-two churches, but four without altar-rails; whilst in the deanery of Flegg, comprising only nineteen churches, there were no fewer than eight in which the rails were wanting. There were also other churches in which the rails were misplaced, as at Thwaite and Wolterton. At Hunworth the rails were thrown by at the east end of the chancel; and at Wigton a part of the old one remained, although wrongly placed. There was evidence that some churches were without altar-rails as late as the second quarter of the last century."

Mr. Manning said that at Wiggenhall St. Mary the communion-table was formerly in the centre of the church.

Mr. Fitch, referring to a paragraph in the paper stating that the rails were to be of such a character as to keep out dogs, said that he recollected going to Pakefield Church and seeing a notice to this effect: "Remember to bring no dogs to church."

The Rev. J. Gunn said that in his memory the communion-table stood in the centre of Tinstead Church. He should like to know whether there were any instances in the Roman Catholic period of altar-rails. He believed not.

Mr. Minns replied that there were no such instances.

DRAINAGE AND WATER SUPPLY OF CANTERBURY.

A REPORT on a scheme of sewerage and water supply for Canterbury has been made to the local Board of Health by their engineer, Mr. Filbrow.

According to this report, Canterbury is in a most deplorable state as regards drainage and water supply. There is no such thing as efficient house drainage. The whole site is surcharged with sewage, and the water supply is pumped from this very site.

"In very many cases the well and the cesspool are in close proximity on the same or adjacent premises, where the practical action daily going on is to put the filth into one hole, and to pump it out, little better chemically, from another in the same or adjoining yard."

No drains or sewers now existing are at all fit or at a proper level to form any part of a new system of sewerage. The present drains and sewers, however, might be used for surface drainage. The separate or exclusive system of sewerage is recommended for adoption, with frequent and free ventilating shafts, the principle of which Mr. Filbrow claims as of his own introduction about sixteen years ago. The sewers will consist of glazed stoneware pipes, from 8 in. by 18 in. diameter, and oval brick sewers from 15 in. by 22 in. to 24 in. by 36 in., with numerous inspection and flushing shafts. Deodorizing by layers of charcoal in the ventilating shafts is not approved of, as a hinderance to ventilation, and hence promotive of escape into houses through shallow and imperfect traps. Open pipes above the roofs are chosen, as the only safe and sure way to carry off the sewer gases. If irrigation be thought of, the outlet must be below the towns of Sturry and Fordwich, but the land is there too wet, being "half-year land," the engineer, therefore, does not recommend irrigation in this case, nor the Watford method, from the cost of pumping and other difficulties. His plan is to erect perfect sewerage works in duplicate, near to a highway about a mile and a quarter from the city, where the sewage will be subsided and deodorized, and the semi-solid manure sold to farmers, while the supernatant water will pass off by an outlet sewer into the river below Fordwich, free from either odour or colour, on the plan established by Mr. Filbrow at Usbridge, where he says it

acts satisfactorily, and has paid its own expenses for the last ten years. The estimate for the sewerage works, including outfall, sewerage works, &c., complete, is 18,060l.

The water supply is recommended to be taken from the Silver-hole spring, with a service reservoir on St. Thomas's Hill. The supply, it is stated, would be continuous and abundant, and the quality excellent. The cost is estimated at 23,638l., besides 6,000l. or 7,000l. for the water company's rights, if the supply be taken into the Board's own hands, as is recommended.

COMPETITIONS.

Schools, Ashford, near Staines.—The committee received eighteen designs in answer to their advertisement, and ultimately selected that sent by Mr. John M. Hooker, architect, for execution.

The New Church at Worksp.—In answer to advertisements for plans for the erection of the new church of St. John's, for Worksp, forty sets of plans were sent in. The plans were exhibited in the Corn Exchange, at the charge of 1s. each, the proceeds to go to the New Church Building Fund. Many availed themselves of the opportunity of viewing them.

COMPETITION DESIGNS FOR HOUSES, GREAT YARMOUTH.

THE public have had access to these drawings for some days. There are between eighty and ninety competitors, whose works well fill the Yarmouth Town Hall, and include more than the usual amount of rubbish, with, of course, redeeming features. The design "Comme il faut" is for a terrace of houses so large as to require centre areas; it is rivalled by "Porte-crayon" and "Alpha." Of the single villas "Apex" and "Fiat" produce a favourable effect; "Suspense" gives both the single villa and the pair; "Omnis Æternitate," "Valentine," and another "Alpha" may close the list. There is more competition for the semi-detached villas than for either the terrace or the single villa, because in this class two premiums are offered, and only one in both the others. In "Ecco A" and "Ecco B" good drawing commends the design (Medieval) to notice; "Comfort, Convenience, and Compactness well considered," "Circumspice," "Palmar qui meruit ferat," and perhaps a few others, "Trefoil" or a second "Omnis Æternitate," may be noticed. When will architects give up hawking their wares at quarter-price?

ACCIDENTS.

AN extraordinary accident has happened on the Lancaster and Carlisle Railway, about a mile and a half south of the Penrith station. It appears that as a goods train from the south was passing Yanwath Bridge the axle of one of the trucks broke and threw several carriages from the line. Among these were a powder-van, an iron one, constructed specially for carrying gunpowder, and containing, it is said, about five tons of gunpowder. Shortly afterwards another goods train from Carlisle, and upon the other line of rails, dashed into the overturned vans upon the up-line, smashing the gunpowder van. A fearful explosion immediately took place. The engine and tender of the train from Carlisle were driven into one another, and the driver and engine were killed, having been blown into the adjacent field, shockingly mangled, and the other wagons of the train were, many of them, shattered to pieces. One effect of the explosion was to set fire to and destroy the train. The permanent way was very much injured, and Yanwath Bridge, which crosses the line at this point, much damaged. The explosion was heard for miles round. At the neighbouring village of Yanwath, the windows and doors of the houses were driven in by the force of the concussion.

At Field Gate, Walsall, Mr. Bradbury, of Birmingham, had been employed to repair a well, and one of the men had descended to insert a kerb to support the brickwork, which was in rather a dilapidated state; but he had scarcely reached the bottom of the well, which is about 70 ft. deep, when the whole of the brickwork, and a large quantity of earth fell upon him and killed him.

A death has occurred at Sheffield from falling on a chisel. Deceased was a joiner and cabinet-maker. He was going along Fir Tree-land, Sheffield, and fell, when a chisel which he had in his side pocket pierced his body, severing one of the main arteries.

An explosion of gas took place lately at Hillhousefield, North Leith. One of the Edinburgh and Leith Gas Company's men was searching for an escape of gas, which had been complained of by the inhabitants in the neighbourhood for several days. He suspected the escape was proceeding from a pipe close to the common sewer, and with the view of ascertaining whether the gas had accumulated in the sewer, he opened one of the man-holes and stupidly put down a light. Immediately on his doing so, an explosion took place. He was thrown against the wall on one side of the street, and severely injured. His "bonnet," or cap, was thrown over a three-storey house, and was found in a garden behind. The explosion must have damaged the sewer for a distance of between 90 and 100 yards, for the paving-stones above it for that space westwards are loosened, and the iron frame and cover of another man-hole at that distance were torn up, as were also the causeway stones around the covers opposite to this part. Several windows of a dwelling-house were broken, and the house itself shaken to its foundation.

At Dartford, in Kent, contractors' workmen have been of late engaged in forming the extension line of railway leading from the South-Eastern line into Mid-Kent. To cross the public road it was found necessary to have a temporary wooden bridge thrown over the thoroughfare. The bridge was finished, and a metal tramway was laid on it. Upon this tramway was placed a travelling-crane. The men were lifting an iron girder by it, weighing several tons, in order to span the road. Suddenly the bridge swayed, first to one side and then to the other, and, without allowing a moment for escape, the structure fell, causing the traveller to topple over with the men on it. Some fell clear of the ponderous machine, but were overtaken by the portions of the fallen materials of the bridge, and became embedded in the debris. One man was found to be dead, and three others seriously, if not fatally, injured. One of these has since died.

EXHIBITION MEMS.

FROM the Potteries a large number of works are going to the Paris Exhibition, especially from Messrs. Minton's and Messrs. Wedgwood's. We can scarcely help regretting that most of the principal objects are designed, modelled, and painted by foreigners.

We do not hear good things of the allegories of London, Dublin, Edinburgh, Liverpool, Manchester, &c., proposed to be put up as window blinds in the English parliament.

The English Commissioner at the Exhibition has announced that from 45,000 to 50,000 English workmen will come to Paris during the summer, and will each receive from their several committees 10s. a day for their expenses.

The Palace itself occupies an area of 140,184 square yards, with a circumference of 1,400 yards. Its shape, our readers know, is that of a parallelogram terminated at both ends by two circles, having for diameter the width of the parallelogram itself.

French products will cover a space of 61,000 square yards. The English products will occupy 21,659 yards, and those of the United States of America 2,900 yards. It will, of course, be necessary to add thereto the space occupied in the Annexes of the Park; and which are of considerable importance.

The specimen of English Domestic architecture in the park attracts great attention: the high-pitched roof and gables, the exhibition of the timber work on the surface, the covering of tiles of variegated form and colour, from black to light-red, and, more than all, the stacks of ornamental chimneys, constructed of moulded cut bricks of various tints, which, like the tiles, are of English manufacture, induce numerous inquiries as to the country of which the style is native. Another surprise of the same kind is reserved for our friends abroad in the form of a hay of the new South Kensington Museum, the materials for which are now being prepared under the superintendence of the son of the architect, the late Captain Fowke. This specimen structure will be of large dimensions, about 60 ft. in height, and of nearly the same width,

and will convey a good notion of our working in brick and terra-cotta.

The courts of Morocco and Tunis are already blazing in gold and colours, as characteristic, and to us as novel, as the decorations of their neighbours—Turkey, Egypt, and the Danubian Principalities; the whole together forming a remarkable contrast with the chaste, solid wood-work of the Russian court close at hand.

In the park the structure now erecting for the Imperial Commissaire-Général begins to present an imposing appearance; it is composed of solid oak framing, put together in divisions before being mounted on a rusticated basement of artificial stone (*Bâton aggloméré*).

The Sultan's mosque and the three buildings of the Viceroys of Egypt now make an imposing appearance. The great temple, in the style of the epoch of the Pharaohs, is being covered within and without with the well-known emblems of the period, and with copies of ancient mural paintings in brilliant hues.

The pavilion of the Bey of Tunis, not far removed from the Turkish and Egyptian group, is a very large building, three stories in height, with a façade capped by two small cupolas, the entrance to which is by means of a hold double flight of steps, in the form of a horse-shoe.

The Art of Music is now to be represented in the Exhibition, in the triple point of view of composition, execution, and history. Prizes are to be awarded to two musical compositions, and a sum of 10,000 fr. may besides be awarded, on the proposition of the committee, to the author of the work which shall be judged worthy of being hereafter introduced as a hymn in international solemnities.

A special committee will organise a series of concerts, in which a small number of eminent artists will be convened to perform the most remarkable musical compositions appertaining to various epochs and different countries.

The *Great Eastern* is now nearly ready for her new duties—that of conveying passengers from New York to Brest for the Paris Exhibition. She has undergone very extensive alterations. The space last occupied by the cable tanks has been fitted up with cabins, berths, and state rooms for passengers. These apartments, numbering over 500, are lofty and convenient. There will be berths for 3,000 passengers. The deck saloon is a splendid apartment, 140 ft. long and 24 ft. wide, and will admit of 500 persons dining together. There are several smaller saloons. Altogether 2,000 persons may dine at once. The total outlay of this outfit will of course be very large.

