GAS AND DUST EXPLOSIONS.

\$

Table 45 shows the number of men killed by gas and dust explosions in the coal mines of the United States, by States, during indicated periods ending December 31, 1913, for which continuous records are available. This table takes cognizance of 6,726 fatalities in the coal mines of the United States due to this cause alone, including both common and exceptional accidents. In addition to these accidents a number of mine disasters occurred prior to the beginning of State mine inspection, which are not included in this table. During the periods covered, the fatalities due to gas and dust explosions were 13.88 per cent of the total number killed, or a fatality rate of 0.46 per 1,000 men employed.

Utah has the highest percentage of fatalities in important coal mining States due to this cause, the rate being 57.75 per cent of the total, or 5.34 per 1,000 men employed. Utah's high rate is due to one disaster at the Winter Quarters mine, in which 200 men were killed at one time. New Mexico has the next highest percentage, 56.51 per cent of the total fatalities for a period of 21 years, or 6.46 per 1,000 men employed. This high rate is due to the Dawson disaster, in which 263 men were killed at one time.

The percentage of fatalities due to gas and dust explosions in some of the States is much higher than in others, whereas the rate per 1,000 men employed may not be in accordance therewith. Here again is shown the fallacy of making fatality comparisons on the percentage basis. In Utah and New Mexico the percentage of fatalities due to falls of roof, 26.76 and 28.17, respectively, indicates exceedingly safe roof conditions in the mines of these States, as this rate is about onehalf the average for the United States, which is 47.49 per cent. But the fatality rate due to falls of roof, based on the number of men employed, in New Mexico is 3.22 and in Utah 2.48, both of which are much larger than the average for the United States, which is 1.57 per 1,000 men employed.

TABLE 45.—NUMBER OF MEN KILLED BY GAS AND DUST EXPLOSIONS IN AND ABOUT THE COAL MINES OF THE UNITED STATES, BY STATES. DURING PERIOD SHOWN ENDED DEC. 31, 1913, FOR WHICH CONTINUOUS RECORDS ARE AVAILABLE.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Number of<br>years in                                                                                                                                                                            | N                                                                                                                                                  | umber kille                                                                                                                                                                                             | d.                                                                                                                       |

a This table is based on Table 5, and is for periods indicated, by States, for which continuous records are available. It does not necessarily check with Tables 3 and 4, for the reason that the latter tables include intermittent records prior to the period having continuous records.

It will be noted from figure 3 that the accidents due to gas and dust explosions were comparatively few from 1875 to 1890, the rate being about 0.30 per 1,000 men employed. Beginning with 1890 the fatality rate has been very irregular, owing to the irregular occurrence of large diasters. The climax was reached in 1907, when seven explosions occurred, in each of which more than 20 men were killed. The number killed by gas and dust explosions in 1907 was 1.417 per 1,000 employed in all coal mines, or 1.796 (Table 68) per 1,000 for the bituminous mines alone. As shown in Table 4, the fatality rate due to this cause has declined since 1907, being 0.457 per 1,000 in 1914 as compared with the average of 0.487 from 1870 to 1913.

In considering the number of men killed in recent gas and dust explosions, it must not be forgotten that the mines are becoming deeper, contain more abandoned rooms and old workings, with the possibility of greater accumulations of gas and dust, are larger, and that more men are employed in the individual mines than in former years, so that when an explosion does occur, there is the possibility of trapping more men than would have happened in the same mine 20 or 25 years ago.

With deeper mines and the resultant old workings, ventilation is not as easy to maintain as in the newer mines, thus permitting the accumulation of gas and dust. The deep slope or shaft mines drain all of the water from the upper workings, leaving the haulage ways and rooms dry, with the result that coal dust will be produced and accumulate in them. Water also drains from the gob and waste piles and they become comparatively dry. Air will circulate through abandoned rooms, caved workings and gob, and in so doing the velocity of the air current is reduced and the suspended dust deposited. The air is actually filtered, leaving its deadly burden of dust to be ignited by an explosion of gas or a blown-out shot.

#### MINE FIRES.

Table 46 shows a list of the principal mine fires which have occurred in the United States since 1869, and in which 1,053 men have been killed. This table does not necessarily check with Table 3, for the reason that it includes one disaster in 1869 not shown in Table 3; TABLE 46.-MINE FIRES IN THE UNITED STATES IN WHICH FIVE OR MORE MEN WERE KILLED.

a Fire and explosion combined.

14355°-Bull. 115-16---6

it also includes 3 disasters in which a mine fire and explosion were combined. Table 47 shows a list of mine fires at mines in the United Kingdom that were due to spontaneous combustion. This table brings out forcibly the dangers due to spontaneous combustion of waste material stored underground. Too much care can not be exercised in the matter of taking care of waste material, such as waste in engine rooms and pump stations, and old timbers, which may be easily ignited should they come in contact with oil-saturated waste. Timber should not be stored with the mine gob where oxidationis likely to take place, as it will add fuel to a fire which may be easily started. All inflammable material should be removed from the mines.

TABLE 47.—LOSS OF LIFE OCCASIONED BY FIRES DUE TO SPONTANEOUS COMBUSTION IN MINES IN THE UNITED KINGDOM, 1893-1912, INCLUSIVE.

a First report of the departmental committee on spontaneous combustion of coal in mines, Home Office, London, 1914.

# EXPLOSIVES.

Table 48 shows by causes and States the total number of fatalities due to explosives, during periods of inspection service for which continuous records are available. The fatality rates due to explosives from 1870 to 1914 are shown in figure 3. In Table 48 are tabulated 3.675 fatalities due to the use of explosives underground. This table has been divided into 14 subheadings showing various causes of accidents while using explosives, and it will be noted that 24.87 per cent are due to premature blasts, 16.79 per cent to handling and transportation, 16.71 per cent to flying pieces of rock or coal. The number of fatalities due to striking unexploded charges in removing débris is small, only three being reported. The small number of fatalities due to thawing of explosives is largely accounted for by the fact that black powder is used to such a large extent in the coal mines. Dynamite is not used so extensively and hence there are not so many accidents due to thawing as in the metal mines, where dynamite is used almost exclusively. Of the 27 fatalities due to thawing explosives, 21 occurred in the anthracite mines of Pennsylvania, where a large amount of dynamite is used. The table presents a detailed study which has not heretofore been available, and it is hoped that it will be of some special use to safety engineers in forming rules and regulations concerning the use of explosives.

The table also gives the percentage of fatalities and the rate per 1,000 men employed. In Kansas and North Dakota nearly onefourth of all coal-mine fatalities is due to the use of explosives. Although in Indiana 19.44 per cent and in Oklahoma 15.77 per cent are due to this cause, the average for the United States is 7.59 per cent.

Table 49 gives the number of fatalities due to explosives in and about the anthracite mines of Pennsylvania from 1870 to and including 1913. This table shows that 1,835 fatalities were due to this cause alone, of which 1,790 were underground, as indicated in Table 48. Table 49 also shows the fatality rate per 1,000 men employed as being 0.225 in 1870. This rate fluctuates more or less, but it has more than doubled in recent years, ranging from 0.414 in 1909 to 0.540 in 1908 and 0.427 in 1913. The average fatality rate per 1,000 men employed in the anthracite field during the entire period of 44 years is 0.354, as compared with 0.05 in the bituminous fields of Pennsylvania, in which there were 185 fatalities as compared with 1,790 in the anthracite field.

Anthracite coal being much harder than bituminous coal, more nearly approaches metal-mining operations, and of course larger quantities of more powerful explosives are required. Table 50 shows that the amount of explosives used in the anthracite field is practically three times the amount used in the bituminous mines of

ġ.

c Compiled from the annual reports of the State mine inspectors.
b This fable is based on Table 5, and is for periods indicated by States for which continuous records are available. It does not necessarily check with Tables 3 and 4 for the reason that the fable is based an fable for meriods prior to the period having continuous records.

78 COAL-MINE FATALITIES IN THE UNITED STATES, 1870-1914.

Pennsylvania. In 1913 the bituminous fields used 14,652,931 pounds of black powder as compared with 44,001,660 pounds in the anthracite mines. The bituminous mines for the same year used 696,162 pounds of dynamite, whereas the anthracite mines used in the same period 16,093,035 pounds. The amount of permissible explosives used in the bituminous fields was 6,715,028 pounds as compared with 3,323,645 in the anthracite fields. Records showing the use of permissible explosives are not complete prior to 1909.

 
 TABLE 49.--FATALITIES IN AND ABOUT THE ANTHRACITE MINES OF PENNSYLVANIA DUE TO EXPLOSIVES.

