The only other field in which active mining is carried on is a few miles east of Socorro. This field contains coking coal, but the beds are so broken by faults and covered by recent material washed in from the surrounding higher land that mining is expensive and uncertain.

# MINING METHODS.

The records of coal production in New Mexico extend back to 1882, during which year 157,092 tons of coal were produced. The production has gradually increased until in 1913 the total amount was 3,708,806 tons. In 1898 the 29 mining machines in use produced 16.5 per cent of all the coal mined. During 1905 and 1906 there were no mining machines in operation, but in 1907 three machines were introduced, and the number has gradually increased until in 1914 45 machines produced 16 per cent of the coal. In 1911 31.2 per cent of the coal was shot off the solid, but with the increase in the amount of machine-mined coal the amount shot off the solid was reduced to 17.6 per cent in 1913. From 65 per cent to 75 per cent of the coal is mined by hand.

The coal mines of New Mexico are operated on single and double entry systems through slopes and drifts. One large company operates a triple-entry system. Coal is mined by the room-and-pillar method. In 1913 there were three longwall mines and three panelsystem mines. Many of the mines are very dry, and humidifiers have been installed. Shot firers are employed. Mule, horse, and electric haulage are in use. The following extracts <sup>a</sup> are from the State mine inspector's report for 1910.

The Tocco mine, near Albuquerque, has the distinction of operating the thinnest coal seam developed in New Mexico, one of the thinnest worked in the United States, and one that ranks also with the thinnest mined in Europe. The seam is from 12 to 15 inches thick, with 1 to 3 inches of bony coal at the top, leaving 10 to 13 inches of clean coal to be mined. A slope has been sunk 355 feet, with an average dip of 25°, and cross entries have been driven about 30 feet apart. The props used are from 10 to  $13\frac{1}{2}$  inches long. The coal is bituminous, free from sulphur, and is a good black-smith's coal. The product of the mine is hauled to Albuquerque, N. Mex., where it is sold for blacksmithing purposes at from \$9 to \$12 per ton of 2,000 pounds.

The mines at Dawson are worked as follows:

Triple main entry; double-cross entry; room-and-pillar, robbing on retreat. All main drift entries are 10 feet wide by 6 feet high; main cross entries, 8 feet by 6 feet.

Cross entries off cross entries are 8 feet wide by 5 feet 6 inches high; main air courses are 10 feet by 6 feet and other air courses 8 feet wide by 6 feet. All workings are substantially timbered and haulage ways and traveling roads are lighted by electricity. Main entry pillars are from 100 to 300 feet thick; main cross entry pillars, 50 to 100 feet. Average length of rooms, 350 feet; room centers, 60 feet; width of rooms, 20 feet; size of room pillars, 40 feet. The mines are ventilated by exhaust fans on the surface. Shots are fired by electricity after all persons are out of the mine.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

By an act of Congress approved March 3, 1891, official inspection of coal mines was authorized in all Territories where the aggregate annual production of such mines exceeded 1,000 tons. The appointment of the inspector was vested in the President of the United States. Under the provisions of this law, the first mine inspector for the Territory of New Mexico was appointed July 1, 1892, and entered upon duty August 30, 1892. Section 15 of the act provided that a full and written report of all fatal accidents should be made to the mine inspector within 10 days after such death shall have occurred: Annual reports for fiscal years ending June 30 were rendered to the Secretary of the Interior. New Mexico was admitted to the Union on January 6, 1912, and the former Territorial mine inspector was continued in office. The office of State mine inspector was created by an act approved June 13, 1912, and the first State inspector was appointed September 20, 1912. The State law requires mine operators to keep a record of all accidents at their mines, to which record the inspector shall have access, and to at once report to the inspector by telegraph or telephone all accidents resulting in death, such immediate report to be followed, within 10 days, by a full and complete written report of the accident. It was made the inspector's duty to proceed without delay to any mine within the State upon receipt of notice of any explosion or other accident resulting fatally or jeopardizing the lives of the men working in such mine. Annual reports are rendered to the governor for years ending November 30.

According to the State inspector, the number of nonfatal accidents published in his annual report is not complete, as the reporting of such accidents is not made compulsory by law, and some operators do not report all injuries at their mines.

In 1915 the State inspector had no clerical or other assistants.

# ACCIDENTS.

Tables 113 and 114 show by causes and calendar years the total number of fatalities in and about the mines of New Mexico, since the beginning of inspection service in 1893 to the end of 1913, as compiled from the territorial and State mine inspectors' reports. The 21-year period from 1893 to 1913 shows 568 fatalities, of which 56.51 per cent was due to gas and dust explosions, 28.17 per cent to falls of roof and pillar coal, and 7.57 per cent to mine cars and locomotives. The fatality rate for New Mexico is exceedingly high by reason of the disaster at Dawson, in which 263 men were killed at one time.

FATALITIES IN NEW MEXICO COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1893 TO 1913, INCLUSIVE.

|                                                                                                                                                                             | Number killed.                         |                                               |                                                |

The fatality rate during this period is 11.43 per 1,000 men employed. By referring to Table 40 it will be noted that the fatality rate for common accidents-that is, those in which less than 5 men were killed at one time-based on the actual number of employees is 4.84 per 1,000 men, for the 10-year period 1903 to 1913, inclusive, excepting 1909. The number of fatalities due to exceptional accidentsthat is, those in which 5 or more men were killed at one time---is 9.70 for the same 10 years. The fatality rate due to common accidents is a little higher than in a number of other States. The one disaster at Dawson overshadows all others and for this reason the total rate is Table 40 also shows that the number of hours exceedingly high. worked per year per man is 2,463, as compared with 1,495 for Ohio and 2.034 for the bituminous mines of Pennsylvania. By reducing the fatality rate of common accidents to the basis of 2,000-hour workers, the rate becomes 3.93 as compared with 3.84 for Ohio and 2.82 for the bituminous mines of Pennsylvania.

From 1903 to the close of 1912 practically all of the men in the mines of New Mexico were employed on a 10-hour basis, but in 1913 the majority of the men were employed 8 hours a day. Table 41 shows the fatality rates on the 2,000-hour basis for a period of years, so that a comparison with other States may be easily made. The tables of statistics for the State of New Mexico follow:

a Stag Canyon explosion, killed 263.

# NORTH CAROLINA.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing formations of North Carolina are contained in the Deep River and the Dan River fields and are of Triassic age. The Deep River field extends from the northern boundary in a southwesterly direction through Durham, Haywood, and Wadesboro, entirely across the State and a short distance into South Cárolina. The field averages about 12 miles wide and contains 250 to 300 square miles. The Deep River coal is bituminous and in some places has been more or less coked by igneous intrusions.

# CHARACTER OF COAL BEDS.

The coal beds dip about  $15^{\circ}$  southeast and vary from 1 foot to 8 feet in thickness. Mining has been conducted in this field in a desultory way since the early sixties. From 1860 to 1865 it is estimated that about 65,000 tons of coal was produced. One of the most important mines worked in recent years is the Cumnock, which is opened by a shaft 8 feet by 12 feet in cross section and 460 feet deep. This mine has been the scene of two serious mine explosions in which 62 men were killed.

The Dan River field consists of a small coal-bearing area in the north-central part of the State and is 50 or 60 miles northwest of the Deep River field. The Dan River field extends from the Virginia-North Carolina line in a southwesterly direction and is about 30 miles long and 4 to 7 miles wide. The coal beds are 2 to 7 feet thick and dip about  $34^{\circ}$ . A small amount of coal was mined from this field during the Civil War, but since that time little mining has been done there.

Tables 115 and 116 give further details concerning the number of men employed, coal produced, accidents, etc. These tables are meager and incomplete, but contain all the data available.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

There is official mine-inspection service a in North Carolina, but as the State is not a regular producer of coal, the occasional output is too small to place the industry on a commercial scale. The tables of statistics for this State follow.

COAL-MINE ACCIDENTS IN NORTH CAROLINA IN WHICH 5 OR MORE MEN WERE KILLED.

# 252 COAL-MINE FATALITIES IN THE UNITED STATES, 1870-1914.

# NORTH DAKOTA.

# AREA AND DISTRIBUTION OF COAL FIELDS.

The coal beds of North Dakota are lignitic, and occupy about 35,000 square miles, or practically the western half of the State. Ninetyseven townships contain at least one bed of lignite 7 feet thick, and at least 100 other townships contain beds 4 to 7 feet thick. The lignite beds are horizontal and occur at depths ranging from near the surface to a depth of at least 300 feet.

# MINING METHODS.

Lignite has been mined in North Dakota by ranchers and others since the territorial days of the State, and the first records of production were obtained in 1884, when 35,000 tons of coal was mined.

The production in 1913 was 495,322 tons.

In 1911 there were practically 100 mines in operation, 20 of which were surface and 80 underground mines. Of the underground mines, 69 were opened by slope or drift and 11 by shaft. The mines are opened by single and double entry and the coal mined by the roomand-pillar method, the rooms being 12 by 100 feet to 22 by 300 feet; pillars are 8 to 20 feet wide. The length of entries varies from 100 to 5,000 feet. In 1911, there were 15 mines with entries over 1,000 feet long. The largest number of deep mines is in Ward County, where the mines vary from surface pits to 200 feet in depth; 21 mines are over 100 feet deep. In Adams County the deepeest mine in 1911 was 300 feet.

Ventilation is usually by an air shaft in connection with slope, drift, or entry.

Mining machines have been in use in a limited way since 1896. In 1914 there were 14 machines in operation, producing 41.1 per cent of the coal mined. Twenty-six per cent was shot off the solid and 6.3 per cent was mined by hand.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The State engineer of North Dakota was made ex-officio State coalmine inspector by an act approved March 14, 1907, with power to employ necessary assistants. The engineer renders biennial reports to the governor, showing the condition of each mine, number of men employed, and such other information as he deems desirable.

The law does not require operators to notify the inspector of mine accidents, but the inspector has requested the operators to report all accidents, however slight. All accidents thus reported are published in the biennial reports of the inspector. No distinction is made between serious and slight injuries.

### ACCIDENTS.

Tables 116 and 117 show the total number of fatalities in and about the coal mines of North Dakota from 1908 to the end of 1913, as compiled from the State mine inspectors' reports. During the 6-year period 1908 to 1913, inclusive, there were 13 fatalities, of which 46.16

FATALITIES IN NORTH DAKOTA COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1908 TO 1913, INCLUSIVE.

per cent were due to falls of rock, 23.08 per cent to explosives, and 15.38 per cent to mine cars and locomotives. The production per fatality during this period was 203,020 tons, or there were 4.93 fatalities per million tons mined. North Dakota has been fortunate in that there have been no serious mine disasters in that State. The fatality rate during this period is 3.12 per 1,000 men employed.

Since 1903 practically one-half of the men have been employed on a 10-hour basis. By referring to Table 40 it will be noted that during this period the men averaged 1,974 hours per year. During the

5-year period 1908 to 1913 (exclusive of 1909) for which complete data are available, the fatality rate based on the actual number of employees is 4.08 as compared with 4.01 based on the number of 2,000-hour workers. Table 41 shows the figures on the 2,000-hour basis for a period of years by States, so that a comparison with other States may be readily made.

The tables for the State of North Dakota follow:

### OHIO.

# AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing area of Ohio covers about 12,600 square miles, and occupies 30 counties in the southeastern part of the State. It is a part of the northwestern side of the great Appalachian coal basin which stretches from northern Pennsylvania to central Alabama. As it lies on the northwestern side of the basin the general dip of the beds is southeast toward the middle, but there are a few small folds which break up the continuity of the southeastward dip, and in some places cause a dip in the opposite direction. The most pronounced fold of this kind trends north to south and enters the State near Marietta. The coal beds and associated rocks extend to the northeast into West Virginia and Pennsylvania and to the southwest into Kentucky.

# CHARACTER OF COAL BEDS.

The coal beds of Ohio are numbered from the bottom upward, coal No. 1 being the lowest bed. Coal No. 1 has been most extensively developed in the northern part of the State, but it occurs in isolated areas along the west side of the field. It is from 3 to 6 feet thick at-Brier Hill and at Massillon. The roof is shale ranging from 5 to 40 feet in thickness. The coal is jointed, hence its name, block coal. It is noncoking, but of good steaming quality. The No. 2, or Wellston bed, is 45 to 75 feet above No. 1 and is seldom more than 2 feet thick, although at Wellston, Jackson county, it is 4 feet thick. The roof is shale and the coal non-coking.

The No. 5 bed, or Lower Kittanning, extends in an almost unbroken outcrop across the State. It is mined in almost every county of the Ohio coal field from southern Mahoning on the north to Hanging Rock on the south. It is generally less than 3 feet thick, but at Mineral Point, Zanesville, and New Castle, it is 4 to 5 feet thick. The coal is of good coking quality, but because of the thinness of the bed mining machines are not used extensively, the coal being largely mined by pick mining.

No. 6 bed, or the Middle Kittanning, also extends under a wido area. In the northern part of Columbiana County it is less than 1 foot thick. In the southern part of the county it is worked extensively, although it is only 20 to 30 inches thick. In Coshocton County, it attains a thickness of 3 feet to 4 feet 10 inches. At Shawnee it is known as the Hocking Valley seam, and in many places contains 10 feet of mineable coal. From 32 to 38 per cent of the State's production comes from this bed. The No. 7, or Upper Freeport, is not so extensive as the lower beds and varies in thickness from 5 feet 4 inches to 6 feet 9 inches. This is one of the best steaming coals in the State.

The No. 8, or Pittsburgh, is the most important bed of the upper coal measures. The coal rests on a bed of fire clay and is 4 to 6 feet thick. This bed extends into West Virginia and into Pennsylvania.