THE NATIONAL GALLERY.

The director of the National Gallery has just issued his annual report, from which we learn that five pictures were purchased during the past year, at a total cost of 8,160*l.*, against 17,277*l.*, the amount expended in 1865. The pictures acquired were—a "Madonna and Child," by Lippo Dalmasio, 400*l.*; "Rhetoric" and "Music," two companion pictures, attributed to Melozzo da Forlì, 600*l.*; a "Portrait," supposed to be a "Contessa Palma" of Urbino, by Picco della Francesca, 160*l.*; and "Christ Blessing Little Children," by Rembrandt, 7,000*l.* Five pictures acquired in previous years were placed in the gallery, and two pictures and one bust were presented to, and accepted by, the trustees. The presentations are portraits of the Rev. George Hoddesford, and Mr. J. C. Bamfylde, by Sir Joshua Reynolds, presented by Mrs. Martha Beaumont; a marble bust of Milreedy, by Weeks, presented by friends of the deceased artist; and "The Remorse of Judas," by Armitage, presented by the painter. Fourteen pictures have been protected with glass, and ten have been repaired, cleaned, and varnished. Curtains have been placed before the Turner drawings at South Kensington, to protect them from the action of light during the time they are not publicly exhibited. We may remark that the process of cleaning, or, rather, "refreshing," to use the inventor's word, introduced by Professor Pettenkofer, of Munich, seems to have been abandoned by the trustees. It was first tried about three years ago, and a very favourable opinion of the process was expressed by the late Sir Charles Eastlake in his report for 1864. Since that time, however, nothing seems to have been done with it.

The number of visitors during the year was 1,531,976, showing a satisfactory increase on the years 1864 and 1865, when it amounted to 1,366,369 and 1,387,254 respectively.

The popularity, amongst students, of a particular picture, may, we think, be fairly estimated by the number of times it is copied. During the last year the favourite amongst the old masters was the "Garvagh Raffaele," as it is called, representing the Madonna with the infant Christ and St. John. Our readers may remember that it is a comparatively recent acquisition, having been placed in the gallery in July, 1865. This picture was copied twelve times, and eight copies were made of Velasquez's portrait of Philip IV. Next comes Vandyck's portrait of C. Vander Geest, better known perhaps as the "Gevartins" portrait, which was copied five times. This is an old-established favourite, and for the two previous years had stood at the head of the list. Murillo's "St. John and the Lamb," "Portrait of Rembrandt," by himself, and Rynsdael's "Landscape with Ruins," were also each copied five times. There appears to have been a slight falling off in the popularity of the well-known portrait of Andrea del Sarto, which was only copied three times against six to eight times in 1865, and 1864 respectively. The exquisite "St. Catherine," by Raffaele, has not appeared in the returns of pictures most frequently copied for the last two years. Amongst modern pictures, Reynolds's "Heads of Angels" was copied nine times, "Age of Innocence" (the favourite during the two preceding years); Dufin's "Surprise," and Dyckman's "Blind Beggar," each seven times. The total number of copies made from pictures belonging to foreign schools, was ninety-seven, the number of pictures copied being forty-six, by twenty-seven different masters. Of the British school, 121 copies were made of forty-nine pictures by twenty-five masters. It will be noticed that, with the exception of the absolute number of copies produced, the figures in both cases are pretty nearly the same.

CHOLERA AND VENTILATION.

The Committee of the Philadelphia Almshouse call attention to the breaking out of cholera at the almshouse in the present year, and to the apparent effect produced by thorough ventilation from the floor, in its prevention and final disappearance from the Institution.

"The disease first attacked four patients and a nurse in one of the wards of the Women's Hospital, which ward, upon close examination, was found to be imperfectly ventilated. This was at once remedied, after which there were no more cases in the hospital."

In the insane department for females, the cholera occurred in several of the wards; these were ventilated by the old plan, from the ceiling or by windows and doors, as the ventilation in this department was not yet perfected, but on the appearance of the disease strenuous efforts were immediately made to push it forward, and it is a remarkable fact that as soon as a thorough ventilation from the floor was established, the cholera disappeared from the Institution. It may be proper here to remark, that heat was introduced into the wards about two hours daily, during the prevalence of the disease, and it is also worthy of note that in no part of the almshouse, although crowded, was there any cholera where the ventilation from the floor was thoroughly perfected."

According to the *Journal of the Franklin Institute*, similar results to those mentioned in this report were observed in the case of the New York Poorhouse, on Blackwell's Island, "where the cholera, after showing itself with great virulence at first (some one hundred cases at a time), was entirely extirpated in five days by a judicious system of ventilation, combined with corresponding treatment, such as exercise in the open air and the like."

THE LONDON WATER-SUPPLY QUESTION.

A PAPER on this subject has been read by Mr. Thomas Beggs, at the Society of Arts, Adelphi. Mr. Beggs urged no special source of supply, but advocated the constant system.

"In all [he remarked] about 150 towns in Great Britain are enjoying the benefits of a constant water supply. Then why not London? It is said that a constant supply which means an unlimited supply of water, could not be sustained from the excessive waste that would ensue, and that all the available resources at command would be exhausted under a waste going on night and day. This has been said in relation to every town, when a constant supply has been proposed. But I have partly answered that by showing the number of towns where the constant supply has been carried out, and it can be further answered by showing that the waste has been much less in the towns where a constant supply has been introduced than in those where an intermittent system prevails. If that is true, where an intermittent system prevails, and the difficulties are met with proper appliances and with determination, they will disappear as they have done in other cases. So far as quantity is concerned, we have at present sufficient, if it be properly economised, to supply the requirements of London."

The subject is, however, generally argued as if the supply of London was insufficient in quantity and im-

perfect in quality. To remove these evils a number of schemes have been proposed, and upon each of them have been expended a large amount of time and no inconsiderable expense. Each of the schemes has its supporters, and the gentlemen who have prepared them are well able to expound and defend them. They propose to bring a supply of water sufficient to supersede all the present sources of supply; and these schemes come recommended to us as the proposals of men of high professional reputation. I will only name a few. Mr. Homer sham proposed to supply London from the neighbourhood of London itself, and a proposal was made for a company—the London Watford Spring-Water Company; and a Bill was prepared, and read for the first time in the House of Commons, on February 6th, 1850. Mr. Bateman proposes to supply us from a source 183 miles away—from the sources of the Severn. Messrs. Hemans and Hassard take us a still greater distance, and propose a supply from Ullswater, a distance of 249 miles away; and Mr. Bailey Denton proposes to obtain a sufficient supply from the Thames watershed. Whether any or none of the plans are adopted, the discussion which must ensue will be of immense advantage in bringing every phase of the question before the great body of consumers. I speak with the greatest possible confidence when I say that I believe a constant supply of water in London is perfectly practicable, and that it might be brought about with a much less consumption of water than that which is now consumed. Improvements in habits, and consequently in morals, have always followed improved dwellings and improved sanitary arrangements, and this is the great encouragement to perseverance in a good work."

ARCHITECTURAL EXHIBITION SOCIETY.

On the 1st inst. the annual general meeting of this society was held, at 9, Conduit-street, when the report and balance-sheet, to which we drew attention in our last, were read and adopted. There can be but little doubt that, if rightly conducted and the profession generally will support it, the annual exhibition may be made useful and attractive, not only to the profession, but to the public at large. The Society proposes this year to add to the attraction of the exhibition by getting artists to exhibit their designs and sketches for fresco and other works more particularly connected with architecture, and by a series of sketches from ancient architectural examples. We repeat that all drawings, &c., for the forthcoming exhibition must be sent to the Galleries by the 6th of next month.

ARCHITECTURAL EXHIBITION.

SIR,—If "the amount paid by the public for admission was very small" last year, would it not be wise to try the effect of reducing the admission fee, and even of opening the exhibition free on certain days, so as to induce the public to go and see it? E. W. T.

THE POSITION OF TOWN SURVEYORS.

WE have received letters from three surveyors in different parts of the country, setting forth the manner in which they have, individually, been treated; but as the statements are *ex parte*, and would provoke replies, for which we could not find space, we must refrain from printing them. One writer, late a surveyor of a town in the south-west of England, who had left another town to go thither, with very strong testimonials, makes out a particularly hard case, having been dismissed, as he asserts, through an individual enemy on the Board. The letter thus concludes:—

"Cannot, under these circumstances, some means be devised by the legislative power of this country to protect the officers whose zeal and assiduous administration and carry out the provisions of one of the most beneficial Acts of Parliament ever passed for the purpose of securing and promoting the public health, from being dismissed in a summary manner? The present system 'destroys confidence, and civil engineers will despise such appointments rather than compete for them; though they ought to be posts of honour, as well as of emolument.'"

In the 1848 Public Health Act there was a clause to prevent surveyors from being dismissed without just and sufficient cause, and the consent of the Home Secretary being obtained to such dismissal.

The conduct which the writer has had to submit to leaves him with a pecuniary loss, damaged health, and a stigma upon his professional character. Is there no remedy for this wrong? There is.

On the 15th of December, 1866, the case, *Wilson v. The North Staffordshire Coal Company*, was tried in the Court of Common Pleas, for wrongful dismissal. Damages, 500*l.*; and salary due, 6*l.* 0*s.* 8*d.* Costs to be paid by defendants."

THE NEW SUPREME COURT, AUCKLAND, NEW ZEALAND.—MR. EDWARD RUMSEY, ARCHITECT.

THE NEW SUPREME COURT, AUCKLAND.

Of the public buildings now in course of erection in Auckland, New Zealand, under the Public Buildings Commissioners appointed by the General Government some time ago, the Supreme Court, Post-office, and Custom House are now fast progressing.

The Supreme Court, the subject of our illustration, is in a forward state. The building is situated on a reserve in front of the old House of Representatives, and presents a prominent feature on entering the harbour. It has four fronts. The one facing Waterloo-crescent and the Government House is formed by an arcade of three pointed arches springing from clustered shafts with carved caps and bases which forms the principal entrance; over which will be the library, a handsome room 45 ft. by 27 ft., entered from the arcade by a circular staircase terminating with an octagonal turret. Above the library and entrance will rise a tower 60 ft. high, surmounted by a leaden roof with dormer.

From under the tower is entered a vestibule or large ante-hall, 50 ft. by 29 ft., which will be devoted to the convenience of witnesses and other persons waiting on the court, and which leads to the chamber of the Supreme Courts, 60 ft. by 30 ft., occupying the centre of the building, having an open panell'd timber roof, and enornment'd by a lantern. The court is surrounded by a corridor 6 ft. wide, connecting it with the judge's chambers, and suites of rooms for the judge, jury, and witnesses, and rooms for the accommodation of counsel.

The registrar's and sheriff's departments will be on the right and left, entered from corridors on either side of the building.

On the upper floor will be an insolvent court, and suites of offices in connexion with the establishment.

The natural slope of the ground has enabled the architect to introduce a basement story at the north end of the building, which he has subdivided into cells and rooms for prisoners awaiting their trial.

The extreme size of the building is 145 ft. by 97 ft. It is being built of pressed bricks from the yards of Mr. Holland, of Newton, with Bath stone dressings. The bricks are of a superior character to any hitherto used in Auckland; they are of a reddish and neutral tinge, and have a pleasing mottled appearance in the distance.

