### COLORADO.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Colorado comprise an area of about 19,700 square miles, but in 3,800 square miles of this territory the coal beds may be 3,000 feet or more below the surface.

The fields may be grouped geographically into three groups, known as the Eastern, Park, and Western groups. The fields of each group occupy more or less irregular synclinal basins along the foothills, and on the sides nearer the mountains the rocks are more or less upturned and disturbed.

The Eastern group includes the Trinidad, Canon City, and Boulder coal fields, which yield about two-thirds of the coal now mined in Colorado. The Park group includes the fields in the South, Middle, and North Parks in the north-central part of the State, and is not extensively developed.

The Western group is the largest in area. It includes the Yampa field in the northern part of the State, and, to the south of the Yampa, the Danforth Hills, White River, Grand Hogback, Glenwood Springs, Crested Butte, Grand Mesa, Book Cliffs, and Durango fields, the Durango being in the extreme southwestern part of the State. About one-third of Colorado's coal is produced in this group of fields.

### CHARACTER OF COAL BEDS.

In the Trinidad field the coal beds are the same as those of the Raton field in New Mexico and range from  $3\frac{1}{2}$  to 9 feet in thickness. In some sections as many as 7 workable beds have been discovered, all of which are contained in the lower 900-foot level of the Vermejo (formerly called Laramie) formation. In the southern part of the field the measures lie nearly horizontal, but to the north the inclination increases slightly, varying from 3° to 10°. The Trinidad field contains a large amount of coking coal and manufactures about 600,000 tons of coke annually. In some mines in the vicinity of Starkville a thick sandstone forms a good roof; in other mines there is a "draw slate" between the coal and sandstone, making a poor roof. In the vicinity of Gray Creek the coal bed is almost level and is rather irregular, ranging from 4 to 14 feet thick.

The second field, as regards production, is the Boulder field, north of Denver. There the coal is much softer than that of the Trinidad field, being classed as subbituminous (black lignite). The associated rocks are also softer, rendering mining more difficult than it is where the rocks are harder and form a better roof. The coal beds range in thickness from 3 to 14 feet and generally are flat-lying, except near the west edge of the basin, where the coal and also the adjacent sandstone and shale beds dip strongly to the east. In the Canon City field the rocks throughout most of the field dip west about 2° to 5°. Along the western margin of the strata is a thrust fault cutting across the coal measures, and near this fault the beds are sharply upturned, in some instances being practically vertical. The coal beds range in thickness from  $2\frac{1}{2}$  to 6 feet and generally are free from partings.

### MINING METHODS.

The production of coal in Colorado dates back to 1864, when about 500 tons was mined. The production for 1913 was 9,232,510 tons. The total production for the State up to the end of 1913 is 175,361,698 tons. In 1911, of 140 of the principal mines 41 were shaft and 99 were slope and drift mines. In Las Animas County, which is the largest producer, over 40 mines are slope mines; only one or two are shaft mines. The room-and-pillar system of mining prevails largely throughout the State.

In the Canon City district, the long-wall system has been used to some extent in coal beds that vary from 3 to 4 feet thick and are tapped by shafts 300 to 400 feet deep. At the Radiant mine, where the coal bed is 3 feet to 3 feet 9 inches thick, a combination of the room-and-pillar and the long-wall methods is used, and the coal is undercut by electric machines. The coal is jointed and breaks.into large lumps. At the Diamond mine, in the vicinity of Canon City, the coal beds dip 55° to 75°. At the Royal Gorge mine the dip is about 50° and the two coal beds mined are separated 5 feet to 7 feet. The lower bed is mined first by upward stoping from a horizontal level. The Littell mine is opened by a shaft 1,065 feet deep (1908), which is the deepest coal shaft in the State. The coal at this point dips about 5° to the west and is  $5\frac{1}{2}$  feet thick.

Coal-mining machines have been in use in Colorado since about 1891, at which time 20 machines were in operation. This number has gradually increased until in 1914 there were 306 machines in use, producing 25 per cent of the coal.

Shooting off the solid is practiced less in Colorado than in many other States, the coal thus mined in Colorado being 11 to 14 per cent of the total coal produced. About 60 per cent of the coal is produced by hand mining methods. The amount of coal mined per man per year in 1887 was 333 tons; in 1913 it was 770 tons.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The Legislature of Colorado, by an act approved February 24, 1883, provided for the appointment of an examining board, to examine applicants for the position of State inspector of mines. From the list of eligibles thus established the governor was authorized to appoint a mine inspector for a term of four years. Section 12 provided that the act should apply to any coal mine where more than 12 men were employed underground. The inspector was required to examine at least once each quarter every mine employing more than 20 men, to make a record of such inspection, showing the number of employees, and number of accidents and deaths, and to file a report in the office of the secretary of state on the first Monday in November preceding the biennial sessions of the legislature. This report was included in the biennial report of the secretary of state.

All accidents causing loss of life or serious personal injury were reported by the operators to the inspector. An act of April 8, 1885, extended the inspection law to cover all mines employing more than 10 men, and required the inspector to examine such mines quarterly. On April 2, 1887, a law was approved directing the inspector to render a biennial report to the governor showing the number of persons employed and the number of accidents and deaths from injuries in and about the mines; the inspector was also authorized to employ clerical or other assistance not to exceed \$1,500 per year.

An act approved April 4, 1913, authorized the governor to appoint a chief mine inspector and the chief thus selected to appoint five deputy inspectors. The chief and deputy inspectors are selected from a list of eligibles established by a board of examiners. The chief mine inspector divided the State into five districts and assigned one deputy inspector to each district. An annual report for the year ending December 31 is rendered to the governor, the report to enumerate all deaths and accidents causing disability for 5 days or more. Operators are required to render monthly reports of fatal and nonfatal accidents to the inspector, in addition to sending to the chief inspector immediate notice of all fatal accidents.

Accidents resulting in 5 or more days' disability, which under the law are reported to the inspector by mine operators, are published in the inspector's annual reports and are classified as serious or slight according to the judgment of the State mine inspector.

In 1915 the inspector was assisted by four deputies.

### ACCIDENTS.

Tables 91 and 92 show the total number of fatalities by causes and calendar years since 1883 as compiled from State mine inspectors' reports. The accompanying tables show the percentage of accidents, classified by principal causes, and fatality rate per 1,000 men employed, over a period of 28 years, 1886–1913, for which continuous records are available. The fatality rate during this period is 7.14 per 1,000 men FATALITIES IN COLORADO COAL MINES BY PRINCIPAL CAUSES DURING 1886 TO 1913, INCLUSIVE.

| 1913                                                                 | Dec. 10                                                          | Vulcan                                                                               | New Castle                                                                     | do                                 | 37                             |

employed. There were 19 accidents in which 5 or more men were killed at one time, representing slightly over 28 per cent of all of the fatalities due to mine accidents. Of the total number of fatalities 49.02 per cent were due to falls of roof and pillar and 29.75 per cent to gas and dust explosions. The average production of coal per fatality during this period was 96,798 tons, or there were 10.33 fatalities for each million tons mined.

Beginning with 1903 and including 1912 about 50 per cent of the men were on a 10-hour basis. In 1913 the 8-hour law became effective and only a few men were employed for a longer day than eight hours. The time element has been taken into consideration and tables compiled on this basis for comparison with other States. The fatality rate for the 10-year period, 1903–1913 (Table 40), based on the actual

number of employees is 8.71, whereas on the number of 2,000-hour workers it is 8.02 per 1,000. During the 10-year period the men averaged 2,172 hours employment per year. Table 41 shows the fatality rate for each year on the 2,000-hour basis, 1903–1913, for each State, so that a true comparison of Colorado with other States may be readily made.

The tables of statistics for the State follow.

