FRANKLIN K. LANE, SECRETARY

BUREAU OF MINES VAN. H. MANNING, DIRECTOR

# COAL-MINE FATALITIES IN THE UNITED STATES 1870–1914

WITH

ł

# STATISTICS OF COAL PRODUCTION, LABOR, AND MINING METHODS, BY STATES AND CALENDAR YEARS

COMPILED BY ALBERT H. FAY

...

WASHINGTON GOVERNMENT PRINTING OFFICE 1916 The Bureau of Mines, in carrying out one of the provisions of its organic act—to disseminate information concerning investigations made—prints a limited free edition of each of its publications.

When this edition is exhausted copies may be obtained at cost price only through the Superintendent of Documents, Government Printing Office, Washington, D. C.

The Superintendent of Documents is not an official of the Bureau of Mines. His is an entirely separate office and he should be addressed:

SUPERINTENDENT OF DOCUMENTS, Government Printing Office, Washington, D. C.

The general law under which publications are distributed prohibits the giving of more than one copy of a publication to one person. The price of this publication is 40 cents.

First edition. April, 1916.

# COAL-MINE FATALITIES IN THE UNITED STATES, 1870-1914, WITH STATISTICS OF COAL PRODUCTION, LABOR, AND MINING METHODS, BY STATES AND CALENDAR YEARS.

Compiled by ALBERT H. FAY.

## PART I.-COAL-MINE STATISTICS FOR THE UNITED STATES BY CALENDAR YEARS.

## INTRODUCTION.

The first data compiled by the Bureau of Mines relating to coalmine accidents in the United States were published in Bulletin 69,ª in which the total fatalities by years and States were tabulated from 1896 to 1912. Since the publication of Bulletin 69, further research has been conducted, with the result that the bureau is now able to publish for the first time all of the fatal accidents described in the State inspectors' reports by States, causes, and calendar years, from the beginning of inspection service to date. For the anthracite mines of Pennsylvania, there is a continuous record since 1870; the records of the Pennsylvania bituminous mines are continuous from 1877, and. with the exception of one year, the Ohio records are complete from 1874 to date. In fact, the records of all of the States, with few exceptions, are complete; and incomplete data for any year may generally be attributed to the fact that no report was published during that year.

The magnitude of the coal-mining industry in the United States is such that too much stress can not be placed on the need of safeguarding the three-quarters of a million men employed. Although the figures given herein show an appalling record for past years, they are not published for the purpose of proclaiming the high fatality rate of the past. They are a record of experience covering a period of 45 years, showing causes and results of many accidents in the coal mines They represent a diagnosis of the hazard of of the United States. the mining industry, pointing out the principal physical causes of accidents, and make available a body of uniform facts that will serve as a basis of preventive measures for use in future operations. is with these great purposes in view that the Bureau of Mines presents the classified data in this report.

<sup>&</sup>quot; Horton, F. W., Coal-mine accidents in the United States and foreign countries: Bull. 69, Bureau of Mines, 1913, 102 pp. ٨

Classification and study of mine accidents on the basis of number of persons killed is common and very old, but fails to throw enough light upon the problem involved. Many serious accidents in mines have no fatal results, hence in a tabulation of fatalities they are overlooked and the real hazard of the industry is not made clear. An accident does not necessarily include an injury that may result therefrom. Such accidents as the breaking of a hoisting cable, an explosion of powder, gas, or dust, a runaway car or motor are all serious. Although no loss of life results, they should be recorded, investigated, and studied to prevent their repetition.

No accurate data for the United States are available showing how far the personal element as related to the miner and his co-worker. the mine foreman, or to the superintendent and others in authority. contributes to accidents. Many accidents are due to inexperience on the part of the miner, his failure to heed orders, a misunderstanding of instructions and last, but not least, carelessness of himself or his fellow worker. A foreman or superintendent may fail to give proper warning regarding the conditions of certain parts of the mine; he may not have inspected certain rooms or entries on the day of a mine accident; the mine may not be properly equipped, or the operator may neglect to comply with the inspector's recommendations. There is, therefore, a personal element on the part of both the operator and the miner that must be considered. Legislation and the enactment of compensation laws will make the operator realize the seriousness of the mine-accident situation, when fatalities and injuries are to be paid for in legal tender of the realm. The miner must be educated and made to realize the dangers he encounters; he must learn that self-preservation and the safety of his fellow workmen should receive his first attention; he should cooperate with his employer, his associates, and the State mine inspector to the end that the mine hazard may be reduced to a minimum. "Cooperation for safety" should be the watchwords of the operator, miner, State inspectors, and all others in any way interested in the mining industry.