# MINING METHODS.

The accompanying table shows the number of mines opened by shaft, slope or drift, from 1892 to 1912, inclusive. At first the singleentry system of mining prevailed, but in the early eighties the doubleentry system was introduced in a number of the larger mines, and now, although the single-entry system still prevails in some mines where the bed is thin, most of the mines are opened by the doubleentry system, also some are opened by the three-entry system.

Mining machines are used extensively in coal beds Nos. 6, 7, and 8. Prior to 1877 all of the coal mined in Ohio was mined by pick. During this year the first mining machines were introduced in the State and the use of machines has steadily increased until in 1913 there were 1,681 machines in operation, producing 21,535 tons each, or in all 90.2 per cent of the coal of the State. The electric machines were introduced in Ohio in 1889 and their number has gradually increased to 1,604 in 1913. In 1891, 89 compressed-air machines were in use in Ohio mines and in 1905 the highest number, 145, was reached. There were only 49 in operation in 1913. Less than 4 per cent of the coal is reported as being shot off the solid, and slightly over 4 per cent as being mined by hand.

Prior to the introduction of mining machines in Ohio, the coalmining work was performed principally by skilled miners from England, Scotland, and Germany. This class of miners has gradually been supplanted in the State by labor from southern Europe. The table on methods of opening and ventilation at Ohio mines follows:

|       | Mines opened by—                                                                                                                                        |                                                                                                                                                       |                                                                                                                                     |                                                                                 |                                                                                                                                                                   | Method of ventilation.                                                                                                                          |                                                                                                                                          |                                                                                                                                |                                                                                                                                              |                                                                                                                                                                                                                                                                               |                                                                                          |                                                                                                                                                                                                                        |

NUMBER OF COAL MINES IN OHIO, CLASSIFIED BY TYPE OF OPENING AND METHOD OF VENTILATION FROM 1892 TO 1913, INCLUSIVE.<sup>a</sup>

<sup>a</sup> State mine inspector's reports.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

By an act approved March 21, 1874, the Legislature of Ohio provided for the inspection of all coal mines in which more than 10 men were employed at one time. Under this act the first State inspector was appointed April 6, 1874, and entered upon his duties the following day. The act made it the duty of any person having charge of any mine to which the law was applicable to report forthwith to the State inspector and the county coroner any explosion or other accident causing loss of life. The inspector was required to render a report to the governor on or before the 1st day of January of each year, and to enumerate therein, among other things, all accidents in or about the mines.

On April 12, 1884, the State was divided into three districts, and the enforcement of the laws relating to mining was intrusted to a chief mine inspector and three district inspectors. The inspection service was also extended to include fire-clay, iron-ore, and other mines, as well as coal mines. The number of districts and district inspectors was increased by statute from time to time, until in 1913 there were 12 districts, each having an inspector. On March 12, 1913 a law was passed, and approved March 18, 1913, discontinuing various State departments and offices, among them being the office of chief mine inspector, and transferring all powers and duties of the inspector to a newly created State industrial commission. Under the provisions of this law, the new commission assumed the duties and functions of the chief inspector of mines on September 1, 1913, and established the office of chief deputy and safety commissioner of mines.

All accidents are reported to district inspectors and are included in the annual reports of the industrial commission. Injuries involving disability for three weeks or more are classified as serious, and all other injuries are slight.

# ACCIDENTS.

Tables 118 and 119 show the total number of fatalities by causes since the beginning of inspection service in 1874 with the exception of the fiscal year 1879, for which no report was published. These tables also show the percentage of accidents, classified by principal causes, and fatality rates per 1,000 men employed for a period of 30

FATALITIES IN OHIO COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1884 TO 1913, INCLUSIVE.

years (1884-1913), for which complete records of employees and fatalities are available. The fatality rate during this period is 2.39 per 1,000 men employed. Ohio has been fortunate in the matter of large disasters, there being only 3 during this period causing the death of more than 5 men at one time, representing only  $1\frac{1}{2}$  per cent

of the total number killed. Falls of roof and pillar are responsible for 65.84 per cent of the fatalities; mine cars and locomotives are second with 12.08 per cent. The average production of coal per fatality during this period was 251,152 tons, or 3.98 fatalities for each million tons mined.

Since 1903 more than 97 per cent of the men employed in the mines have been on an 8-hour day. The time element, therefore, has been taken into consideration and tables compiled on this basis for comparison with other States. The fatality rate for the 10-year

period 1903 to 1913 (Table 40) based upon the actual number of employees is 2.94, whereas based on the number of 2,000-hour workers it is 3.94. During the 10-year period the men averaged 1,495 hours of labor per man, as compared with 2,132 hours in West Virginia, and 2,034 hours in the bituminous mines of Pennsylvania. Table 41 shows the fatality rate for each year on the 2,000-hour basis for each State, so that a true comparison of Ohio with other States may be readily made. The tables of statistics for the State follow.

# OKLAHOMA.

# AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Oklahoma have an area of about 10,000 square miles. In general the rocks of these fields dip slightly west under the Great Plains, but in Oklahoma the regular westward dip is interfered with by many local folds. On this basis the coal fields of the State may be divided into two parts as follows: (1) that part north of Canadian River in which the rocks are only slightly disturbed, and (2) the part south of Canadian River in which there are many strong anticlines and synclines that make the coal beds dip in various directions and at different angles. The part north of Canadian River is the southward continuation of the Kansas fields, but with the coal beds in greatly reduced thickness. The part south of Canadian River is similar to and a continuation of the folded and faulted fields of Arkansas. Local faults occur in the McAlester anticline near Mc-Alester.

On the northern slope of the McAlester anticline the coal-bearing rocks are tilted until the coal beds are almost vertical, and from Hartshorne to Atoka the beds are also steeply upturned. In this respect the Oklahoma coal fields are similar to those of Washington, certain parts of Colorado, and the anthracite fields of Pennsylvania. They differ from the coal fields of Washington in that the coal has not been crushed or changed in character by structural movement of the inclosing rocks.

The southern part of the coal field is the more important, as more than three-fourths of the coal mined in 1913 came from that section. The larger part of an area embracing Craig, Rogers, Tulsa, Wagoner, Okmulgee, Muskogee, McIntosh, Haskell, Sequoyah, Le Flore, Coal, Latimer, and Pittsburg counties, all in the eastern part of the State, is known to contain coal.

### CHARACTER OF COAL BEDS.

There are seven coal beds in this field that are thick enough to be worked on a commercial scale. There are, however, two groups of beds from which most of the coal mined in the southern part of the field has been obtained. These are the Hartshorne coal beds, generally two in number, at the top of the Hartshorne sandstone, and the two McAlester coal beds near the top of the McAlester shale, and from 1,500 to 1,800 feet above the Hartshorne group. The Hartshorne beds are in places about 50 feet apart, and in other places they meet. West of Wilburton the upper bed is absent. The lower bed is 4 to 5 feet thick and the upper one is about  $4\frac{1}{2}$  feet thick. East of Wilburton there are two beds about  $2\frac{1}{2}$  feet thick in the McAlester group; but about Hartshorne, McAlester, and Savanna there is only one bed, which ranges in thickness from 3 to 5 feet.

The Henryetta field in Okmulgee county was recently opened. It contains a bed of coal averaging 3 feet in thickness, and lying practically horizontal at depths varying from 100 to 200 feet, and is worked mostly by machines. The coal is not as good as other Oklahoma coals but serves as a good steam and railroad fuel, and can be produced more cheaply than the other coals to the south of Okmulgee County. Two important mining towns, Henryetta and Dewar, have recently been built as a result of the development of this coal field. The Henryetta coal field, unlike the southern coal fields, is not on segregated lands. The coal beds in Pittsburg, Coal, Latimer, and Le Flore counties and part of Haskell County, are on segregated coal lands belonging to the Choctaw and Chickasaw Indian Nations.

# MINING METHODS.

The earliest records of coal production in Oklahoma are for 1880, when 120,947 tons of coal was produced. The production in 1913 was 4,165,770 tons. About 60 per cent of the mines are opened by slopes and drifts with lengths on the incline varying from 50 to 3,500 feet. The shaft mines number about one-third of the mines in the State, and vary in depth from 70 to 800 feet. The coal is mined entirely by the room-and-pillar method. Some of the mines are quite gaseous, and much dust is produced in mining.

In 1896 there were 56 mining machines in operation, which produced 14 per cent of the coal mined in the State. In 1898, there were 75, which produced 19.9 per cent of the coal. The use of mining machines gradually declined until in 1907 there were only 11 machines in operation, producing less than 1 per cent. Since that date, the number of machines has gradually increased until in 1913, there were 103 machines in operation, producing 16.1 per cent of the coal.

Shooting off the solid is practiced to such an extent in Oklahoma that in 1912, 86.4 per cent of the coal was thus produced. This proportion, however, was by the increase of machines in 1913 reduced to 80.9 per cent. The laws of the State compel the payment of wages on the basis of run-of-mine, hence a tendency to encourage the practice of shooting from the solid. Holes are usually drilled 6 to 10 feet deep, and sometimes as much as 14 feet with no undercutting nor channeling. Sufficient powder is charged to break the coal with the result that much fine coal is produced. In some instances

these long holes are charged with dynamite. Dust is scattered throughout the mine, the roof is loosened more or less, and at least 15 per cent of the coal shot down is thrown into the gob and lost. This method of mining produces unsafe conditions in the mine in addition to being wasteful, as much of the coal is so badly crushed that it is unfit for commercial uses.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The act of Congress establishing a mine-inspection service in all Territories where the output of coal exceeded 1,000 tons annually was approved March 3, 1891. Under this act the first inspector in Indian Territory (now Oklahoma) entered on duty March 20, 1893. Mine operators were required to report to the inspector all cases of fatal accidents at their mines, such report to be in writing and made within 10 days after such death occurred. Annual reports for fiscal years ending June 30 were rendered to the Secretary of the Interior.

A State department of mines and mining was created by an act approved April 6, 1908, and under the provisions of this law the appointment of a chief mine inspector and three district inspectors was authorized, the inspectors to investigate all accidents, injuries, and deaths at mines. The first report of the State inspector covers the period from November 16, 1907, to October 31, 1908, and annual reports since the latter date have been issued for fiscal years ending October 31.

It has been the practice of mine operators to report to the inspector all fatal and serious accidents. Since the enactment of the compensation law, all accidents causing a disability of one day or more are reported. All accidents reported are included in the inspector's annual reports and are classified as fatal or nonfatal, but no distinction is made between serious and slight injuries.

In 1915 the inspection force consisted of one chief inspector and three deputy inspectors.

### ACCIDENTS.

Tables 120 and 121 show the production of coal, number of men employed, and the number of fatalities in and about the coal mines of Oklahoma. The fatalities as tabulated have been compiled from the Territorial and State mine inspectors' records, and are complete from 1893 to and including 1913. During this period of 21 years, there were 729 fatalities representing a rate of 5.45 per 1,000 men employed.

The amount of coal produced per fatality during this period was 71,111 tons, or there were 14.06 fatalities per million tons mined. Of the total number of fatalities during this period 35.94 per cent was due to gas and dust explosions, 20.99 to falls of roof and coal, and 15.77 per cent to explosives. Mine cars and locomotives claim 10.70 per cent of the fatalities. Since the beginning of inspection service March 20, 1893, to and including 1913, there were 12 mine disasters in which 5 or more men were killed at one time, as shown in the accompanying list.

Since 1903, the majority of the employees at the coal mines in Oklahoma have been on an 8-hour basis. Fatalities have, therefore, been calculated on the basis of a 2,000-hour year, showing that the rate for Oklahoma on this basis is 6.81 for the period of 1903 to 1913, except 1909. This compares with 5.08 based on the number of actual employees for the same period. The number of hours worked per year per man is 1,406, as compared with 1,564 for Kansas, and 2,132 for West Virginia. The Oklahoma rate based on the actual number

a Census year.

of employees appears to be slightly less than the fatality rate in West Virginia, but when reduced to the uniform basis of fatalities per 2,000-hour workers, the rate becomes 6.81 for Oklahoma, as compared with 5.18 for West Virginia. For comparative purposes, Tables 40 and 41 have been compiled so that it is an easy matter to compare Oklahoma with other States. The tables of statistics for the State of Oklahoma follow:

# STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN ${\color{black} \mathbf{OKLAHOMA.}}^{a}$

| Year.                | Number<br>of men<br>affected.     | Total<br>days<br>lost.                      | Average<br>number<br>of days<br>lost per<br>man. | Year.                                     | Number<br>of men<br>affected. | Total<br>days<br>lost.                             | A verage<br>number<br>of days<br>lost per<br>man. |

### **OREGON.**

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal in Oregon is subbituminous. The Coos Bay field, which is the principal one in the State, occupies a small structural basin in the vicinity of Coos Bay and contains 230 square miles. It extends north and south and is about 30 miles long, with a maximum width of 11 miles. There are other coal fields in the State, but none of them has been worked to any extent, so do not enter into the question of mine accidents. The Coos Bay field may be divided into six parts, consisting of four basins and two arches. The basins containing workable coal are the Newport, Beaver Slough, Coquille, and South Slough. The arches contain no coal. The structure of these basins may be considered as simple, the dip being slight. There are a number of faults, but these are of little importance.

The Newport basin, the principal one that has been worked, contains about 6 feet of coal in three benches, yielding 5 feet of coal that can be mined. The roof is sandstone and requires comparatively little timbering. The top bench of coal is usually left with the upper parting to form the roof.

The Beaver Slough basin contains five beds, the most important being the lowest one, which contains over 6 feet of coal. This bed has been mined at Beaver Hill.

### MINING METHODS.

The first records of coal production for Oregon are for the year 1880, when 43,205 tons was reported. Three mines have been opened by drifts and slopes in the Newport basin, and the coal is mined by the room-and-pillar method. In the Beaver Slough basin one or two mines have been opened by slopes and a small amount of coal has been mined by the pillar-and-chute system.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

No provision has been made by the State of Oregon whereby accidents in or about coal mines shall be reported to a State official. The coal production of the State since 1880 has averaged less than 64,000 tons annually. Reports of accidents have, since 1910, been voluntarily rendered to the Federal Bureau of Mines by the mine operators at the close of each calendar year.