#### GEORGIA.

### AREÅ AND DISTRIBUTION OF COAL FIELDS.

### Parker<sup>a</sup> describes the coal-productive area of Georgia as follows

The coal-productive area of Georgia underlies portions of two counties in the extreme northwestern corner of the State. The Walden Basin of Tennessee crosses Dade County, in Georgia, and extending southwesterly becomes the Blount Mountain and Warrior Basins in Alabama. The Lookout Basin, a narrow outlying area, extends from Etowah County, in Alabama, in a northeasterly direction into Walker County, Ga. The total area of the coal fields in Georgia is estimated at 167 square miles the smallest coal area of any Appalachian State. Not all of the field is workable. Extensive operations have been carried on in both counties, however, but all of the production in 1913 was by two companies operating in Walker County. On account of its high percentage (80 per cent) of fixed carbon and its low sulphur content, the Lookout Mountain coal (Walker County) gives a large product of excellent coke which is sold to the furnaces of Chattanooga and of other points in Tennessee and in Georgia.

The earliest report by the United States Geological Survey on the production of coal in Georgia is for 1860, when 1,900 tons were mined. The production gradually increased to its highest point in 1903, when 416,951 tons were produced, and since then has gradually declined to approximately 200,000 in recent years. No mining machines are used in the coal mines of Georgia. The reports of the United States Geological Survey show that all of the coal in 1913 <sup>b</sup> was shot off the solid. Of the total production, approximately onethird of the coal is washed.

### ACCIDENTS.

Tables 93 and 94 show the total number of fatalities by causes and calendar years since 1909. They also show the percentage of accidents and fatality rate per 1,000 men employed. The average production of coal per fatality during this period was 148,111 tons, or there were 6.75 fatalities per million tons mined.

a Figures for 1909 are from Mineral Resources, U. S. Geol. Survey; others from reports of mine operators as received by the Bureau of Mines.

### ILLINOIS.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The Illinois coal field is the western part of a broad and relatively flat basin which extends castward into Indiana and southeastward into Kentucky. On the southwestern border of the field the coal beds are turned up perceptibly, and on the south the margin is marked by a much steeper fold, which is overturned and faulted near Shawneetown where it crosses Ohio River. On the north border the coal beds are bent into a low, though sharply defined anticline which extends from La Salle southeastward toward Clark County. Minor folds, local in extent, occur in different parts of the basin, but in general the beds dip gently from the margins of the field to a central deep area where the coal-bearing rocks have a thickness of about 1,500 feet.

### CHARACTER OF COAL BEDS.

There are in the Illinois field a number of coal beds of varying thickness, each of which, however, is fairly regular and continuous over large areas. The coal production of Illinois is from six beds, Nos. 1 to 3 and 5 to 7. No. 6 is the most important and averages 6 feet thick. This bed produces over 50 per cent of the coal; No. 5 produces 25 per cent; and No. 2, 10 per cent.

The beds are practically horizontal and have been opened at different depths in the various counties. In Gallatin County two coal beds have been mined at depths of 60 and 180 feet, the upper being 5 feet thick and the lower 3 feet thick. In Macoupin County, near Virden, coal No. 5 is 7 feet 8 inches thick at a depth of 320 feet. In St. Clair County, near Belleville, coal No. 6 is 8 feet 4 inches thick at a depth of 380 feet. In Marion County, at Centralia, coal No. 6 is 7 feet thick at a depth of 569 feet and at Sandoval 6 feet thick at a depth of 603 feet. In Sangamon County the principal coal bed is 6 feet thick with a good limestone roof and is opened by shafts varying from 65 to 225 feet in depth. In Perry County the Belleville, or No. 6, coal bed is 5 to 6 feet thick at depths varying from 30 to 200 feet and dips slightly north. A shaft at Assumption, Christian County, is 1,003 feet deep, being the deepest in the State.

Illinois coal is bituminous, but has a moisture content as it comes from the mine of 7 to 16 per cent. The best coal contains 7 to 10 per cent of ash, one-half to 3 per cent of sulphur, and 40 to 50 per cent of fixed carbon.

### MINING METHODS.

The record of coal-production for Illinois begins in 1833, during which year 6,000 tons were mined. The production for the State has gradually increased until in 1913 it amounted to 61,618,744 tons.

As in Indiana, the shaft mines largely predominate over slope and drift mines, which number less than 50. In 1897 only 52 out of 853 mines used the longwall method, and these were in the northeastern part of the State in the No. 2 bed, where the coal is only 3 feet thick. In the other mines the room-and-pillar system of mining prevails with slight alterations for individual mines or different coal beds. In 1897 only one-half of the coal was undercut before blasting, leaving about 50 per cent as shot off the solid. In 1912, 40 per cent of the coal was shot off the solid, but in 1913 this was reduced to 32.3 per cent. In 1888 there were 272 mining machines in the mines, producing 18.9 per cent of the coal, and in 1913 there were 1,845 machines, which produced 53 per cent of the coal, or 17,685 tons per machine. The coal, being horizontal and uniform, is well adapted to machine mining.

Most of the mines are dry, and but little pumping is required. The deeper mines are drier than the shallow ones and require sprinkling to prevent accumulation of dust.

# REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The inspection of coal mines in Illinois was inaugurated by virtue of an act of the general assembly approved March 27, 1872, which became effective July 1, 1872. By section 11 of this act the county surveyors were constituted ex-officio inspectors of mines within their respective counties, each with authority to call to his aid a reputable practical miner. The act also provided that all accidents causing loss of life or serious personal injury at any coal mine or colliery should be reported to the county mine inspector, and that all fatal accidents should also be reported to the coroner of the county in which the accident occurred. It was made the duty of the inspector to investigate all accidents thus reported to him, and all expenses incident to his investigation were payable by the county in which the accidents occurred.

By an act approved June 18, 1883, effective July 1, 1883, the State was divided into five mining districts, and a State mine inspector for each district authorized. Each county was authorized to appoint an assistant mine inspector, if it so desired, such county inspector to perform his duties under the direction of the district mine inspector. The act directed that accidents should thereafter be reported to the district mine inspector instead of the county inspector, and that fatal accidents might be reported to a justice of the peace in the absence or inability to act of the county coroner.

Subsequent laws have made no change in the reportability of mine accidents as above set forth. There are now 12 inspection districts in the State.

14355°-Bull. 115-16-12

### ACCIDENTS.

Tables Nos. 95 and 96 show the total number of fatalities by causes and calendar years since 1885, and the total production of coal. They also show the percentage of accidents, by principal causes, and fatality rate per 1,000 employed over a period of 29 years, for which continuous records are available. During this period there were 3,409

FATALITIES IN ILLINOIS COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1885 TO 1913, INCLUSIVE.

fatalities or 2.52 per 1,000 men employed. There were 14 accidents in which 5 or more men were killed at one time, representing about 12 per cent of the total fatalities. These large accidents include the mine fire at Cherry in which 259 men were killed at one time. The average production of coal per fatality during this period was 251,900 tons or 3.97 fatalities per million tons mined.

Practically all of the mines in Illinois are operated on an 8-hour basis so that a comparison with 10-hour States on the basis of days worked is not a proper method. The time element has therefore been taken into consideration and a table compiled on the basis of the actual number of hours worked so that a true comparison with other

States may be made. The fatality rate for the 10-year period, 1903–1913 (Table 40), for Illinois on the 2,000-hour basis is 3.26 as compared with 2.55 based on the actual number of men employed. During the 10-year period, the men averaged 1,567 hours per year as compared with 2,132 hours in West Virginia.

The tables of statistics for the State of Illinois follow:

STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN ILLINOIS.  ${}^{\alpha}$

<sup>a</sup> Fiscal year ending June 30. "Other Causes" doubtless include fatalities belonging under other headings, but no information is available for a more detailed classification. The 84 fatalities under "Other Causes" in 1883 include 69 deaths due to inrush of water at the Diamond mine, Braidwood, III., Feb. 16, 1883.