## SOURCES AND SCOPE OF STATISTICS.

The fatalities classified in the State tables have been compiled from the State mine inspectors' reports. The details relating to each individual fatality, as published by the inspectors, have been carefully reviewed and the fatality classified according to the cause of the death as reported. The date of the accident has also been taken into consideration, so that all of the tables have been prepared on the basis of a calendar year. Thus, for the first time, the coal-mine fatalities of all the States are placed on the same basis. It is hoped that those States that classify fatalities by fiscal years will realize the value of a uniform classification and will adopt the calendar year as their basis. Inasmuch as figures based on the calendar year have been used throughout this bulletin, it has not been possible to make the State tables check absolutely with the published reports of the inspectors. Some of the States have years ending June 30, others in May, September, October, or November.

In the compilation of these tables, all fatalities that were not directly attributable to the mining industry have been eliminated, including coke-oven accidents, suicides, natural causes, and murders. In a number of the earlier reports accidents of this character were included in the inspectors' returns.

Data relating to the production since 1807, the number of men employed since 1889, the number of days worked, the number of mining machines in use since 1891, the percentage of coal mined by different methods since 1911, the spot value of the coal, and notes on the coal areas and distribution have been taken from the annual volumes of the Mineral Resources of the United States, published by the United States Geological Survey. The data relating to mining methods have been compiled from both the reports of the United States Geological Survey and the State mine inspectors. It is not feasible to indicate the source of each individual item by footnotes, as that would be both burdensome and confusing. The general statement as above given, it is hoped, will indicate plainly the source of the data herein. Wherever practicable, footnotes have been inserted, showing the source of tables and direct quotations.

Notes relating to the mine-inspection service were compiled from the State mining laws and submitted to the individual State inspectors for verification and comment, and their corrections or additions have been included.

## ACKNOWLEDGMENTS.

Acknowledgments are due to the following persons for technical assistance that has made possible the completion of the data compiled herein, and for suggestions that have been used in the preparation of the tables and other data: Dr. J. J. Rutledge, mining engineer, E. S. Boalich, mine statistician, and W. W. Adams, clerk, of the Bureau of Mines; M. R. Campbell, geologist, of the United States Geological Survey, who revised the notes on the various coal fields of each State; and the State mine inspectors, who supplied missing data and revised notes relating to the mine-inspection service of their respective States.

## NUMBER OF MEN EMPLOYED.

'Although the majority of the State mine inspectors' reports give the number of men employed in the coal-mining industry for each year, many of the reports are based on fiscal years, and as the fatalities have been classified according to calendar years, the actual number of employees would not be in accordance therewith. Some of the inspectors have included coke-oven employees, and as coke-oven accidents have been excluded, these workers should be omitted. It seemed best, however, that the number of employees should be obtained from one source, as in so doing the statistics relating to employees would be on the same basis for all the States. The bureau has, therefore, used the number of employees as reported by the United States Geological Survey since 1889 (except 1909 and 1911). As the figures have been collected by one bureau, they are on a uniform basis and, furthermore, they are for calendar years and do not include coke-oven employees. For comparative purposes the number thus reported employed will be much better than one based on reports from 25 or 30 sources and for varying fiscal years.

The number of employees in the coal-mining industry for the year 1909 was compiled by the mining division of the Bureau of the Census and was published by the United States Geological Survey in 1910, as 666,552. In 1912 State figures for 1909 were compiled by the same bureau and published by the Bureau of Mines in Technical Paper 48,<sup>a</sup> in Bulletin 69,<sup>b</sup> and in each of the monthly statements of coal-mine fatalities to date. These publications have had wide circulation and have been used by many mining companies, State officials, and insurance organizations, and for this reason the figures showing coal-mine employees in 1909 as previously published by the bureau have been used in this bulletin.

The final census figures for 1909, published in 1913, show the number of employees on December 15, 1909, as 743,293. That figure, however, includes a certain number of coking establishments and, furthermore, as the coal-mining industry employs the largest number of men at that season of the year, the number reported on that date is too high to represent a fair average.