### ACCIDENTS.

The production of coal, number of men employed, and the number of fatalities, as far as complete records are available, are given in Tables 122 and 123. The fatalities at coal mines have been recorded only since 1909, but the number of employees has been reported since 1890. For the five years for which continuous records are available, the accident rate in Oregon is comparatively low, being 2.69 per 1,000 men employed, but on the tonnage basis it is high, being 10.37 fatalities per million tons mined. There have been no serious coal-mine disasters in Oregon. The tables of statistics for the State follow:

FATALITIES IN OREGON COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEAR 1909 TO 1913, INCLUSIVE.

### STRIKES AND LOCKOUTS.

During 1914, the first year in which there were labor troubles in Oregon, 21 men were on strike, resulting in the loss of 798 days, or an average of 38 days per man.

[Figures for total production and columns 2, 3, and 8 compiled from Mineral Resources, U. S. Geol. Survey. Figures in column 4 reported direct to the Bureau of Mines by the Table 122--PRODUCTION, NUMBER OF MEN EMPLOYED, AND NUMBER OF MEN KILLED IN AND ABOUT THE COAL MINES IN OREGON, BY CALENDAR YEARS. ALSO TONNAGE MINED PER MAN, AS WELL AS THE NUMBER AND KIND OF MINING MACHINES IN USE.

### PENNSYLVANIA (ANTHRACITE).

### AREA AND DISTRIBUTION OF COAL FIELDS.

The anthracite coal fields of Pennsylvania occupy portions of Sullivan, Lackawanna, Luzerne, Carbon, Schuylkill, Dauphin, and Northumberland and Columbia counties in the northeastern part of the State. They comprise an area of 480 square miles, and form four distinct fields, as follows: The northern or Wyoming-Lackawanna field, in Luzerne and Lackawanna counties; eastern-middle or Lehigh field, in Luzerne and Carbon counties; southern or Schuylkill field, in Dauphin and Schuylkill counties; and western-middle field. A brief description of each field is given in the following paragraphs:

### CHARACTER OF COAL BEDS.

The coal beds of the anthracite fields of Pennsylvania are described by Stoek " as follows:

### NORTHERN FIELD.

From Forest City to Pittston and from Pittson to Nanticoke, north of the Susquehanna, the maximum dips are  $10^{\circ}$  to  $20^{\circ}$ , while between Pittston and Nanticoke, south of the Susquehanna, steeper dips, ranging from  $60^{\circ}$  to  $70^{\circ}$ , are found, and near Glen Lyon the measures are overturned and badly broken. There are numeous anticlines and synclines in the measures which can sometimes be traced on the surface, the synclines being often marked by ridges and the anticlines by valleys.

A marked feature of the northern field is the buried valley of the Susquehanna, extending from Pittston to Nanticoke. This is the bed of a former glacial stream which has cut down into the coal measures in places, thus cutting out large areas of the upper coal beds. The valley is now filled with sand, and there are numerous pot holes in it, which add an element of uncertainty and danger to the mining.

The Wyoming-Lackawanna basin is deepest (2,200 feet) midway between Wilkes-Barre and Nanticoke. About 4 miles above Pittston, near Lackawanna station, only 100 to 150 feet of the coal measures are left, but northeast from here, several miles above Scranton, the coal measures sink again to a depth of 700 feet, and then rise and spoon out beyond Forest City.

It is difficult to state the number of workable beds, as beds are now being worked in the upper end of the Lackawanna Valley which a very few years ago were neglected and considered unworkable. The splitting of a large coal bed into several smaller beds, which divide and are sometimes separated by as much as 200 feet of rock, renders it impossible to correlate beds in different parts of the field until continuous sections can be made by means of actual mine workings. As the result of measurements of 891 sections by the second geological survey of Pennsylvania, 81.8 per cent of the total coal in the Wyoming basin is or may be considered marketable coal, the remaining 18.2 per cent being interbedded slate, shale, and other refuse. The deposits in this section are particularly free from refuse, and the comparative freedom of this section from plication and folding gives a high percentage of marketable coal.

### EASTERN-MIDDLE FIELD.

The structure of the eastern-middle field is simple, consisting of a succession of anticlines, usually with broad flat crests and shallow intervening basins only about

a H. H. Stock, The Pennsylvania anthracite coal fields: 22d annual rept., 1900-1901, U. S. Geol. Survey, 1901, p. 69.

500 to 600 feet deep, the sides dipping 10° to 40°. This gives a large extent of outcrop, and the comparative shallowness of the basins has been very favorable to mining, so that the field has been extensively developed and its structure quite thoroughly determined. The Mammoth, Buck Mountain, Primrose, Parlor, Portland, and Gamma beds vary in thickness in different localities. The second geological survey of Pennsylvania estimated that from 75 to 77 per cent of the total thickness of coal was marketable.

### SOUTHERN FIELD.

The southern field consists of a number of connected basins which grow gradually deeper from north to south, culminating along the foot of Sharp Mountain in very deep, highly upturned, and greatly contorted measures. The Pottsville conglomerate in this region is very thick, ranging from 1,100 to 1,475 feet. It is made up of coarse materials, and contains a number of valuable coal beds, especially at the western end. At the point where the main field subdivides into the two westwardly extending basins there are 6 Lykens Valley beds in the conglomerate, each 3 to 10 feet thick. The coal measures proper are at least 2,500 feet thick, and 20 different coal beds have been worked. From measurements of 275 sections the second geological survey estimated 72 per cent of the coal as marketable.

#### WESTERN-MIDDLE FIELD.

In the western-middle field the beds incline steeply, the average dip being 35 to 40 degrees. There has been much folding, sliding, and shifting of strata, which has crushed the coal in many places and mixed with it slate and bony coal partings. The coal measures are 1,200 feet thick, and contain from 10 to 12 different beds, many of them of great thickness and with comparatively small intervening barren intervals. The Lykens Valley beds are also found in the conglomerate, or No. 12, and toward the western end of the field these beds are mined; 1,144 sections throughout the field give 23 per cent of refuse in the coal, but it is not safe to estimate more than 75 per cent of the original deposit as marketable coal.

Fire damp is found in many of the deeper mines, particularly in the Wyoming region and in the western end of the Schuykill region. In a number of mines it is present in such quantities that the use of safety lamps is absolutely necessary.

### MINING METHODS.

In each of the anthracite fields there are a number of places where the coal outcrops near the surface, and where conditions are favorable for mining the coal by open-pit methods. The overburden is stripped by hand labor, steam shovel, or wire-rope tramway and the coal quarried out and hauled by incline to the surface, or if the stripping pit communicates with the underground workings the coal may be taken through underground haulage ways to the bottom of the shaft or slope and then hoisted to the surface.

Most of the mines are shaft and slope mines, the slopes being driven in the coal from the outcrop, and the shafts being always vertical and usually so placed as to cut the coal at the lowest possible elevation on the property in question. The room-and-piller system is the one usually used for underground mining, but owing to the deposits being steeply inclined and more or less irregular, the system has to be adapted to meet local conditions in mining the various beds. It is impossible to carry out a typical room-and-pillar system, as in the flat bituminous coal beds. The details of the system under different mining conditions vary so widely that a comparison of mining methods from different districts or localities gives the impression that the coal is mined by several systems having nothing in common. On close inspection, however, the fact is disclosed that they all have three features which are identical:<sup>a</sup> (1) The breasts, or rooms, or working places are all long and comparatively narrow; (2) they are driven nearly parallel to each other; and (3) they are separated by long narrow pillars of coal, broken only by small openings for ventilation.

These three features, which are common to all anthracite workings in Pennsylvania, are the identifying characteristics of the "pillar-andbreast," "pillar-and-room," "post-and-stall," "stoop-and-room," or "bord-and-pillar" system. The geologic peculiarities of the anthra-cite coal beds explain why the mining methods differ so radically in detail from those employed in other beds. Coal beds ranging from 3 or 4 feet up to 70 feet in thickness are worked on dips varying from horizontal to vertical.

From the bottom of the shaft or slope a gangway and a parallel airway are driven in opposite directions from the shaft or slope and along the strike of the bed. From these gangways rooms or breasts are turned either at right angles or obliquely, the angle of turning being dependent upon the dip of the seam.

"Flat workings" is a term applied to those coal beds which vary from horizontal to a dip of about 25°. When the coal bed is flat, it is usually opened by a shaft sunk through the overlying measures. Gangways are driven from the bottom of the shaft, and when they have reached a sufficient distance to permit a thick pillar of coal being left to protect the shaft, breasts are opened from the upper side of each gangway.

Where the inclination is more than 30°, the coal will slide without the use of sheet-iron chutes, and it then becomes necessary to stop up the lower end by a battery, built of logs or heavy planks. This acts as a support for the broken coal and allows the breast to fill to the face with coal, thus giving the miners a broken-coal platform on which to stand while working.

The battery workings may be divided into two general classes: (1) Where the coal is stored in the breast and the rock and refuse taken out through a chute, and (2) where the rock is stored in a breast and the coal taken out through chutes. Details of the various modifications of these systems are given fully by Chance.<sup>b</sup>

a Chance, H. M., Mining methods and appliances used in the anthacite coal fields: Second Geol. Survey of Pennsylvania, 1883, p. 129. b Chance, H. M., loc. cit.

<sup>14355°-</sup>Bull. 115-16-19

In the anthracite mines rotary drills are used and the coal is broken by the use of black powder. Dynamite or giant powder is used largely for rock work and sometimes for driving gangways in coal. Dynamite shatters the coal so badly that it is not used extensively for the mining of coal. The coal is not undercut as a general rule, and it is only recently that special mining machines have been developed for the anthracite field.

Table 50 shows the amount of explosives used in the anthracite fields from 1899 to 1913. It will be noted that the increase in the amount of dynamite used has been about fivefold since 1899, whereas the amount of black powder used has increased only about one-third. In 1909 permissible explosives were introduced into the anthracite mines and in five years the quantity used has increased from 666,807 pounds to 3,323,645 pounds in 1913. The fatalities due to the use of explosives in the anthracite mines are given in Table 49.

Every known form of haulage is to be found in the anthracite mines; the main ones are indicated in Table 54. The number of horses and mules used in the mines has remained practically the same since 1898, averaging about 15,000 per year. The number of steam locomotives used has almost doubled, whereas the number of electric locomotives has increased from 24 in 1898 to 781 in 1913. The number of compressed-air locomotives has increased from 10 in 1898 to 161 in 1913. Cars are usually gathered from the rooms by mules except where the grade is sufficient to run the cars out by gravity. The cars vary in size from 70 to 140 cubic feet and in capacity from  $1\frac{3}{4}$  to 4 tons. They are usually built of wood with iron bands, although steel cars have been introduced in recent years.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The official inspection of coal mines in Pennsylvania was established by an act approved April 12, 1869, applicable only to anthracite mines in Schuykill County. The appointment of the inspector was vested in the governor, and the inspector was required to investigate the cause of every accident resulting in death or serious injury. Mine operators were required to report to the inspector within 24 hours all accidents resulting in death or personal injury. The inspector rendered annual reports to the governor and enumerated therein all accidents in and about the mines.

An act approved March 3, 1870, terminated the services of the inspector appointed under the act of April 12, 1869, and authorized the governor to appoint, upon the recommendation of the examining boards, six mine inspectors—three for the counties of Luzerne (including what is now Lackawanna County) and Carbon and three for the counties of Schuylkill, Dauphin, Northumberland, and Columbia. Annual reports, in which all accidents were enumerated, were rendered to the governor. An act approved April 5, 1870, divided the inspection counties into two districts and authorized the appointment for each district of a clerk, to whom the inspectors were required to render monthly reports of deaths and injuries.

On May 9, 1871, an act was approved requiring coal companies in counties where there was no inspector to furnish a report of all accidents to the auditor general, who was required to publish an annual report and state therein the causes of such accidents. The auditor's report was published under the title of "Mineral Statistics of Pennsylvania." The act of April 25, 1873, transferred the authority to appoint the mine inspectors from the governor to a majority of the board of examiners provided for by the act of March 3, 1870, but the appointive power was again vested in the governor by an act approved May 18, 1878. On June 30, 1885, an act was approved applicable to all anthracite mines employing more than 10 men. The anthracite counties were divided into seven districts and the inspectors were required to render annual reports to the secretary of internal affairs. The number of inspection districts was increased to eight by an act approved June 2, 1891. An act of July 15, 1897, made it unlawful to employ as a miner any person not holding a certificate of competency from the miners' examining board established by the act. An act of July 15, 1897, established a bureau of mines in the department of internal affairs.

An act approved June 8, 1901, effective January 1, 1902, changed the manner of selecting the mine inspectors by making the office elective instead of appointive. The number of elective districts was reduced to 6, but the number of inspectors was increased to 15. It was provided that the inspectors should be elected from among a list of eligibles certified to the secretary of state by the examining board. The inspectors so elected rendered monthly reports to the chief of the Bureau of Mines and also rendered annual reports to the secretary of internal affairs.

An act of April 14, 1903, established the department of mines.

On May 3, 1905, an act was approved increasing the number of districts to 7, and the number of inspectors to 20, and requiring the inspectors to make annual reports to the chief of the department of mines. An act of May 5, 1911, provided for 8 elective districts and 21 inspectors, and an act of June 1, 1915, increased the number of anthracite inspectors to 25.

Under the inspection laws, it is the practice of the operators to report to the district inspectors all injuries causing disability for 6 days or more. The district inspectors, in their reports to the department of mines, omit accidents of a less serious nature, so that only the more serious injuries are published in the annual report of the department of mines. The department has not officially defined a serious injury, and it is left to the descretion of each district inspector as to which of the accidents reported to him by mine operators may be eliminated from his report to the department.