### INDIANA.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing area of Indiana amounts to about 6,500 square miles and includes 26 counties in the southwestern portion of the State. Nineteen of these counties are producing coal on a commercial scale. The coal measures contain over 20 horizons, in which coal beds of varying thickness have been found. Of these eight are of workable thickness over much or all of the field and several others are locally of workable thickness. In the center of the field as many as seven or eight beds are workable in a single area. Ordinarily over most of the field not more than three workable beds will be found.

The coal measures in Indiana have a total thickness of approximately 1,300 feet. Of these 1,300 feet there are 600 feet of barren beds at the top, a 500-foot interval which contains most of the workable coals, followed in descending order by 200 feet or more of rocks consisting mainly of sandstone.

### CHARACTER OF COAL BEDS.

The eight different coal beds mined vary from 3 to 9 feet in thickness. The coal in the eastern part of the field is called block coal or semiblock because of its breaking into rectangular blocks. It is very pure, noncoking coal. The strictly "block coal" is found in Fontaine, Parke, Clay, and Owen Counties. South of that the coals in the easternmost counties are semiblock. The block coal occurs in small basins which vary in extent from a few acres to several square miles, owing to the irregular surface of the rocks upon which they were laid down. The coal may be 3 to 5 feet thick in the center of a basin but thins out gradually toward the edges. The western counties of the Indiana field contain bituminous coal. The bituminous beds vary from 3 to 10 feet in thickness, most of the workings being in beds over 5 feet thick. In 1910, 26 mines were mining coal from beds over 7 feet thick. These coals lie regularly with a slight pitch to the west and southwest, and in many parts of the field are regular in thickness. Practically all of the mines have a clay floor and shale roof. The No. 5 coal is overlain with black shale, commonly broken with pyrite concretions, that locally will hold up indefinitely over a 40-foot room without any posts. Most of the beds, however, have roofs of shale that tends to disintegrate rapidly in the summertime, especially in the air passages, and requires close posting.

### MINING METHODS.

The earliest records of coal production in Indiana are for 1840, when 9,682 tons were mined. The production increased gradually until in 1913 it was 17,165,671 tons.

Most of the commercial mines are opened by shafts varying from 50 to 450 feet deep, only a few being opened by slopes and drifts. From the shafts the mines are opened by main entry and air course, each 8 feet wide, separated by a 12-foot pillar. The coal is mined almost exclusively by the room-and-pillar method, which varies in detail in different districts and even in different coal beds of the same district. The mines are usually well equipped with the latest appliances, including electric machines and self-dumping cages.

Mining machines were first used in 1884. The "block coal" was first successfully mined by machines in 1894. In 1891 there were 47 mining machines in operation and in 1913 there were 732 which produced 56.7 per cent of the coal mined during the year. Of the total number of machines used 365 were of the chain-breast type. The average production per machine in 1913 was 13,302 tons.

About 30 per cent of the coal mined is shot off the solid; hand mining produced only about 11 per cent of the total output in 1913.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

An act approved March 8, 1879, which became effective May 1, 1879. authorized the governor to appoint a mine inspector, whose duty was to inspect each coal mine in the State at least twice a year. The inspector was required to render annual reports to the governor and to state therein the number of mines operating, the production of each mine, and such other information as the inspector deemed necessary. On February 26, 1889, the department of geology and natural science was created and placed under the supervision of a director, who was also the State geologist. The department consisted of four divisions: Geology and natural science, mines and mining, mineral oils, and natural gas. The chief of each division was appointed by the geologist. The office of mine inspector was abolished, and the chief of the division of mines and mining, to be known as the inspector of mines. was directed to perform all duties previously performed by the mine inspector. Annual reports of the inspector were included in the annual reports of the department. The inspector was authorized to employ one assistant.

An act approved March 2, 1891, covering coal mines employing 10 or more men, made it the duty of mine operators to report, under penalty, all mine accidents causing death, and upon receipt of such a notice the inspector and coroner were required to investigate the cause of the accident. The act of March 4, 1891, restricted the appointment of inspector of mines to persons who had passed an examination satisfactory to the State geologist. On March 6, 1897, an act was approved directing mine operators to report to the inspector all accidents which prevented the usual working of a mine for 24 consecutive hours, or resulted in injuries causing death or requiring the attendance of a physician or surgeon. On March 11, 1901, the number of assistants to the inspector was increased to two, and on March 9, 1907, the number was further increased to four. The latter act also required that each mine should be inspected at least three times each year.

An act approved March 6, 1911, created a bureau of inspection, to consist of three departments: Inspection of mines, inspection of boilers, and inspection of factories. The new bureau was placed under the supervision of a chief inspector appointed by the governor. The governor also appointed three deputies, one for each of the departments comprising the bureau. Each deputy inspector was authorized to appoint five assistants, with the approval of the chief inspector.

Up to 1915 it was the practice of operators of mines employing 10 or more men to report to the inspector all accidents causing death or requiring the attendance of a physician or surgeon, and all such accidents were published in the inspector's annual reports. Injuries causing disability for two weeks were classified as serious, all others being considered slight.

The legislature of 1915 passed a workmen's compensation act, effective September 1, 1915, to be administered by the Industrial Board of Indiana, which was also provided for by the act. The department of inspection of mines and mining was transferred to the industrial board. Under the compensation law all employers of labor are required under penalty to report to the board all accidents causing injury to an employee whereby the employee is incapacitated for work more than one day. The department of mines, under the jurisdiction of the industrial board, consists of one chief inspector and five assistants, who are appointed by the board with the concurrence of the governor.

#### ACCIDENTS.

The accompanying tables show the total number of fatalities by causes and calendar years since 1881 as compiled from State mine inspectors' reports. They also show the percentage of accidents, by principal causes, and the fatality rate per 1,000 men employed for a period of 19 years for which continuous records are available. The fatality rate during this period is 2.16 per 1,000 men employed.

Indiana has been fortunate in that it has had but few disasters (only four) during this period in which 5 or more men were killed at one time, the total number being 29 fatalities, or slightly over 4 per cent of the entire number. To offset this, however, there were 132 fatalities due to explosives, representing 19.44 per cent of the total. The average production of coal per fatality during this period was 291,062 tons, or 3.44 fatalities per million tons mined.

Indiana, like Illinois, is an 8-hour State, and in order to make it comparable with other States, where 9 or 10 hours are considered a working day, a table has been compiled whereby the time element has been taken into consideration. The fatality rate for the 10-year period 1903-1913 (Table 40) based on the actual number of employees

is 2.20 as compared with 2.95 on the 2,000-hour basis. Table 40 gives all of the States on this basis for the 10-year period, so that a comparison with other States may be made. During this period the men worked 1,487 hours per year as compared with 2,034 hours for the bituminous fields of Pennsylvania.

The tables of statistics for the State of Indiana follow.

STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN INDIANA. $\boldsymbol{a}$ 

| Year.                                                                | Number<br>of men<br>affected.                                                              | Total .<br>days<br>lost.                           | Average<br>number<br>of days<br>lost per<br>man. | Year.                                                                         | Number<br>of men<br>affected. | Total<br>days<br>lost.                                                                                | Average<br>number<br>of days<br>lost per<br>man. |

### IOWA.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Iowa are in the Pennsylvanian series of the Carboniferous system and occupy the central and southern part of the State. The total coal-bearing area is about 20,000 square miles, of which 13,000 square miles include outcropping coal beds that are considered workable under the present economic conditions. In 1913, 21 counties were reported as coal producers.

The principal producing areas are in Marion, Mahaska, Monroe, and adjacent counties, which produced 43 per cent of the coal in 1913; Polk, Jasper, and Dallas counties of the same group produced 32 per cent; and Appanoose and Wayne counties, containing the Mystic or Centerville bed, produced 17 per cent. This bed is very persistent over a considerable area.