The amount of the present contract is 23,777*l.*, which comprises the entire building with the exception of the internal fittings and finishings, which will cost about 6,000*l.* more.

The building is being erected under the superintendence of Mr. Edward Rumsey, architect, of Auckland, who took the Royal Academy gold medal some time ago; and the contractors are Messrs. Amos & Taylor, late of Melbourne.

PROPOSED REREDOS AND SEDILIA; CHURCH OF ST. MARY REDCLIFF, BRISTOL.

The chief aim of the committee with whom the restoration of the Church of St. Mary Redcliff has rested, having rightly been the maintenance and re-establishment of the fabric, they have persistently applied the comparatively small funds coming annually into their hands to the

restoration of the exterior, which, when they commenced their work, was a crumbling ruin. The exterior work, however, is now considerably advanced; and so, too, is that of the interior; the latter mostly by the distinct subscriptions of individuals. The present rector, the Rev. H. G. Randall, is therefore setting himself to obtain further attention to the fittings of the church. Tenders have been received for properly lighting it with gas: a scheme for filling the various windows with stained glass has been sketched, and some now stained windows are being made. The chancel has long been in a condition little short of discreditable, but something is now to be done to remedy this, and it has been determined by some zealous friends to erect a reredos in accordance with the design of which we give a view in our present number. It will be chiefly of Caen stone; the small shafts being of coloured marbles, the statuettes probably of alabaster, and some few decorative portions of mosaic work. The bas-reliefs, which it is hoped may be executed in a high style of art, represent the Crucifixion, the Agony in the Garden, and Christ bearing his Cross.

It was suggested by a lady at the last meeting of "The Canynges Society" that the reredos should be the offering of those of her own sex who are interested in the restoration of the church. This idea is being acted on, and about 620*l.* have been already contributed towards it. The cost, however, would be considerably more than this sum, so that assistance is still needed.

The view includes the sedilia, &c., proposed to be undertaken hereafter, to render the design complete. Statuettes of the evangelists would fill the niches at the sides.

PROPOSED REREDOS AND SEDILIA: CHURCH OF ST. MARY REDCLIFF, BRISTOL.—MR. GODWIN, ARCHITECT.

INTENDED NEW THEATRE, BRISTOL.

THE tenders for this building were opened on Saturday last, and that by Messrs. Davis & Son was accepted, at 10,125*l.* for the theatre and two shops in the Park-row frontage. This amount does not include decorations, seating for boxes, furnishing, or stock scenery, for which an additional 4,000*l.* is reserved. The theatre will stand isolated, so that lights will be obtained on all four sides. The area of ground covered will be 105 ft. wide by 130 ft. long, with saloons and shops towards Park-row 50 ft. by 50 ft. additional. The principal dimensions are as follows:

From curtain line to front of dress circle	44 <i>f.</i> 6 <i>in.</i>
" " " upper circle	47 6
" " " gallery	50 0
Width of the proscenium opening	30 0
Height	27 0
Height-pit floor to ceiling	45 6
Depth of stage	60 0
Width of ditto between walls	64 0
Width of ditto including two scene docks	100 0
Height from ditto to gridiron floor	57 0
Depth from ditto to sills	21 0

The accommodation provided in each part of the house is as follows:—

Dress circle	310
Orchestra stalls	50
Twelve private boxes	50
Pit	800
Upper boxes and amphitheatre	350
Gallery	500
Total	2,400

The architect is Mr. C. J. Phipps.

THE LIGHT AND AIR QUESTION.

IN the House of Commons a few days ago Mr. Goldney called attention to the existing state of the law as regarded the right of access of light and air to ancient windows; and said that the space applicable for commercial purposes in the city of London and elsewhere was daily becoming more limited. The only way of increasing the accommodation accordingly was by heightening the buildings. This remedy was, however, a constant source of difficulty and litigation, the law being that any person within the city of London being the owner of a small building could stop any improvement which tended to diminish or detract from the light or air he enjoyed. Since the passing of the Prescription Act of 1834 any right of this kind that had been enjoyed for twenty years became a permanent right. This right had not unfrequently been made a subject of extortion, and a person wishing to heighten his house either had to pay a sum by way of compensation, or give up all hopes of improvement. Almost as long ago as the reign of Richard II. it appeared to have been anticipated that the city would grow into something like its present size; and a custom, which had been held to be good in law, prevailed that although a party might have had light and air in certain windows for any time, still an ancient tenant had the right, notwithstanding, to run up his house to any height he chose; and, further, that a jury of twelve aldermen, with the Lord Mayor as assessor, should sit to determine the relative rights of these parties. Since the Prescription Act of 1834 came into operation, giving the right to a perpetual use of the light and air then enjoyed, the elements of litigation began to arise. However anxious a man might be to improve his property, he was deterred from doing so, owing to the present state of the law; and in rebuilding it he was obliged to limit himself to the old height and the old style, and possibly to a very contracted space, whereby the public interest as well as his own materially suffered. Surely it might be practicable for that House, as the public convenience was so much concerned in that matter, so to legislate that the owner of the dominant tenement, where his rights were prejudiced by any improvements of that kind, should be entitled to compensation by damages, instead of being enabled to obtain a perpetual injunction from the Court of Chancery to prevent such beneficial improvements from being carried out? If wished to ask the Government, therefore, whether they did not think it feasible to introduce some measure by which the law on that subject might be put into a more satisfactory state; and he would, if necessary, move for a select committee to inquire into the matter.

The Attorney-General felt that it would be impossible for him to accede to any such motion. The subject was, no doubt, one of great and growing importance, although he thought the

hon. gentleman entertained somewhat exaggerated notions with respect to it. As late as the year 1834, the law with regard to it had been carefully considered, and the right of which the hon. member complained was then settled. In the City of London up to that time there was a custom that the owner of the ancient tenement might build from the old foundation, and that the owner of the old foundation might disregard the rights of others. It was then thought desirable to alter that. The owner of the tenement had a right to a certain light; it was his property, and it was so declared by statute, if he had enjoyed the light for twenty years. The courts had held that the construction of the statute was quite clear. The right, however, might be taken away when the interests of the public required it on payment of compensation. It was impossible for the Government to take up that question, at all events during the present session.

BUILDINGS OF THE LEEDS INDUSTRIAL DWELLINGS COMPANY.

THIS block of dwellings, in Shannon-street, the first of this class of buildings erected in Leeds, was commenced in June last year. The ground plan comprises six dwellings, one of which has a shop attached; the first, second, and third floors have external stone galleries of communication reached by a stone staircase,—the object of this arrangement being to avoid the house-dutty. Each of these floors has six dwellings; each tenement has, alternately, two and three rooms; the living-room being fitted up with coal-place, slopstone, meat safe, and cupboard, grate, with oven and boiler, and water laid on over each slopstone. It is to be regretted that the plan is not square. For ventilation there are external and internal ventilating air bricks, and Arnott's patent ventilators, in each chimney-breast. A wash-house, fitted up with boiler and sink, and having water laid on, is provided for the use of each floor. On the landings of the staircase are provided water-closets, fewer than they should be: a dust-shaft, with hatches for every floor, communicates with an ash-pit in the basement. The building, of a plain character, is of red brick, with stone heads and cills to the windows. The columns, girders, and railing of the gallery are of cast-iron. The total cost of this block is 1,440*l.* The architects are Messrs. Adams & Kelly, of Leeds and Dewsbury.

CLIFTON SUSPENSION BRIDGE.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the meeting held February 12th, Mr. John Fowler, president, in the chair, the paper read was a "Description of the Clifton Suspension Bridge," by Mr. W. H. Barlow. Although we early gave a full account of the bridge, the completed particulars by the Engineer may be usefully recorded in our pages. In the Clifton Bridge as executed, he said, there were three chains on each side, supporting longitudinal stiffening girders of wrought-iron, with open-work cross girders, the hand-railing of the bridge being made also to form longitudinal stiffening girders, with open-work sides. The principal dimensions were—span, 702 ft. 3 in.; distance from centre to centre of chains, 20 ft.; width of bridge, including roadway and footways, 31 ft.; versed sine of curve of chains, 70 ft.; and height of roadway above high-water, 248 ft. The chains were carried upon the piers by wrought-iron saddles, placed upon roller frames of cast-iron, the rollers being made of cast-steel. The heads of the roller frames were at an inclination of 1 in 20, rising towards the river. At a distance of 196 ft. from the centres of the piers, land saddles were placed, which were similar in construction to the saddle upon the piers, except that they had no roller frames, but were bedded upon brickwork in cement set upon the solid rock. The distance from the land saddles to the anchorage was 60 ft., with an average inclination of 45°; and in this distance the three chains gradually diverged, until they were 5 ft. apart, where they were inserted through castings forming separate anchorage plates for each chain. The three chains were in such a relative position to each other as to produce an equal horizontal distance of nearly 8 ft. from the centres of the suspension-rods throughout the bridge. The suspension-rods transmitted their strain to the

chains only at the joints; so that the links of the chain had no other strain upon them than that due to the direct tensile strain in the direction of their length. The duty of maintaining an equal action upon all three chains in supporting the roadway was performed by the strength and stiffness of the longitudinal girders. All the links were tested to a strain of 10 tons per square inch.

The arrangements for the erection of the chains comprised a temporary suspended staging, constructed of eight iron wire ropes, each capable of bearing 35 tons. Six of these ropes served to support a timber platform, and two were at a height of 3 ft. 6 in. above, to form a hand-railing on each side. The upper ropes were attached to those below, so as to act in conjunction with them in sustaining any weight upon the staging. Another rope was fixed above, for the purpose of carrying two light travelling frames, suspended on wheels, which were moved as required by light ropes, and by means of which links were taken from the piers to the men engaged in erecting the chains. The work was commenced at the anchorage plates at each end simultaneously, the lower chain being put in first. At the anchorage plates the whole of the links, twelve in number, were inserted; then eleven, ten, nine, and so on until the chain was diminished to one link; after which it was continued at one link and two links alternately from the piers, until it met in the middle of the centre opening. The wire-rope staging was designed to carry the weight of the centre portions of the chain, formed of one link and two links alternately, with the men and tools required to erect it. The calculated breaking weight of the staging was 224 tons, evenly distributed, and the weight it had to carry was 40 tons. The suspended platform was kept below the intended level of the chains, and the links were supported upon it by packing-pieces which could be raised or lowered. When the links of the chain were united in the middle, the packing-pieces were lowered until the chain took its own bearing, and thus relieved the staging from the action of its weight. At this stage of the proceedings the chain was adjusted for length, by means of keys arranged for that purpose in the first links from the pier saddles. The next operation was that of adding links on each side of the centre links, which was accomplished, by an ingenious and simple apparatus, with such rapidity, that on some days more than one hundred links were added. The chains on the Bristol or eastern side having been completed, the staging was removed to the other side, and the remaining three chains were put up in a similar manner. When the chains were erected, and the suspension links were fixed, the suspension rods and cross girders were attached, by means of a moveable crane, upon a long base frame, weighing upwards of 5 tons, and travelling upon a temporary railway. This crane was so contrived and balanced, that it could carry a cross girder, with an equivalent length of the longitudinal girders, a considerable distance in advance of the wheels upon which it travelled. Thus, when placed upon the abutment, it held the first cross girder in its intended position, until the men attached the first pair of suspension rods to it and to the chains. Planking was then laid from the abutment to the cross girder, and the railway was lengthened. The travelling crane next took up the second cross girder, and advanced with that to its position, and held it in like manner until it was attached to the chain. The planking and roadway were again lengthened, and the third cross girder fixed, and so on from both ends of the bridge, until the roadway met in the middle. The remaining operations of connecting the longitudinal girders, adjusting the several parts of the work, and laying the roadway were then proceeded with.