TABLE 50.-EXPLOSIVES USED IN THE COAL MINES OF PENNSYLVANIA.ª

<sup>a</sup> Ann. Rept. Department of Mines of Pennsylvania, 1913, pp. 59, 75.

#### PERMISSIBLE EXPLOSIVES.

The number of fatalities per 10,000 men employed, due to explosives used in the bituminous coal mines of the United States from

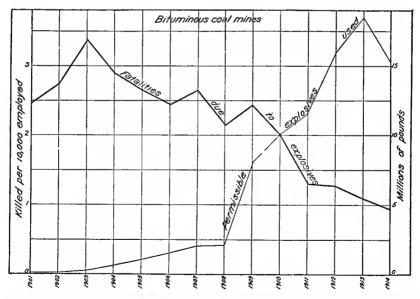

FIGURE 5.—Number of men killed per 10,000 employed, by explosives, in the bituminous coal mines of the United States, compared with the amount of permissible explosives used, 1901-1914. (Based on Table 68.)

1901 to 1914, inclusive, are shown in figure 5. The figure also shows the amount of permissible explosives used for the same period. This period is taken for the reason that in 1901 there were no permissible explosives used in the coal mines of the United States. In 1902 this class of explosives was introduced, there being 11,300 pounds used during that year. In preparing this chart, the amount of permissible explosives used in the anthracite mines has been eliminated, leaving the figures for bituminous mines only. This chart shows the rapid increase in the use of permissible explosives and, at the same time, a corresponding decrease in the fatality rate. None of the serious mine disasters have been attributed to permissible explosives.

Table 51 shows the amount of black powder, high explosive other than permissible, and permissible explosive used in the coal mines of the United States, geographically grouped, wherein the mining conditions are more or less of a similar character. This table is for the two years 1913 and 1914.

 TABLE 51.—QUANTITY OF EXPLOSIVES USED IN THE COAL MINES OF THE UNITED STATES DURING 19:3 AND 1914.ª

a Fay, A. H., Production of explosives in the United States during 1914: Tech. Paper 107, Bureau of Mines, 1915, p. 13. <sup>b</sup> Not including Pennsylvania anthracite field.

#### FALLS OF ROOF.

Table 52 shows the number of fatalities due to falls of roof and pillar coal in and about the coal mines of the United States, by States, during periods ending December 31, 1913, for which continuous records are available. During these various State periods there were 23,011 fatalities due to falls of rock and coal alone. This represents 47.49 per cent of the total number of fatalities, or a fatality rate of 1.57 per 1,000 men employed. (See fig. 3. Pls. I and II.)

It is not always in the mines having the strongest roof where the least number of fatalities occur. When a mine is known to have a bad roof, the miner, foreman, and all others concerned will take special precautions to use plenty of timber to keep the roof in place. Furthermore, the roof will be tested frequently and the miner will be on the lookout at all times when he knows that roof conditions With a strong roof, however, such precautions are not are bad. The miner and the foreman consider the roof safe and give taken. it no further thought. This leads to negligence, and as a result many of the fatalities due to roof falls happen where roof conditions are considered the best.

a This table is based on Table 5, and is for periods indicated by States for which continuous records are available. It does not necessarily check with Tables 3 and 4 for the reason that the latter tables include intermittent records prior to the period having continuous records.

Falls of roof form the principal cause of accidents in coal mines, a fact that should command the serious attention of the inspectors, operators, mine foremen, and the miners. Roof falls are bound to happen, yet with proper precautions, use of sufficient timber, and care on the part of the foremen and miners the number of accidents from this cause should be reduced to a considerable extent.

#### HAULAGE SYSTEMS.

Table 53 shows the number of men killed underground by mine cars and locomotives covering periods for which continuous records are available, including 1913. This class represents one-eighth of the total number of men killed in and about the coal mines, or 0.42 per 1,000 men employed. During the periods covered 6,056 men were killed by mine cars and locomotives. (See fig. 3. Pls. I and II.) This number, however, does not include accidents due to electricity on haulage systems nor injuries inflicted by animals. Details relating to haulage systems of all of the various States are not available, but as an example to show the character of haulage used it has been possible to prepare tables for Illinois, Ohio, West Virginia, and the anthracite and bituminous mines of Pennsylvania.

Table 54 shows the number of horses and mules and steam, electric, and compressed-air locomotives used in the Pennsylvania coal mines from 1898 to 1913. The number of animals used in anthracite haulage has not changed materially during this 15-year period. The number of steam locomotives has practically doubled, the number of electric locomotives has increased from 24 to 781, and the number of compressed-air locomotives has increased from 10 to The number of horses and mules used in bituminous haulage 161. in Pennsylvania has doubled during this period. The number of steam locomotives has increased but slightly, whereas the number of electric locomotives has increased from 122 in 1899 to 1,933 in 1913. The use of compressed-air locomotives has increased in about the same ratio as in the anthracite field, there being 13 in 1899 and 168 in 1913.

TABLE 53.—NUMBER OF MEN KILLED UNDERGROUND BY MINE CARS AND LOCOMOTIVES IN THE COAL MINES OF THE UNITED STATES, BY STATES, DURING PERIOD SHOWN ENDED DEC. 31, 1913, FOR WHICH CONTINUOUS RECORDS ARE AVAILABLE.«

a This table is based on Table 5 and is for periods indicated, by States. for which continuous records are available. It does not necessarily check with Tables 3 and 4 for the reason that the latter tables include intermittent records prior to the period having continuous records.

In 1900 of the total amount of coal mined in Illinois, 5.5 per cent was transported by electric haulage underground, 10.1 per cent by cable haulage, and 84.4 per cent by horse and mule haulage. In 1912 the electric haulage systems handled 67.7 per cent, the cable haulage 0.7 per cent, and horse and mule haulage 31.6 per cent. In figuring these percentages the amount of coal handled by hand and

a Compiled from State mine inspector's annual reports.

other haulage was small and was therefore disregarded. Table 55 shows the percentage of coal handled by the three systems. The fatalities, shown in a parallel column, include in addition to those due to mine cars and locomotives underground, 13 fatalities due to animals and 8 fatalities from electric shock as being attributable to the haulage system. The table shows in general an increasing rate, which is due not so much to electricity as to the more rapid transit and the nearer approach to railroad operations.

Table 56 shows the number of mine locomotives in use in West Virginia from 1899 to 1913. The number of mines using locomotives in 1899 was 63, while in 1913 it was 502. The number of electric locomotives has increased from 24 in 1899 to 1,365 in 1913. The number of steam locomotives has decreased slightly, having dropped

from 64 in 1899 to 46 in 1913. The use of compressed-air locomotives has not increased and in 1912 gasoline locomotives were introduced, 17 being installed in that year and 28 in 1913.

a Compiled from the annual reports of the State mine inspector. **b** Not reported.

In Table 57 is shown the number of electric haulage motors used in Ohio from 1889 to 1913. In 1889 there was only one electric haulage motor; in 1913 there were 612. The table also shows the increase in the number of electric and compressed-air mining machines.

# ACCIDENTS DUE TO ELECTRICITY.

Table 58 shows the number of fatalities by States in and about the coal mines due to electricity since its introduction into the mines. These include both surface and underground fatalities, of which there were 710. The largest percentage of this number of fatalities was due to direct contact with the trolley wire. This group represents practically 50 per cent of the total number of fatalities. The next largest group is that due to contact with machine feed wire, by which 131 were killed, representing 18.45 per cent. The miscellaneous column is unfortunately large, inasmuch as sufficient details were not given in the description of the individual accidents in order to enable a proper classification of these fatalities. Many of them were reported simply as ''electrocuted,'' no details whatever being given; hence this column represents 128 fatalities, or 18 per cent of the total.

2

In Table 59 is given a classification of accidents due to electricity as compiled from the coal-mine inspectors' reports of Great Britain. The majority of the fatalities were caused by alternating current at voltages ranging from 250 to 650. It is to be expected that the majority of the accidents should be within this range of voltage, as it is used almost exclusively at the mines.

TABLE 60.—NUMBER OF MEN KILLED BY SHAFT ACCIDENTS IN AND ABOUT THE COAL MINES OF THE UNITED STATES, BY STATES, DURING PERIOD SHOWN ENDED DEC. 31, 1913, FOR WHICH CONTINUOUS RECORDS ARE AVAILABLE.ª

a This table is based on Table 5, and is for periods indicated, by States for which continuous records are available. It does not necessarily check with Tables 3 and 4 for the reason that the latter tables include intermittent records prior to the period having continuous records.