The census report for 1909, page 196, also gives the number of employees on the 15th day of each month during the year, the average of which is 681,090. The same report also gives the number of men employed on the 15th of each month during the year by States, the average of which is 680,872, as compared with 666,552, published by the United States Geological Survey and the Bureau of Mines. These two census figures, although agreeing closely, seemingly include certain coke workers. Taking everything into consideration, it is believed that the Bureau of Mines is justified in adhering to its first published figures (666,552), although this fails to check with the final census figures by about 2 per cent.

For the year 1911 the bureau collected accident statistics and at the same time obtained direct from the operators the number of men employed, both on surface and underground. The number of employees thus obtained has been used throughout this bulletin.

## UNDERGROUND AND SUBFACE EMPLOYEES.

Complete statistics showing separately the total underground employees, as well as surface employees at coal mines are not avail-

a Horton, F. W., Coal-mine accidents in the United States, 1896-1912, with monthly statistics for 1912, 1913, 74 pp.

b Horton, F. W., Coal-mine accidents in the United States and in foreign countries, 1913, 102 pp.

The number employed since 1889, as reported by the Geologiable. cal Survey, is combined as one item, but coke-oven employees are not included. As there are no separate data for these two classes of employees, Table 6 has been prepared, the underground and surface employees being calculated on the basis of the 1911 returns to the Bureau of Mines. In this year 122,513 surface employees were reported at coal mines (exclusive of coke workers) or 16.82 per cent of the total. The total number employed each year since 1895 has been separated on the above basis, with underground and surface fatality rates calculated independently. The 20-year period chosen is considered sufficiently long to be thoroughly representative and thus to throw a little more light on the real underground hazard. For example, the fatality rate in 1913, based on all employees, was 3.725 per 1,000, whereas the underground rate was 4.218, or 13 per cent higher than the combined rate. The surface rate for the same year was 1.283. Similar comparisons with other years may be made.

## COAL-MINE FATALITIES IN THE UNITED STATES, 1839-1914.

Table 1 shows by calendar years the total number of fatalities recorded for the coal-mining industry of the United States as compiled from the State mine inspectors' reports, and from other authentic sources. This table shows that since 1839 to the end of 1914, 53,078 men have been killed in and about the coal mines in the United States. This number, however, is not complete, as mining was carried on in all of the coal-mining States several years prior to inspection service, and as the number of fatalities that occurred in the early period of the industry has not been recorded, except for a few of the larger disasters in which 5 or more men were killed.

The 49,733 fatalities given in Table 2 represent those occurring in 89.46 per cent of the industry as based on the tonnage from 1807 to the end of 1913. The fatality rate per million tons mined during the 10 years from 1870 to 1879 was 8.70. If this figure be taken as representative of the early stages of the industry and applied to the remaining 10.54 per cent of the production from 1807 to and including 1909, not represented by accident statistics, an estimated 9,000 fatalities should be added to the 49,733, making the total to the end of 1913 as 58,733. The total fatalities to the end of 1914 are, therefore, 61,187, of which number 53,078 are accounted for in Table 1.

The total number of fatalities shown in Table 1 does not necessarily agree with the totals shown in Tables 2, 3, and 4, because in the latter tables only those fatalities have been included for which the corresponding number of men employed was obtainable. In Table 1 the figures covering 1888 to the end of 1914 do check with the above tables. Prior to 1888 the table covers a number of mine disasters in States in which the number of men employed was not obtainable. In the subsequent discussion of mine accidents Table 1 is ignored and the lessons to be drawn are based on Tables 2, 3, and 4, which contain complete comparable data for 49,733 fatalities.

Figures for the total production of coal in the United States from 1807 to the end of 1914, and the total number of men employed in the industry since 1889 are given in Table 2 and are plotted in figure 1. The table and the figure show the total number of men killed in and about the coal mines in the United States for which complete records are available. It will be noted that in 1870 the percentage of the industry covered by the mine-inspection service (fig. 2), based on the production, was 47.42 with 35,600 men employed. The figures for the total number of men employed are not available. In 1871 the percentage of the industry represented by the production was 41.25 with 37,488 men employed. The figures for the first four years, 1870 to 1873, include only the anthracite mines of Pennsylvania. From 1874 on, a number of other States adopted inspection service, so that by the close of 1888, 87.29 per cent of the production was from States having inspection and representing 285,517 men. The first complete record of the number of men employed in all of the coal-mining States was in 1889, when 311,717 men were employed. Of this number, 283,198, or 90.85 per cent, were employed under the inspection service. The percentage of the production represented by in-