### ACCIDENTS.

Tables 124 and 125 show the total number of men employed and the number of men killed from the beginning of inspection service in 1870 to date. During the period 1870 to 1913, inclusive, 17,716 fatalities occurred in and about the anthracite mines, representing a rate of 3.42 per 1,000 men employed. The amount of coal mined per fatality was 124,968 tons, or there were 8 fatalities per million tons mined.

Table 125 shows the number of fatalities by causes, in conformity with the latest reports of the State mine inspector and so adapted as to conform with the standard form used by the Bureau of Mines. This classification gives much more detail than is ordinarily available, and it is believed will be of material assistance to operators, inspectors, and others, who are making a study of mine accidents, their causes, and their prevention.

Of the total number of fatalities that have occurred during this period, 41.65 per cent was due to falls of roof and coal; 13.56 per cent to mine cars and locomotives; 10.10 per cent to explosives; and 7.59 per cent to explosions of gas. The percentage of fatalities due to explosives in the anthracite mines is practically 5 times that in the Pennsylvania bituminous fields, given in tables relating thereto, whereas the rate per 1,000 men employed is 7 times as high as it is in the bituminous fields of the State.

Since 1869 to the end of 1914 there have been in the anthracite field 80 accidents in each of which 5 or more men have been killed at one time. A complete list of these disasters is shown in the accompanying table.

|                                                                                                                                                                    | N                                                               | umber kill                                                      | ed.                                                                             |

ACCIDENTS IN PENNSYLVANIA ANTHRACITE MINES IN WHICH 5 OR MORE MEN WERE KILLED—Continued.

Since 1903, the Pennsylvania anthracite mines have been operated on a 9-hour working day, and, for comparison with other States in which the mines are operated 8 or 10 hours, Table 40 has been compiled. The table shows that the number of hours worked per year per man in the anthracite field is 1,985, as compared with 2,034 for the bituminous field. The fatality rate in the anthracite field based on the actual number of employees is 3.73, during the 10-year period 1903 to 1913, except 1909, whereas based on the number of 2,000-hour workers it is 3.76. The difference in this instance is slight, but for Ohio, where the hours worked per year are 1,495, the fatality rate

NUMBER OF HOURS WORKED IN AND ABOUT THE PENNSYLVANIA ANTHRACITE MINES AND THE FATALITY RATE BASED ON THE NUMBER OF 2,000-HOUR WORKERS.

a Compiled from annual volumes of Mineral Resources, U. S. Geol. Survey. b Approximate.

based on the actual number of men employed is 2.94, and on the number of 2,000-hour workers is 3.94. The fatality rate in Ohio on this basis more nearly equals the rate in the anthracite field than when based on the actual number of employees. From these tables, comparisons with other States may be readily made. The tables of statistics for the anthracite mines of Pennsylvania follow:

TABLE 124-PRODUCTION, NUMBER OF MEN EMPLOYED, AND NUMBER OF MEN KILLED IN AND ABOUT THE COAL MINES IN **PENNEYLVANIA** (ANTHRACITE), BY CALENDAR YEARS. ALSO TONNAGE MINED FER MAN, AS WELL AS THE NUMBER AND KIND OF MINING MACHINES IN USE.<sup>a</sup>

| gures for total production and all items below horizontal lines sciected from Mineral Resources, U. S. Geol. Survey. Figures in column 4 and all items above horizontal lines in columns 3 and 8 from State mine inspectors' reports. Figures in columns 5, 6, and 7, and averages in columns 9 and 10 prior to 1901, calculated.] |

| 1886<br>1887<br>1887<br>1887<br>1887<br>1889<br>1889<br>1889<br>1889                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                        |

## PENNSYLVANIA (BITUMINOUS). AREA AND DISTRIBUTION OF COAL FIELDS.

The bituminous coal fields of Pennsylvania are in the western and southwestern part of the State, and comprise the northern end of the great Appalachian series of coal measures. The fields include about 14,200 square miles, covering 12 counties and parts of 21 other counties. The structure conforms to the system of Appalachian folding in long northeast-southwest waves, locally modified more or less by minor cross folds. In the northwestern part of the area the strata gently undulate, with extremely slight dips, generally of but a few feet to the mile, but in passing eastward these undulations increase to well-marked folds along the eastern margin of the main body of the coal field.

### CHARACTER OF COAL BEDS.

The bituminous coal fields of Pennsylvania are described by Parker<sup>a</sup> as follows:

The coal-bearing rocks all belong to the Pennsylvania series and have a total thickness in the southwest corner of the State of about 2,600 feet. The great bulk of the coal mined comes from the Allegheny and the Monongahela formations, formerly known as the "Lower" and the "Upper Productive Coal Measures." Below the Allegheny formation is the Pottsville, containing, in the western part of the State, the Sharon and the Mercer coals, which have been worked only in restricted areas. The Allegheny formation, with a thickness of 250 to 350 feet, contains at least seven coal horizons, all of which yield workable coal locally. They are called, beginning at the bottom, the Brookville, Clarion, Lower Kittanning, Middle Kittanning, Upper Kittanning, Lower Freeport, and Upper Freeport coals. It is now definitely recognized that the coals of these horizons do not occur in continuous beds, and in many cases not in exactly the same horizons; yet it is clear that the corresponding geologic horizons mark times of conditions generally favorable for coal formation, and that no coal of wide extent is found at other levels. As a rule, the coal beds are not characterized by details of section, roof, or floor by which they can be clearly recognized, except over limited parts of the field. No one of them is continuously workable, but the Lower Kittanning and the Upper Freeport coals are widely workable, and the Lower Freeport has a splendid development over several counties in the northeast part of the field. The Brookville or A coal is of workable thickness in spots over a large part of the marginal belt of the coal measures, especially in Jefferson, Clearfield, Center, Cambria, and Somerset counties. The Clarion or A' coal reaches workable thickness in about the same belt, though the two are seldom of workable thickness in the same section. Both of these coals are apt to be impure when thick. The lower Kittanning or B coal is the most persistent, uniform, and reliable of the Allegheny coals, although it is thinner than the Freeport coals, seldom exceeding a thickness of 4 feet. It is exposed in workable thickness and purity in 11 of the counties. The Middle and the Upper Kittanning horizons, C and C', contain but little workable coal, though the Upper Kittanning shows cannel coal at a number of points and stands fourth in productivity. The Lower Freeport coal, D, is finely developed in Clearfield, Jefferson, Indiana, and Cambria counties-in the well-known Moshannon (Clearfield), Reynoldsville-Punxsutawney, and Barnesboro-Patton basins. Over most of the rest of the territory this seam is either worthless or of too low grade for competition in the present market. The Upper Freeport or E coal is a variable and complex bed, extending in gross workable thickness over most of its area, although over a considerable

a Parker, E. W., Coal: Mineral Resources of the United States for 1910, U.S. Geol. Survey, pt.2 p. 195.

part of this territory it is too much broken up and too impure for profitable mining. It appears to be entirely absent in some localities.

As a whole, the Allegheny formation yields about 40 per cent of the total output of bituminous coal in the State.

For about 600 feet above the Upper Freeport bed occurs the Conemaugh formation or "Lower Barren Measures." It contains six or more coals, which, however, are workable only in very restricted areas, their best development being found in the Berlin Basin in Somerset County.

Just above the Conemaugh formation lies the Pittsburgh coal, the most uniform in quality and thickness, and for a given area the most valuable coal bed in the bituminous field of Pennsylvania. Although not of as high a grade as the best Allegheny coals to the east, and although varying greatly in quality from east to west, on the whole the Pittsburgh coal, on account of its thickness, its regularity, its high grade, its adaptability for the production of coke and illuminating gas, has long been the most famous bituminous coal bed in America. It is confined to the southwestern part of the State. The bed gives 9 feet of available coal over large areas, and seldom runs under 4 feet. Above the Pittsburgh coal occur the Redstone, Sewickley, Uniontown, and Waynesburg coals, which are of good workable thickness locally, but in the presence of the great Pittsburgh coal are but little mined.

### METHODS OF MINING.

The earliest records of the United States Geological Survey show that bituminous coal has been mined in Pennsylvania since 1840. Most of the bituminous coal mines of Pennsylvania are opened by drift from the outcrop, or by a gentle slope down the dip of the bed. There are but few relatively deep mines as compared with the deep coal mines of Europe, the anthracite fields of Pennsylvania, or the metal mines. In the earlier years of the industry many of the mines were opened by single entry, but in recent years the larger operations and newer mines are opened by double or triple entry. The room-and-pillar system is used throughout the bituminous fields of Pennsylvania.

In 1896 about 12 per cent of the coal was reported as being mined by machines. The amount of coal produced by machines has steadily increased until in 1914 it was 53.8 per cent. Shooting off the solid is not extensively practiced, the total amount of coal thus produced being less than 3 per cent. About 35 per cent of the coal is reported as being mined by hand. In 1914, there were 6,326 machines in operation.

Table 54 shows the increase in mechanical haulage in the bituminous mines from 1899 to the close of 1913. In 1899 there were 122 electric locomotives in operation and in 1913, 1,933. The number of compressed-air locomotives has also increased from 13 in 1899 to 168 in 1913. The number of mules and horses used in underground haulage has practically doubled since 1898. The amount of black powder (Table 50) used in the bituminous coal mines has a little more than doubled since 1899, whereas the use of dynamite increased gradually from 1899 to 1907. Since 1907 the amount of dynamite used has decreased rapidly, and has largely been replaced by the use of permissible explosives.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The first law providing for the inspection of bituminous mines in Pennsylvania, approved April 18, 1877, applied to all mines employing more than 10 men, except mines which did not generate fire damp, black damp, or other dangerous or noxious gases. A board of examiners was provided for the purpose of examining applicants for appointment as mine inspector. From a list of eligibles thus established the governor was authorized to appoint three inspectors, one for each of three districts into which the bituminous coal fields were to be divided by the examining board. Each inspector was required to examine all mines in his district as otten as possible, to make a record of such examinations, showing the number of employees, number of deaths and injuries in and about the mines, and to file a record thereof each month in the office of the secretary of internal affairs, to be included by the secretary in the annual report of his department. Operators were required to notify the district inspector of all fatal and serious accidents, and on receiving such notice the inspector was required to visit the mine and investigate the cause of the accident.

An act approved May 25, 1878, repealed the provision in the law of April 18, 1877, which exempted from the inspection law those mines which did not generate fire damp, black damp, or other noxious or dangerous gases. The law of June 3, 1881, increased the number of inspection districts to four, and the number was further increased to six by an act approved June 13, 1883. The latter law also required the inspectors to make annual reports to the secretary of internal affairs.

On June 30, 1885, the examining board was authorized to divide the bituminous coal fields into eight districts, the governor to appoint a mine inspector for each district. An act approved May 15, 1893; authorized the examining board to further divide the bituminous fields into districts of not less than 60 mines nor more than 80 mines, and the governor was authorized to appoint an inspector for each district established by the board.

The number of inspectors was increased in 1894 to 10, in 1901 to 12, in 1903 to 15, in 1905 to 16, in 1906 to 18, in 1907 to 20, in 1909 to 21, in 1911 to 25, in 1912 to 26, in 1913 to 28, and in 1915 to 30.

Mine foremen were required to make monthly reports to the district inspector showing all accidents resulting in personal injury to mine employees. On June 9, 1911, an act was approved by which the State was divided into 25 bituminous districts and the chief of the department of mines was authorized to increase the number of districts with the approval of the governor. The district inspectors were directed to render both monthly and annual reports to the chief of the department of mines, and to enumerate all accidents in and about the mines. Under the inspection laws it is the practice of the operators to report to the district inspectors all injuries causing disability for 6 days or more. The district inspectors, in their reports to the department of mines, omit accidents of a less serious nature, so that only the more serious injuries are published in the annual report of the department of mines. The department has not officially defined a serious injury, and it is left to the discretion of the district inspectors as to which of the accidents reported to them by mine operators may be eliminated from their reports to the department.

### ACCIDENTS.

Tables 126 and 127 show the production of coal, number of men employed, and the number of fatalities in and about the bituminous coal mines of Pennsylvania. The record of the number of men employed and the fatalities is complete from the beginning of inspection service in 1877 to the end of 1913. The fatalities, as shown in the accompanying tables, have been compiled from the annual volumes of the State mine inspectors' reports. In a few instances slight changes have been introduced, owing to the fact that some of the earlier inspectors' reports included accidents at coke ovens, and others included deaths due to natural causes. In all cases where sufficient information was given, all fatalities that occurred which were foreign to the mining operations have been excluded from the tables.

During the 37-year period 1877 to 1913, inclusive, there were 9,473 fatalities attributed directly to the coal-mining industry. This represents a fatality rate of 2.87 per 1,000 men employed. The amount of coal mined per fatality, during the entire period, was 271,832 tons, or there were 3.68 fatalities per million tons mined. Since 1879, there have been 37 mine disasters in each of which 5 or more men were killed at one time, the total fatalities thus represented being 1,268, or about 13 per cent of the entire number since 1877. Of the total number of fatalities, 56.93 per cent was due to falls of roof; 15.33 per cent to mine cars and locomotives; and 13.82 per cent to gas and dust explosions. The fatality rate due to explosives is exceedingly low, being only 1.95 per cent of the total, as compared with 24.81 per cent in Kansas, 19.44 per cent in Indiana, 13.47 per cent in Illinois, and 3.27 per cent in West Virginia.

a Not included in State inspector's tabular statement of mine fatalities.

Table 127 showing the fatalities by causes has been amplified from the bureau's regular form by subdivisions under "Falls of roof and coal," "Gas and dust explosions," "Miscellaneous underground," and "Miscellaneous surface." This is in conformity with the State inspector's latest reports, and in no way does it conflict with the bureau's classification in comparing fatalities by causes with those of other States. The main headings have been maintained as indicated in the table by numerals; the subheadings are indicated by letters. This classification gives operators, inspectors, and others an opportunity to study the mine accidents more in detail.