The sectional area of the chains at the pier was 481 square inches, and in the centre of the span 440 square inches. The weight of the chains between the piers was 554 tons, and that of the suspension rods, longitudinal and transverse girders, cross-bracing, hand-railing, roadway, &c., about 440 tons. The strain at the centre due to the chains, was 680 tons, that due to the weight of the platform, &c., was 597 tons, and that produced by a maximum moving load of 70 lb. per square foot, was 817 tons; or, together, 2,094 tons, which was equal to 4.76 tons per square inch of the sectional area of the chains at the centre of the span. The suspension-rods were each rather more than 2 in. in section. The greatest weight that could come upon a pair of rods, including their maximum load, was

about 13 tons, which would produce a strain of 44 tons per square inch. The anchorage plates and the hearing plates of the saddles were so arranged, that the maximum pressure upon the brickwork could not in any case exceed 10 tons per square foot. In order to provide for the effects of expansion and contraction, and to allow for the movement occasioned by wind and by the passage of heavy loads across the bridge, the two extremities of the roadway were furnished with jointed ends or flaps, 8 ft. long, which gave perfect freedom of motion, both vertically and in the direction of the length of the bridge.

The works were commenced at Clifton, in November, 1862, by Messrs. Cochrane, the contractors, under the superintendence of their resident manager, Mr. Airey, and the bridge was opened for public traffic on December 8th, 1864. The total cost of the ironwork, including the purchase of the chains of the Hangerford Bridge and their carriage to Clifton, was 24,975*l*. Previously to opening the bridge, it was tested by a dead weight of 500 tons of stone, distributed over the surface, when a total deflection was produced of 7 inches in the centre. On the removal of the test-load the centre of the bridge rose to its former position within one-sixteenth of an inch, but the middle of the southern half of the bridge did not rise again to its former height by an inch, while the northern side rose above its original position. This was probably due to the change in the direction and force of the wind before and after the testing.

The author stated that the most severe strain which the bridge had to resist was that resulting from heavy gales of wind, especially those from the north-west or south-east, being nearly in the direction of the deep gorge of the River Avon at the place where the bridge was constructed. On these occasions three effects were observed. First, there was a small horizontal deflection, which was just sufficient to be perceptible to the eye when placed in line with the suspension rods. Secondly, there was an undulation from end to end of the bridge, the maximum rise and fall being, in Mr. Airey's opinion, as much as 6 inches above and 6 inches below the mean level of the roadway. Thirdly, the land chains, between the piers and the land saddles, which carried no suspension-rods, were liable to be deflected laterally, notwithstanding their weight, the longitudinal strain upon them, and the comparatively small surface exposed to the wind.

The author remarked that, considering the facility with which suspension bridges could be constructed, and the comparatively inexpensive nature of the scaffolding or temporary staging required for erecting them, there appeared to be no reason why spans of much greater magnitude should not be accomplished. The spans already crossed by bridges on this principle far exceeded those of any form of girder. The largest girder ever built was that of the Britannia Bridge over the Menai Straits, which was 460 ft. between the bearings. The largest suspension bridge was that at Fribourg, which was stated to be 880 ft.; while the Niagara Suspension Bridge was 820 ft. from centre to centre of the towers, and it had been in daily use for nearly twelve years for the passage of railway trains. Suspension bridges had not hitherto been adopted in this country for railway purposes, under the impression that the principle of construction necessarily involved such an amount of flexibility as to render them unfit for the passage of trains; but it must be considered that the larger the bridge, and the greater the ratio of the weight of the bridge to the weight of the moving load, the less was the disturbance of form caused by a passing load. Moreover, it was quite practicable to stiffen a suspension bridge so as to render it nearly as rigid as a girder, of which the Lambeth Bridge, from the designs of Mr. P. W. Barlow, was an example. The subject of stiffening suspension bridges with the least quantity of material was one well deserving attention. In a detached girder the upper and lower booms must each be capable of bearing the strains produced by the weight of the bridge and its load, and the diagonals must be strong enough to transmit the whole of those strains; whereas, in a stiffened suspension bridge, the chain was the only member required to bear the strains produced by the weight of the bridge and its load; while the diagonal bracing or stiffening, need be no more than was sufficient to prevent disturbance from the moving load. In relation to this subject the author stated he had found by experiments on solid bars, made in 1858, as well as from a theoretical investigation of the case as applied to

lattice girders, that, in a continuous girder, if, instead of using an equal depth throughout, a greater depth and a greater sectional area were given over the piers, an increase of strength was obtained in a much higher ratio than that of the increased weight of metal employed. Another point deserving of consideration was the best form of link and fastening for the chains of a suspension bridge, to which Sir Charles Fox had directed attention. But where the object was to construct bridges of very large span, another, and perhaps the most important consideration, was the employment of a stronger material. In this respect the introduction of steel was calculated to have a marked influence. Many of the properties of steel were at present unknown; but it had been determined by experiments that its tensile strength was nearly double that of wrought iron, and that it could be made quite as malleable. Its powers of resistance to compression did not show the same proportion of strength; but in the application of steel to the chains of a suspension bridge, it was the tensile strength which operated.

DWELLINGS FOR THE POOR.

LIVERPOOL ARCHITECTURAL SOCIETY.

At the last meeting, Mr. T. J. Kilpin, president of the society, in the chair, read a paper "On Dwellings for the Poor." He commenced by saying that many of the poorest artisans of the present day were better housed and fed than the noblest baron in the Norman age; which we altogether deny, by the way. He then proceeded to detail the horrible style in which many artisans and labourers lived, and referred to the efforts that were being made to remedy that evil. He alluded to the bill of Mr. Torrens, at present before the legislature, and congratulated the town on the fact that the local legislature had preceded the imperial legislature, in proof of which he quoted the beneficial results that had accrued from the grand jury presentments in Liverpool. The corporation, he said, "recently directed the borough engineer to prepare plans for the description of dwelling-houses so much wanted, and to endeavour so to arrange and construct them if possible that they might yield a fair per-centage on the outlay. These plans were completed some months since, and the public attention has been directed to them; but considering apathy, I am sorry to say, has been shown with regard to them. The builders have, to use a familiar expression, 'fought shy of them,' expressing the utmost readiness and alacrity to erect them if the corporation would build them and become landlords, but respectfully declining to incur the risk of doing so themselves. But it seems from the bill introduced into the House of Commons, that where private enterprise falters, hesitates, or declines, the local authorities are to step in, and when necessary, to be assisted by a loan. This the corporation of Liverpool would not act in the matter, or they should do so of their own accord, I have no hesitation whatever in saying, after a careful examination of the plans, a calculation of the cost of erecting them, and of the income to be derived from the houses when erected, that a most ample remuneration would accrue for the capital expended. The plans are now being revised, and still further improvements are being made in their arrangements and construction, and will shortly, I believe, be again brought before the public notice."

DUST AND ASHES.

The Works Committee of the Vestry of St. Pancras have received tenders for the removal of the dust from the houses in the parish for the year ensuing, the lowest of which amounted to 1,770*l*., to be paid by the vestry to the contractor. The amount of the last contract was 1,050*l*., paid by the contractor to the vestry, making a difference in the terms of 2,820*l*.. The lowest tender for the removal of road sweepings and gully soil when swept to the sides of the streets was 6,150*l*.; the amount of the last contract 4,055*l*.; being an increase of 2,095*l*.. The committee thereupon determined to re-advertise for tenders, when the lowest of those sent in for the removal of the dust was 1,270*l*., and for the removal of road-sweepings 5,615*l*., which were accepted.

On the receipt of the first of the above-named tenders, Mr. W. B. Scott, the chief surveyor to the vestry, was requested to report to the vestry upon the advisability of the vestry undertaking the removal of the dust and road sweepings, and in his report he states,—

"The quantity of dust and refuse removed from the houses in the parish amounts to 23,000 to 25,000 loads per annum, each load being equal to 1½ chaldron. This dust is all screened, and picked over by hand, and converted into breeze, ashes, hard core, and soft core. The 'breeze' is composed of the finer particles of dust, and is used in brickmaking for tempering and mixing with the clay. The ashes, which from many districts contain large quantities of coal, are used for burning the bricks. Hard core (otherwise dust-yard pickings) is used for the formation of roads. Soft core is composed of vegetable and other perishable refuse, and is burnt where the dust-yards are in open situations, and barged away into the country where the yards are in inhabited localities, and the supply from St. Pancras is sufficient for the manufacture of fifty millions of bricks. The price of breeze this time last year was from 8*s*. to 10*s*. per chaldron. It is now 3*s*. to 4*s*. per chaldron, and will probably be lower. A depreciation of 4*s*. per chaldron will represent a difference of money of 100,000*l*. of the parish of 4,000*l*. to 5,000*l*.. The value of the hard core does not fluctuate much, and is not worth more in the dust-yard than about 1*s*. per load. The cost of barging away the soft core is about 2*s*. per load.

To enter upon the removal of dust, the vestry would require 32 carts for the average work, and to be provided for the heavy 40 carts. These carts would cost about 25*l*. each, equal to 1,020*l*.; for these, horses and drivers could be obtained as required. A large wharf would be necessary with a staff of foremen and clerks, and then nothing more would be required but the purchase of the manufactured article. The vestry, instead of being able to dispose of the breeze, would be unable to get rid of it at all. I estimate the cost of collecting the dust would be about 6,000*l*. a year, without reckoning the cost of what is disposed of. I am decidedly of opinion that it would not be advisable for the vestry to entertain the idea of dusting the parish. Profit is made by collecting the business with that of slopping, and both with that of brickmaking and in most cases with that of speculative building also. If carried out by the vestry, the work would probably be done more to the satisfaction of the inhabitants, but it is entirely a matter of expense. The ever-increasing population of the metropolis produces an amount of the material much greater than the increased demand. Nothing could have kept up the price of breeze at the height of late years, but the enormous public works that have been carried out."

Upon this report of Mr. Scott, the Works Committee resolved not to go into the business of dust contractor.

The Works Committee of St. Pancras has accepted the tender of Mr. Culverhouse for the supply of road materials:—

	Per yard.
Loamy gravel	20 9 4
Hard core	0 2 0
Burnt ballast	0 2 11
Dust-yard pickings	0 2 6
Clean rough gravel	0 6 8

The tender of Mr. Crofts was accepted for,—

Hand-picked flints	40 11 10
Pit flints	0 8 4

THE BIRMINGHAM SCHOOL OF ART.