spection States for the same year was 90.54. From 1889 to date the percentage of production and the number of men employed under inspection service agree with each other within less than 1 per cent. Beginning with 1910 complete figures are available for all of the States, thus representing 100 per cent of the industry. Beginning with 1870, the fatality rate per million tons mined was 13.47 (see fig. 2). This has been gradually reduced until in 1914 it was 4.78. The average amount of coal produced per man per year in 1870 was 440 tons, whereas in 1913 it was 762 tons, and in 1914, 673 tons. Although the figure for tons per man per year was less in 1914 than in 1913, the figure for tons mined per day per man was 3.25 in 1914 as compared with 3.20 in 1913.

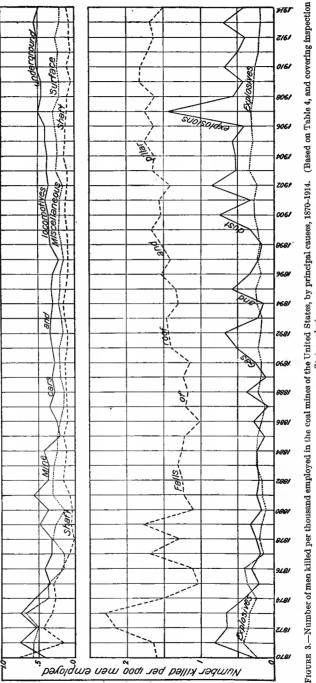

Table 2A shows the number of men employed in and about the coal mines by States and calendar years from 1889 to 1914 inclusive.

Table 3 shows the total number of fatalities in the inspection States, for which reports were issued, by calendar years and causes, from 1870 to the end of 1914. This table is a summary of the State tables presented in Part II of this bulletin, as compiled from the State mine inspectors' reports.

Table 4 shows coal-mine fatalities by principal causes, the total number of fatalities, the percentage of the grand total, and the number killed per 1,000 employed (see fig. 3) for a period of 44 years, from 1870 to and including 1913. During this period 23,260 men were killed by falls of roof and pillar coal. The fatalities due to falls of roof and pillar coal in 1870 were 1.60 per 1,000 men employed, while in 1913 it was 1.69. There seems to be but little variation from these figures throughout the 44-year period, the average being 1.554.

Fatalities due to mine cars and locomotives (fig. 3) in the earlier years of inspection service show a slight decrease to about the year 1885. In 1885 the percentage of fatalities due to mine cars and locomotives was 8.01, or 0.206 per 1,000 men employed. Both the percentage and the rate per 1,000 men employed have increased until in 1913 the total percentage was 15.22, while the number killed per 1,000 employed was 0.567.

With reference to gas and dust explosions (fig. 3) both the percentage of the fatalities and the rate per 1,000 men employed are erratic. The lowest figure was in 1887, when 4.36 per cent of the total number of fatalities was due to gas and dust explosions, or practically one fatality per 10,000 men employed. This rate has increased in an irregular manner, reaching the highest point in 1907, when the total percentage of fatalities due to this cause was 29.49, or 1.417 fatalities per 1,000 men employed. Since 1907 there has been some reduction in both percentage and the rate per 1,000 men employed, but this is irregular and in all cases higher than it should be.

Accidents due to explosives also show a decrease from the beginning of inspection to about 1887. From 1887 to 1903 there was an increase, and from 1903 to date the rate has gradually declined.

The fatalities due to shaft accidents (fig. 3) are gradually decreasing, the rate per 1,000 men employed in 1870 being 0.758, while in 1913 it was 0.083.

Table 5 contains the same grouping by causes as does Table 4. It, however, shows fatality rates by States for continuous periods for which records have been published. It contains 1,279 less fatalities than Table 4, by reason of the fact that intermittent records prior to the period of continuous records have been omitted. (See Pls. I and II.)