#### MINE SHAFTS.

Table 60 shows the number of fatalities, by States, due to accidents at shafts and subdivided into four different groups, as falling down shafts, objects falling down shafts, cages or skips, and miscellaneous. During the period represented 1,811 were killed by shaft accidents, of which number 843 occurred in and about the anthracite mines. The large number of fatalities at the anthracite mines is not exceptional for the reason that practically all of the mines are opened by shafts, whereas in the bituminous mines, except some in the Central and Western States, the majority of the mines are opened by slopes and drifts. During 36 years only 217 were killed by reason of shaft accidents at the Pennsylvania bituminous mines, while in Illinois during the 29-year period 266 men were thus killed. The average number of men employed per year in the Pennsylvania bituminous mines is about twice the number employed at the Illinois mines (Table 7), showing that the high Illinois rate, which is more than three times as high as at the bituminous mines of Pennsylvania, is due to the fact that the mines are operated through shafts instead of slopes and drifts. The Illinois mines are more nearly comparable with the anthracite mines in this respect.

More than one-half of all fatalities at shafts are due to persons falling down the shaft, either from the surface or from the various landings. Cages and skips are responsible for slightly over one-third of the shaft accidents. These two causes offer a good field for safety work, and, as shown in Table 4 and figure 1, the accidents at coal-mine shafts are being reduced by reason of vigilance on the part of the inspectors and the installation of safety devices by the operators.

# SURFACE SHOPS AND YARDS.

Table 61 shows the number of men killed at surface works about coal mines in the United States during continuous periods as indicated including 1913. The fatalities recorded in this table do not include accidents to coke-oven workers, as these have been eliminated in every case where sufficient information was given to identify the victim with the coking industry. The number of surface fatalities as shown is 3,573, representing 7.37 per cent of the total number killed in and about the mines. The rate per 1.000 men employed is 0.24. Of the total number killed 2,321 were at the surface workings of the anthracite mines and a large percentage of these were killed in the breakers. The accidents in the breakers have been included by reason of the fact that this is one of the branches of the industry which is absolutely necessary to prepare the coal for the market The coke-oven fatalities of the bituminous field were eliminated for the reason that they are considered foreign to the preparation of the coal for market. It is a second step in which the coal, so to speak, is manufactured into another product.

Almost one-half of the surface fatalities are due to mine cars and locomotives and railway cars and locomotives, thus pointing out the need for closer supervision and better equipment of haulage systems. Boiler explosions and bursting steam pipes are responsible for 214 fatalities. Machinery claimed 775 victims, 629 of which were at the anthracite mines and include many breaker accidents.

a This table is based on Table 5, and is for periods indicated, by States for which continuous records are available. It does not necessarily check with Tables 3 and 4, for the reason that the latter tables include intermittent records prior to the period having continuous records.

### ACCIDENTS CLASSIFIED BY OCCUPATION.

Data for mine accidents as related to the occupation of the employee are far from complete. Many of the mine inspectors' reports give the occupation of the man who has been fatally injured, and from these reports it is an easy matter to actually compile figures for certain States showing the total number killed in each occupation. However, these reports, with but one or two exceptions, fail to give the actual number of men employed in the specified occupations, and since data of this character are lacking, it is not possible to arrive at any true comparative hazards for the various occupations. The fatality figures may show a larger number of men killed in one occupation, possibly ten times as many, than in some other class of work. At the same time, there may be twenty times as many men engaged in this particular work, so that the hazard would not be as great as indicated by the actual number of men killed. For example, there are relatively few shot firers in the mines as compared with other underground employees, and the actual number of shot firers killed is therefore much smaller than in some other occupations, yet it is an extremely hazardous occupation. To obtain the relative hazard of each occupation the number engaged therein is necessary.

Mine inspectors' reports for the State of Pennsylvania from 1902 to 1913, inclusive, show both the number of men killed in certain of the principal occupations and the corresponding number of men employed therein. Table 62 shows fatalities by occupations in the anthracite mines from 1881 to 1913, inclusive. The corresponding number of men employed, however, is shown only for miners and

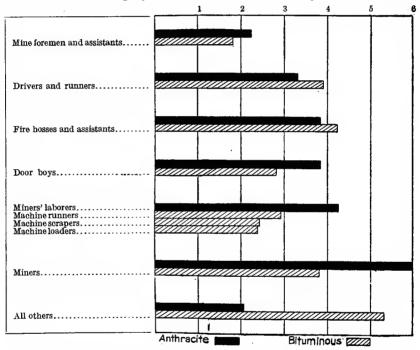

FIGURE 6.—Average number of men killed per thousand employed in anthracite and bituminous mines of Pennsylvania, by occupation, 1902-1913. (Based on Tables 62 and 63.)

miners' laborers. Beginning with 1900 complete figures to and including 1913 are given for the number killed, as well as the number employed in the various occupations. The highest fatality rate is for the anthracite miners, which averages for the period 1900 to 1913, 6 per 1,000 men employed. The fatality rate for the miners' laborers is 4.29 per 1,000 employed. The fatality rate for fire bosses and assistants is 3.86, as compared with 4.29 in the bituminous mines. The rate for mine foremen and assistants is also higher, being 2.28 as against 1.86 in the bituminous mines. The relative occupational hazards for the two periods covered, for both the anthracite and bituminous coal mines of Pennsylvania, are graphically shown in figure 6.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Total. ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |        |        |            |        |                                     |       |

a Compiled from annual reports of the Department of Mines, Harrisburg, Pa.

95

Table 63 shows the number of men employed and number killed, classified by occupations, in the bituminous mines of Pennsylvania from 1902 to 1913, inclusive. During the 12-year period the fatality rate for miscellaneous employees was 5.35 per 1,000 men employed; fire bosses, 4.29; drivers and runners, 3.96; and miners, 3.83.

# NONFATAL INJURIES IN COAL MINES IN THE UNITED STATES.

There are no complete records of the nonfatal injuries at the coal mines in the United States. In 1911 the bureau collected direct from the operators statistics relating to nonfatal injuries for that year. The number of serious a injuries reported was 9,106 and of slight injuries, 22,228. These reports were doubtless incomplete, as many of the mining companies were not keeping complete records of all accidents at their mines. Furthermore, there were but few compensation laws in effect which compelled the operators to keep records of nonfatal injuries.

The number killed per 1,000 employed in the metal mines is less than in the coal mines when compared on an equal time basis of 300-day workers. In view of this fact there is no reason to believe that the number of nonfatal injuries should be less in the coal mines than in the metal mines.

The best figures available on this subject are those collected by the United States Bureau of Mines for the metal-mining industry. The bureau has issued reports covering a period of four years, 1911 to 1914, in which the number of nonfatal accidents reported represent about 30 per 1,000 wherein the injured person was off duty 20 days or more by reason of disability. The bureau's reports show that approximately 150 men per 1,000 received minor injuries resulting in a disability varying from 1 to 20 days. These figures are based upon voluntary reports of the mining companies to the Bureau of Mines. Since there is no Federal law requiring these reports, it is believed that the above rates are too low. This view is supported by a special study of metal-mine accidents for 1914, which contains the reports of 258 companies whose accident records are reasonably complete. The study shows that 50 per 1,000 are seriously injured (disabled 20 days or more), while 270 per 1,000 are slightly injured (disabled 1 to 20 days). These injuries, however, apply only to, and are based on, 75,000 men employed either underground or in the open-pit mines, excluding all surface, shop, and mill men. Taking the average metal-mine rate for a period of four years as a basis of injuries in the coal mines, there would be approximately 22,900 persons seriously injured and 114,500 persons slightly injured each year.

<sup>&</sup>lt;sup>a</sup> Serious injuries include those causing a loss of time of 20 days or more. A slight injury is one causing a loss of more than one day but less than 20.

In 1911 two-thirds of the serious and slight injuries in the coal mines were due to falls of roof and pillar coal and mine cars and locomotives. About one-half of the nonfatal injuries in the metal mines were due to these two causes, showing that there are more injuries in the coal mines from them than in the metal mines. The coal mines have a much larger area of roof exposed than do the metal mines, and in most cases the haulage system is more extensive by reason of the longer haul and the excess tonnage handled, thus increasing the coal-mine hazard as compared with metal mines. These being the principal causes of nonfatal injuries, there seems reason to believe that the above estimate is too low rather than too high.