The annual meeting of subscribers and friends to this school has been held in the Rotunda of the local society of art, Lord Dartmouth, the president for the year, took the chair. The report stated that, notwithstanding the financial disasters and stagnant trade of the past year, the number of students has been 1,07, showing a decrease of only two from the numbers registered on the books for the preceding year. The amount of school fees has been 77*l*. 9*s*. 6*d*., showing an increase of 33*l*. 10*s*. 6*d*. over the receipts of last year from the same source. At the National Competition of Art Schools held at South Kensington in May last, under regulations of the new minute of Council, one gold medal out of ten awarded, one silver medal out of twenty, and two bronze medals out of fifty-one, were taken by students of the Birmingham school. The number of competing schools was above ninety. In addition to these, twenty-two prizes of books were awarded, and also fourteen prizes at the local examination in March last. Special prizes had been offered for the best designs in several departments, and the results had been very satisfactory. At the meeting the following list of the number of manufacturers, with the number who were subscribing to the school, was given by Mr. Aitken:—

In Birmingham, Subscribers.	
Brassfounders	290
Electro-plate and plated ware ..	2
Jewellers and gilt toys	350
Buttons	216
Glaziers	30
Papier maché and jaspers	52
Die-makers	185
Engravers	163

He said he hoped that manufacturers would show their appreciation of ornamental art, as applied to industry, by subscribing more liberally to the school than they had hitherto done.

"FAIR PLAY FOR THE LAW COURTS."

Sir,—In your paper of last Saturday, the 2nd inst., you have inserted a letter headed "Fair Play for the Law Courts' Competition," and signed "A Member of the Solicitors' Committee," animadverting upon Mr. Field, the secretary to the Courts of Justice Commission.

The Solicitors' Committee, of whom the writer of that letter therein alleges that he is one, is a committee of members of the Courts of Justice Commission, and consists of Mr. Hume, Mr. Cookson, Mr. John Young, and myself.

I am expressly authorised by my three colleagues to deny, and for myself I deny, that we, or any of us, wrote that letter, or had any knowledge of it, before we saw it in your journal.

Mr. Field, the excellent secretary of the Commission, needs no defence by us, and we, therefore, confine ourselves to pointing out the imposition practised upon you and your readers by the writer of the letter.

ALFRED BELL,
Chairman of the Solicitors' Committee.

Sir,—My letter in your last number has caused a little hubbub, so I am told, and the architectural clerk's unhappy looks testify that my reference to Dr. Percy's private letter has opened his eyes to the painful results of allowing one's feelings to get too much control over one's tongue. The secretary's face is more inscrutable, but there is a hubbub, whatever his looks may say; and that being the case, my object, I consider, has been gained; for it may be presumed that "hubbub" means inquiry, and inquiry in this case is certain to result in "fair play." Never mind how I got my information: the doors of the Commission stand hospitably open, and I got it, and sent it you, and the facts it contains are still facts, though it happens that you dubbed me wrongly.

A MEMBER OF THE SOLICITORS' COMMITTEE.
* We misanderstood a postscript of our correspondent, and applied a wrong signature.

VANDALISM AT TENBY.

MR. EDWARD ROBERTS writes as follows:—In your last number, under this heading, it was stated, as a fear, that destruction awaited the ancient town gates. I am happy in being able to say that the Mayor of Tenby and others are alive to the necessity of preserving them, if possible. The subject was brought before the British Archaeological Association by Sir Gardner Wilkinson, and some correspondence ensued which resulted in an assurance that certainly one, if not both, of the doomed gates will be retained. I may add, that this appears to be entirely due to the exertions of Sir Gardner and the Association, aided by some local savans.

BUILDERS AND ARCHITECTS.

MR. NISBET, secretary to the Builders' Association, Edinburgh branch, writes as follows:—"I am desired to inform you, that the directors having sent a deputation to Messrs. Peddie & Kinnear with reference to the conditions proposed to parties estimating for St. Cuthbert's New Poor-house, the deputation have to day had a meeting with these gentlemen, when they agreed that the offers should be according to plans, specification, and schedules of measurement. In the event of a strike, additional time is to be allowed; and Mr. George Young, advocate, is named referee in the event of disputes." The tender is to be marked—"To the extent of the schedule of measurement."

SUGGESTIONS FOR IMPROVING THE SQUARES OF LONDON.

No localities add more to the melancholy aspect of the metropolis than its squares and public places. Who would be at all surprised to see tombstones in any of the railed plantations east or west of Tottenham-court-road? Can any one promenade in these dingy sooty shrubberies, overlooked by drawing-rooms and nurseries, with either complacency or advantage? Nor am I sure that the large trees in straggling and straggling upwards towards the light con-

tribute to the health of the surrounding inhabitants. Seeing, then, that these gloomy plantations are but the most miserable apologies for rusticity, would it not be better to adopt some other mode of laying them out more consistent with "in town" conditions? In the squares of the dullest Continental town there is always some life stirring about the central statue or fountain, and the very open airiness of the place is infinitely more cheerful than abortive attempts to convert similar localities into sylvan woods. I believe the right garniture of large intramural spaces to be fountains, statues, flower-heds, gravel walks, and a very moderate plotting of tree-shrubs, large wood being, in my opinion, altogether out of place.

With regard to Trafalgar-square, I would only suggest that the present water-jets should be removed, the basins filled with earth and set with flowers; that the entire expanse of sloppy and dusty asphalt should be taken up, and the area paved with dark slate or black marble, to be carried in a bay round the column and its adjuncts, bounded by a dwarf wall, and converted into a reservoir for clear water, which would reflect gallery, column, and lions with magnificent effect.

We require colour and water to enliven this dull city. W. CAVE THOMAS.

IRON MONUMENTS.

An "Old Founder" writes,—If any more large lions, or other savage beasts of colossal stature, should be required by the public, I think I can indicate a much less costly mode of obtaining them than paying Baron Marochetti 400*l.* per ton for casting them.

There is no more practical difficulty, the models being supplied, in casting a lion than a column or a girder, perhaps less than in an engine cylinder, and I shall be very glad to supply any number of lions, griffins, sphinxes, &c., &c., up to 10 tons each, for 50*l.* per ton; and I will engage that after six months' exposure to a London atmosphere my cast-iron beasts or monsters shall look as well and rather better than the bronze ones.

Bronze is very nice for a chimney-piece ornament, when you can preserve the rich colour of the metal, which is its great charm; but I appeal to any of the open-air statues in London whether it is not utter folly to put this costly material in situations where it so rapidly loses its colour and oxidises to a very considerable extent.

If cast iron be well soaked with linseed oil while the iron is hot, it takes a fine rich tone of colour, and will resist oxidation very much better than any bronze exposed to the open air that I have ever seen.

Sir Edwin Landseer is fully entitled to every shilling of his money for his magnificent models, but 11,000*l.* for casting them is—well, never mind what!

"STARVATION WAGES." "WHO FIRST TO BLAME."

Sir,—Very painful accounts have for some time appeared of starvation wages, even for excessive labour, at Bethnal-green. Let us inquire whether the "other world" may not have had for a long time something to charge itself with; and what might be the antidotes. No aphorism of Napoleon I. was perhaps better than—"Impossible" is the word of fools.

A daily paper (I am not certain which) stated, from some correspondent, years ago, that there were two parties mainly answerable for this,—First, the "public," who have a craving—I hope more thoughtless than unprincipled—for cheapness, the actual effect of three parts starvation to the workers; second, the "vendors," who seem too often quiet acquiescers in the compact. Once, and once only, have I known a very leading suburban draper both remonstrating with (of course very politely) and informing some ladies who had murmured at a trifling rise in price in some article, by telling them the simple truth,—that the makers there were "just beginning to live," after long starving, through the small advance they objected to.

Surely this should be satisfactory, as I hope it was then, to all right-thinking persons. How far making and selling fewer things at a higher price would answer the purpose I cannot say; but would it not be better for all to be willing to pay more, even if they retrenched in some other point, than the labourer might have his due? Little need to exaggerate the picture; but I doubt not that the miserable "Song of the Shirt" is far from unparalleled in other branches of work.

If even some "houses" were to charge higher prices, and insist on knowing (with power of proof) that "living wages" were paid at the "fountain-head," I can but think that the conscientious public would rally round them. Nor need we, I think, doubt that even royalty might interest itself in the matter, after her Majesty's remonstrance with railway evils or short-comings.

If these humble observations should lead to useful thought on the subject, I should be thankful to Providence. D.

BUILDERS' TROUBLES.

Sir.—A short time since an advertisement appeared in two papers (at least), one a local, the other yours, requiring tenders for the erection of a house at Fairfield, and stating that the plans and specifications might be examined at the office of the architect, Mr. J. B. Newton; and I, fully intending to join in the competition, sent two persons there (one from my residence, Margate), on purpose to examine the plans, &c., when they were directed to the surveyor's office (after having been requested to copy a piece of paper on which the particulars were printed, the first of which was that quantities would be ready in a few days, and would be forwarded to the builders free of charge). On getting there they could not see the plans for about four hours after, as they were not somewhere. However, after seeing them, they obtained a promise at this office that the quantities would be sent home all right.

To my surprise, a week ago, I saw the amounts of the tenders in the *Builder*, without having heard one word about the matter previously. I, therefore, wrote at once to the architect, who answers me that, since the advertisement, it was found desirable to have a select competition, and that he could not find any promise had been made to me of having the quantities, although I had it in the particulars. Can I obtain any compensation for my trouble? RICHARD PARAMOR.

WHERE IS THE SANITARY INSPECTOR FOR ST. PANCRAS?

Sir.—The *Builder* being the promoter both of the sanitary and moral condition of the public, may I trespass on you to expose the undermentioned abuse, which is permitted under the very nose of the police and parish officials?

In a quiet street in St. Pancras, bounded on one side by the vestry-hall and by the police-station on the other, it is the practice nearly every evening for a number of horses (half a dozen at a time), filthy carts, and men, belonging to a contractor in an adjoining street, to halt on their return home from their daily labour, and in front of the windows of the houses, both men and horses, commit a most disgusting nuisance, to the great scandal of the inhabitants. The result in another respect is abominable. But few of the houses lately have been free from fever. The inhabitants have sent a written request to the contractor to stop it; one of the parish surveyors has been asked to interfere; the cartmen have been continually desired to move; but all to no purpose! Though decency forbids, still they come. To the *Builder*, therefore, they appeal to bring public opinion to bear on the authorities, to preserve the public health and morals, and induce the contractor to keep his nuisances to his own stableyard. AN INHABITANT.

CHURCH-BUILDING NEWS.

Ashford.—The new church has been just finished, at a cost of 3,800*l.* The church is to be a free one, and the sittings unappropriated. The committee have determined not to open the church until the whole of a remaining debt of 200*l.* is paid.