Since 1903 practically one-half of the men in the bituminous coal mines of the State have been on an 8-hour basis, as shown in the accompanying table, the remainder being 9 and 10 hour men. In order to make a true comparison of Pennsylvania with other States Tables 40 and 41 have been compiled showing the fatality rate based on the actual number of men employed and also on the number of calculated 2,000-hour workers. The number of hours worked per year per man in the Pennsylvania bituminous fields is 2,034, so that there is but slight variation in the fatality rate based on the actual number of employees during the 10-year period 1903 to 1913 (except 1909) which is 3.39 per 1,000, and that based on the number of 2,000hour workers, which is 3.34. The number of hours worked in Virginia is 2,447, in West Virginia 2,132, and in Ohio 1,495. With such varying periods of exposure to the hazards of the mining industry, it is essential that the time factor be taken into consideration.

NUMBER OF HOURS TO THE WORKING DAY, BY YEARS, IN AND ABOUT THE PENNSYLVANIA BITUMINOUS MINES.4

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 31<br>28<br>28<br>28<br>28<br>28<br>28<br>28<br>28<br>28<br>28<br>28<br>28<br>28 |   |

a October to Dec. 31 only.

### TENNESSEE.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Tennessee are from 50 to 70 miles wide and extend northeast and southwest across the State from Chattanooga on the south to Middlesboro, Ky., on the north. The coal-bearing areas comprise about 4,400 square miles, of which it is estimated about 47 per cent may contain coal of economic value.

The coal fields may for convenience be divided into a northern and a southern division. The northern area, which produces most of the coal mined, may be subdivided into the Jellico Basin, comprising parts of Campbell and Scott counties; the Wartburg Basin, including parts of Morgan, Anderson, and Scott counties; and the Middlesboro Basin, including Campbell and Claiborne counties. The southern division, which is known as the Chattanooga district, includes the Sewanee Basin, a part of the Cumberland plateau, the Walden Ridge Basin, and the Lookout Basin.

### CHARACTER OF COAL BEDS.

The coal for the most part is bituminous throughout the State, but there is a limited area of cannel coal in the Jellico district. The beds, though reasonably uniform in thickness over limited areas, are relatively thin and the coal is variable in quality. The coal beds are nearly horizontal in most regions of extensive development except for local folds and rolls. The coals in the northern districts are a good grade of steam and domestic fuel, whereas in the southern districts the Sewanee coal is better adapted for coking purposes.

The Jellico coal in the Jellico district varies from 3 to 4 feet and the Blue Gem coal from  $1\frac{1}{2}$  to 2 feet. Many mines are operated in these two beds, but most of them are mines with a small output. The coal in the Middlesboro Basin varies from 4 to 5 feet in thickness and is extensively mined in Mingo Hollow and elsewhere. The coal in the Wartburg Basin is variable in thickness and quality, ranging from 3 to 5 feet in thickness.

The coal in the Chattanooga district is nearly horizontal except over local areas, as along Walden Ridge, where it is greatly disturbed. The Sewanee coal ranges from about  $2\frac{1}{2}$  to  $4\frac{1}{2}$  feet in thickness and is generally found badly crushed and contorted and sometimes intimately mixed with "rash," which in this crushed form is very difficult to separate from the coal.

### MINING METHODS.

The earliest records for the production of coal in Tennessee are those of 1840, during which year 558 tons were mined. The production has gradually increased and in 1913 amounted to 6,903,784 tons. The mines are practically all opened by drifts, a few by slopes, and only two by shafts, and the coal is mined largely by the room-and-pillar system. Few of the mines in the State are large producers and in many of them mule haulage alone is used. Roof conditions average fairly good when proper precautions are taken in timbering. About 57 per cent of the mines are ventilated by fans and about 30 per cent by furnaces. Most of the mines are wet and there is little chance for dust to gather, but some of them are very dry and considerable dust is produced in mining the coal. In a few of the dry mines adequate sprinkling cars are provided, but in two or three dry mines no attempt is made to sprinkle, and the mines are dangerously dusty.

There were 8 coal mining machines in use in 1897 and 252 in 1913. The amount of machine-mined coal for the latter year was 26.7 per cent of the total output, or 7,312 tons per machine. In 1912, 32.9 per cent of the coal mined was shot from the solid and in 1913, 37 per cent was mined by this method; 36.3 per cent was mined with hand picks.

As early as 1891 an agreement between mine operators and miners prohibited shooting coal off the solid, but this contract is too frequently broken in practice.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The first mine-inspection law of Tennessee was passed April 7, 1881. It required that all accidents at mines should be reported to the inspector of the district in which the mine was located, and, if fatal. to the county coroner. The enforcement of the law was intrusted to the geologist of the bureau of agriculture, statistics, and mines, with power to employ such assistants as were necessary. The inspector was required to preserve in his office a record showing the cause of all accidents in the mines. An act approved March 29, 1887, consolidated the inspection service and placed it under the jurisdiction of one mine inspector, whose office was maintained at Chattanooga, and to whom all accidents were to be reported by the mine operators. The inspector rendered annual reports to the governor on January 1 of each year. On March 23, 1891, an act was approved by which the office of mine inspector was consolidated with the bureau of labor and mining statistics, under the supervision of the commissioner of the bureau of labor, statistics, and mines. The scope of the work of the new bureau was made to include the inspection of all mines, collieries, mills, and factories, and all accidents at such establishments resulting in loss of life or serious personal injury were to be reported to the commissioner of the bureau, the commissioner to render annual reports to the Governor.

An act of April 3, 1903, separated the mine inspection service from the bureau of labor and mining statistics, established the office of chief mine inspector, and authorized the governor to appoint one chief inspector and two district mine inspectors, the chief to specify the counties which should compose the two districts. The act applied to both coal and metal mines, and the chief inspector was required to render annual reports to the governor, and to enumerate therein all accidents, both fatal and nonfatal.

### ACCIDENTS.

Tables 128 and 129 show the production, number of men employed, and number killed in and about the coal mines of Tennessee as compiled from the reports of the United States Geological Survey and the State mine inspector's reports. Continuous records of fatalities have been kept since 1891 to the end of 1913. During this period there were 859 fatalities, representing a rate of 4.30 per 1,000 men employed. The amount of coal produced per fatality was 119,280 tons, or there were 8.38 fatalities per 1,000,000 tons mined. Of the total number of fatalities 42.03 per cent was due to falls of roof; 39.47 per cent to gas and dust explosions, whereas mine cars and locomotives caused 5.70 per cent, and explosives a like percentage.

FATALITIES IN TENNESSEE COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1891 TO 1913, INCLUSIVE.

COAL-MINE ACCIDENTS IN TENNESSEE IN WHICH 5 OR MORE MEN WERE KILLED.

|      | Date.  | Name of mine. | Location of mine. | Nature of accident. | Number<br>killed. |
|------|--------|---------------|-------------------|---------------------|-------------------|
| 1901 | May 27 | Richland      | do                | Mine explosiondo    | 20                |
| 1902 | May 19 | Fraterville   | Coal Creek        | do                  | 184               |

Since 1895 there have been five disasters in which 327 men were killed. A list of these disasters is given in an accompanying table.

Since 1903 slightly over one-half of the men have been employed at the mines on a 9-hour basis. During the 10-year period 1903 to 1913, excepting 1909, the men were employed 2,100 hours during the year. The fatality rate based on the actual number of employees as shown in Table 40 is 3.40, but when computed on the basis of equivalent 2,000-hour workers becomes 3.23. By comparing Tennessee with Ohio on the basis of actual number of employees, it will be noted that the Tennessee rate is much higher, being 3.40 as compared with 2.94 for Ohio. The men in Ohio were employed 1,495 hours per annum, so that reducing the fatality rate to 2,000hour workers the Tennessee rate is 3.23 as compared with 3.94 for Ohio. A similar comparison may be made with other States in tables 40 and 41.

NUMBER OF HOURS TO THE WORKING DAY, BY YEARS, IN AND ABOUT THE COAL MINES OF TENNESSEE.«

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 8-hour day.                 |                                        | 9-hour day.                      |                                                    | 10-hour day.                      |                                                    | Men em-<br>ployed                                 | Total                                                             |

#### TEXAS.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing rocks that carry bituminous coal comprise an area in northern Texas a little more than 200 miles long and 45 miles wide, but coal beds are limited to an area of about 8,200 square miles in Wise, Palo Pinto, Erath, and McCulloch counties. The structure of this field is a gentle monocline, the beds dipping northwest about 100 feet to the mile.

In the southern part of the State, near Eagle Pass, Maverick County, is a Cretaceous coal bed which is mined to some extent.

The Tertiary lignite beds extend entirely across the State from Mexico to Arkansas; the known workable areas cover about 2,000 square miles, and there are about 53,000 square miles that may contain workable beds. Of the total amount of coal mined, about onehalf is lignite.

#### CHARACTER OF COAL BEDS.

In the bituminous field there are three workable beds, but the ones most largely mined are No. 1, which is the lowest, and No. 7, which is the highest. These coals are of Carboniferous age. No. 1 is continuous for at least 80 miles, and in Wise County is 14 to 26 inches thick; in Park County, 18 to 26 inches thick; in Palo Pinto County, 26 inches thick; and in Erath County, 28 inches thick.

With few exceptions the coal bed has a strong shale roof and shale floor. The No. 7 bed has the same structural features as No. 1 and is continuous for about 250 miles. It is 12 to 42 inches thick. Near Cisco the bed is 33 inches thick.

In the lignite field the beds that are worked are thick, generally ranging from 6 to 8 feet.

#### MINING METHODS.

The earliest coal-production report for Texas was in 1884, when 125,000 tons of coal was mined. The production for 1913 was 2,429,-144 tons. Of the 48 mines in operation in 1913, 8 were opened by slopes, and 43 were opened by shafts varying from 45 to 418 feet in in depth. About one-half were opened by single entry and one-half by double entry. One-third of the mines are operated by the longwall method, and two-thirds by the room-and-pillar method. Steam hoists are used at practically all of the mines. Electric and mule haulage are used underground, while 3 mines were using gasoline motors.

The majority of the mines are ventilated by fans and only two by furnaces. In 1897, there were 5 mining machines, and in 1913, 24 machines. In 1913, 61.5 per cent of the coal was mined by hand and 4.2 per cent by machines, and 25 per cent was shot off the solid.

#### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The law enacted by the Texas Legislature April 30, 1907, authorized the governor to appoint a State mine inspector for all coal mines, upon the recommendation of an examining board, also provided for by the act. The first inspector was appointed September 30, 1909, and was directed to see that the provisions of the mining law were properly enforced. The law, however, did not require mine operators to report accidents to the State inspector.

#### ACCIDENTS.

Tables 130 and 131 show the production of coal and the number of men employed in the mines of Texas since 1889. Complete accident records, however, were not kept prior to 1909. During the 5-year period 1909–1913, there were 25 fatalities reported in and about the coal mines of Texas, representing a rate of 1.06 per 1,000 men employed. The amount of coal mined per fatality was 412,359 tons or 2.43 fatalities per million tons mined. Texas has been free from serious mine disasters.

FATALITIES IN TEXAS COAL MINES, BY PRINCIPAL CAUSES, DURING 5 YEARS 190 TO 1913, INCLUSIVE.

|                                                                                          | Number killed.   |                               |                             |  |

Since 1903, practically one-half of the men in the State have been employed on an 8-hour basis. Tables 40 and 41 have been compiled for comparative purposes. It will be noted that the employees of Texas worked 2,101 hours per year. The fatality rate for the period 1903 to 1913, inclusive, except 1909, based on the actual number of employees, is 1.08 per 1,000 men employed, and based on the 2,000hour days becomes 1.05. This rate may be readily compared with rates of other States by referring to Table 41. The tables of statistics for the State follow:

#### NUMBER OF HOURS TO THE WORKING DAY, BY YEARS, IN AND ABOUT THE COAL MINES IN TEXAS.a

#### UTAH.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing areas of Utah comprise about 10,570 square miles, which are roughly divisible into three fields. The Wasatch field is the largest, and includes parts of Carbon, Emery, Grand, Uinta, and Wasatch counties. The next largest field is in the southern part of the State, and occupies the larger part of Garfield, Iron, and Kane counties. The other field is in Summit County, in northern Utah, and is relatively unimportant, although mining operations at Coalville have been carried on since 1870. The greatest amount of development has been in Carbon and Emery counties, Carbon County producing about 90 per cent of the coal mined in the State. The principal districts in Carbon County are Sunnyside, Kenilworth, Castlegate, Pleasant Valley, Spring Canyon, and Hiawatha-Black Hawk.

### CHARACTER OF COAL BEDS.

The coal and the associated rocks in the Wasatch field have been subjected locally to serious folding and displacements, but in general the deformation has been uniform, resulting in regular structure and low dips. In western Carbon County and in Emery County the coal-bearing rocks are highly folded and cut by numerous faults, which render mining expensive and uncertain. But in the eastern part of the developed field the coal either lies nearly flat or dips only  $3^{\circ}$  to  $7^{\circ}$ .

The beds as a rule are thinner in the eastern than in the western part of the field. The coal in two beds, both of which are mined, in the Sunnyside district is about 14 feet thick, whereas in some of the western districts, as at Kenilworth and Hiawatha, the coal of a single bed ranges from 15 to 20 feet thick.

The coal beds in general are not uniform in thickness over large areas and in many places are known to be very lenticular. Rolls and "horsebacks" are common in some districts and in many places the latter oftentimes cut out a considerable part of the coal bed.

The southern coal field has never been exploited on a commercial scale, but the coal ranges in thickness from 4 to 8 feet.