## REDUCTION IN FATALITY RATES AND THE GROWTH OF MINE-INSPECTION SERVICE COMPARED.

The relation between mine-inspection service and the fatality rates at coal mines from 1870 to date is shown in figure 2. The upper curve represents the actual percentage of coal produced under inspection service to the close of 1909. From 1910 to 1914 the Bureau of Mines has received accident reports direct from the operators in those States wherein there is no mine inspection. These States are California, Georgia, Idaho, North Carolina, and Oregon. The coal produced in the noninspection States is less than 0.1 per cent of the total so that the curve from 1910 to 1914 may be accepted as representing the inspection service.

In 1869, 179 men were killed in a mine fire at Avondale, Pa. The following year a law provided for systematic inspection of the anthracite mines. Pennsylvania was therefore the first State to establish a mine-inspection system. From 1870 to 1873 the curve shown represents the anthracite fields only. The fatality rate in 1870 in the anthracite mines was 5.93 per 1,000 men employed, whereas the number of fatalities per million tons mined was 13.47. Corresponding figures for 1914 for the Pennsylvania anthracite field are 3.31 fatalities per 1,000 men employed, and 6.55 fatalities per million tons mined. There are no records to show what the fatality rate in anthracite mines was for years previous to 1870. It was. however, high in 1869, on account of the Avondale disaster. The year 1870 was apparently normal as shown by the actual number of men killed in the anthracite field during the next few years, so that the number of fatalities in 1869 must have been more than 350, with not to exceed 35,000 men employed.

The next State to appoint a mine inspector was Ohio, in 1874, and the first complete inspection year for the Pennsylvania bituminous mines was in 1878, so that after 1874 other States have been added to the inspection list. Tables 8 to 39 show by years the number of inspection States for which complete records have been obtained, and it is upon these tables that the totals shown in Table 2 and the curves in figure 2 have been based.

During the first 10 years (fig. 2) of mine inspection the fatality rate per 1,000 men employed and the number of fatalities per million tons of coal mined declined rapidly. From 1880 to 1897 the fatality rate per 1,000 men employed remained practically stationary, while the number of fatalities per million tons mined showed a very slight reduction. From 1897 to 1907 the number killed per 1,000 employed increased considerably, reaching the highest point in 1907. Since that year there has been a marked decline.

The increase in the fatality rate from 1897 to 1907 is not necessarily due to less efficient mine inspection. The conditions under which mines were operated were changing. The mines were growing deeper; there were more old abandoned workings for accumulation of gas and dust; and more men were employed in the individual mines than in former years; so that in case of a gas or dust explosion, the likelihood of trapping more men was greater by reason of a larger number of men being employed. During this period there was an influx of foreign laborers, many of whom came from the agricultural districts of southeastern Europe. They had no experience in mining, did not know the English language, and hence were not capable of understanding and carrying out orders that were made in a tongue foreign to them. Although the inspection service has been increasing in efficiency from year to year, the various hazards, for the reasons mentioned, are also increasing.

The increasing fatality rate due to mine disasters, from 1897 and culminating with 1907, has been the means of the passage of more stringent laws concerning the operation of coal mines. Every disaster is thoroughly investigated by State and Federal authorities, as well as by the local engineers of the operating company, to determine the exact cause, so that similar disasters may be prevented in the States are establishing rescue and first-aid stations, and future. nearly every large mining company has its safety engineer and safetyfirst committees with the necessary rescue and first-aid equipment. An educational campaign on mine-accident prevention has been conducted since 1907 with the result that there is much closer cooperation of miner, foreman, operator, and inspector than in former years. Permissible explosives and improved types of safety lamps have been introduced into many of the mines. Explosibility of coal dust has been studied and precautions adopted to render the dust inert. The work of these various agencies has resulted in a gradual decline in the fatality rate from 1907 to 1914.

## **Missing Page**

## COAL-MINE FATALITIES, BY YEARS AND CAUSES, FROM THE BEGINNING OF INSPECTION IN 1870 TO 1914.

Tables 8 to 39, inclusive, show by causes and calendar years all of the fatalities occurring in and about the coal mines in the United States by combining those States for which there are complete inspection records. In the compilation of these tables all fatalities have been omitted for which the corresponding number of employees was not given. Thus one State may appear in a certain year and not in another simply because the records were incomplete. With reference to fatalities from 1870 to 1873, inclusive, which are represented only by the anthracite mines of Pennsylvania, the reader is referred to Table 125 under that State. The percentage of the industry covered by these tables, the number of men employed, and the fatality rate per 1,000 men employed, and per million tons of coal mined are shown in Table 2