### CHARACTER OF COAL BEDS.

The Iowa coal is bituminous, non-coking, and contains a high percentage of sulphur in the form of pyrite. The coal is used largely for steaming purposes. Practically all of the beds are horizontal or dip about 10 feet per mile. Most of the coal beds are opened by shafts of different depths, as follows: Lucas County, 321 feet; Appanoose and Wayne counties, 200 feet; Adams County, 400 feet; Polk County, 156 feet; Webster County, 16 to 100 feet; and Marion County, 150 feet. There are a few slope and drift mines.

The coal beds of the Des Moines group (the lower part of the Pennsylvanian series) vary from  $3\frac{1}{2}$  to 5 feet or more in thickness and, with the exception of the Mystic bed, are somewhat faulted and irregular. The thickest coal in the State occurs in Marion County, where beds 4 to 12 feet thick have been opened. The Mystic or Centerville bed is about  $2\frac{1}{2}$  feet thick, has a strong roof, and is adapted to longwall mining methods.

### MINING METHODS.

Coal mining in Iowa began about 1840, for which year the records show a production of 400 tons. The production has gradually increased until in 1913 it was 7,525,936 tons.

Nearly all of the mines are operated through shafts and the coal is mined by the longwall and room-and-pillar methods. In 1891, 9 machines were introduced into the mines and the number gradually increased to 56 in 1898. Since that date the number of machines has been gradually reduced. Of 62 mines in Appanoose County in 1904, 16 used the room-and-pillar method and 46 the longwall method. Longwall mining machines are used rather extensively. A large amount of coal is shot off the solid, but records showing the extent to which this is practiced are not available prior to 1911. In 1912, 69 per cent, and in 1913, 72.3 per cent of the total production was shot off the solid. The hand-mined coal amounts to about 20 per cent of the total, while that produced by machines is less than 2 per cent.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

Section 1567 of the Iowa Code of 1873 directed that the board of supervisors of each county in which coal or other minerals were found should appoint an inspector of mines, who, upon application of mine owners, operators, or employees, examined the atmosphere of such mines as affecting life or health. If gas was found in sufficient quantities to jeopardize life or health, the inspector was authorized to require the operator to provide additional shafts or entrances for proper ventilation, and a penalty was provided for failure to carry out such demands of the inspector.

On March 18, 1874, the foregoing provisions were superseded by a law requiring the county inspectors, who were appointed as under the previous law, to examine each mine twice a year, provided more than 10 miners were employed therein. Operators were required, under penalty, to notify the inspector of all fatal and serious accidents, and, if fatal, to notify the county coroner also. The inspector was required to examine into the causes of accidents and to preserve a record of his inspections. The law of March 30, 1880, consolidated the inspection service under the jurisdiction of one State mine inspector appointed by the governor. The act applied only to mines employing more than 15 men, and the inspector was required to make an annual report to the governor, enumerating therein all accidents in and about the mines. An act approved March 18, 1884, extended the inspection law to cover all mines employing more than five men. and required the inspector to render biennial reports to the governor on August 15 preceding the regular session of the State legislature.

On April 10, 1886, the governor was authorized to divide the State into three districts and appoint a mine inspector for each district, the inspectors to report to the governor as before. A law of April 12, 1888, provided for a board of examiners to examine candidates for the office of mine inspector. By an act approved May 6, 1911, mine operators were required to report on August 1 of each year to the district inspector, for the year ending July 1, the number of employees in and around the mines, in addition to sending to the inspector an immediate notice of fatal and nonfatal accidents.

All injuries, whether serious or slight, are reported to the district mine inspectors, but only those causing disability for at least 10 days are considered serious injuries and published in the inspectors' annual reports.

#### ACCIDENTS.

The accompanying tables, Nos. 99 and 100, show the total number of fatalities by causes and calendar years since 1880, as compiled from the State mine inspectors' reports. These tables also show the percentage of accidents, classified by principal causes, and fatality rate per 1,000 men employed, over a period of 26 years for which

FATALITIES IN IOWA COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1888 TO 1913, INCLUSIVE.

| 1893, Feb. 14 | Chicago and Iowa | Albia             | Mine explosion      | 8       |
| 1902, Jan. 24 | Lost Creek No. 2 | Oskaloosa         | Do.                 | 20      |

continuous records are available. The fatality rate during this period is 2.22 per 1,000 men employed. Iowa has been fortunate in that there have been but two disasters, in which five or more men were killed at one time. The fatalities represented by these two disasters are only 4 per cent of the total number killed during the above period. Of the total number of fatalities, 59 per cent were due to falls of roof and pillar coal, 10.53 per cent to mine cars and locomotives, and 10.25 per cent to explosives. The average production of coal per fatality during this period was 204,390 tons, or 4.89 fatalities for each million tons mined.

Since Iowa is an eight-hour State, the time element has been taken into consideration, and tables have been compiled on this basis for comparison with other States. The fatality rate for the 10-year period, 1903–1913 (Table 40), based upon the actual number of employees, is 1.94, whereas based on the number of 2,000-hour workers it is 2.27. During the 10-year period the men averaged 1,704 hours per year, as compared with 2,447 hours for Virginia. Table 41 shows

NUMBER OF HOURS TO THE WORKING DAY, BY YEARS, IN AND ABOUT THE COAL MINES IN IOWA.a

|       | 8-hour day.                                                        |                                                                                                  | 9-hour day.                                         |                                                               | 10-hour day.               |                               | Men em-<br>ployed                                                        |                                                                                                                       |

.

### KANSAS.

### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing measures of Kansas comprise about 18,600 square miles, of which 3,100 square miles are known to contain workable coal beds. The coal-bearing area occupies a strip covering about 3 to 4 counties wide entirely across the eastern end of the State, but the best beds are found in Cherokee and Crawford counties in the southeast corner.

The coal beds of this State belong to the Carboniferous system and occur in the southwest extension of the coal-bearing rocks of the Iowa-Missouri field. About 90 per cent of the coal mined in the State is from the Weir-Pittsburgh beds in Crawford and Cherokee counties. About 6 per cent of the coal is produced in the Atchison-Leavenworth district from a depth of 700 feet to 1,150 feet.

### CHARACTER OF COAL BEDS.

The coal beds of Crawford and Cherokee counties are practically horizontal, and occur at depths of 30 feet to 250 feet. The coal is bituminous, and produces a large amount of dust when mined. The beds vary in thickness from 3 to 10 feet, those in the Cherokee shale being very irregular. The thicker parts of the workable beds lie in "swamps" or basins of very irregular outline. Rolls in the floor and roof cause differences of level of 20 to 30 feet in many of the mines and a difference of as much as 60 feet has been observed in a single mine. It seems that these irregularities are due to unevenness of the original bottom upon which the coal was formed.

### MINING METHODS.

The earliest statistics of coal production in Kansas are for 1869, when 36,891 tons were mined. In 1913, the production was 7,202,-210 tons. Practically all of the coal is mined by the room-and-pillar system, but some longwall mining is done in Osage County. About 85 per cent of the mines are opened by shaft; 11 per cent are strip pits, and 4 per cent are drift mines. In southeastern Kansas considerable coal is mined by stripping with a steam shovel. In places as much as 40 feet of cover is removed in stripping.

Mining machines were introduced into Kansas about 1897 but their use has been confined to a limited number of mines. In 1908, there were 17 machines in use; in 1913, only 9 were used, producing 0.3 per cent of the coal mined in the State, 14.8 per cent was mined by hand, and 85.5 per cent was shot off the solid.

The State mine inspector in his report for 1913 states that in Crawford and Cherokee counties 982,546  $12\frac{1}{2}$ -pound kegs of powder were used, or one keg for every 7.22 tons of coal produced. In addition, he also estimates that 1,029,000 pounds of dynamite and 46,450 pounds of permissible powder were used.

He also states that:

The extreme danger in the increased and excessive amount of explosives used is hereby made apparent and can not be gainsaid. Had these figures of dynamite and permissible powder been reversed the condition under which the mines were operated, in my opinion, would have been vastly improved as far as their safety is concerned. This may also account in a certain measure for the grade of coal produced at some of the mines.

### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The governor of Kansas was authorized by an act approved February 27, 1883, to appoint an inspector of coal mines for two years from June 30, 1883. Mine operators were required to report to the inspector all accidents causing serious or fatal injuries. and, if fatal, to the coroner of the county in which the mine was located. A monthly report by the inspector, showing the number of accidents and deaths from injuries and number of men employed. was required to be filed with the secretary of the State board of agriculture on or before the first Monday in each month. The act of March 13, 1885, required the inspector to render annual reports to the governor on the 1st day of February of each year. The mine operators were required by the act of March 13, 1897, to render quarterly reports of accidents to the State mine inspector. The method of selecting the mine inspector was changed by an act approved January 6, 1899. By this act an association of miners was authorized, consisting of a delegate from each organized body of five or more miners in any county, city, or mining camp in the State. The State association held annual meetings and elected a president, vice president, and secretary, and the secretary so elected succeeded to the duties of State mine inspector.

On February 5, 1913, an act was approved creating a department of labor and industry under the control of a commissioner of labor and industry. The commissioner was made ex officio factory and mine inspector, with authority to appoint an assistant of at least five years' experience in coal mining. In 1914 the inspection of coal mines was carried on by the assistant commissioner and five deputies.

All injuries, whether serious or slight, are reported to the inspector and are included in his annual reports, but no definition is given as to what constitutes a serious or slight injury.

### ACCIDENTS.

Tables 101 and 102 show, by causes and calendar years, the total number of fatalities since 1884, excepting 1886, 1888, and 1892, for which years reports are not available. These tables also show the percentage of accidents, classified by principal causes, and fatality rate per 1,000 men employed for a period of 21 years for which continuous records are available. The fatality rate during this period is 2.45 per 1,000 men employed. Of the total number killed

(1893-1913), 49.05 per cent of the fatalities were due to falls of roof and pillar coal, and 24.81 per cent to explosives. The amount of coal mined by shooting off the solid is approximately 80 per cent of the total production. The average production of coal per fatality during the 21 years was 203,153 tons, or 4.92 fatalities for each million tons mined. The average production per man a year was 497 tons, or 2.56 tons per day.

During the period 1884 to 1913, inclusive, there were three mine disasters in which 52 men were killed, representing slightly less than  $8\frac{1}{2}$  per cent of the total number killed in the coal mines of Kansas.

In Kansas, more than 95 per cent of the men are on an eight-hour basis, and for comparative purposes the time element has been taken into consideration and tables compiled. It will be noted that the fatality rate for the 10-year period, 1903–1913 (Table 40), based on actual number of employees, was 2.70 per 1,000 men employed, and reduced to a 2,000-hour basis was 3.45 per 1,000. Table 41 shows

NUMBER OF HOURS TO THE WORKING DAY, BY YEARS, IN AND ABOUT THE COAL MINES IN KANSAS.a

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |    |              |         |          |

#### KENTUCKY.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The two coal fields of Kentucky are located in the extreme eastern and western parts of the State.

The Eastern coal field has an area of about 10,270 square miles, of which about 70 per cent may be considered as productive. The rocks in this field are practically horizontal, except those in Bell and Harlan counties, which lie in the great synclinal trough east of Pine Mountain. In the middle of this trough the coal beds are flat-lying, but on either rim they dip steeply toward the axis of the trough. The stresses which caused the great trough have produced several minor folds in its bottom and also a few faults, which cause considerable trouble and expense in mining. The principal producing counties are Bell, Floyd, Harlan, Johnson, Knox, Laurel, Lee, Letcher, Perry, Pike, and Whitley. In 1913, the field produced 11,098,906 tons, as compared with 8,517,640 for the Western field.

The Western field is a continuation of the Indiana-Illinois field and has a coal-bearing area of about 6,400 square miles, of which 65 per cent may be considered as productive. This field, which includes Butler, Daviess, Hancock, Henderson, Hopkins, McLean, Muhlenberg, Ohio, and Webster counties, is the southeastern part of the big flat basin that carries the coal of Indiana and Illinois, but the rocks are much more disturbed in the Kentucky part than they are in those parts lying in the other States. The line of disturbance, extending in an east-west line across southern Illinois, continues across the western Kentucky field. Along this line from Shawneetown, Illinois, to Litchfield in Grayson County, the rocks are tilted and broken by faults to such an extent that mining is difficult and expensive.

#### CHARACTER OF COAL BEDS.

The Eastern field belongs to the Pottsville group of the Allegheny formation and contains 12 or more coal beds of workable thickness and quality. The coal of these beds is usually of high-grade gas or coking quality and some of it is cannel coal. The Blue Gem and Jellico beds, which extend into Tennessee, average about 22 inches thick. This coal is extensively mined and finds a ready market as a domestic and steam fuel. Other coal beds contain 8 to 9 feet of workable coal. In Breathitt County one of the coal beds that is extensively worked is 30 inches thick and has a thin shale roof above which is a stratum of limestone. In Pulaski County, one of the important beds is 35 inches thick and has a dip of about 1 per cent. In Bell County, one of the most productive beds is 36 to 42 inches thick and is horizontal.

There are three important coal beds that are worked in various parts of the western district. Coal A (No. 12) is about 80 inches thick at the Pierce mine in Muhlenberg County, it is of excellent steaming quality and has been used to a limited extent for coking. but is not of commercial importance for this use. The thickness of this bed varies and in general the roof is fire clay and shale. Coal B (No. 11), known also as the Danville bed, is one of the principal sources of commercial coal. It varies in thickness from 12 to 84 inches and is cut by clay slips and disturbed by rolls. It is 40 to 100 feet below the surface and is 25 feet below the No. 12 coal. At the Pierce mine, Muhlenberg County, the coal is 78 inches thick, and in Hopkins County, is about 84 inches thick. At Madisonville there is a thin stratum of shale between the coal and a limestone capping, whereas at Nortonville the limestone rests directly on the coal. Bed D (No. 9, equivalent of No. 5, Illinois) is more regular than the other coal beds and produces about 75 per cent of the coal of the western district. It is 56 to 60 inches thick and extends throughout the larger part of 8 counties. It is about 300 feet below the surface and is opened by shafts. Coal Fb (No. 5), also known as the "Fourfoot" coal, is extensively mined at De Koven, Union County, where it has a maximum thickness of 54 inches. The roof is black shale 14 to 2 feet thick. There are a number of other coal beds in the State, varying in thickness from a few inches to 40 and 50 inches. some of which are worked.

#### MINING METHODS.

Coal mining in Kentucky began in a small way in 1828, during which year 328 tons were reported as the annual production. The production has gradually increased until in 1913 it was 19,616,600 tons. The majority of the coal is mined by the double-entry, roomand-pillar method. In the eastern part of the State practically all of the mines are opened by drift or slope, whereas in the western field there are a number of shaft mines. In 1900 there were 23 shaft mines in the State, the others being opened by slopes or drifts. The following description <sup>a</sup> given by Dr. C. J. Norwood covers the mining methods of the year 1889.

Almost without exception, the mines of Kentucky are worked on the "pillar-androom" system, with either single (with parallel air course) or double entry, usually the former. Sometimes one portion of the bank will be worked with single entry and another portion with double. The only two instances, known to the writer, in which long wall was tried resulted in failure; and one instance in which square work was attempted resulted in crushed pillars. The rooms are usually turned every 30 or 33 feet, and widened to from 18 to 21 feet. The necks are usually 6 to 12 feet long by 6 to 8 feet wide in the western field, and 8, 12, 18, or 20 feet long by 6 to 9 feet wide in the eastern field. The lengths of the rooms vary so greatly that a general statement on

a Report of the inspector of mines of Kentucky, 1889.

that point can not well be given. Sometimes they are driven a distance of 600 feet from one entry through to the other; again, rooms are started from parallel entries to meet midway, and will be driven up only 200 to 250 feet.