#### MINING METHODS.

Coal was first mined on a commercial scale in Utah in 1870, when 5,800 tons was produced. The production in 1913 was 3,254,828 tons, and in 1914, 3,103,036 tons was mined. Most of the mines are opened by drifts, entries, or slopes, and the coal is mined by the room-and-pillar method. The principal mines are worked on the double-entry system and at one of the typical mines the rooms are 24 feet wide by 400 feet long, separated by 40-foot pillars. Wherever the coal extends 7 to 9 feet in thickness the excess is left on the roof and is taken down only when the pillars are drawn. Most of the mines are comparatively dry and the coal yields considerable dust when mined. The State mining law requires extensive sprinkling systems in such mines and most of the operators rigidly observe the law. Coal is rarely shot from the solid and is usually undercut (by machine or hand pick) or sheared before being shot. Electric shot-firing systems are in common use.

Coal-mining machines were first introduced into Utah in 1896 and in 1913 there were 50 machines in operation. During 1913 the machine-mined coal equaled 19.2 per cent, coal mined by hand-pick methods equaled 74.2 per cent, and that shot from the solid equaled 4.2 per cent.

#### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

An act of Congress approved March 3, 1891, authorized the President of the United States to appoint a mine inspector for each Territory in which the aggregate annual production of coal exceeded 1,000 tons. Under the provisions of this law the first mine inspector for Utah was appointed August 23, 1892. Section 15 of the act provided that a full and written report of every fatal accident should be made to the mine inspector within 10 days after such death should occur. Annual reports for fiscal years ending June 30 were rendered to the Secretary of the Interior. Utah was admitted as a State in January, 1896, and under a law approved April 5, 1896, the first State inspector was appointed April 6. The State inspection law covered all coal and hydrocarbon mines employing more than six men, and the inspector was required to examine all such mines at least quarterly, and to render an annual report to the governor. Mine operators were required to report to the inspector every fatal accident within 10 days after the accident, and every nonfatal accident involving disability for one week or more. An act approved March 20, 1911, authorized the employment of a deputy inspector and repealed the provision of the previous laws limiting the inspection service to mines employing more than six men.

All accidents reported to the inspector by mine operators are published in the inspector's annual report, but only those involving disability for at least 30 days are classified as serious accidents.

#### ACCIDENTS.

Tables 132 and 133 show the number of men employed, the production of coal, and the number of fatalities as compiled from the best records available. The State mine inspectors' reports show fatal accidents back to 1892, and are complete from that year to date. The total number of men killed during the period 1892 to 1913, representing 22 years, was 355 or 9.25 fatalities per 1,000 FATALITIES IN UTAH COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1892 TO 1913, INCLUSIVE.

| Location of mine    | Schofield.                     |
| Nature of accident. | . Powder and mine explosion.   |
| Number killed       | .200.                          |

;

men employed, of which number 57.75 per cent was due to gas and dust explosions. This includes the explosion at the Winter Quarters mine in 1900, in which 200 were killed at one time. This one disaster represents 56.34 per cent of the total fatalities during the 22-year period. Falls of roof represent 26.76 per cent, or 2.48 fatalities per 1,000 men employed. The quantity of coal produced per fatalitity was 89,252 tons, or 11.20 fatalities per million tons of coal mined.

Since 1903, the mines have been operated on an 8-hour basis, and for comparison with States having 9-hour and 10-hour working days, Tables 40 and 41 have been compiled. It will be noted that during the period 1903 to 1913, except 1909, the men were employed 2,109 hours per year. The fatality rate based on the actual number of employees is 4.15 per 1,000, whereas, when reduced to the uniform basis of 2,000-hour workers, it becomes 3.93, which compares favorably with the rate in Ohio, where the rate on the same basis is 3.94. Similar comparisons with other States may be made by reference to Table 41. The tables of statistics for the State follow.

e Sept. 28 to Dec. 31. è Probably originatod by an explosion of powder magazine underground. ¢ Inspector's report gives detailed description of 9 fatalities, while one table in his report shows 10 giving no details.

#### VIRGINIA.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing area of Virginia comprises about 1,550 square miles in the Appalachian region, 200 square miles in the Brushy Mountain fields, and 150 square miles in the Atlantic Coast region. Of the latter, the larger part is in the Richmond Basin. This basin extends in a north and south direction through parts of Goochland, Henrico, Powhatan, and Chesterfield counties. It is about 30 miles long, with a maximum width of 10 miles, and its eastern edge is about 13 miles from Richmond. There are also one or two other isolated fields in the Atlantic coast region, but mining in these has been of little importance.

The Brushy Mountain fields include long narrow strips of coalbearing rocks nearly across the State. These rocks are of lower Carboniferous age and are some of the oldest coal-bearing strata known in this country. Some of the coal is of the semianthracite rank.

The Appalachian region includes a large area in the southwestern part of the State, with the principal mines in Wise, Russell, Tazewell, and Lee counties. More than one-half of the coal mined in the State comes from Wise County. The coal-bearing rocks lie in a broad, flat, synclinal trough lying between the southeastern edge of the coal field and Pine Mountain. In the middle of the trough the beds are generally flat, except where they are disturbed by small folds and faults. On the edges of the trough the beds are strongly tilted, in some places even standing vertical.

#### CHARACTER OF COAL BEDS.

The coal in the Richmond Basin is a bituminous coking coal. The coal beds are steeply inclined and are 4 to 30 feet thick, and in a number of places have been cut by intrusions of diabase, producing natural coke. It has been estimated by Shaler and Woodworth that at a distance of one mile from the outcrop the depth of the beds is 2,500 feet, and it is possible that the beds may extend to a depth of 4,000 feet. The coal beds are broken by faults that make systematic mining difficult.

The coal beds in the Brushy Mountain fields range from 3 to 12 feet in thickness, but the beds contain many partings of shale which make mining expensive and the products of the mines difficult to market. Although desultory mining has been done on these coal beds for a long time, only a little coal has reached the market.

In the main bituminous field the coal beds are much more numerous and valuable. In Lee County 12 beds of coal are of workable thickness, ranging from  $2\frac{1}{2}$  to 6 feet thick. In the Big Stone Gap district the most important coal bed is the Imboden, which ranges from 4 to 13 feet in thickness. There are also a number of beds from 4 to 8 feet thick lying above the Imboden.

On Toms Creek the Upper Banner coal, ranging from 5 to 8 feet thick, is the most important bed. This bed has a shale roof and a hard shale floor.

In Dickenson County the coal beds below the Gladeville sandstone are thin, but above that sandstone 10 beds are recognized, which range in thickness from 2 to 12 feet. The Lower Bolling bed is 4 feet thick with shale roof and clay floor. The Glamorgan bed is  $4\frac{1}{2}$ feet thick with shale roof and shale floor. The Pardee bed is about  $9\frac{1}{2}$  feet thick.

#### MINING METHODS.

Coal was first mined in the Richmond Basin in 1750. In 1789 regular shipments were made. Production records begin with 1822 with 5,400 tons. The larger mines are opened by slopes and vertical shafts, the latter being 400 to 500 feet deep. In the earlier days colored labor was employed under the supervision of English and Welsh miners, and the mining systems were largely adapted from English practices. In recent years Hungarian and colored labor is employed, largely under the direction of local or Pennsylvania managers. With the development of the southwestern Virginia field the Richmond Basin remained practically dormant after 1883. Renewed activity has prevailed during the last 4 years.

As in West Virginia, the room-and-pillar method of mining prevails largely throughout the Appalachian region with practically all of the mines opened by drift entries. In 1887 there were only 8 mining machines in operation, but in 1913 there were 187 machines, producing 47.6 per cent of the coal; 19.7 per cent was mined by hand, and 32.6 per cent shot off the solid. The production per man in 1913 was 964 tons.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The mine-inspection service of Virginia was established in accordance with an act approved March 13, 1912, applying to all coal mines in which five or more persons were employed in a period of 24 hours. The appointment of the inspector was vested in the commissioner of the bureau of labor and industrial statistics, to whom the inspector was required to render annual reports for years ending June 30. Mine operators were required to report to the inspector all accidents causing loss of life or serious personal injury, stating the cause of such accident, and the inspector, if he deemed it necessary from the facts reported, was required to visit the scene of the accident and render such assistance and advice as he deemed necessary for the future safety of the men.

No rules have been adopted by the Bureau of Labor as to what constitutes a serious injury such as the law requires shall be reported to the inspector, but all accidents of which the inspector receives notice are included in his annual report to the commissioner.

In 1915 one coal-mine inspector was employed.

#### ACCIDENTS.

Tables 134 and 135 show the production of coal beginning with 1822, the number of employees beginning with 1888, and the number of fatalities from 1909 to date. Although Virginia was one of the first States to produce coal, yet systematic records of accidents in that State have not been kept until recent years. There have been a number of serious mine explosions, extending as far back

FATALITIES IN VIRGINIA COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1909 TO 1913, INCLUSIVE.

as 1839, as shown in the accompanying list. During the five years, 1909 to 1913, for which continuous records are available, there have been 251 fatalities, representing 6.37 fatalities per 1,000 men employed. The quantity of coal produced per fatality was 138,644 tons, or 7.21 fatalities per million tons of coal mined. Of the total number of fatalities during the 5-year period, 52.19 per cent was due to falls of roof-and-pillar coal, 12.75 per cent to mine cars and locomotives, and 9.96 per cent to gas and dust explosions.

Practically all of the men employed in and about the coal mines in Virginia are on a 10-hour basis, hence to permit comparisons with States on the 8-hour or the 9-hour basis, Tables 40 and 41 have been compiled. The number of hours worked per man a year in Virginia is 2,447 as compared with 2,132 hours in West Virginia, and 1,495 hours in Ohio. In order that true comparisons may be made with reference to the hazard of the mining industry, the time element has been taken into consideration and rates worked out on the basis of the number of 2,000-hour workers, as shown in Tables 40 and 41. Based on the actual number of employees, the rate for the 4 years 1910 to 1913 is 6.74 per 1,000. This reduced to the basis of 2,000hour workers becomes 5.26 per 1,000, as compared with 5.18 for West Virginia, and 3.94 for Ohio. Table 41 shows figures for the other States worked out on a similar basis, so that comparisons may be readily made. The tables of statistics for the State follow.

#### WASHINGTON.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Washington comprise an area of about 1,800 square miles in the northwestern part of the State. They may be grouped into four fields, as follows: North Puget Sound, including Whatcom and Skagit counties; south Puget Sound, including King and Pierce counties; Roslyn Basin, in Kittitas County; and the southwestern field, including Lewis and Cowlitz counties. King, Kittitas and Pierce counties are the principal producers.

The north Puget Sound field extends from the coast south of Bellingham northeastward to the foot of Mount Baker. It is the south limb of a great syncline. The coal beds dip to the northwest at varying angles, ranging from 35° near the coast to 90° at Cokedale and 45° at Glacier. The quality of the coal ranges from coking bituminous coal at Cokedale and Blue Canyon to anthracite at Glacier.

The south Puget Sound field is characterized by a series of parallel folds, usually in a north-south direction. The principal mines at Wilkeson and Carbonado are on the west slope of an anticline, where there are a number of overthrust faults. The structure in this field is complicated by folding and faulting and the intrusion of igneous rocks.

The Roslyn field, in Kittitas County, is a more regular basin, with a slight pitch to the southeast. The dip of the coal-bearing rocks varies from  $10^{\circ}$  to  $20^{\circ}$ , and the basin is free from faults.

The southwestern field is in general a broad, flat basin, but on the east side, next the Cascade Range, the coal beds are badly covered by lava flows. Here the coal is of low rank, being classed generally as the lowest grade of subbituminous coal.

#### CHARACTER OF COAL BEDS.

The coals of Washington vary from lignite through semibituminous to bituminous coking coal. In a number of the districts the coal produces a large amount of slack or fine coal when mined.

Near Bellingham the coal bed that is now worked is 14 feet thick, whereas at Cokedale there are beds 20 feet thick. Gas is prevalent in these mines. The Blue Canyon bed has an average thickness of 7 feet, and at Glacier it is about 6 feet thick, but badly crushed and distorted.

The coal beds in the South Puget Sound field are more numerous, but the strata are so disturbed that coal beds can seldom be identified from mine to mine, even though the properties are contiguous and in some cases the mine workings connect. The center of production in King County is about Black Diamond. The principal beds here are the Upper McKay, which ranges from 4 feet 4 inches to 4 feet 9 inches, and the Lower McKay, which is 4 feet 7 inches to 6 feet 3 inches in thickness. At New Castle there are four productive beds, varying from 4 to 12 feet in thickness, some of which have been worked down the dip to a depth of about 2,000 feet. At Renton there are two beds, varying from  $7\frac{1}{2}$  to 8 feet in thickness. The most important producing area in Pierce County includes the mines on Carbon River from Wilkeson on the north to Montezuma on the south. At Wilkeson there are three coal beds, averaging each about 6 feet thick. At Carbonado at least 10 coal beds, which range in thickness from 2 feet to more than 8 feet, have been worked. The Wingate bed, about 5 feet thick, is the best in the mine. The Carbonado mine has considerable gas, especially on the west side of Carbon River.

In Kittitas County the mines are gaseous, one disastrous explosion occurring during 1910, in which 10 men lost their lives. Another explosion occurred in 1902. At Roslyn coal is being mined from beds 4 feet 6 inches thick from a shaft 604 feet deep. The roof consists of shale. At Clealum, in the same district, coal is being mined from a bed 4 feet 2 inches thick at a depth of 250 feet.

### MINING METHODS.

The coal beds are faulted and upturned in many sections, so that it is necessary to mine coal from steeply inclined seams. The mines are opened by shafts, slopes, and drifts. In the Roslyn field the beds are very dry and require sprinkling to prevent the accumulation of dust. The double-entry room and pillar systems of mining are used. At Carbonado the mines are opened by slopes and drifts, some of which extend nearly 2 miles into the mountain side.