14355°-Bull, 115-16---5

# CUSTOMARY BASIS FOR COMPUTING FATALITY RATES.

The customary basis for computing fatality rates is on the number of men employed in the industry. This basis is faulty to the extent that under existing conditions it is not possible to obtain the exact number of men at work, for the reason that all of the men do not work throughout the year. There are always a number of men who work a few days at one property and either quit or are discharged and go to other mines. The actual number of men on the pay roll is, therefore, much higher than the number of men really at work in the mines, and unfortunately it is the former figure that the operators too frequently report. It is also imperfect in that no distinction is made concerning the number of working hours per day. In some States the 8-hour day prevails, whereas in others 9 or 10 hours constitute a legal day.

The comparison of fatality rates on a percentage basis is far from being correct. For example, there may be 1,000 fatalities due to various causes in a certain group of mines, 50 per cent of which may be attributed to some one cause, as falls of rock, and 25 per cent to some serious gas and dust explosion. The difficulty with the percentage basis is that the number killed in a large disaster enters into the total number of men killed in that particular group of mines. When the total is thus abnormally increased the effect is to decrease the percentage rate of each of the other causes to balance the excess which is due to the one large disaster. In the assumed case above cited, in which 25 per cent of the fatalities were due to a gas and dust explosion, the elimination of the number killed (250) in this particular disaster from the total would leave only 750 fatalities, and the percentage of fatalities due to falls of rock, which in the first case was 50 per cent, would be increased to 66<sup>2</sup>/<sub>3</sub> per cent, although the actual number, 500, killed by falls of rock remains the same, and roof conditions have not changed.

The tonnage basis for comparison is also open to some criticism in that mining conditions are not the same in all mines or States. One mine may be in a coal bed 7 or 8 feet thick, and another mine in a bed 2 feet 6 inches thick. It is evident that a miner working in thick coal can produce more tons per year than a miner working in thin coal. The first mine would show a lower fatality rate on the tonnage basis, although in each mine the men were exposed to the mining risk the same number of days per year, indicating that the thicker coal bed is safer than the thinner bed. As a matter of fact the thinner coal bed is the safer of the two, as shown by the low fatality rate in Iowa as compared with the rates of Illinois and Indiana and some other States.

For certain purposes, each method has its champion, and in order to meet the requirements of all, the three bases have been used throughout this bulletin. But for true hazard rates, that one serves

best which takes into account the number of men and the time they are engaged in a hazardous occupation. This necessitates reducing all labor to a standard year of a certain number of hours, 2,000 or 3,000 as the case may be, representing a definite number of days (shifts) of 8 or 10 hours each. The ideal method would be for the operators to report the actual number of hours' labor for which wages were paid during the year. This figure divided by 2,000 would give the number of 2.000-hour employees; that is, the actual number of men who were exposed to the mining hazard the full 2,000-hour They would, therefore, all be on the same time basis. period. The total number of hours divided by 3,000 would place the employees on a 300 (10-hour) day year, but inasmuch as coal mines are operated less than 2,000 hours per year, the shorter year is more nearly in keeping with actual conditions, and therefore preferable. Figures approximating this condition are given in Tables 40 and 41.

TABLE 40.—FATALITY RATES BASED ON THE NUMBER OF 2,000-HOUR WORKERS AS COMPARED WITH THE RATE BASED ON THE NUMBER OF MEN REPORTED AS EM-PLOYED, 1903-1913, INCLUSIVE, EXCEPT 1909.

|                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                 | I                                                                                                                                                                                                     | 00011                                                                      |                                                                                                                                      | I                                                                                                                  |                                                                            |                                                                        |                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                              |

TABLE 41.—FATALITY RATES PER 1,000 MEN, BY STATES, COMPARED ON A UNIFORM BASIS OF 2,000-HOUR WORKERS.¢

 $a\,$  For details from which this table is derived see special tables under each individual State.  $b\,$  Complete data not available.

# COMPARISON OF FATALITY RATES ON A UNIFORM TIME BASIS.

In the comparison of mine accidents the time element should be taken into consideration. In other words, the length of time that a man is exposed to the mining risk is an important factor in arriving at the true risk in the mining industry, and especially so when one State is compared with another. With this end in view, Tables 40 and 41 are based upon a uniform period of two hundred 10-hour shifts.