In the western field the rooms are almost invariably single. In the eastern one they are often double, or two rooms are worked from a single "parting."

It is not uncommon for rooms to be turned from the main entry, in the eastern field; in the western one it is seldom done.

In both fields single entry, with parallel air-course (rooms sometimes being turned from the air-course), is the more common of the two systems followed. Double entry is oftener followed in the western field than in the eastern. Sometimes, when single entry with parallel air-course is adopted it is ultimately modified, in order to curtail expenses, by continuing room width what began as narrow work.

In the eastern field all of the openings, with one exception, (a short slope), are drifts, considerably above the level of drainage. (And the mines there are the wettest in the State). In the western one, the coals are reached by shafts, slopes and drifts.

These methods have not changed materially except possibly in the increased number of mining machines since their introduction in 1884. In 1893, there were 70 machines in operation in the Kentucky coal mines, which produced 20 per cent of the State's output. The number of machines has gradually increased until in 1913, 1,263 mining machines produced 73.2 per cent of all of the coal mined in Kentucky.

Shooting off the solid has been and still is prevalent in Kentucky, but with the increase in the number of mining machines, there is a slight decrease in the amount of coal shot off the solid. In 1911, 16.2 per cent of the coal was thus mined and in 1913, 15.7 per cent.

A large amount of the underground haulage is by mules, which are used largely for gathering the coal from the working face and delivering it to a rope haulage or electric haulage system.

#### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The mine-inspection law of Kentucky was approved by the governor and became effective May 10, 1884. The law related only to mines in which more than 5 persons were employed at one time. The first State inspector was appointed May 12 and entered on duty May 14, 1884. He was required, among other things, to report to the governor not later than October 10 on the condition and operation of the coal mines and to enumerate in his report all accidents in or about the mines. The law, however, contained no provisions compelling operators to report accidents to the State inspector, and the official record of mine accidents in Kentucky from 1884 to 1888 is therefore somewhat incomplete. The defect in the original law was remedied by an act approved April 6, 1888, making it the duty, under penalty, of mine operators to furnish accurate information to the State inspector, on blanks supplied by him, as to all accidents in or about the mines. An act approved March 23, 1914, designated the office of inspector of mines as the department of mines and changed the inspector's title to chief inspector of mines. The act applies to all coal mines in which 6 or more men are employed, and requires the superintendents of such mines to render to the chief inspector monthly reports of all fatal and serious accidents, showing the cause of such accidents, and such other information as the chief inspector may require. Fatal accidents are also required to be reported immediately to the district inspector. Each district inspector is required to examine each mine in this district at least once every four months. Monthly reports are rendered by the assistant inspectors to the chief inspector, and annual reports are rendered to the chief inspector within 60 days after the close of the calendar year. The act requires that the chief inspector shall prepare and file his annual report for printing within six months after the close of the calendar year.

The first assistant inspector was provided for by the acts of December 3, 1892, and June 9, 1893, and he entered upon his duties July 1, 1893. Since that time the inspection force has been further increased, so that in 1915 the force consisted of one chief inspector and five assistant inspectors.

It is the practice of mine operators to report to the inspector all accidents causing death or injury resulting in disability for at least 7 days, and all such accidents are published in the inspector's annual reports. Nonfatal injuries are classified into three classes: Serious, severe but not serious, and slight. The inspector has defined these classes as follows: Serious injuries include fractures, paralysis, dangerous injuries to internal organs, injuries permanently affecting muscles (as may come from burns, cuts, lacerations), dislocations, injuries necessitating amputation, crushed bones, and injuries of similar importance; severe but not serious injuries include those that, while they may be painful and cause loss of a week or more, leave no permanent effects or are not dangerous, such as bruises, cuts, and strains; slight injuries include bumps, scratches, strains and minor hurts that cause no cessation of work, or only for a few days (less than a week). Slight injuries are not recorded in the inspectors' annual reports.

#### ACCIDENTS.

The accompanying State tables (Nos. 103 and 104) show the total number of fatalities by causes and calendar years since 1884, as compiled from the State mine inspector's reports. They also show the percentage of accidents and fatality rates per 1,000 employed by principal causes, over a period of 26 years (1888–1913) for which continuous records are available. The fatility rate during this period is 1.98 per 1,000 men employed. There were 10 accidents in which 5 or more men

this basis for comparison with data on other States. The rate for the 10-year period (1903-1913) under consideration, based on the actual number of employees is 2.23 per 1,000, whereas on the number of 2,000-hours workers it is 2.36 per 1,000 (Table 40). During the 10-year period the men worked 1,885 hours per annum as compared with 2,447 hours per annum in Virginia. The tables of statistics for the State of Kentucky follow:

STATISTICS OF STRIKES AND LOCKOUTS IN AND ABOUT THE COAL MINES IN KENTUCKY.a

a Includes 5 fatalities at mine not under jurisdiction of inspector.

#### MARYLAND.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Maryland, a southward extension of those in Somerset County, Pa., occupy a strip along the western border of Allegany County about 20 miles long and averaging 5 miles in width and the greater part of Garrett County, comprising a total area of 455 square miles. The coal measures occupy broad, open, north and southwest synclinal folds, which are separated by eroded anticlines and are in the lower Carboniferous or Devonian rocks. There are five basins, known as Georges Creek, Upper Potomac, Castleman, Lower Youghiogheny, and Upper Youghiogheny. The present production of coal is almost exclusively mined from the first two basins. The prominence of the Georges Creek basin has led to the use of the name of Georges Creek coal, and until recent years practically all of this coal came from the Pittsburgh seam or "Big Vein." The coal beds are usually flat, seldom attaining a dip of 10°.

#### CHARACTER OF COAL BEDS.

The following description of the principal coal-producing beds of Maryland is taken from the report<sup> $\alpha$ </sup> of the Maryland Geological Survey on Allegany County for the year 1900:

The Elkgarden or "Big Vein" is more extensively developed in the Georges Creek basin, especially in the vicinity of Frostburg, than in West Virginia, where it derives its name. The "Big Vein" varies in thickness from 5 to 7 feet up to more than 20 feet, the latter thickness having, moreover, been exceeded at one or two isolated points where pockets of unusual thickness have been reached. Its usual thickness is from 10 to 12 feet, and in general it has been found to thicken southward. The coal is very clean and of the highest quality, affording a low percentage of both ash and sulphur. It is in most respects the finest steam coal known and is extensively used where the highest grade coals are demanded.

The Elkgarden coal occurs at the base of the Monongahela formation, and is probably the equivalent of the Pittsburgh vein of Pennsylvania and West Virginia, although on account of the structural conditions under which it is found it differs materially from the latter in its physical and chemical properties.

Thin, persistent bands of slate or dry partings subdivide the "Big Vein" coal into three definite members, each of which possesses special characteristics. These beds are known as Roof coal, Breast coal, and Bottom coal.

The Roof coal includes several more or less important layers of coal of varying purity and thickness, separated by thin beds of shale. Except in the northern part of the basin these roof coals are not removed in mining, since they are of particular importance as a support for the overlying strata.

The Breast coal is the thickest and the most valuable member of the "Big Vein" coal. North of Frostburg it seems to retain its purity through a thickness of scarcely more than 2 feet, while south of Lonaconing it is sometimes more than 7 feet thick and without impurities. Near the top there is a 2 to 8 inch layer of bony coal, but this is rarely sufficiently impure to necessitate its rejection. Near the bottom there is a

a Clark, W. B., and others, The mineral resources of Allegany County: Rept. Maryland Geol. Survey, 1900, pp. 177-178.

4 to 6 inch band of soft "mining ply," which is jet black, has a brilliant luster, and shows a strong tendency to break into small cubical blocks.