A number of the larger collieries in Washington have opened their mines by slopes and the coal is mined by the pillar-and-breast system, about 90 per cent of the coal being extracted. In the northern field the coal beds are opened by shafts and drifts and in some cases the coal seams are gaseous.

In 1896 there were three mining machines in use, producing only 3 per cent of the coal. The number of machines remained about the same until 1909, when there were 18 machines, and in 1913 there were 63 machines, producing 7.2 per cent of the total coal. Shooting off the solid is used for more than one-third the total production.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

An act approved November 28, 1883, effective January 1, 1884, authorized the governor of the Territory of Washington to appoint an inspector of coal mines for all mines employing more than 10 men. In addition to rendering an annual report to the governor, the inspector was required to make a special report on all accidents

14355°—Bull. 115—16—22

causing loss of life or serious bodily injuries. Operators were required to notify the inspector and coroner of all fatal accidents, and upon such notice an investigation was conducted to determine the cause of the accident. The act of February 4, 1886, required operators to notify the inspector of all serious accidents as well as fatal accidents.

On February 2, 1888, an act was approved by which the Territory was divided into two inspection districts, with an inspector for each district appointed by the governor. The State legislature enacted a law which was approved March 5, 1891, relating to the inspection of coal mines, but the requirement as to the reporting of fatal and serious accidents was not changed. The inspectors were appointed by the governor upon the recommendation of an examining board, and were required to file annual reports with the secretary of state before February 1, covering the previous calendar year.

The act of March 6, 1897, provided that the inspection law should apply to all coal mines employing 10 or more men, but that operators of mines enploying less than 10 men should notify the inspector as soon as 10 men were employed.

On March 5, 1907, a law was approved providing one mine inspector for the entire State until there are 60 mines in operation, and dividing the State into districts, containing not less than 10 nor more than 60 mines each, and an inspector for each district, as soon as the number of operating mines in the State exceeds 60. An act approved March 13, 1911, authorized the State mine inspector to appoint, with the consent of the governor, a deputy inspector, who should hold office during the pleasure of the State inspector.

Prior to 1912 it was the practice of the operators to report only those injuries causing at least 30 days' disability, but since that year, when the workmen's compensation law became effective, the operators have reported all injuries resulting in disability for 5 days or more and these are published in the inspector's annual reports. Serious injuries are those resulting in 30 days' disability, all others being considered slight injuries.

In 1915 the inspector was assisted by one deputy.

#### ACCIDENTS.

Tables 136 and 137 show the production of coal, the number of men employed, and the fatalities in coal mines as compiled from the reports of the United States Geological Survey and the State mine inspectors' reports. Complete records of fatalities from the mine inspectors' reports are available from 1889 to 1913, a period of 25 years. During this time there were 640 fatalities, representing a rate of 6.14 fatalities per 1,000 men employed. The amount of coal produced per death was 93,606 tons, or 10.68 fatalities per

million tons of coal mined. During this period there have been 10 mine disasters in which 5 or more men have been killed at one time, making a total of 202 fatalities. Of the total number of fatalities during this 25-year period 30.47 per cent was due to gas and dust explosions; 28.44 per cent to falls of roof and coal; and 12.65 per cent to mine cars and locomotives.

Practically all of the mines in Washington are operated on an 8-hour basis, and for purposes of comparison with 9 and 10 hour States, Tables 40 and 41 have been compiled. The number of hours worked per year per man is 2,023. The fatality rate based on the actual number of employees is 4.64, as compared with 4.58 when reduced to the equivalent of 2,000-hour workers. Table 41 gives similar data for all of the States, so that comparisons of one State with another may be readily made.

On account of the coal beds being badly upturned, necessitating working on steep pitches or dips, there is an unusual percentage of accidents due to coal, rock, or timber sliding down from a working face, from cars getting loose and running down an incline, and from men falling down chutes or slopes. About 30 per cent of the fatalities belong to this group, as shown in the accompanying table. In nearly all of the States, the bituminous coal beds are comparatively flat, but Washington is an exception in this respect. Outside of certain fields in Oklahoma and Colorado, and the anthracite fields in eastern Pennsylvania, there is not a district where the coal beds are as steeply inclined as in Washington. The tables of statistics for the State follow: STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN WASHINGTON. $^{a}$

#### WEST VIRGINIA.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of West Virginia occupy all of the area on the Western slope of the Appalachian Mountains. The entire area of the State is 24,022 square miles, of which an area of approximately 17,000 square miles is coal-bearing. Thirty counties are important producers. The 6 counties heading the list, in the order of their production in 1913, are McDowell, Fayette, Marion, Harrison, Kanawha, and Logan, each of which mined more than 4,000,000 tons of coal.

There are seven important fields, the three in the northern part of the State being (1) Fairmont field, including Harrison and Monroe counties; (2) Elk Garden (Piedmont), or Upper Potomac field, including Mineral, Grant, and Tucker counties; (3) Phillipi field, including Preston, Barbour, and Randolph counties. The four fields in the southern part of the State are as follows: (1) New River field, including Fayette and Raleigh counties; (2) Kanawha field, including Kanawha and parts of Boone and Putnam counties; (3) Pocahontas field, including McDowell and Mercer counties, W. Va., and Tazewell County, Va.; and (4) Big Sandy field, which is a continuation of the Kanawha district into Logan and Mingo counties.

In general the coal beds and the associated sandstones, limestones, and shales of the West Virginia fields dip northwestward toward the axis of the great Appalachian trough, which passes through the northwestern part of the State from the southwest corner of Pennsylvania to Wayne County on Big Sandy River. Notwithstanding the general regularity of this great trough, the southeastern side, especially in northern West Virginia, is affected by a number of anticlinal folds trending in the same direction as the axis of the great trough. These smaller folds cause the dips in places to be much steeper than the normal, and on the southeast flank of the arch, to be toward the southeast. This is well illustrated in the synclinal trough in Preston County east of the Chestnut ridge anticline.

#### CHARACTER OF COAL BEDS.

All of the West Virginia coal is bituminous or semibituminous, the majority of which is of high rank.

The coal increases in rank from west to east across the State, the semibituminous coals being limited to small fields along the margin of the area. These fields of semibituminous coal are Pocahontas, New River, and Upper Potomac (Georges Creek). These coals are preeminently steam coals, going into the market as "smokeless," but they also are used to a limited extent in coke making.

The most important coal in the Fairmont and Elk Garden districts is the Pittsburgh (Elk Garden or 14-foot) bed, with an average thickness of 8 feet 6 inches, of which 7 feet is usually mined. The Waynesburg and Sewickley coal beds occur in the Fairmont district, but are little worked. They vary in thickness from 5 to 10 feet. The Elk Garden district also contains the Thomas or Upper Freeport,  $2\frac{1}{2}$  to  $3\frac{1}{2}$  feet thick, and the Davis (Upper Kittanning or "Six-Foot") bed, varying from 4 to 11 feet in thickness. In the Kanawha district, the most important beds are "No. 2 Gas" and the Eagle (soft coking coal), varying in thickness from 3 to 5 feet, and the Coalburg and No. 5 (splint coal), varying from 4 to 6 feet thick.

In the New River field the principal beds are the Sewell, varying in thickness from 3½ to 5 feet; Fire Creek, averaging 3 feet, and the Beckley, varying from 4 to 6 feet. The Pocahontas field produces coal from the "No. 3" bed, which is 4 to 11 feet thick, averaging about 6 feet. In recent years considerable development work has been done on the "No. 4" and also on the Sewell bed.

#### MINING METHODS.

The earliest records showing coal production of West Virginia are for 1863," during which year West Virginia became a State, and 444,648 short tons was mined. This tonnage has gradually increased until in 1913 the production amounted to 71,308,982 short tons.

As the majority of the beds outcrop at various places, nearly all of the mines are opened by drifts or slopes, few shafts being necessary for mining operations. The room-and-pillar method of mining is extensively used. In 1913, there were 1,479 locomotives in use in the mines, of which 1,365 were electric, 46 steam, 40 compressed air, and 28 gasoline.

Mining in the Elk Garden district began in 1881. In 1891, there were 8 machines used in the State of West Virginia, and this number has gradually increased until in 1913 there were 2,541 machines in use. The average production per machine in 1913 was 15,116 tons. About one-half of the machines used are of the chain-breast type. Of the total amount of coal mined, 55.3 per cent in 1913 was mined by machines; 43.6 per cent was mined by hand, and only 0.8 per cent was shot off the solid.

#### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

An act approved March 11, 1879, authorized the judge of any circuit court in any county to appoint a mine inspector for such county, upon a petition signed by 100 voters showing that any coal mine employing more than 10 men was not sufficiently ventilated. Inspectors so appointed were required to report in writing on the first day of every term of said court the condition of all such mines and whether

a Prior to 1863 the production of coal in what is now West Virginia was reported as of Virginia.

any employee had been injured, and the cause of such accident. By an act approved February 26, 1883, the inspection service was placed under the jurisdiction of a State mine inspector, and applied to all coal mines employing 15 or more miners. The inspector was required to render an annual report to the governor, showing number of employees, and number of persons killed or injured. The act of February 20, 1890, divided the State into two inspection districts and authorized the governor to appoint a mine inspector for each district, each inspector to render annual reports to the governor for years ending June 30. A chief mine inspector was authorized by the act of February 17, 1897, assisted by four district inspectors, who rendered monthly reports to the chief inspector. The department of mines was created by the act of February 25, 1905, and placed in charge of the chief mine inspector. The act of February 27, 1907, changed the title of chief mine inspector to that of chief of the department of mines, and the inspection law was extended to cover all mines employing five or more men. Various laws have increased the number of district inspectors until in 1914 there were twelve such inspectors.

#### ACCIDENTS.

Tables 138 and 139 show the production of coal and number of men employed, together with the fatalities in the coal mines in the State. The fatalities have been compiled from the reports of the State mine inspectors and are based on a calendar year, and do not, therefore, necessarily agree with the inspectors' figures published for fiscal years. During the period from 1885 to 1913, for which continuous complete records are available, there were 4,748 fatalities, representing 4.97 fatalities per 1,000 men employed. The amount of coal produced per fatality during this period was 160,635 tons or 6.23 fatalities per million tons of coal mined. During this period there have been 30 mine disasters, in each of which 5 or more men were killed.

Of the total number of fatalities during the 29-year period, 51.64 per cent were due to falls of roof and coal; 21.82 to gas and dust explosions; and 11.73 to mine cars and locomotives. Fatalities due to explosives were comparatively few, representing only 3.27 per cent of the total. The percentage of fatalities due to explosives in Oklahoma for a period of 21 years was 15.77; in Ohio, for a period of 30 years, 7.02; and in Illinois, for a period of 29 years, 13.47.

Since 1903, both the 9-hour and the 10-hour day have prevailed throughout the State, there being more than 50 per cent of the men employed on a 10-hour basis. For a true comparison with other States where an 8-hour or a 9-hour day prevails, the time element has been taken into consideration, and Tables 40 and 41 have been compiled on the basis of the actual number of men employed over a 10-year period, 1903 to 1913, inclusive, except 1909; also on the basis of 2,000-hour workers. The fatality rate during the 10-year period based on the actual number of employees is 5.53 per 1,000, and reduced to the equivalent of 2,000-hour workers becomes 5.18. The number of hours worked a year per man in West Virginia is 2,132, as compared with 1,495 for Ohio. The Ohio rate based on the

NUMBER OF HOURS TO THE WORKING DAY, BY YEARS, IN AND ABOUT THE COAL MINES IN WEST VIRGINIA.<sup>a</sup>

actual number of employees is 2.94, and reduced to the equivalent number of 2,000-hour workers becomes 3.94, so that the difference between the figures for the two States is not so great as would appear when the rates are based on the actual number of employees. Similar comparisons in these details may be made with other States by referring to Table 41. The tables of statistics for the State follow:

STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN WEST VIRGINIA.<sup>a</sup>

#### WYOMING.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Wyoming comprise an area of about 25,000 square miles. In addition to this area, in which the coal beds are fairly well known, there are a number of deep basins such as Bighorn Basin, Wind River Basin, and Green River Basin, aggregating 16,000 square miles, in which coal beds are doubtless present, but are at such a depth as possibly to be unavailable.

The most important region in point of quality of coal and quantity produced is the Green River Basin, including the belt of disturbed rocks in Lincoln and Uinta counties. This region comprises about 18,000 square miles underlain by coal-bearing rocks, but an area of only 8,000 square miles contains coal beds that are now accessible. This region includes the Kemmerer and Rock Springs districts, which produce practically all of the high-grade coal of the State. The production of this region in 1913 was about 4,500,000 tons.

The region of next importance is the Powder River region, which has an area of 74,000 square miles. Of this, an area of about 11,000 square miles is believed to be underlain by coal beds more than 3 feet thick. The coal in this field is subbituminous, and Sheridan is the chief center of production.

In the Bighorn, Wind River, and Hanna Basins and in the belt of disturbed rocks in Lincoln and Uinta counties the coal beds are considerably disturbed and in places dip at high angles, but in other fields the dips are low and regular, or the beds are practically flat.

#### CHARACTER OF COAL BEDS.

The general structure of the Rock Springs district of the Green River field is that of a dome, the axis of which is about 90 miles long extending north and south. The coal beds on the west of this anticlinal axis dip 5° to 30°, whereas those on the east vary from 5° to 10°. There are many normal faults of less than 100 feet in displacement. There are four coal-bearing groups, containing 20 beds 2 to 12 feet thick, aggregating 90 feet at Rock Springs, Sweetwater County, which produced in 1913 about 35 per cent of the State's output.

In the Kemmerer district, Lincoln County, there are three principal coal beds known as the Upper, Main, and Lower Kemmerer beds. These range from 4 to 14 feet in thickness and are generally considered as the best coals in the State. They dip 20° to 25° to the west. This district has the distinction of containing the thickest coal bed that has been mined in the United States. It is 84 feet thick in the old prospect entry, but as the coal slacked badly the mine was abandoned.