The tables under the various States show the number of 8, 9, and 10 hour men over a period of 10 years. There are also a number of men unclassified, but for this comparative study they have been taken as 9-hour men. Concerning the actual number of working hours E. W. Parker says: <sup>a</sup>

It should be remembered, however, that when the length of the working day is stated, reference is made to the number of hours the mines are supposed to have been in operation and not to the number of hours worked by the miners. In both the anthracite and bituminous fields practically all the coal is mined by contract at an agreed rate per ton or other basis of payment. The miner is an independent contractor and is not obliged to put in a certain number of hours at his working place. The figures in the following table really indicate the number of hours the men were given an opportunity to work and do not mean that all the employees worked 8, 9, or 10 hours, as the case might be.

a Mineral Resources of the United States for the calendar year 1913, U. S. Geol. Survey, 1915, p. 754.

Since the settlement of the anthracite strike of 1902 the mines in that region have been operated on a 9-hour basis, with the exception of engineers and pumpmen, who work 8 hours, and of the miners, who work by contract.

While these figures as previously stated, may not be strictly exact, it is certain that in an 8-hour State there will not be many 10-hour men. Yet it is believed that in a 10-hour State the majority of the men will work about two hours longer than in an 8-hour State. Inasmuch as these labor statistics were all collected by one bureau, the United States Geological Survey, they are all on the same basis, and for comparative purposes should serve nearly as well as exact figures. They are the only figures available by which it is possible to attempt a study of mine accidents in relation to the length of exposure to the many dangers attending the industry.

Exact data along these lines are desirable; and it is hoped that mining companies, State officials, and industrial-accident commissions will realize the importance of arriving at a true risk and cooperate in obtaining such information as may reveal the true accident hazard in the mining industry.

The State tables (see list of States in Tables 40 and 41) cover a 10-year period from 1903 to 1913 inclusive, except for the year 1909, for which complete data are lacking. This information is available for 24 States, and the varying hours, number of employees, and the working days have been given proper weight, with the result that the total number of working hours in each State has been computed for the 10year period, and their sum gives the total number of working hours in all the States. This divided by the number of men reported working gives an average year of 1,909 hours for the United States as a unit. The working hours in each State divided by 2,000 gives the equivalent of 2,000-hour workers, upon which fatality rates may be based. The number of calculated 2,000-hour workers is given in parallel with a column showing the number of employees as reported.

Table 40 shows the number of working hours per year in each State as varying from 1,314 in Arkansas to 2,447 in Virginia. The Pennsylvania anthracite field works 1,985 and the Pennsylvania bituminous 2,034 hours per year. In view of the fact that this range varies from a few hours below to a few hours above 2,000, and that the average for the United States is 1,909, a 2,000-hour year has been adopted for calculations in the accompanying tables. It is more nearly in keeping with actual mining conditions to base the calculations on a 2,000hour year than it would be to base them on a 3,000-hour year, as is frequently done in factories, metallurgical works, and in other industrial plants. Anyone desiring a 3,000-hour basis may obtain it by adding 50 per cent to all of the rates given in Tables 40 and 41.

Table 40 gives the number of fatalities that are due to exceptional accidents and those due to common accidents, the exceptional acci-

dent being one in which five or more men are killed at a time, and the common accident one that occurs in every-day mining operations, wherein usually one or two men but not more than four, may be involved at a time.

The length of time during which miners are exposed to the hazards of the industry varies in different States, due to both commercial requirements and labor organizations. The number of hours a day is largely regulated by labor organizations and State laws, and the number of days worked a year is regulated more or less by commercial conditions. When the demand for coal is slight the output is curtailed by working part of the time, or by closing the mines entirely for several weeks to await better market conditions.

The actual average number of days that the mines are operated each year is given in the State tables. The tables show that this number varies from year to year for the same State. For example, in 1906 Colorado averaged 268 working days, while in 1911 the mines were operated 207 days. Arkansas in 1903 operated 223 days, and in 1910 only 128 days. Ohio varied from 161 days in 1908 to 206 days in 1913. With such wide differences in the number of days that the mines are in operation, it is evident that the hazards in each State are not the same.

Another reason why they are not comparable is that the number of hours worked per day is not the same in each State. For example, Ohio, Indiana, Illinois, Iowa, and a number of other States are on an 8-hour basis with but few 9-hour and 10-hour men. On the contrary, in Alabama, Kentucky, West Virginia, Maryland, and a few others, the majority of the men work 9 hours and many of them 10 hours, as shown in the State tables.