Eastbourne.—St. Saviour's Church has been consecrated. It is built from designs by Mr. George E. Street, architect. The materials employed are red brick, with Bath stone dressings. The style is Geometrical. The church consists of a nave, chancel, and side aisles, with organ-chamber, vestry, and west porch. The nave is 90 ft. long and 35 ft. wide. There are six bays, the last of which, as it joins the chancel, is placed diagonally, so as to form with the chancel-arch an apse. The nave is lighted by a clerestory, the windows of which are 10 ft. high by 5 ft. wide. The basement of these windows is about 25 ft. high, and is supported upon arches and stone-pillars. The ridge-tile of the nave is at a height of 70 ft.; but the interior roof is hoarded upon principals, which form an arch, the apex of which is 10 ft. below this. Tie-rods of iron are inserted, and bind the whole together. The chancel is 28 ft. deep, and terminates in an apse. It is lighted by four windows, 14 ft. high by 7 ft. wide, of which the base is 15 ft. from the ground. The roof is groined in brick, with stone ribs, these latter springing from shafts of Devonshire marble. The lower parts of the walls are left for future decoration. The floor of the chancel is laid with Godwin's encaustic tiles, relieved with white marble and Warwick stone. The glazing throughout is in three tints of green cathedral glass, and arranged in squares of different sizes. In the windows of the south aisle and nave apse, Powell's stamped quarries are introduced; these are marked with Mr. Street's pateras. The glass is very thick, giving a cool silvery effect. The side-aisles are narrow, and are covered with a lean-to roof. The windows are proportionally small, and are of two lights. The building is without the tower and spire, which are intended to rise from the west end of the north aisle. The glass on the roof are in three colours, and arranged in diamonds. The walls throughout are 3 ft. thick, with a hollow space of 4 in., and are bonded together with iron clamps. The work has been carried out by Mr. Peerless, builder. The stonemason's work has

been completed under the superintendence of Mr. Patchett, foreman to Messrs. Parsons, of Eastbourne and Lewis. The sole cost of the building, about 8,000*l.*, is borne by Mr. George Whelpin, who, we understand, intends also to endow it, and wholly or in part to build a parsonage house.

Wombwell.—A meeting of the ratepayers of Wombwell has been held for the purpose of taking into consideration the formation of a cemetery for the township. The meeting decided that the Burial Board should be instructed to expend 3,500*l.* in the buildings and site. A piece of ground containing about six acres, belonging to the representatives of the late Mr. Joseph Eastwood, was selected. The cost of the site was stated to be about 1,200*l.* Three acres of land are proposed to be laid out at present, half of which is to be consecrated, and the other half appropriated to interments by the Dissenting portion of the inhabitants. Mr. Dobbs, of Rotherham, was appointed architect of the works.

Newbottle.—The church here has been reopened for divine service, after having undergone a restoration, rendered necessary partly by the lapse of time and partly by alterations made in the original structure. The chancel has now been restored, certain windows having been replaced by others, and various other alterations effected. In the course of the repairs of the chancel a sedilia, long walled up, was brought to light, as well as a Gothic window. The roof of the chancel, and the church generally, has been opened up, and the old pews, which were in a dilapidated and discreditable condition have been replaced by open seats. A new organ, built by Mr. Bevington, of London, has been added, and the comfort of the building has been provided for by Rimington's heating apparatus. The churchwardens and other promoters of the restoration did not think it necessary to engage the services of a professional architect, but they were subsequently glad to avail themselves of the assistance and advice of Mr. Hannaford, who was then engaged in superintending the improvements at King's Sutton Church. Messrs. Franklin & Son, of Deddington, were the builders, who also executed the carvings on the wooden screen. The cost of restoring the chancel has been mainly defrayed by Mr. W. C. Cartwright and Mr. T. L. M. Cartwright. The amount expended on that portion of the building is about 200*l.* The expense of the remaining repairs is about 600*l.*

being to the street will be the principal front. There will be a tower at the entrance corner towards Micklegate, containing one of the staircases to the galleries. The tower is to the top of the parapet 54 ft., and to the top of the pinnacles 61 ft. It will be covered with a high-pitched roof of ornamental slating, having iron cresting on the ridge. At the opposite end of the front will be two gables, the one being the church, and the smaller one the transept of the church. The former will have a porch in the centre, with a two-light window upon each side. Above will be a three-light window, having trefoil heads, with a single trefoil-headed window upon each side, while above this will be an ornamental circular window. The transepts will have a four-light trefoil-headed window in the bottom part, with a three-light tracery window to light the gallery. The aisle windows will be in two tiers, divided by a moulded string. The lower tier will have two-light tracery windows, and the upper tier narrow three-light trefoil-headed windows. The clerestory will be lighted by four circular windows. The end elevation will consist of three deeply-moulded doorways. The one doorway is in the tower. Above the doorway, at the opposite side, there will be an ornamental rose window lighting the upper part of the gallery stairs, which will be covered in with a high-pitched roof. Upon each side of the central doorway, which will be wider than the others, there will be a single-light trefoil-headed window, and above the door a three-light tracery window. The architect is Mr. W. Peachey, of Darlington. The contractors for the several works are, for the brick and stone work, Messrs. C. Bowman & Co.; plastering, Mr. M. Croft; slating, Mr. T. F. Wood; carpenter and joiner's work, Mr. W. Bellerby; plumbing, Mr. Fuller; and glazing, Mr. J. Dickinson; painting, Mr. Bonfield; and smith and ironfounder's work, Mr. Bonfield; and warming, Messrs. J. Longbottom & Co. The cost, including everything but school fittings, will be 3,538*l.*; and the total cost, including the land, will be about 5,000*l.* Of this 1,000*l.* have been contributed by Mr. G. E. Foster, of Cambridge, and 2,000*l.* more by other friends, leaving a debt of about 2,000*l.*

TELEGRAPHIC.—The reduction in the tariff for messages sent by the Atlantic cable from a minimum of 10*l.* to 5*l.* will take place on or about the 15th of this month, and, as on the former occasion, official notification will be made only a day or so before the change.

THE ECLIPSE OF THE SUN.—The eclipse took place on Wednesday morning at the time calculated on, but the condition of the weather was such that few facts of any value were obtained, though elaborate preparations had been made in several quarters. A poetical correspondent got a fancy out of the appearance that was presented in the sky, and stated it thus:—"The clouds rasing past the sun give to it the appearance of a poor persecuted victim, striving to escape from the incubus that has fastened on it, and which, vampire-like, seems to be sucking away its life." Those who watched the eclipse will recognise at once the force of the "conceit."

INCREASED FOOTWAY IN FRONT OF THE MANSION HOUSE.—The railings in front of the Mansion House have been removed, and the space flagged. Although only about a yard in width is thus added to the footway, the whole length of the Mansion House front, the gain to the public is immense, as the traffic in this part of the City of London is very crowded. We noted a piece of bungling management on the part of those who had charge of the work. The paviers were busy finishing their work just at the moment the Prince of Wales and a large company were arriving at the Mansion House, to attend the meeting of the National Lifeboat Association, on the 28th ult. A little extra effort might have avoided the unseemly scene.

THE ROYAL POLYTECHNIC INSTITUTION.—The ordinary general meeting of the proprietors of the Royal Polytechnic was held on Saturday afternoon last, at the Institution. The Rev. J. B. Owen, chairman of the Board of Directors, presided. It appeared from the report that the receipts had been greater than in the corresponding half of last year, and although a large sum had been expended in repairs and improvements, there remained a handsome balance for dividend. The number of visitors to the Institution during the half-year exceeded 111,000*l.* The directors recommended the payment of a dividend at the rate of 4 per cent. for the half-year, making the dividend for the year 7 per cent. A vote of thanks was passed to Professor Pepper for the attention he continued to give to the interests of the Institution.

WORK IN THE PARIS EXHIBITION.—The earth-works of the Paris Exhibition, including all the cutting and filling in the park, have amounted to upwards of half a million cubic yards, according to *Engineering*. The ironwork of the building amounts to 13,200 tons, of which nearly 10,000 tons are in the great machinery gallery. The prices of the wrought-iron work have been, for the great gallery, 23*l.* per ton, with the exception of the sash irons, which were 31*l.* The corrugated plates were 28*l.* 10*s.* per ton, fitted. For the inner galleries the price of the cast-iron work, in columns, arches, consoles, &c., was 13*l.* 5*s.* per ton. The Coignet *béton* has cost 11*l.* 12*s.* per cubic metre, or about 2*s.* per cubic yard. The windows of the machinery gallery present a surface of no less than 53,700 square yards, and the other galleries have nearly 25,000 square yards of glass.

STATUE OF SIR CHARLES BARRY.—The accounts have been closed, and stand thus. The expenditure has been,—

	£ s. d.
By amount of bills paid, 1861-1867, viz.:-	
Mr. J. H. Foley, for the statue, and for erecting it	908 15 0
Mr. W. Field, for the marble plinth, carving the background, and sundry extra works	169 10 0
Mr. J. G. Crace, for gilding and embellishing the architectural details of the arch, &c., adjoining the statue	46 9 0
Mr. J. Massey, for two small plaster models of the statue and the adjoining portion of the building	29 1 0
Printing, writing, advertising, postage, and sundry small disbursements	44 12 0
It was met thus,--	£1,198 7 0

	£ s. d.
To amount of subscriptions	1,039 0 0
Additional subscription from Mr. J. Lewis Wolfe, being the balance of the account	168 7 0
	£1,198 7 0

Mr. Wolfe had previously subscribed 200*l.* The next largest subscribers were Messrs. Lucas, who gave 100*l.*

Books Received.

VARIORUM.

The publication of the second volume of Mr. Fergusson's "History of Architecture in all Countries" (Murray, Albemarle-street) completes the work, the "History of Modern Architecture" already issued forming the third volume. We shall early give it that full review to which its importance and value entitle it. Compared with the "Hand-book," the volume now before us may be called a new work, the greater part of the matter and half the illustrations (which are above 650 in number) being entirely fresh.

The April number of the *Art Journal* will contain the first part of the Illustrated Catalogue of the Paris Exhibition. It will include 100 engravings, illustrating works of Froment Maurice, Hunt & Roskell, Sy & Wagner (Berlin), Esington, Harry Emanuel, Weise, Benson, Rudolph, Odot, Christoffe (jewellers and goldsmiths, of Paris or London), Copeland, Minton, the Imperial and Royal manufactories of Dresden, and Berlin (porcelain), Durenne (cast-iron), Brecheaux (fans), Servant, Claprentier (bronzes), Jackson & Graham, Gillows, Trollope (furniture), Dobson (glass), and others.

Miscellaneous.

CHIMNEY-POTS IN GALEs.—A correspondent suggests that chimney-pots might be screwed on to metallic collars secured into the brick-work, as the potter could easily form the working; and a few turns on the collar would permanently fix the pot.

EXHIBITION OF HISTORICAL PORTRAITS IN PARIS.—The Pompeian house built for Prince Napoleon, in the Avenue Montaigne, has passed into the hands of M. Arsène Houssaye, the well-known editor of the *Artistes*, who is now engaged in preparing an exhibition of portraits. It is said that the project has been well received, and that the collection is likely to be a highly interesting one, including many fine and curious works, especially of the revolutionary period.

DISSENTING CHURCH-BUILDING NEWS.

York.—The foundation-stone of a Baptist church has been laid here, in Priory-street, Micklegate. It is to accommodate 700 persons. The building will stand with its side to Priory-street. The style is the Early Decorated. The plan consists of a nave and aisles, with transepts. The extreme length of the nave will be 78 ft.; the width 24 ft. 6 in.; height to the eaves above the clerestory, 32 ft. 6 in., and to the collar-beam of roof (where it is celled), 44 ft. 6 in. The extreme width will be 44 ft. between the aisle walls, and 49 ft. 6 in. across the transepts. The arcade below the clerestory will be of brick, with plaster moldings, and supported upon cast-iron columns, with foliated capitals. A gallery will be erected over the aisles and across the ends over the vestibules. At the opposite end an arched recess will be provided for the organ and choir. The front of the galleries will be in pitch pine, with Quebec pine panels in the lower part, and ornamental ironwork in the upper part, the framing being relieved with ornamental chamerling. The iron columns supporting the arcade will divide the gallery front into bays, as they are seen the entire height. The organ-gallery front will be in ornamental woodwork entirely. A platform will be provided instead of a pulpit, below the floor of which will be the baptistery, made in Ransome's patent concrete stone. The steps from the baptistery will lead direct into the vestries. The seats will be all open benches, with ornamental ends. Behind the church, with its end to the street, will be a lecture-room, 40 ft. by 21 ft.; minister's vestry, lobby, and staircase to school-room, which will be 45 ft. by 25 ft. The timberwork of the roof of both church and schools will be exposed to view. The roof of the church will have curved ribs below the collar-beam, and terminating upon ornamental stone corbels in the spandrel of the arcade. The exterior will be faced with stone, the dressings will be in Whity stone, and the walling of Bradford sets, in thin beds. The side

COUNTENANCED BY SMOKE.—The last scientific toy we hear of from America is in the shape of some cigar-holders made of paper and quill, each showing a blank medallion, on which, however, a photograph is developed in a few moments when the holder is used for its intended purpose. It appears from experiment that the ammonia of the smoke is the developing agent, but the exact nature of the action has not yet been explained.