14355°—Bull. 115--16—23

In the Powder River field, immediately cast of Sheridan, there are 5 coal beds as follows: Healy, 10 to 15 feet thick; Felix, 6 to 30 feet thick; Arvada, 5 to 10 feet thick; Roland, 3 to 7 feet thick; and Smith, 4 to 10 feet thick. South of Sheridan is a small area, known as the Buffalo district, containing the Healy bed, which is about 15 feet thick, and the Walters bed, which is 35 feet thick. These beds are also horizontal. Sheridan County in this field produced 15 per cent of the State's 1913 output.

In the Little Snake River field the coal beds are inclined from horizontal to about 35°. The coal is 3 to 12 feet thick, with shale and sandstone roof.

In the Bighorn Basin the beds dip  $3^{\circ}$  to  $56^{\circ}$ , varying from 5 to 10 feet in thickness. Little coal has been mined from this area.

#### MINING METHODS.

The earliest statistics of coal production in Wyoming are for 1865, when 800 tons of coal was produced. In 1913 the production was 7,393,066 tons.

In most of the mines thus far developed in the Rock Springs district the roof and floor of the coal beds are firm and give little trouble. The majority of the mines are opened by slopes and a few by shafts. The room-and-pillar method of mining is used in coal beds varying from 4 to 8 feet in thickness. In the Rock Springs district a large percentage of the coal is mined by shooting off the solid. There is comparatively little gas in the mines.

In the northern part of the State, in Sheridan County, mines are opened by drifts and the coal is mined by room-and-pillar methods. The coal beds are thicker than in the Rock Springs district, varying from 10 to 19 feet, and in places are 25 to 30 feet thick.

Mining machines have been in use in Wyoming since about 1890. In 1913 there were 195 machines in use, producing 41 per cent of the coal; 36.7 per cent was mined by being shot off the solid; and 21.9 per cent by hand mining. A number of the mines are using electric coal-cutting machines, and haulage is by mules and electricity.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The inspection of coal mines was placed under the jurisdiction of a Territorial mine inspector by an act approved February 25, 1886, covering all coal mines in which 10 or more men were employed. Operators were required to render to the inspector immediate reports of all fatal and serious accidents. All fatal accidents were to be reported to the county coroner also, and upon such notice an investigation was conducted to determine the cause of the accident. The inspector rendered quarterly reports showing number of accidents and deaths from injuries, number employed at the mines, etc., and published his report in at least one paper in each county in which there were any coal mines. The act of February 17, 1903, divided the State into two inspection districts and authorized the governor to appoint a mine inspector for each district, the inspector to render quarterly reports of accidents. By the act of February 27, 1909, the inspectors were required, within one week after the examination of each mine, to send a written report of such examination to the governor and also to file with the governor an annual report not later than December 1 of each year. There are no regular deputy or assistant inspectors, but the district inspectors are authorized to appoint temporary deputies to investigate accidents when it is impossible for the district inspectors to be present in person.

Prior to the enactment of the workmen's compensation law, mine operators reported to the inspectors only those injuries resulting in disability to an employee for at least 14 days, and these were published in the inspectors' annual reports. Under the compensation law, which became effective April 1, 1915, all accidents at mines are required to be reported.

#### ACCIDENTS.

Tables 140 and 141 show the production of coal and number of employees since 1889 to the end of 1913. The fatality records are not so complete, continuous records being available only from 1908 to the end of 1913. During this period of 6 years there were 241 fatalities in and about the coal mines, representing 5.21 fatalities per 1,000 men employed. The production of coal per fatality was 169,801 tons, or 5.89 fatalities per million tons of coal mined. Of the total number of men killed during the 6-year period, 47.30 per cent was due to falls of roof and coal; 27.80 per cent to gas and dust explosions; and 9.13 per cent to mine cars and locomotives.

| FATALITIES IN WYOMING GOAL MINES. BY PRINCIPAL CAUSES, DURING THE YEARS |  |  |  |  |  |  |  |  |

Since 1881 there have been 11 coal-mine disasters, in each of which five or more men were killed at one time, representing 428 fatalities. A list is given in the accompanying table.

Since 1907 the mines in Wyoming have been operated on an 8-hour basis, and for comparison with States having 9-hour and 10-hour days, the time element has been taken into consideration. The number of hours worked per annum per man in Wyoming for the 10-year period 1903 to 1913, except 1909, was 2,137. The fatality rate during the 5 years 1908, 1910, 1911, 1912, and 1913, for which complete records are available, is 5.38, based on the actual number of employees, whereas if based on the equivalent number of 2,000-hour workers it becomes 5.71. By referring to Tables 40 and 41, comparisons with other States may be readily made. The tables of statistics for the State follow:

| NUMBER OF HOURS TO | THE WORKING DAY, BY YEARS, | IN AND | ABOUT THE COAL |
|--------------------|----------------------------|--------|----------------|
|                    | MINES IN WYOMING.ª         |        |                |

TABLE 142.—NUMBER OF MEN KILLED IN AND ABOUT THE COAL MINES IN THE UNITED STATES DURING THE CALENDAR YEAR 1015, WITH THE FATALITIES CLASSIFIED ACCORDING TO CAUSE.

a Includes promature blasts, explosion of misfires, suffocation by gases from explosives, etc.

354 COAL-MINE FATALITIES IN THE UNITED STATES, 1870-1914.

#### PUBLICATIONS ON MINE ACCIDENTS AND METHODS OF COAL MINING.

Limited editions of the following Bureau of Mines publications are temporarily available for free distribution. Requests for all publications can not be granted, and applicants should select only those publications that are of especial interest to them. All requests for publications should be addressed to the Director, Bureau of Mines, Washington, D. C.

BULLETIN 17. A primer on explosives for coal miners, by C. E. Munroe and Clarence Hall. 61 pp., 10 pls., 12 figs. Reprint of United States Geological Survey Bulletin 423.

BULLETIN 20. The explosibility of coal dust, by G. S. Rice, with chapters by J. C.W. Frazer, Axel Larsen, Frank Haas, and Carl Scholz. 204 pp., 14 pls., 28 figs.

BULLETIN 42. The sampling and examination of mine gases and natural gas, by G. A. Burrell and F. M. Seibert. 1913. 116 pp., 2 pls., 23 figs.

BULLETIN 45. Sand available for filling mine workings in the Northern Anthracite Coal Basin of Pennsylvania, by N. H. Darton. 1913. 33 pp., 8 pls., 5 figs.

BULLETIN 46. An investigation of explosion-proof mine motors, by H. H. Clark. 1912. 44 pp., 6 pls., 14 figs.

BULLETIN 50. A laboratory study of the inflammability of coal dust, by J. C. W. Frazer, E. J. Hoffman, and L. A. Schol<sup>1</sup>, jr. 1913. 60 pp., 95 figs.

BULLETIN 52. Ignition of mine gases by the filaments of incandescent electric lamps, by H. H. Clark and L. C. Ilsley. 1913. 31 pp., 6 pls., 2 figs.

BULLETIN 56. First series of coal-dust explosion tests in the experimental mine, by G. S. Rice, L. M. Jones, J. K. Clement, and W. L. Egy. 1913. 115 pp., 12 pls., 28 figs.

BULLETIN 60. Hydraulic mine filling; its use in the Pennyslvania anthracite fields; a preliminary report, by Charles Enzian. 1913. 77 pp., 3 pls., 12 figs.

BULLETIN 62. National mine-rescue and first-aid conference, Pittsburgh, Pa., September 23-26, 1912, by H. M. Wilson. 1913. 74 pp.

BULLETIN 68. Electric switches for use in gaseous mines, by H. H. Clark and R. W. Crocker. 1913. 40 pp., 6 pls.

BULLETIN 69. Coal-mine accidents in the United States and foreign countries, compiled by F. W. Horton. 1913. 102 pp., 3 pls., 40 figs.

BULLETIN 83. The humidity of mine air, with especial reference to coal mines in Illinois, by R. Y. Williams. 1914. 69 pp., 2 pls., 7 figs.

BULLETIN 99. Mine-ventilation stoppings, with especial reference to coal mines in Illinois, by R. Y. Williams. 1915. 30 pp., 4 pls., 4 figs.

BULLETIN 101. Abstracts of current decisions on mines and mining, October, 1914, to April, 1915, by J. W. Thompson. 1915. 138 pp.

TECHNICAL PAPER 4. The electrical section of the Bureau of Mines, its purpose and equipment, by H. H. Clark. 1911. 12 pp.

TECHNICAL PAPER 6. The rate of burning of fuse as influenced by temperature and pressure, by W. O. Snelling and W. C. Cope. 1912. 28 pp.

TECHNICAL PAPER 7. Investigations of fuse and miners' squibs, by Clarence Hall and S. P. Howelf. 1912. 19 pp.

TECHNICAL PAPER 11. The use of mice and birds for detecting carbon monoxide after mine fires and explosions, by G. A. Burrell. 1912. 15 pp.

TECHNICAL PAPER 13. Gas analysis as an aid in fighting mine fires, by G. A. Burrell and F. M. Seibert. 1912. 16 pp., 1 fig.

TECHNICAL PAPER 14. Apparatus for gas-analysis laboratories at coal mines, by G. A. Burrell and F. M. Seibert. 1913. 24 pp., 7 figs.

TECHNICAL PAPER 15. An electrolytic method of preventing corrosion of iron and steel, by J. K. Clement and L. V. Walker. 1913. 19 pp., 10 figs.

TECHNICAL PAPER 17. The effect of stemming on the efficiency of explosives, by W. O. Snelling and Clarence Hall. 1912. 20 pp., 11 figs.

TECHNICAL PAPER 18. Magazines and thaw houses for explosives, by Clarence Hall and S. P. Howell. 1912. 34 pp., 1 pl., 5 figs.

TECHNICAL PAPER 19. The factor of safety in mine electrical installations, by H. H. Clark. 1912. 14 pp.

TECHNICAL PAPER 22. Electrical symbols for mine maps, by II. II. Clark. 1912. 11 pp., 8 figs.

TECHNICAL PAPER 28. Ignition of mine gas by standard incandescent lamps, by H. H. Clark. 1912. 6 pp.

TECHNICAL PAPER 29. Training with mine-rescue breathing apparatus, by J. W. Paul. 1912. 15 pp.

TECHNICAL PAPER 39. The inflammable gases in mine air, by G. A. Burrell and F. M. Seibert. 1913. 24 pp., 2 figs.

<sup>4</sup> TECHNICAL PAPER 43. The effect of inert gases on inflammable gaseous mixtures, by J. K. Clement. 1913. 24 pp., 1 pl., 8 figs.

TECHNICAL PAPER 44. Safety electric switches for mines, by H. H. Clark. 1913. 8 pp.

TECHNICAL PAPER 47. Portable electric mine lamps, by H. H. Clark. 1913. 13 pp. TECHNICAL PAPER 48. Coal-mine accidents in the United States, 1896-1912, with monthly statistics for 1912, compiled by F. W. Horton. 1913. 74 pp., 10 figs.

TECHNICAL PAPER 52. Permissible explosives tested prior to March 1, 1913, by Clarence Hall. 1913. 11 pp.

TECHNICAL PAPER 58. The action of acid mine water on the insulation of electric conductors; a preliminary report, by H. H. Clark and L. C. Ilsley. 1913. 26 pp., 1 fig.

TECHNICAL PAPER 69. Production of explosives in the United States during the calendar year 1912, compiled by A. H. Fay. 1914. 8 pp.

TECHNICAL PAPER 71. Permissible explosives tested prior to January 1, 1914, by Clarence Hall. 1914. 12 pp.

TECHNICAL PAPER 75. Permissible electric lamps for miners, by H. H. Clark. 1914. 21 pp., 3 figs.

TECHNICAL PAPER 76. Notes on the sampling and analysis of coal, by A. C. Fieldner. 1914. 59 pp., 6 figs.

TECHNICAL PAPER 77. Report of the Committee on Resuscitation from Mine Gases, by W. B. Cannon, George W. Crile, Joseph Erlanger, Yandell Henderson, and S. T. Meltzer. 1914. 36 pp., 4 figs.

TECHNICAL PAPER 78. Specific-gravity separation applied to the analysis of mining explosives, by C. G. Storm and A. L. Hyde. 1914. 13 pp.

TECHNICAL PAPER 84. Methods of preventing and limiting explosions in coal mines, by G. S. Rice and L. M. Jones. 1915. 45 pp., 14 pls., 3 figs.

TECHNICAL PAPER 100. Permissible explosives tested prior to March 1, 1915, by S. P. Howell. 1915. 15 pp.

MINERS' CIRCULAR 5. Electrical accidents in mines, their causes and prevention, by H. II. Clark, W. D. Roberts, L. C. Ilsley, and II. F. Randolph. 1911. 10 pp., 3 pls.

MINERS' CIRCULAR 8. First-aid instructions for miners, by M. W. Glasgow, W. A. Raudenbush, and C. O. Roberts. 1913. 67 pp., 51 figs.

MINERS' CIRCULAR 12. Use and care of miners' safety lamps, by J. W. Paul. 1913. 16 pp., 4 figs.

MINERS' CIRCULAR 13. Safety in tunneling, by D. W. Brunton and J. A. Davis. 1913. 19 pp.

MINERS' CIRCULAR 14. Gases found in coal mines, by G. A. Burrell and F. M. Seibert. 1914. 23 pp.

MINERS' CIRCULAR 15. Rules for mine-rescue and first-aid field contests, by J. W. Paul. 1913. 12 pp.

MINERS' CIRCULAR 16. Hints on coal-mine ventilation, by J. J. Rutledge. 1914. 22 pp.

MINERS' CIRCULAR 21. What a miner can do to prevent explosions of gas and coal dust, by  $G_{2}$  S. Rice. 1915. 24 pp.