The Bottom coal is  $2\frac{1}{4}$  to 3 feet thick and generally contains two thin slate bands. Other impurities are sometimes present, but they are seldom of a very serious nature. On account of the slate bands the bottom coal for many years was not mined, but under an improved system of mining these thin slates are now easily removed and the coal readily taken up.

The Davis (6-foot coal bed) is one of the most important of the small-vein coals of the State. The report <sup>a</sup> describes it as follows:

Near Westernport, where the seam approaches 6 feet in thickness, the coal has been mined for a number of years, and although seldom put upon the market as a competitor of the "Big Vein" coal, it has nevertheless supplied a considerable part of the demand in Westernport and Piedmont and is now finding a wider market.

Throughout the lower Georges Creek Valley the Davis coal reaches a greater thickness and is more important than any other coal except the "Big Vein." This coal always contains partings of either shale or sandstone, while bone-coal is not infrequent. There is at times considerable sulphur in the lower bench. At some points in the lower Georges Creek Valley the Davis vein is quite clean and, in general, seems to improve in quality southward. The Davis vein in Allegany County generally has a roof composed of shale, overlain by heavy sandstone. The Davis coal is situated about 125–150 feet above the base of the Allegany formation. This vein is generally regarded as the approximate equivalent of the lower Kittanning coal of Pennsylvania.

The Thomas (3-foot coal) varies in thickness from 2 feet 6 inches to 3 feet 2 inches. The coal is clean and has been successfully opened north of Westernport. The bed has a characteristic shale roof and a fire-clay floor. The coal is generally regarded as the equivalent of the Upper Freeport.

#### MINING METHODS.

The earliest records of the production of coal in Maryland are for 1820, during which year 3,000 tons of coal was mined. The production has generally increased until in 1913, 4,779,839 tons was mined. Most of the Maryland mines are worked by the room-and-pillar method from drift entries, there being only a few slope mines. Tailrope haulage is used to some extent, whereas mule haulage is used extensively. There are relatively few mining machines in use and these are of the pick or puncher type. In 1900 there were 10 machines in operation, producing 138,014 tons, or 3.4 per cent of the coal mined in the State. In 1904 the machine-mined coal amounted to 10 per cent of the total production. In 1913, 91.5 per cent of the coal was mined by hand, 1.7 per cent by machine, and 6.2 per cent was reported as being shot off the solid. Although the greater part of the Maryland production is mined by hand, the record of individual efficiency of the miners is high. The average production of each man in 1913 was 847 tons, or 3.42 tons for each working day.

#### **REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION** SERVICE.

An act approved March 30, 1876, authorized the governor to appoint a mine inspector for Allegany and Garrett counties whose duty it was to inspect every coal mine at least once each month. When notified by the coroner of either county, the inspector was required to attend inquests and to investigate the causes of fatal accidents at the mines. Annual reports were rendered to the governor and all mine accidents were enumerated therein. On March 24, 1902, a law was approved extending the inspection service to include clay and fire-clay mines, and directing the inspector to examine all mines as often as possible, but at least once every two months. All fatal and serious accidents in and about the mines were required to be reported to the inspector by mine operators.

It is the practice of the operators to report all accidents to the inspector, and all accidents thus reported are published in the inspector's annual reports. Injuries causing less than 7 days' disability are considered as slight.

Up to 1915 the mine inspector employed no deputy or assistant inspectors.

#### ACCIDENTS.

Tables 105 and 106 show the number of fatalities and men employed from the beginning of inspection service, 1876, to date, as compiled from the State mine inspectors' reports. The fatality rate for the years for which continuous records are available, 1889 to

COAL-MINE ACCIDENTS IN MARYLAND IN WHICH 5 OR MORE MEN WERE KILLED.

| Date               | 1909, Jan. 25.    |
|--------------------|-------------------|
| Name of mine       | Washington No. 5. |
| Location of mine   | Franklin.         |
| Nature of accident |                   |
| Number killed      |                   |

1906 and 1909 to 1913, inclusive, covering 23 years, is 1.87 per 1,000 men employed. The amount of coal produced per fatality was 459,193 tons, or there were 2.18 fatalities per million tons mined. During this 23-year period 220 men were killed, of which number 57.73 per cent was due to falls of roof and 13.64 per cent to mine cars and locomotives. Maryland has been remarkably free from gas and dust explosions; the fatality rate from explosives is also low, representing only 2.27 per cent of the total number killed.

The 10-hour day prevails in Maryland and for comparison with data on 8 and 9 hour States Tables 40 and 41 have been compiled. The fatality rate for the 8-year period 1903 to 1906, and 1910 to 1913,

.

#### MICHIGAN.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal-bearing area of Michigan comprises about 11,000 square miles and occupies a basin in the central part of the lower peninsula between Lake Huron and Lake Michigan. The field extends from Jackson County on the south to Roscommon County on the north and from Tuscola County on the east to Kent County on the west. The principal mining operations are in Bay and Saginaw Counties in the northeastern part of the field.

#### CHARACTER OF COAL BEDS.

The structure of the field is a comparatively flat basin modified by minor undulations. There are at least seven coal-bearing horizons in which coal may be considered as workable at certain places. The three principal coal beds are the Upper and Lower Verne and the Saginaw. The Upper and Lower Verne beds usually are close together and in a number of places are mined as one bed of coal. These beds vary in thickness from place to place, but the thickness of a single bed is not generally more than 3 feet. The combined thickness of the two beds within 10 feet of strata may be 7 feet. These coal beds are more or less undulating and in one instance a rise of 22 feet within 150 feet without faulting has been noted. In consequence of this irregularity many of the working plans of the mines in which the workings follow troughs are very irregular, and as most of the merchantable coal is less than 4 feet, some being less than 2 feet thick, large areas of this coal are left untouched. They are 100 to 150 feet below the surface. The Saginaw bed is somewhat deeper.

#### MINING METHODS.

The records for coal production for Michigan began in 1860, when 2,320 tons of coal were mined. The production in 1913 was 1,231,786 tons. Practically all of the, mines are opened by shafts 100 to 150 feet deep. The room-and-pillar system of mining is the principal method in use. The longwall method was tried at one or two mines but it was abandoned for the reason that there was too much danger of shattering the roof and letting in water from the glacial overburden. Mining machines were first introduced in Michigan in the Bay City district and became an important feature in Michigan mines in 1899, when 25 machines produced slightly over 10 per cent of the coal. In 1913, 70 per cent of the coal was produced by machines and 29.5 per cent shot off the solid.

#### **REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION** SERVICE.

The legislature of Michigan, by an act approved May 2, 1899, authorized the commissioner of labor to appoint an inspector of coal mines, the inspector to examine all coal mines in the State and to report. from time to time, the results of his examinations to the commissioner of labor. The results of the inspector's examinations were incorporated in the regular annual report of the commissioner. The inspector was authorized to enter any coal mine at any time for the purpose of inspection or to collect statistics relating to "hours of labor, wages, industrial, economic and sanitary questions or matters, scales and oils." It was specified in an act approved May 10. 1905, that the law applied to "any shaft in process of sinking, and any opening projected for the purpose of mining coal." On June 2, 1909, a law was approved directing the commissioner of labor, under whose supervision the inspection of coal mines was carried on, to include in his annual reports beginning April 1, 1910, a statement showing the number of persons employed and the number and character of accidents in all departments of labor in the State.

All mine accidents are reported to the inspector and are published in his annual report to the commissioner of labor. Serious and slight injuries are neither segregated nor defined.

In 1915 the inspector employed no assistants.