THE SANITARY CONDITION OF LIVERPOOL.—In the Commons Mr. Sammelson recently asked the Home Secretary whether he would lay upon the table the report of Mr. Taylor on the sanitary state of certain parts of Liverpool, and on the condition of the dwellings of the poor in that town; and whether he had received from the local authorities any satisfactory assurance that the recommendations of Mr. Taylor would be promptly carried into effect. Mr. Walpole, in reply, said that the report was a very long and valuable one, and had only recently been delivered at the Home Office. He would go through it without delay, and would then state whether the report and the other papers on the subject could be laid on the table of the House.

DUNFERMLINE: THE PALACE RUINS.—Lord Provost Whitelaw has issued a notice to the inhabitants of Dunfermline, in which he says:—"As some misunderstanding exists as to the virtue of the decision of the House of Lords in this case, recently delivered, and as some ill-advised persons and boys have forced access into the palace grounds, the magistrates deem it their duty to announce that, until the judgment of the House of Lords is applied, the inhabitants have no legal right to force access to the grounds." In the same notice he says:—"The magistrates are at present taking steps to obtain permission from the Commissioners of Her Majesty's Woods and Forests to open the grounds to the public, and also to make arrangements for the future preservation and management of the grounds; and until the judgment is applied, the magistrates earnestly trust that no attempt will be made to force an entrance to the grounds."

GAS.—The Canterbury Gas Company have declared a dividend for the last half-year at the rate of 6 per cent. per annum.—The Tunbridge Gas Company have declared a dividend of 7½ per cent. for the past year, besides placing 250l. to their reserved fund, and having a balance of 183l. over.—The Cardiff Gas-light and Coke Company have declared a dividend at the rate of 10 per cent. on their old shares, and 5 per cent. on their new, for the last half-year.—The following resolution, moved by Colonel W. Fatten in the Commons, has been agreed to:—"That it be an instruction to the Committee of Selection that it has power to refer every gas and water bill of the present session, excepting those relating to the metropolis, against which a petition endorsed for hearing, before the referees has been presented, to the Court of Referees in stead of to a committee of the House, with power to the referees to inquire into the whole subject-matter of the bill, and to report thereon to the House." The resolution was agreed to.

THE HUTTON VIADUCT.—The North-Eastern Company have made great progress with the works for the reconstruction of this large structure, which carries the main line to Scarborough across the Derwent in an oblique direction, and at a height sufficient to avoid interference with the Malton navigation. The new viaduct will be much shorter than the old wooden one, but will still consist of four openings of about 90 ft. each, the new viaduct being one half of the width of the present bridge higher up the river. One coffer-dam has been formed on the East Riding side, and two others on the North Riding side, all in the lacustrine and river deposits. These have been carried down some 16 ft. through layers of gravel, sand, clay, and peat. The bottoms of these coffer-dams have been "piled" with old iron rails, and among these a bed of concrete has been thrown, upon which the piers for the superstructure are to be built. Owing to the depth of water, however, the two piers in the river could not be formed in coffer-dams. In lieu thereof three piles of hollow cast-iron are driven down to the rock, and these piles are bolted together on cast-iron plates laid on the top, and then braced by iron bands in all directions. Upon the iron platforms thus formed the piers are to be built, none of the masonry (except in flood) being in the water. The piers will be of stone and brick, and the permanent way will rest on sixteen huge girders of riveted iron plates.

BUNHILL-FIELDS BURIAL-GROUND.—The question of this last resting-place of four acres being given up to bricks and mortar at the end of the year is one now exciting the attention of the religious world, as also of the corporation of the City, which public body are most desirous that it should be preserved, but they cannot come to terms with the reverendness of the Ecclesiastical Commission. It behoves Churchmen as well as Dissenters to co-operate immediately in the carrying out to a good result of some plan for the preservation of Bunhill-fields.

THE ARTISANS' AND LABOURERS' DWELLING BILL.—The Metropolitan Board of Works have referred this Bill for consideration to their works and general purposes committee. The chairman at a recent meeting remarked that there could be no doubt that the principle was correct, that when a house become a source of annoyance or danger to the persons living in its neighbourhood, the owner or lessor should be compelled by law to permit its being taken down. A magistrate might make the necessary order on just cause being shown by witnesses on oath. Mr. Saunders said he approved of the clause giving the local authorities the power to open blind allies, a course which was most necessary for the health of many London quarters. He did not believe that the Bill would lead to any increase of taxation.

DEATH OF NINE CHILDREN BY FIRE.—A shocking catastrophe has occurred at Accrington. Beneath an infant-school, where about 100 children attended, were varnishing and heard knitting works, with hot stoves and pipes, and only a wooden staircase to the school. A fire broke out suddenly in the varnishing shop while all the children were in the school, and the staircase immediately took fire, so that only a few of the children could with great difficulty be got out. Ladders were procured, and scores of the little creatures were thus saved from a dreadful death. Indeed, it is wonderful that only nine were destroyed, for the place burnt like tinder and was completely gutted. To have so many children collected in so dangerous a place as a varnishing shop was certainly wrong. A verdict of accidental death has been given.

CHURCH CONSECRATION.—The case of Parker v. Leach was an appeal from a judgment of the Chancery Court at York, to the Judicial Committee of the Privy Council, under a proceeding of "perturbation of a seat" in the parish church of Waddington, in the diocese of Ripon and province of York. The question raised and decided was whether a parish church, after alterations and part rebuilding, should be reconsecrated? The church in question was, in 1825, under the authority of a faculty, rebuilt in some of its parts, and had new buildings introduced into it by way of repair, but an important portion of the original consecrated structure remained untouched. The Judicial Committee held the church never ceased to be a parish church, and required no reconsecration after the above alterations. It was stated, also, that there was no authority for the doctrine that where the communion-table of a parish church has been taken down and replaced by a new one, it requires reconsecration, for the communion-table of a Protestant church is not analogous to the altar in a Roman Catholic church.

THE LATE MR. JOHN PHILLIP, R.A.—The remains of the late admirable artist, Mr. John Phillip, who died at his house, Campden-hill, Kensington, on the 27th ult., have been interred in Kensal-green Cemetery. Many members of his profession and some few literary friends were present. Mr. Phillip was born at Aberdeen on the 2nd of May, 1817, and had thins at the time of his death nearly completed his fiftieth year. His parents were in humble circumstances. He began life about the age of twelve as a painter's boy, and even in his boyhood his love for art showed itself strongly. Every hour of leisure he devoted to painting pictures. Mr. Pryce Gordon, an Aberdeen gentleman, was so much struck with some of these early efforts, that he brought the talents of the boy painter, Phillip, under the notice of the late Lord Panmure, who immediately took him most heartily by the hand; and, with the view of doing him all the good in his power, sent him to study in London under Mr. T. M. Joy. It was not, however, till after a visit to Spain—where he went in search of health—in the year 1851, that Phillip found his true field as a painter. His last pictures were his best. The English School has lost a great colourist.

WORKS OF ART FROM ROME.—Lately-published statistics of commerce in art inform us that, in the year 1866, the modern paintings exported from Rome represented the value of 138,841 scudi; modern sculptures, 311,387 scudi; ancient pictures, 7,305 scudi; and antique sculptures, 11,967 scudi; the total amount of such exports being 2,523,594 francs,—considerably above that reported for the preceding year.

PUBLIC HEALTH ACT.—This Act (11 and 12 Vict., c. 63), gives full compensation "to all persons sustaining any damage by reason of the exercise of any of the powers" of the Act. It was held by the Court of Common Pleas, in the case of *Hall v. The Mayor and Corporation of Bristol*, that this extends only to damage which would give a right of action if the works causing it were carried out without the authority of the statute.

PLAN OF THE CITY OF WORCESTER.—The Streets, Water, and Sewerage Committee have agreed to recommend for acceptance by the town council the tender of Mr. H. Webb, surveyor, of Foregate-street, for a map of the city, on a scale of 40 ft. to an inch, at a cost of 640l. The committee also ordered that there should be a constant supply of water to the city night and day. The new waterworks were reported as being in a satisfactory state of progress.

CRIPPLEGATE.—Amongst the improvements lately made in the City, is the removal of four old houses in Well-street, Cripple-gate, and the erection on the site of an extensive warehouse, having a frontage of 90 ft., and an average depth of 35 ft. The height from paving to coping is 62 ft. There are seven floors in all, with staircase and lift at each end of the building communicating with each floor, and arrangements for supply of water, so that the building may be used for manufacturing purposes or otherwise. Mr. W. Henshaw has carried out the works, under the superintendence of Mr. George Grayson, architect.

PHOTOGRAPHIC PROGRESS.—The well-known "ghost" process Professor Mack now proposes to apply to anatomical preparations in an ingenious way. Taking the skull, for instance, says *Galvani*, he photographs it stereographically on the photograph of the annular apparatus, so that the whole interior of the ear is seen through the temporal bone. It is easy to conceive the immense advantages that may be derived from this system. Suppose it were required to show photographically the exact position of the heart and its immediate connexions in a given posture of the person, that part would then be photographed first from a model and the whole body over it. The latter would thus form a transparent outline showing the relative positions of the inner and outer parts. Might not the whole skeleton, too, be thus seen, clothed with its muscular and vascular systems? This would form a highly interesting sort of stereograph.

MR. RUSKIN ON "CO-OPERATION AND COMPETITION."—In a letter which has been printed Mr. Ruskin says on this subject:—"All mastership is not alike in principle. There are just and unjust masterships; and while, on the one hand, there can be no question but that co-operative partnership is better than unjust and tyrannous mastership, there is very great room for doubt whether it be better than a just and benignant mastership. At present you, every one of you, speak and act as if there were only one alternative, namely, between a system in which profits shall be divided in due proportion among all; and the present one, in which the workman is paid the least wages he will take, under the pressure of competition in the labour market. But an intermediate method is conceivable,—a method which appears to me more prudent, and in its ultimate results more just than the co-operative one. An arrangement may be supposed,—and I have good hopes also may one day be effected,—by which every subordinate shall be paid sufficient and regular wages, according to his rank, by which due provision shall be made out of the profits of the business for sick and supernumerated workers, and by which the master, being held responsible, as a minor king or governor, for the conduct as well as the comfort of all those under his rule, shall on that condition be permitted to retain to his own use the surplus profits of the business which the fact of his being its master may be assumed to prove that he has organized by superior intellect and energy."