It is not a fair classification to place the fatality rate of an 8-hour State on an equal basis with that of a 10-hour State, when the men of the latter State are exposed to the mining risk 25 per cent longer. Every hour adds 12<sup>1</sup>/<sub>2</sub> per cent to the hazard, as compared with an 8-hour day. As an example of unfair comparison Ohio and Montana may The fatality rate for Ohio (Table 40) is 2.94 per 1,000, based be cited. on the actual number of men working, regardless of the time element. and the rate for Montana is 4.08 per 1,000. When the rates are reduced to a common basis of 2,000 working hours a year, the Ohio rate becomes 3.94 and the Montana rate 4.23, so that the difference on the 2,000-hour basis is 0.29, as compared with 1.14 per 1,000 on the customary basis. The same comparison may be made for other States. In Virginia many of the mines are worked 10 hours a day and from 200 to 280 days per year, thus increasing the time of exposure and giving on the customary basis a fatality rate of 6.74, which, if reduced to the 2,000-hour year, becomes 5.26, comparing favorably with West Virginia at 5.18 per 1,000.

# **Missing Page**

Table 41 shows the fatality rate by States and calendar years, for a 10-year period wherein all rates are based on the number of 2,000hour workers. The detail figures from which this table is derived will be found in the special tables in Part II under each individual State.

Plate III shows comparative fatality rates at the coal mines of the States in which coal is produced, based on a uniform period of 2,000 working hours per year, thus placing all of the States on a comparable basis, as indicated in Table 40. The circles represent the fatality rate per 1,000 men employed, wherein only the "common accidents" are considered. The solid circles represent the fatality rate per 1,000 men employed, for the "exceptional accidents." This chart represents the average of each State for a 10-year period, except where noted in Table 40. The common-accident hazard varies somewhat from one State to another, yet the difference is much smaller than usually shown where the time element is not taken into consideration.

# PRINCIPAL CAUSES OF MINE ACCIDENTS.

# COAL-MINE DISASTERS.

A summary of the coal-mine accidents in the United States in which 5 or more men were killed at one time, together with the number of such accidents, is given in Table 42. This table shows that since 1839 there have been 297 mine disasters in which 5 or more men were killed at one time, representing 7,590 fatalities. Of this number, 6,126 were killed by gas and dust explosions, 199 of the disasters falling into this class. There were 30 mine fires, claiming 809 victims. There were 144 accidents in which 5 to 9 men were killed at one time, representing 911 fatalities. Although this group represents the greatest number of accidents, the largest number of men killed is in that group in which from 100 to 199 fatalities resulted from a single disaster. There were 12 such disasters, resulting in 1,715 fatalities. Details relating to individual accidents classified in this table are given in Table 44. TABLE 42.-COAL-MINE ACCIDENTS IN THE UNITED STATES IN WHICH FIVE OR MORE MEN WERE KILLED, CLASSIFIED ACCORDING TO CAUSE AND NUMBER KILLED.

[See fig. 4.]

a Exceptional accidents are defined as those in which 5 or more men are killed at one time. Common accidents are those in which less than 5 men are killed at one time.

Table 43 shows, in parallel columns, by years since 1870 the number of men killed in common accidents and those killed in exceptional accidents, with fatality rates for each. For the entire period the rate for the exceptional accidents was 0.45 per 1,000 men employed, and for the common accidents 2.87. The rates for 1914 are slightly below the average. In figure 4 the total fatality rate is represented by a solid line, the common-accident rate by a dotted line, and the exceptional-accident rate by dashes. These curves show the lowest total and common-accident rates between 1885 and 1890. Since then these rates have increased to 1907, from which year there is a decline in the

fatality rate. This table shows that 6,692 men were killed in exceptional accidents since 1870, whereas the number killed in common accidents was 43,036. The number of fatalities represented in this table is based on those States for which complete inspection reports have been rendered.

Table 44 gives a *revised* list of all of the mine disasters<sup>a</sup> for which records are available from any source whatever since 1839 to and including 1915. This table presents details of the summary shown in Table 42.

| :            | Date.              | Name of mine.               | Location of mine.                            | Nature of accident.                         | Killed.               |