Tables 64, 65, and 66 show the injuries as reported by the State mine inspectors in their latest published reports for the States indicated. These tables represent 6,719 injuries, which have been classified according to the part of the body injured, and also by causes. The accidents are also tabulated by States with reference to the part of the body injured and the cause of the injury. These tables are far from being complete, inasmuch as they represent only the more serious injuries. For example, the report for Illinois includes only those accidents in which the injury resulted in a loss of 30 days' time or more. In some of the States no time is specified and no statement given to indicate what class of injuries is included in the report.

These tables will be of some assistance to the hospital department of the various coal mines, inasmuch as they point out the part of the body receiving the most injuries and will give the surgeons and others an idea as to the surgical equipment necessary to properly take care of the injuries to be expected in and about the coal mines.

|                | Number. | Percentage.    |
|----------------|---------|----------------|
| Head           | 427     | 6.36           |
| Face           | . 290   | 4.32           |
| Shoulders      | 330     | 4.91           |
| Arms           | 544     | 8.10           |
| Hands          | 948     | 14 <b>. 11</b> |
| Body           | 1, 190  | 17.71          |
| Hip and pelvis | 281     | 4.18           |
| Legs           | 1, 987  | 29.57          |
| Feet           | 722     | 10.74          |
| Total          | 6, 719  | 100.00         |

NUMBER AND PERCENTAGE OF INJURIES RECEIVED BY MEN EMPLOYED IN AND ABOUT COAL MINES, BY PARTS INJURED.

...

With the enactment of compensation laws in the various States, it is hoped that in the near future there will be more complete data available to afford a basis for a detailed study of nonfatal injuries.

[See also fig. 7.]

However, sufficient data concerning fatal injuries have been collected and tabulated herein to form a basis for an intensive study of the various accidents by causes. Any safety device, rule, regulation, law, or instruction to miners that will reduce fatal accidents will also reduce the nonfatal accidents. The difference between the two

classes of accidents is only one of degree or severity. The cause still remains the same: fall of rock, mine car, or explosive. If a falling rock strikes a man on the head or body it may kill him, but if it strikes only his foot or hand, seriously injuring him, the cause, fall of rock, is the same. By removing the cause of fatal accidents, the number of nonfatal accidents will be greatly reduced.

### FATALITIES AT BITUMINOUS COAL MINES.

Inasmuch as bituminous coal mining differs so much from the mining of anthracite, Tables 67 and 68, covering the bituminous coal-mining industry from 1890 to and including 1914, have been

compiled. Complete data prior to 1890 would be desirable, but for a study of present-day mine accidents it is believed that these tables go back sufficiently far to show the actual hazards of the bituminous mines.

The total production and the number of men employed in all bituminous mines of the United States are given in Table 67. In the second part of the same table are given the production and number of men employed in those States which are under inspection service and for which accident records are available. In 1890, 89.60 per cent was represented by inspection States, whereas for the same year \$5.96 per cent of •the employees were in the same group.

Table 68 shows the fatalities at bituminous mines by the same groups of causes as in Tables 4, 5, and 6, which include the anthracite mines. It also shows the actual number killed in each group and the percentage of fatalities due to each class, as well as the number killed per 1,000 men employed.

Figure 8 shows the fatality rates by principal causes from 1891 to 1914. In 1890 the number killed by falls of roof and pillar coal per 1,000 men employed was 1.259. This rate gradually increased until

106

in 1909 it was 1.951. Since 1909 the rate has been decreasing until in 1914 it was 1.548 per 1,000 men employed. With reference to mine cars and locomotives the fatality rate per 1,000 men employed in 1890 was 0.163. The rate increased quite uniformly to 0.593 per 1,000 employed in 1913. The rate for 1914 was slightly lower. The fatality rates due to gas and dust explosions have been very erratic, reaching the highest point in 1907, when the rate was 1.796 per 1,000 employed. Since the year 1907 this rate has decreased, although irregularly, to 0.523 per 1,000 employed in 1914.

The fatality rate due to explosives gradually increased from 1890, during which year the rate was 0.182 per 1,000 employed, to 1903, when it reached its highest point, 0.339 per 1,000. Since the introduction of permissible explosives and more strict rules concerning the handling and use of explosives, together with more efficient mineinspection service, the fatality rate has gradually decreased until in 1914 the number killed per 1,000 employed was 0.096. This reduction is illustrated in figures 5 and 8.

The number of accidents at shafts has decreased slightly, whereas the number of those on the surface shows a gradual increase.

The percentage of coal mined by machines since 1891, when the first records are available, is shown in figure 10. In 1891 only 5.26 per cent of the bituminous coal was mined by machines. The quantity has steadily increased year by year until in 1914, 51.7 per cent of the coal was reported as machine mined. The upper curve in figure 10 includes all hand-mined coal as well as that shot off the solid as distinguished from the machine product. Details of accidents as related to machine mining follow.

### MACHINE MINING.

A study of coal-mine accidents would not be complete without some reference to machine mining. It would be very desirable, indeed, if it were possible to tabulate data for a period of years, showing the actual number of men employed in machine-worked mines, together with the corresponding casualties occurring therein. Data of this character are not available, however, and hence it is impossible to make such a study. The United States Geological Survey, however, has for a number of years, 1896–1913, collected and published data showing the percentage of coal mined by machines in each State, and this information is used as a basis for the study of mine accidents as tabulated herein.

In comparing figures of production, number of men employed, fatalities, etc., for the 18-year period, those States have been included in which complete accident-fatality records and the number of employees are available. Inasmuch as details are lacking to show the number of mines where mining machines are used, the only other alternative whereby comparative results may be obtained is to group the States according to the percentage of coal mined by

machines. Four groups have therefore been used as follows: Group I includes those States in which less than 20 per cent of the coal produced was mined by machines, leaving the other 80 per cent of the coal as mined by hand or shot off the solid. Group II includes those States in which 20 to 39 per cent of the coal produced was mined by machines. Group III includes those States in which 40 to 59 per cent of the coal produced was mined by machines. Group IV includes those States in which 60 per cent or more was produced by mining machines.

<sup>a</sup> Compiled from annual volumes of Mineral Resources, U. S. Geol. Survey.

GROUPING OF STATES, ACCORDING TO PERCENTAGE OF COAL MINED BY MACHINES, FOR THE PERIOD 1896-1913, AND NUMBER OF YEARS EACH STATE IS REPRESENTED IN EACH OROUP.

[Group I, less than 20 per cent mined by machine; Group II, 20 to 39 per cent; Group III, 40 to 59 per cent; Group IV, 60 per cent or more.]

The fatalities during this period have been divided into two classes, namely, common and exceptional. Common accidents are those of daily occurrence in which less than 5 men are killed at one time. Exceptional accidents are defined as those including mine disasters in which 5 or more men are killed at one time.

#### PRODUCTION.

Table 73 shows the production of coal for Group I from 1896 to 1913. The production of this group, 113,995,776 tons in 1896, has gradually declined until in 1913 it was only 39,509,308 tons. Group II (Table 76) produced in 1896, 16,780,981 tons and reached its highest point in 1902. In 1913 the production of this group was 41,373,914 tons. A number of States, in Group II, passed from this group into Group III (Table 79) in 1904, so that Group III, while not producing any coal in 1896, produced 340,591,068 tons in 1913. Group IV (Table 82), in which more than 60 per cent was mined by machines, does not make its appearance until 1900. It then dropped out for four years and appeared again in 1905 with 25,552,950 tons. In 1913 this group produced 57,048,913 tons.

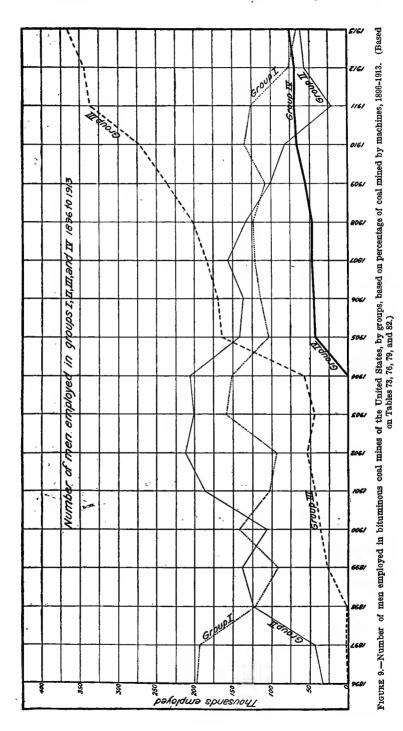

# NUMBER OF MEN EMPLOYED.

Tables 73, 76, 79, and 82 show the number of men employed in each group for the period covered (fig. 9). The number employed in Group I, 197,180 men in 1896, has gradually declined until in 1913 there were 67,714 employed in this class of mines. Group II began in 1896 with only 34,306 men and gradually increased to 207,976 men in 1904. At the close of 1904 a large percentage of this group passed into Group III, so that although Group III does not show any employees in 1896 there were 366,880 employees in 1913. The number of men in Group IV varies from none in 1904 to 75,452 in 1913.