EDINBURGH CO-OPERATIVE BUILDING COMPANY.—The quarterly meeting of the shareholders of this company has been held. From the report it appeared that a number of houses have been sold during the past quarter at Leith. Sixteen houses in course of erection at Maryfield are nearly completed, and will be fit for occupation at Whit Sunday. The building of other six houses and a shop is being proceeded with at the same place. Twelve of these houses have been sold during the quarter. Since last general meeting of the company, fourteen houses have been sold at Stockbridge, where an additional block has also been commenced.

NEW TILE WORKS, BURSLEM.—The encaustic tile manufacture has recently taken another step in advance in the Potteries. Three or four years ago Messrs. Boulton & Worthington, of Burslem, took out a patent for the manufacture of encaustic tiles from powdered clay subjected to a great pressure. This patent was purchased by Messrs. Malkin & Co., who, in November last, commenced operations at works erected specially for the purpose at Newport, Burslem. The slip-house machinery is driven by an engine of twelve-horse power, and there are three kilns on which the slip is desiccated; after which it is ground to powder, and is then ready for the presses. Of these there are nine in all, some of which are used for making plain wall tiles and quarries, and others for ornamental tiles. The plain tiles are made in great numbers by means of unpatented presses. The slives for drying the tiles are heated by steam pipes, and those set apart for the encaustic tiles are so arranged that the tiles are placed in on one side by the makers, and taken out on the other by the placers. From the produce of the first oven several pavements have been prepared for the Paris Exhibition. The designs at present produced are mostly Gothic in style.

THE SEWAGE QUESTION.—At a recent meeting in Liverpool Lord Robert Montagu delivered an address upon this question. His Lordship stated, that fifteen years ago he himself tried the utilization of sewage upon land, and so astonished was he with the results, that he then determined that if ever an opportunity offered he would do all in his power to urge the general utilization of sewage throughout the country. He spoke, therefore, from experience. After alluding to his well-known connexion with the Parliamentary Committee and bills on the subject of sewage, one of which, the Sewage Utilization Act, was passed in 1855, he went on to show, firstly, the absolute necessity of utilizing the sewage of towns; secondly, the enormous gain that might be expected to accrue from such a practice. After the address, Mr. J. F. Bateman, C.E., said the experiments made showed that where sewage had been utilized, the result had been a considerable improvement in the value of land. The work proposed to be tried in Liverpool was extremely simple. It was proposed merely to carry out a portion of the scheme, so as to enable the public to realise the fact that sewage could be utilized. The company formed in Liverpool intended to try 200 or 300 acres, or more, if necessary, at the north end of the town.

METROPOLITAN IMPROVEMENT RATE.—Mr. Ayrton's Bill, reciting that a portion of the charge for permanent improvements in the metropolis ought to be borne by the owners of rateable property therein, proposes to enact as follows—That the Metropolitan Board of Works in assessing on the several parts of the metropolis the several sums to be charged thereon for defraying the expenses of the execution of the Metropolitan Management Acts of 1855, 1856, and 1862, shall distinguish as being assessed for a special rate, to be called the "Metropolis Improvement Rate," such parts of those several sums as the Board from time to time shall think fit, not exceeding in any year 4d. in the pound on the rateable annual value of the property in the several parts of the metropolis. The rate is to be applied towards permanent improvements authorized by Parliament, or to which the City Commissioners of Sewers, or any vestry or district Board, contribute out of rates at their disposal at least half the cost. The rate is to be borne partly by the occupier and partly by the landlord, or the several landlords or lessors; and the occupier is to deduct thereof one half of the sum which he pays for the Metropolitan Improvement Rate in respect of each pound of rateable value, whether the rent is greater or less than the rateable value."

A FEATURE OF THE STRIKES.—The strikes of men engaged in the iron works and collieries of the district traversed by the Midland Railway have cost the company 10,000l. in loss of traffic alone.

THE MAIDENHEAD SEWAGE.—In reply to a letter from the town clerk to the Thames Conservators requesting to be informed whether the filtered sewage water of the town would be allowed to pass into the Thames, the Board of Conservators decline to sanction it, and refer to the chemical character of the water passed from the Ealing sewage works as analyzed by their analytical officer of the Board, Dr. Letheby. The Local Board have, therefore, requested to be allowed to send to the Board a deputation on the following question:—"Suppose the filtering process is carried out to a greater extent than at Ealing, will the filtered sewage water then be allowed to enter the Thames?"

NEW BRIGHTON PIER.—An ordinary general meeting of the New Brighton Pier Company, which has been incorporated under a special Act of Parliament, at a nominal capital of 30,000l., in 3,000 shares at 10l. each, has been held in Liverpool. The company are now erecting an iron pile-pier at New Brighton, on the Mersey, with a promenade and saloons, the profits to be derived from tolls for usage. Mr. E. Birch, of Westminster, is the engineer. The report submitted stated that the first column of the pier was fixed on the 19th of December last. One-half the foundations for the whole of the columns are already fixed, several columns erected, and girders and other materials on the spot. Mr. Birch constructed the similar pier at Brighton, in Sussex.

BARROW-IN-FURNESS.—A correspondent says: "A town of about 20,000 inhabitants, grown up from a village of scarcely one-tenth of that population in the short space of seven years, is a unicorn in European geography. There have been instances before this of quickly-grown towns in some of the iron districts of England, such as Middlesborough-on-Tees or Merthyr Tydvil, but these precedents can hardly be compared, as regards rapidity and extent of rise, to the recently-commenced and still continuing increase of Barrow-in-Furness. The appearance of this now important town has a striking peculiarity. Its streets of newly-built houses, and others in course of construction; its gangs of busy workmen engaged in building, erecting, and fitting up new structures of all kinds; the bustling noise, and the visible tendency which exists everywhere to progress with the utmost speed, bear some resemblance to the hasty preparations for some enormous fair or other extraordinary occasion."

THE GREAT WESTERN STATION AT READING.—The new down station is now approaching its completion. The site has been found very troublesome on account of its being once a valley, which it was necessary to fill up with ballast, in order to form a roadway to the old station—the depth being from the surface of the original bottom, 25 ft. 6 in. The station is in the Italian style, very freely treated, with very low wings, and a tower in the centre of the building. The exterior walls are of white bricks supplied by the Coalbrookdale Company's brickyard in Shropshire. A close joint has been obtained, and they have been set in fine putty, and left a ruled joint. The dressings are of Bath stone, selected from a bed known as the Lodgestry Bed, on account of its durability. The centre portion of the building and under the verandah are entirely of Bath stone, with moulded and carved panels and wreaths over the windows and doors. The windows generally throughout the building are designed with carved trusses supporting the shelf terminating with pendants of running foliage. The carving has been carried out under the superintendence of Mr. Charles Allen, of Birmingham. The chimneys are of Bath stone. The total length of the building is 221 ft. 2 in., and it is 46 ft. broad, and comprises first and second class waiting-rooms, refreshment-rooms, with kitchen, scullery, &c.; booking telegraph, parcels, inspectors' and engineers' offices, cloak-room, and superintendent's residence. It is proposed to approach the up-station by an underground passage. The plans were prepared from designs by Mr. Lane, the company's chief engineer, and have been carried out by Mr. H. Lovatt, of Wolverhampton, under the direction of Mr. H. Charlton. The clerk of the works was the company's local engineer, Mr. T. Blackall, of Reading.

RESTORATION OF WREXHAM CHURCH.—The scraping of the walls of the old church have brought to light over the chancel arch a large painting, which as far as it can be deciphered at present seems to be a picture of the Last Judgment. They have been directed to preserve it as perfect as possible, and some thoughts, according to the *Cheshire Courier*, are entertained of restoring it.

IMPROVEMENTS AT SANDRINGHAM.—During the absence of the Prince and Princess of Wales many improvements have been carried out on the Sandringham estate. The new model farm buildings, in which the Prince of Wales's prize and other stock will be fed, are progressing. They are situated on the Home Farm, at the back of the royal gardens, and comprise two yards, surrounded with feeding and fattening boxes, &c., the same principle being adopted in the ventilation as in the royal kennels. Seven additional labourers' cottages have just been completed, and are replete with every accommodation, the prince seeking to the utmost to discharge his duty towards the cottagers on the royal estate. The new wing of Sandringham House progresses, and will probably be ready for use by the autumn.

TENDERS

For the erection of two houses Nos. 24 and 30, Shepherd Street, May Fair. Mr. S. L. Moyer, architect. Quantities supplied:—
Stoner.....£1,857 0 0
Sapwell.....1,794 0 0
Walton.....1,552 0 0

For a pair of semi-detached residences at Fulham, for Mr. T. Cross:—
Stimpson.....£1,510 0 0
Brass.....1,480 0 0
Whitlock.....1,450 0 0
Richards.....1,414 0 0
Wignore (accepted).....1,269 10 0

For a pair of houses in the North-end-road, Fulham, for W. Kitchin:—
Amos.....£896 0 0
Smith.....800 0 0
Wilson.....785 0 0
Wignore (accepted).....750 0 0
Johnson.....739 0 0
Ward.....735 0 0

For building printing-offices, Bartholomew-close, Mr. John Byrne, architect:—
Gillet & Wisbey.....£3,200 0 0
Mansfield & Son.....2,906 0 0
Pattman & Co.....2,685 0 0
Meyers.....2,688 0 0
Piper & Wheeler.....2,600 0 0

The Builder.

VOL. XXV.—No. 1258.

Something about Indian Appointments.

HE way in which matters are managed in India interests a large body of persons in England, so that many of our readers, besides those amongst them who intend presenting themselves in July next for examination, in response to the advertisement of the Secretary of State for India, may be glad to hear something about the Public Works Department in that country. What we are about to say must not be taken as the statements of outsiders and mere journalists. It is the result of combined experiences, and represents faithfully, as we believe, the opinions of a large body of persons competent to judge and entitled to speak.

It may be as well to mention at the outset, that the Government in India stand greatly in need of a reinforcement of civil engineers in the grade of assistant engineers. The altered economy of the native army, whereby every officer in it is considered a staff officer, and entitled to a staff salary, varying from 10*l.* to 60*l.* a month in the infantry, in addition to the pay of his rank, amounting to the fixed rates of 23*l.* a month on posting; 37*l.* after twelve years' service; 64*l.* after twenty years' service, and so on, tends to make military men indolent of extra regimental employment. And as cadets are no longer sent out, and the Queen's regular army is being turned to, and expected to furnish volunteers for the native army, there will in a year or two not be a surplus officer to be had for a department like that of the public works, in which the staff salaries also range from 10*l.* to 60*l.* in the working grades, and there are no valuable prizes whatever, but plenty of disagreeable and laborious work to do.

A separate engineer service, as far as India is concerned, has been all but abolished, and we understand the conditions of the Public Works Department are not such as to render it particularly agreeable to officers of Royal Engineers. Accordingly, unless the Government are ready to pay a fair price, they will find it soon very difficult to carry on their public works efficiently for want of qualified engineers. There are two considerations that would naturally weigh with a young man on turning his thoughts towards an Indian career,—first, and foremost, the emoluments; and, secondly, the nature of the service. It is true, this is not quite the European way of judging of a profession; but as all service in a tropical and unhealthy country must be full of hardship and risk—as India is far off and by no means pleasant to live in—and as work has to be done in the midst of a population animated with a dislike to British rule and hatred of British ways, it would be insane in any one not