## EFFECT OF MACHINE MINING ON FATALITY RATES.

Table 69 shows by States and years the number of mining machines in use from 1891 to 1914. During this period the number of machines has increased from 545 to about 17,000, and the production per year per machine has increased from 11,398 tons in 1891 to 14,802 tons in 1913. Table 70 shows the number of each of five different types of machines in use since 1899.

As there has been an enormous increase in the use of mining machines, Tables 69 to 85 have been compiled for the purpose of analyzing accidents as related to this method of mining. When mining machines were first introduced, there were many who felt that they added another serious hazard to the coal-mining industry.

Although their use may have increased the number of accidents due to machinery and electricity, yet the results shown in Tables 69 to 85 and figures 10 to 15 do not seem to bear out the first impression. The increase of accidents due to machinery and electricity seems to be more than offset by the decrease in fatalities due to explosives, as shown in Table 5.

As indicated, the fatality rate, in those groups where the percentage of machine mining is largest, is lower than in those groups where the amount of coal undercut by hand or shot from the solid is the largest.

As indicated in Table 71 and figure 10, the first three groups are practically of the same rank, each employing slightly over 2,000,000 men during the 18-year period. Group IV is much smaller, employing only 522,293 men. The total production for the first three groups is nearly the same, so that comparisons for those groups may be made on an equal basis. The total number of men killed in exceptional accidents, in all of the groups, was 5,183, and in common accidents. 21.475. In Group I the number of fatalities due to exceptional accidents was 2.476, representing a rate of 1.11 per 1.000 employed. The exceptional-accident rates per 1,000 men employed are 0.76 for Group II, 0.38 for Group III, and 0.20 for Group IV. The rates for common accidents are 2.98 for Group I, 2.81 for Group II, 2.92 for Group III, and 2.62 for Group IV. There is a gradual decline in the total-fatality rate, ranging from 4.09 per 1,000 employed, in Group I, to 2.82 in Group IV. The number of fatalities per million tons mined in Group I is 6.89 for the entire period, and in Group III, which has the lowest rate, is 4.00, for Group IV it is 4.16.

In Table 72 (figure 11), the four groups are compared by principal causes of accidents, showing the percentage of fatalities and the number killed per 1,000 men for each group.

### CAUSES OF ACCIDENTS.

The fatalities due to falls of roof (figure 11) are practically the same for each of the four groups, ranging from 1.70 in Group I per 1,000 men employed to 1.79 in Group III. The percentage of fatalities due to falls of roof is lowest in Group I, ranging from 41.66 in Group I to 60.90 in Group IV. The comparison on a percentage basis is not however as true as that based on the actual number of men employed. A sudden increase or decrease in one particular class of accidents affects the total, and percentages derived from this base will be more or less altered. When comparisons are made on the basis of actual number of employees, a large disaster due to one cause will not alter the comparisons for the other causes as the rates are derived from a base that remains unchanged.

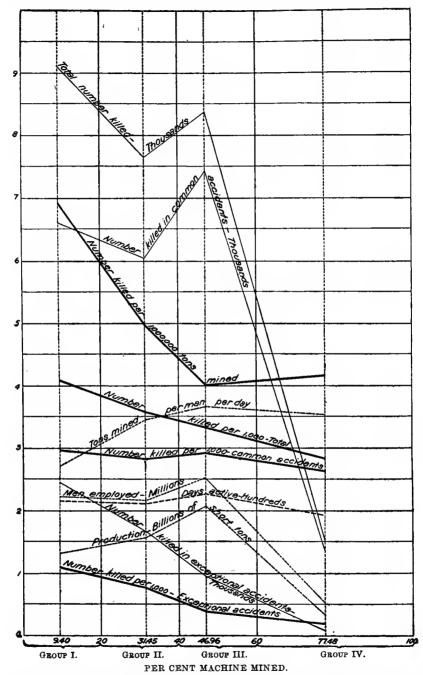

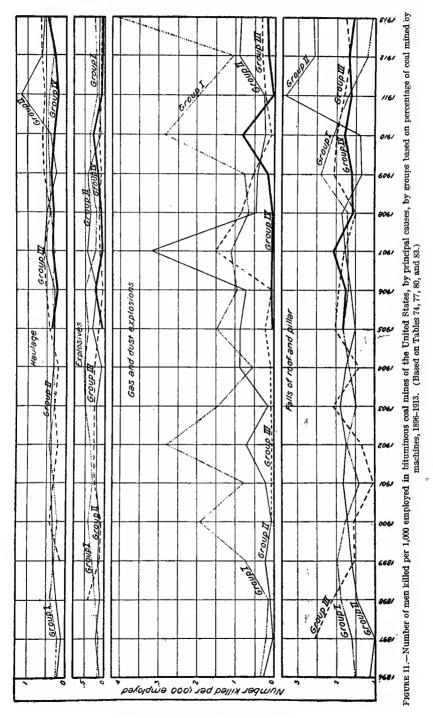

FIGURE 10.—Total number killed, fatality rates, menemployed, tons produced, and days active at the bituminous coal mines of the United States, by groups based on the percentage of coal mined by machines, 1896–1913. (Based on Table 71.)

There is but little difference in the fatality rate by reason of accidents due to mine cars and locomotives (fig. 11). In Groups I and IV the rates are practically the same, being 0.35 and 0.34 respectively, but in Groups II and III the rates are slightly higher.

## GAS AND DUST EXPLOSIONS.

The most striking difference in the number of fatalities in the various groups is in accidents due to gas and dust explosions. It will be noted that 29.40 per cent of all of the fatalities in Group I were due to gas and dust explosions, and that the percentage due to this cause declines as the percentage of machine-mined coals, only 6.92 per cent of the total fatalities in Group IV being due to this cause. As stated above, the percentage comparison is not as fair as that based on the number of men employed. The fatality rate in Group I due to gas and dust explosions was 1.20 per 1,000 men employed during the 18-year period, in Group II the rate was 0.66, in Group III, 0.39, and in Group IV, 0.19 per 1,000 employed. These differences are shown in figure 11.

#### EXPLOSIVES.

As would be expected, the fatality rate due to explosives (fig. 11) is higher in Group I than in the other groups. In Group I the maximum amount of explosives is used and much of the coal mined is shot off the solid; its fatality rate is 0.33 per 1,000 men employed. In Groups II, III, and IV, where less explosives are used, the fatality rates are 0.23, 0.12, and 0.15 per 1,000 employed, respectively. In the latter two groups there is a minimum amount of explosives used in the coal mines.

With reference to miscellaneous underground, shaft, and surface accidents there is no variation of importance.

#### MINING CONDITIONS.

These figures are not absolute proof that lower fatality rates in Group IV as compared with Group I are due to the larger use of machines in the mines of Group IV. Many small mines are included in Group I in which hand mining prevails. The small mines do not always have the most improved equipment, and many times less attention is given to safety measures. The mines in Group I use a maximum amount of explosives, are operated under all classes of roof conditions, and include all types of coal beds ranging from thick to thin with various degrees of inclination, from horizontal to vertical.

The hand-mining mines are in most cases operated more hours a day and, as shown in Table 71, more days a year as compared with Group IV. The number of days active is 218 for Group I, 212 for Group II, 227 for Group III, and 192 for Group IV. With the excep-

tion of Kentucky, the employees in Group IV are all on an 8-hour basis. The other groups contain many 9 and 10 hour men.

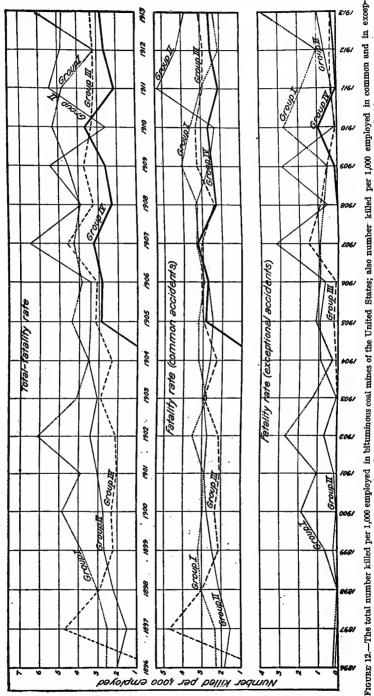

As regards the mines in which the major part of the coal is mined by machine, they include but few small mines and hence have more systematic management. When a mine has reached the stage where the management is financially able to install machines, it is usually conducted on a more business-like basis than are the small and poorly financed properties, has better haulage systems, and more efficient ventilation. In machine mining a minimum amount of explosives is used and in a mine where machines are introduced it is essential that good roof conditions prevail and that the coal bed is of reasonably uniform thickness. Also machines are operated in the flatter lying beds and are seldom used in the steeply inclined measures. The majority of the States in which the largest percentage of coal is mined by machines are operated on an 8-hour basis and less days per year, hence the time of exposure to the dangers of mining is less.

# FATALITY RATES ON BASIS OF COAL MINED BY MACHINE.

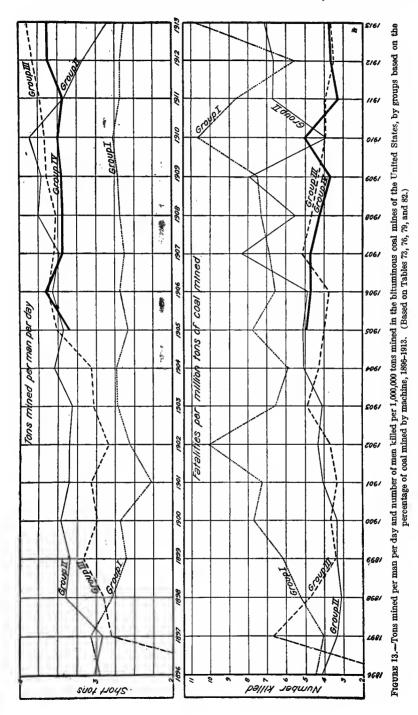

The total fatality rate at the four groups of mines, based on the percentage of machine-mined coal, from 1896 to 1913, is shown in figure 12. The upper part of the figure represents, as indicated, the total fatality rate at bituminous coal mines during this period. The second or middle part of the figure shows the fatality rate due to "common" accidents, that is, those in which less than 5 men are killed at one time. These rates are reasonably close together, Group IV showing the lowest and Group I, as a whole, the highest rate. The lower part of the figure shows the fatality rate due to "exceptional" accidents. Here again Group I is high, and is followed closely by Group II; Group IV is exceedingly low.

The amount of coal mined per day per man in the various groups of mines is given in figure 13. The curves show that in Group I, in which less than 20 per cent of the coal was mined by machine, the average number of tons mined per day is 2.72 (Table 73), while in Group III it ranges from 2.80 to about 3.90 tons per day. Group II is more erratic, and since 1910 many of the mines originally in this group have passed into Group III, so that since that year there has been a decrease in the amount of coal produced per man per day. Group IV remains practically stationary, with an average of 3.53 tons per day.

Figure 13 also shows the fatalities per million tons mined according to the four groups outlined above. In Group I the fatality rate is exceedingly high when based on the number of tons mined per fatality. This rate varies from 4.06 to 10.68, the average being 6.89 (Table 73). As would be expected, the number of fatalities per million tons produced in Groups III and IV are considerably lower than in the other two groups, the average being, respectively, 4.00 and 4.16.

tional accidents, by groups based on percentage of coal mined by machine, 1896-1913. (Based on Tables 73, 76, 79, and 82.)

### PART II.—COAL-MINE STATISTICS FOR EACH STATE BY CALENDAR YEARS.

### INTRODUCTION.

The following pages give detailed information of the coal-mining industry by States, arranged in alphabetical order, and calendar years. Most of the information has a bearing on the accident hazard. Comments are made on the coal-bearing area of each State, the character of the coal beds, that is, whether the beds are thick or thin, flat or inclined, and data are given concerning the roof conditions. There are also notes on the methods of mining, whether long-wall, roomand-pillar, etc., with statements as to whether the coal is mined by hand, machine, or shot off the solid.

In the State tables are complete figures for the production of coal from the beginning of the industry to the end of 1914; also the number of men employed, the number of fatalities, and the fatality rates per 1,000 men employed and per million tons of coal produced since the beginning of inspection service. The tables also give the number of days the mines were operated each year, the number of tons of coal mined per man, per day, and per year, together with the number of mining machines in use since 1891, or since their introduction into the mines, if adopted at a later date.

There is also for each State one table showing all the fatalities by causes and calendar years, for which complete records are available, and with this as a start it should be an easy matter for each State to continue its records on the calendar-year basis. There will also be found under each State data as to the number of hours worked per day and the number of men employed in each group of 8, 9, or 10 hour workers. Fatality rates have also been calculated on the basis of a uniform year of 2,000 hours, so that true comparisons of one State with another may be readily made. Under each State will also be found a list of all of the mine disasters in which five or more men were killed at one time. The last table under each State gives data concerning strikes and lockouts, showing the number of men involved and the total amount of time lost.

While the area of the coal fields will be found under each State, the accompanying table shows, in addition, the estimated original supply, the production in 1913, and the total production to the close of 1913; and in the last column is shown the estimated available supply of coal in the various States at the close of 1913 as estimated by the United States Geological Survey.

AREAS OF THE COAL FIELDS BY STATES, ESTIMATES OF ORIGINAL AND PRESENT SUPPLY, AND THE PRODUCTION TO THE CLOSE OF 1913-Contd.

a Including Arkansas and Texasignite fields of Gulf province. • Encludes slatshe coal from Nevada. • Encludes slatsgause miles supposed, but not definitely known, to contain usable coal, and 28,470 square miles in which the coal lies under cover 3,000 or more feet in thickness.

135

### ALABAMA.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The Alabama coal fields form the southwestern end of the Appalachian coal region, which extends from Pennsylvania to Alabama. There are four distinct fields: The Coosa field, on the southeast; the Cahaba field, somewhat west of the Coosa; the Warrior field, 7 to 10 miles west of the Cahaba field; and the Plateau field, in the northeast corner of the State and northeast of the Warrior field, and not entirely separate therefrom. These fields were originally connected, but have been separated since their formation by erosion along the lines of faults or anticlines. The total remaining area is now about 8,500 square miles not including the area, probably of considerable size, beneath younger rocks to the southwest of the visible margin of the coal-bearing rocks.

### COOSA FIELD.

The Coosa field, or basin, is a structural trough 6 miles wide extending for 60 miles through Shelby and St. Clair counties and containing about 260 square miles. It is faulted along its southeast margin, so that in general only the western half of the trough remains. The coal beds dip to the southeast at angles varying with the locality from 10° to 50°. However, the structure is less simple than the above description indicates, for at the north end there are a number of small subordinate basins due to local faults and folds, and in the southern two-thirds, the structure, although it is rather more regular, is affected by internal faults and folds. The conglomerate, sandstone, and shale, which comprise the coal-bearing rocks, are of great thickness, probably not less than 10,000 feet as a maximum. The best known part of the field is the northeast, where there are 18 coal beds, each of which varies considerably in thickness from place to place, the minimum thicknesses varying from zero to 24 feet and the maximum thicknesses from 8 inches to 5 feet 8 inches. These beds lie in the small subordinate basins above mentioned and in the upper 4,000 feet of the rocks, so that their total area is probably not over onetenth of the area of the field, say 35 square miles. In the other parts of the Coosa trough the coal beds are not so well known but appear to be few and comparatively thin. Excepting two beds the character of the Coosa coals has not been adequately determined. So far as shown by the tests made, the coal is high-grade bituminous with low sulphur and medium ash contents and of about the hardness of the southern Appalachian coals generally. One bed is reported to yield good coking coal.

### CAHABA FIELD.

The Cahaba field, or basin, like the Coosa field, is a synclinal trough lying a few miles west of the Coosa field. It is about 68 miles long and extends from the northeastern part of Bibb County through Shelby County into St. Clair County, its average width is about 6 miles except in the southwest third where it expands to twice that width, and its area is about 350 square miles.

Like the Coosa field the eastern half of the Cahaba trough is faulted. except for a few miles at the south end, where the southeast limb of the syncline in a vertical or slightly overturned attitude is preserved. Along the western margin of the trough the dip varies from 10° to 60° southeast. In the north half of the field this southeast dip prevails to the fault in the southeast, but extending along the middle of the southern half of the field the southeast dip is interrupted by a high anticline with a vertical dip on the northwest limb and a dip of 40° on the southeast limb near the crest, but diminishing gradually to a low dip southeastward to the boundary fault, except for the few miles where the southeast limb of the trough is preserved. In this area the rocks bend abruptly upward and stand vertical at the surface. In addition to these major folds, there are a number of subordinate basins along the southeastern margin, caused by transverse folds with dips of all degrees up to vertical. Several faults of varying magnitude are known, but apparently faults are few.

The coal-bearing strata, conglomerate, sandstone, and shale, are about 9,000 feet thick in the southern part of the field and about 5,000 feet in the northern part.

In the southern part there are at least 17 coal beds that in some part of their extent are 2 feet or over in thickness, the thickest bed being 5 to 6 feet. Most of the beds, with the exceptions of local thinning or thickening, range from 2 to 4 feet in thickness.

The coal is high-grade bituminous with a low to medium ash content, a generally low sulphur content, and, as a rule, is of average hardness. It is said to make a good quality of coke, but the yield is lower than the Warrior coals, so that the product is all consumed as domestic, steam or gas coal.

### WARRIOR FIELD.

The Warrior coal field, or basin, lies 7 to 10 miles west of the Cahaba field and extends westward nearly to the State boundary. It is a quadrangular area, including all or parts of the following counties: Jefferson, Walker, Tuscaloosa, Fayette, Marion, Franklin, Lawrence, Winston, Cullman, Morgan, and Blount. The Warrior field is not definitely separated from the Plateau field on the northeast, and their limits have not yet been definitely defined. The combined area of the two fields is about 7,600 square miles. Along the southeast edge of the Warrior field the strata dip 90° to 40°, or less, to the west; but throughout the remainder of the field are nearly flat or gently and broadly warped. The rocks, conglomerate, sandstone, or shale are about 3,000 feet thick.

The number of workable coal beds is about fifteen. They constitute the following groups from below upward: Black Creek, Mary Lee, Pratt, and Brookwood, each named from its most important coal bed. The bottom of the Black Creek group is about 900 feet above, and the top of the Brookwood is about 2,300 feet above, the bottom of the coal-bearing rocks, so that the main coal beds extend through about 1,400 feet of strata.

The Black Creek, the lowest and most extensive bed, averages about 3 feet thick and is an excellent domestic coal, for which it is mainly used. The Mary Lee group contains five beds, but at all points one "big seam," which possibly may be everywhere the same bed, or at different points may be one or another of the five beds. This "big seam" is of great areal extent, varies from 5 to 10 feet in thickness, and includes many thin or a few thick clay partings. The Pratt group likewise contains five coal beds, of which three are important, one of the three being the Pratt bed, which over large areas is 3 to 5 feet thick, with at some places a thin parting or two and at others being all clean coal. The Brookwood group includes three or four beds, of which the Brookwood bed is the most important, being 3 to 7 feet thick. This group, being high in the coal-bearing rocks, occupies only a relatively small area in Tuscaloosa County. The "Big seam," Pratt, and Brookwood beds are the thickest in the Warrior basin. In 1899 the Pratt beds yielded 65 per cent of the total coal production from the basin, and in recent years about 33 per cent.

The average composition of 23 samples of the different coal beds of the Warrior basin is approximately as follows: 2.4 per cent moisture, 28.4 per cent volatile matter, 59 per cent fixed carbon, 10.2 per cent ash, and 1.74 per cent sulphur. It is a high-grade bituminous coal of medium hardness and a domestic steam and coking coal. Practically all the coke consumed in the State is made from coal from the "Big seam," Pratt bed, and the beds of the Brookwood group, of which the principal one is the Brookwood.

### PLATEAU FIELD.

The Plateau field comprises a long belt on Sand Mountain extending from the Warrior field, with which it is continuous on the southwest, to the northeast corner of the State, a number of detached areas to the northwest of the Sand Mountain belt, the detached area of Lookout Mountain, and the semi-detached area of Blount Mountain on the southeast of Sand Mountain. These various areas lie mainly in Madison, Jackson, DeKalb, Etowah, Marshal!, and Blount Counties.

The character of the rocks is the same as in the other fields, but their thickness and the number and thickness of coal beds are not well known. There are perhaps four or six different beds, more or less local in extent, which range from 2 to 4 feet in thickness.

Except on the western edge of Blount Mountain, where the rocks are vertical, the dip is slight and in most parts of the field the rocks are nearly flat.

### MINING METHODS.

Coal mining was first begun in the Coosa basin in 1836, and in the Cahaba field in 1856. General uniformity in mining methods prevails throughout the Birmingham district with the exception of slight modifications which are rendered necessary by differences in the geologic structure. In the Coosa and Cahaba basins the coal-bearing strata generally dip from 5° to 30°, but, as on the southeastern margin of the Cahaba basin, the dip is 60° or in places even 90°. Practically all of the mines are opened by slopes, the main entry following the dip of the coal. From these slopes the coal is mined by the roomand-nillar system. In the central and western parts of the Warrior field, where the coal beds are nearly flat and the coal is above the drainage levels, the mines are opened almost exclusively by drifts. Along the southeastern margin of the Warrior basin, where the dip is 40° to 90°, the mines are opened by slopes; at a few mines shafts are employed for reaching the lower coal. Shafts are also used in the southern part of the basin where the coal-bearing formations pass below the drainage level. The room-and-pillar system of mining also prevails in this part of the district. In 1899 only one mine was reported as using the long wall system, and only 31 per cent of the output was mined by machines, whereas in 1913 the machine-mined coal amounted to 23.3 per cent. The number of machines in operation in 1899 was 53, and in 1913, 377. In 1912, 35.1 per cent of the coal was shot off the solid, and in 1913, 39.9 per cent, an increase of 5.8 per cent. Tail rope, endless rope, electric, and mule haulage are employed.

### ROOF.

So far as the character of the roof is concerned, whether sandstone or shale, it is generally strong. The roof of the Thompson bed

14355°-Bull, 115-16-10

(southern part of the Cahaba field) is of shale 10 feet thick that slakes rapidly and falls badly, so that it is necessary to put in heavy timber in the main haulage ways. A fragile shale roof is reported in a few mines.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The office of inspector of mines of Alabama was created by an act approved February 18, 1891, applying to all coal, iron, or other mines where 20 or more men were employed underground. The inspector was appointed by the governor, and was required to examine every mine at least once every three months. By an act approved February 16, 1893, the operators were required to notify the inspector of fatal accidents, and the inspector, at the operator's request or the request of three miners, examined into the cause of such accidents, and preserved in his office a record of each accident of which he received notice. Biennial reports were rendered to the governor. The act of February 18, 1895, made it the duty of mine operators to report to the inspector serious as well as fatal accidents in and about the mines. A chief inspector and two associate mine inspectors were provided for by the act of February 16, 1897, the chief inspector to report biennially to the governor. The act of April 18, 1911, authorized the governor to appoint an inspector of coal mines for each 24 million tons of coal mined, or majority fraction thereof, based on the output for previous years as compiled by the chief mine inspector, one of the inspectors so appointed to be designated chief inspector, and the others associate inspectors. and one of them to be a mining engineer. The law required the inspector to report to the governor before the legislature convened.

The practice of mine operators in Alabama is to report to the inspectors all accidents causing 10 days' disability. A serious injury is considered as one causing disability for 30 days, a slight injury being one which disables an employee 1 to 29 days. Only the serious injuries are published in the inspector's annual reports.

In 1915 there were one chief inspector and six district inspectors.

### ACCIDENTS.

The accompanying tables show the number of fatalities by causes and calendar years since 1893 as compiled from the State mine inspectors' annual reports. These tables also show the percentage of accidents, classified by principal causes, and the fatality rate per 1,000 men employed over a period of 21 years for which continuous records are available. The fatality rate during this period is 5.25 per 1,000 men employed. Since 1897 to the end of 1913 there have been 12 disasters in which 5 or more men were killed at one time, representing a total of 500 fatalities, or approximately 27 per cent of the total

FATALITIES IN ALABAMA COAL MINES, BY PRINCIPAL CAUSES, DURING 21 YEARS, 1893 TO 1913, INCLUSIVE.

|                                                                                                                                                                             | N                                         | ımber kill                                                                             | ed.                                             |

killed from 1893 to 1913. Falls of roof are responsible for 38.31 per cent of all the fatalities since 1893; gas and dust explosions combined represent 33.32 per cent. The average production of coal per fatality was 118,865 tons, or there were 8.41 fatalities per million tons mined.

Since 1903 practically 62 per cent of the men employed in the mines of Alabama have been on a 10-hour basis. This alone partly accounts for the higher rate when compared with Iowa or Ohio, in which States all of the men are on an 8-hour day. The average number of hours worked a year per man is 2,255, as compared with 1,495 for Ohio or 1,704 for Iowa (Table 40). The fatality rate reduced to a 2,000-hour basis becomes 5.78 for the 10-year period 1903–1913, as compared with 6.52 per 1,000 men actually employed.

NUMBER OF HOURS TO THE WORKING DAY. BY YEARS, IN AND ABOUT THE COAL MINES IN ALABAMA.<sup>a</sup>

Tables have been compiled showing the fatality rates for all the States both on the basis of actual employees and the number of 2,000-hour workers, so that by referring to Tables 40 and 41 a true comparison of Alabama with other States may be readily made. The tables of statistics for the State follow:

# STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN ALABAMA.<sup>a</sup>

### ARKANSAS.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The semibituminous coal field of Arkansas occupies the westcentral part of the State, having a length from east to west of 75 miles. At the Oklahoma-Arkansas line it is about 50 miles wide and at the eastern extremity about 25 miles wide. It comprises about 1,580 square miles, of which 75 per cent is considered as productive. The coal-bearing rocks occupy the larger part of Crawford, Franklin, Sebastian, Johnson, and Logan counties.

The lignite field of Arkansas occupies the eastern part of the State and is possibly coextensive with the Tertiary rocks of the Mississippi Valley. The estimated area of these rocks is 6,000 square miles, but workable lignite has been discovered at only a few places, and at no place is it mined on a commercial scale.

### SEMIBITUMINOUS FIELD.

The semibituminous field is the eastward extension of the Oklahoma fields, but in Arkansas there is only one coal bed of commercial importance, the Hartshorne, which lies just above the massive Hartshorne sandstone and at the base of the Spadra shale. This coal is mined extensively in the vicinity of Huntington, Midland, Greenwood, and Jenny Lind, in the western part of the field, and is from 3 feet to 8 feet thick. Where the bed is less than 4 feet thick, it is generally clean coal, but where the thickness increases to 6 or 8 feet the bed is broken by many soft shale partings.

The field as a whole is a broad, open synclinal basin or trough, with many minor folds and faults that break the regularity of outline and seriously interfere with economical mining. The Hartshorne coal bed outcrops around the rim of the basin, but only part of the exposed outcrop is thick enough to mine under present conditions.

The coal is of high rank, comparing favorably with the Pocahontas and New River coals of the Appalachian region. In the west end of the field it is semibituminous, but its rank increases eastward to semianthracite about Spadra and Russellville.

### MINING METHODS.

The first records of coal production in Arkansas extend back to 1840, when 220 tons of coal were mined. The production has gradually increased to 1913, when 2,234,107 tons were produced. Most of the mines are opened by shafts, but a few are opened by slopes. The room-and-pillar method of mining prevails throughout the State. About 99 per cent of the coal produced comes from the Huntington field, from what is known as the Hartshorne seam of Oklahoma. Coal-mining machines were used in Arkansas in 1896, at which time there were 14 machines in operation, producing about 3 per cent of the coal. Fifteen to 20 machines were kept in operation until the close of 1902, and from that year until 1910 no mining machines were used in the State. In 1911 there were 14 machines in use, producing a little more than 1 per cent of the coal mined. In 1913 there were 27 machines, producing slightly over 11 per cent of the coal. In 1912, 92 per cent of the coal was shot off the solid; in 1914, 78 per cent was thus mined.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

By an act approved March 7, 1889, the legislature of Arkansas established a Bureau of Mines, Manufactures, and Agriculture, under the supervision of a commissioner, whose duties included the collection and publication of statistics setting forth the extent of the mineral resources of the State, the purpose being to encourage immigration to Arkansas. The act made no provision for the investigation or reporting of mine accidents, but a subsequent law, approved April 4, 1893, which was still in force in 1914, provided for the appointment by the governor of a mine inspector, to whom all fatal or serious accidents in coal mines should be reported by mine operators. The inspector investigates all fatal accidents to determine the cause thereof. He is required to personally inspect all coal mines in the State where 20 or more men are employed underground, to insure the safety and health of the workmen, and to see that the provisions of the act are properly observed and enforced. The act is not applicable to mines employing less than 20 men. Annual reports are rendered to the governor on the 1st day of November of each year.

Mine operators report to the inspector all injuries resulting in at least two days' disability, and these are included in the annual reports which the inspector renders to the governor. Injuries involving 10 or more days' disability are classified as serious, all others being considered slight injuries.

In 1915 the inspector employed no assistants.

### ACCIDENTS.

The accompanying tables (Nos. 87 and 88) give the production, number of employees, and number of men killed in and about the coal mines of Arkansas, compiled from the best records available. The accident records began with 1897, although the inspection service began at an earlier date. There are no records for the years 1899, 1900, and 1904, and the record for 1903 is incomplete. For the 9-year period for which continuous records are available, 1905 to 1913, inclusive, 107 men were killed, representing a fatality rate

| FATALITIES IN | ARKANSAS | COAL MINES,  | BY PRINCIPAL | CAUSES, | <b>DURING 9 YEA</b> | ARS, |

complete data are available, is 2.36 per 1,000 men employed. This, however, reduced to a common basis of 2,000-hour workers, shows a rate of 3.74 per 1,000. Table 41 shows the other States worked out on a similar basis, so that comparisons may be readily made. The tables of statistics for the State follow:

### CALIFORNIA.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The area and distribution of the coal fields of California are described by Parker<sup>a</sup> as follows:

There are in California a number of small, widely separated coal fields, chief among them the Mount Diablo field of Contra Costa County, the Corral Hollow field of Alameda County, a small area in Amador County, the Priest Valley and Trafton fields of San Benito County, and the Stone Canyon field of Monterey County. The first two, which are on the eastern border of San Francisco Bay, and consequently in the westcentral part of the State, produce black lignite or subbituminous coal. The areas in Monterey County are more to the south and in or near a region which has been considerably distorted. The coals are of the same geologic age as those farther north, but they have been altered into true bituminous coals. The alteration in the San Benito County area has not progressed so far as in the case of the Monterey County coals, but they closely approach the bituminous grade. None of them possess coking qualities.

The records of the State Mining Bureau of California show a production of coal in that State as early as 1861. It was at that time one of the 16 coal-producing States, and, relatively, of some importance as a coal producer. During the latter part of that decade and throughout the following decade the coal production of California exceeded 100,000 tons annually and reached a maximum of 236,950 tons in 1880. Since 1881 the production has been irregular, having been influenced chiefly, up to the beginning of the present century, by the imports of Australian and British Columbian coals, the receipts of Australian coals depending principally upon the wheat production and shipments from the Pacific coast. Since 1900, with the great increase in the production and use of petroleum which began in that year, coal production in California has fallen to an insignificant quantity.

### ACCIDENTS.

Tables 89 and 90 show the production of coal and the number of men employed since 1889, for which reasonably complete records are available. Records of fatalities, however, date back only to 1909. In 1876 there was one explosion at Nortonville, in which six men were killed, and in 1909 there was another at Chancellor, which also killed

COAL-MINE ACCIDENTS IN CALIFORNIA IN WHICH FIVE OR MORE MEN WERE KILLED.

|      | Date.   | Name of mine. | Location of mine. | Nature of accident. | Numher<br>of men<br>killed. |  |
|------|---------|---------------|-------------------|---------------------|-----------------------------|--|
| 1876 | July 24 | Black Diamond | Nortonville       | Mine explosiondo    | 6                           |  |
| 1909 | Jan, 19 | Stone Canyon  | Chancellor        |                     | 6                           |  |

six men. As is shown by the table following, the coal-mining industry of California is small, hence little attention has been given to the collection of accident and labor records. With the passage of the compensation laws no doubt more complete records will be available in the future. The tables of statistics for the State follow:

a Parker, E. W., The production of coal: Mineral Resources of the United States for 1913, U. S. Geol. Survey, 1914, pp. 819-820.

Table 80.—PRODUCTION, NUMBER OF MEN EMPLOYED, AND NUMBER OF MEN KILLED IN AND ABOUT THE COAL MINES IN **CALIFORNIA**, BY CALENDAR YEARS; ALSO TONNAGE MINED PER MAN, AS WELL AS THE NUMBER AND KIND OF MINING MACHINES IN USE. [Figures compiled from Mineral Resources, U. S. Geol. Survey, except figures in column 4, which were reported direct to the Bureau of Mines by the operators. Figures in columns 9 and 10 calculated.]