#### ACCIDENTS.

Tables 107 and 108 show the total number of fatalities by calendar years and causes from 1899 to 1913, inclusive, as compiled from the State mine inspector's reports. Beginning with 1900 to and including 1913, for which continuous records are available, 98 men were killed,

FATALITIES IN MICHIGAN COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1900 TO 1913, INCLUSIVE.

|                                                                                                                                                                           | Number killed.                      |                                                  |                                          |  |

| Total, 14 years                                                                                                                                                           | 98                                  | 100.00                                           | 2.16                                     |  |

representing a fatality rate of 2.16 per 1,000 men employed. Of the total number of fatalities 52.04 per cent was due to falls of roof-and-

pillar coal, 15.31 per cent to explosives, and 10.20 per cent to shaft accidents. Michigan has been fortunate in the matter of mine disasters, none having occurred in which 5 or more men were killed at one time. No fatalities are reported as due to gas and dust explosions. The average production per fatality during the 14-year period above referred to was 200,919 tons, or 4.98 fatalities per million tons mined.

Since 1905 practically all of the men employed in and about the mines of Michigan have been on an 8-hour basis. This, to a certain extent, accounts for the low fatality rate compared with other States, in which the men are employed 9 or 10 hours. The average number of hours worked per year per man in Michigan was 1,620

during the 10-year period, 1903–1913, as compared with 2,172 in Colorado or 2,034 in Pennsylvania (bituminous) and 2,447 in Virginia. The fatality rate (Table 40) based on the actual number of men employed, is 1.83 for the 10-year period, as compared with 2.26 based on the 2,000-hour workers. Table 41 shows the fatality rates for a period of 10 years based on the 2,000-hour year for all the States, so that by referring to this table a true comparison of Michigan with other States may be seen. The tables of statistics for the State of Michigan follow:

papers. The totals are from inspectors' reports.

#### **MISSOURI.**

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The productive coal area of Missouri comprises much of the northern half of the State, and a strip on the western border. It extends north into Iowa and west into Kansas. As in Iowa, the terms Des Moines and Missouri groups are applied to the upper and lower coal-bearing measures, respectively, both of which are in the Pennsylvanian series of the Carboniferous system. The Des Moines, which includes nearly all the coal beds of present economic importance, outcrops in about 16,000 square miles and also underlies the Missouri group in about 8,000 square miles.

#### CHARACTER OF COAL BEDS.

In the north-central part of the State the coal beds are horizontal; in the western and northwestern part they dip northwest about 8 feet per mile.

The Missouri coal is low-grade bituminous, and more than 90 per cent is produced from the Des Moines group. The Bevier field in the north-central part of the State produces about 30 per cent of the coal from a bed varying 3 feet to 6 feet in thickness. The roof is sandy shale and sandstone of only moderate stability. The bed in the Lexington field is 14 to 26 inches thick and produces 25 to 30 per cent of the coal. The roof is a black, slaty shale with a strong limestone cap rock and is almost ideal for longwall mining.

The Southwestern field includes Henry, Barton, and Bates counties and produces about 20 per cent of the coal from a coal bed 3 to 4 feet thick. In these counties there are a few open-pit mines. The Novinger field (Adair County) produces about 10 per cent of the coal from a bed that is about  $3\frac{1}{2}$  feet thick. There are several smaller fields in other parts of the State.

#### MINING METHODS.

The earliest statistics of coal production for Missouri date back to 1840, when 9,972 tons of coal were produced. The production for 1913 was 4,318,125 tons.

In 1912 there were about 214 mines in operation of which 136 were opened by shaft, 36 by slope, 25 by drift, and 7 were strip pits. Of this number 102 used the longwall method, and 94 the room-andpillar method of mining. The longwall method is used almost exclusively in the Lexington field, where the coal is thin and has a good roof. In the other fields various forms of room and pillar methods are used. Electric haulage is used in 13 mines; mule haulage in 94, and hand haulage in 41 mines. Fifty-eight mines were ventilated by natural draft, 52 by furnaces, and 88 by fans. Hoisting at 80 mines was by steam power, at 3 by electricity, at 64 by horsepower, and at 5 by hand power. Mining machines have been used in Missouri since 1896, when 4 machines were operated, producing 2.6 per cent of the coal. The number of machines has gradually increased until in 1913 there were 104 machines producing 20 per cent of the coal. It is reported that 46.8 per cent is shot off the solid, and 23.6 per cent is mined by hand.

#### **REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION** SERVICE.

The first mine-inspection service of Missouri was provided for by the act approved March 23, 1881, authorizing the court of every county where coal mines were situated to appoint a county mine inspector. It was made the duty of mine operators to report to the inspector, under penalty, all fatal and serious accidents at their mines, and, if the accident was fatal, it was to be reported to the county coroner, or, in his absence or inability to act, to any justice of the peace in the county. If deemed necessary from the facts reported, the inspector was required to go to the scene of the accident, render assistance, investigate the cause of the accident, and preserve a record of his investigation with the other records of his office. The county inspectors rendered annual reports to the "Commissioner of Labor Statistics," showing causes of accidents, number employed in and about the mines, etc.

The law of March 30, 1887, consolidated the inspection service under the jurisdiction of a State mine inspector appointed by the governor on the recommendation of a board of examiners. The inspector thus appointed rendered annual reports on October 15 to the bureau of labor statistics.

The act of April 26, 1899, created a bureau of mines, mining, and mine inspection, and authorized the appointment of two mine inspectors—one for coal mines and the other for lead and zinc mines—the inspectors being given authority to appoint a secretary. The act of March 27, 1901, required the inspector to report to the governor by April 15 of each year. An assistant inspector was authorized by the act of March 30, 1907. The coal-mine inspection force was increased by the act of March 25, 1913, which authorized the appointment of a chief inspector and two assistants inspectors, the chief inspector to render annual reports to the governor on January 1 in accordance with existing laws.

It has not been definitely determined in Missouri when an injury is sufficiently serious to come within the requirement of the law that it shall be reported to the inspector, but it is the practice of the operators to report all injuries causing three or four days' disability, and these are published in the inspector's annual reports. Of the injuries reported to the inspector, those resulting in disability of an employee for at least 30 days are classified as serious, all others being considered slight injuries.

#### ACCIDENTS.

The number of accidents in the coal mines of Missouri, by causes and calendar years, is contained in Tables 109 and 110. These tables also show the total number and percentage of fatalities classified by principal causes, and the fatality rate per 1,000 men employed for a period of 26 years (1888–1913), for which continuous records are

FATALITIES IN MISSOURI COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1888 TO 1913, INCLUSIVE.

|                                                                                                                                                                             | N                                      | amber kille                                                    | ed.                                            |

COAL-MINE ACCIDENTS IN MISSOURI IN WHICH 5 OR MORE MEN WERE KILLED.

|              | Date.              | Name of mine.                   | Location of mine. | Nature of accident. | Number<br>killed. |
|--------------|--------------------|---------------------------------|-------------------|---------------------|-------------------|
| 1888<br>1915 | Mar. 29<br>Feb. 18 | Keith and Perry No. 6.<br>Atlas | Rich Hilldo       | Mine explosiondo    | 24<br>5           |

available. The fatality rate during this period is 1.78 per 1,000 men employed. During the 26 years there was only one serious mine disaster, in which more than 5 men were killed at one time. This was a mine explosion in 1888 in which 24 men were killed, representing slightly over 6 per cent of the total number of fatalities during the period covered. Falls of roof and pillar coal are responsible for 62.17 per cent; gas and dust explosions, 10.58 per cent; and explosives, 11.38 per cent. The average production of coal per fatality was 229,541, or there were 4.36 fatalities per million tons of coal mined.

About 97 per cent of the men employed in the coal mines of Missouri since 1903 have been eight-hour men. As there are a number of States in which men are employed 9 or 10 hours per day, the time element has been taken into consideration, and tables compiled on this basis for comparison with other States. The fatality rate for the 10-year period 1903-1913 (Table 40), based on the actual number of men employed, is 1.30 per 1,000, and on the number of 2,000-hour workers is 1.70. During the 10-year period the men averaged 1,539 hours per year as compared with 2,463 hours in New Mexico, 2,132

#### MONTANA.

#### AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of Montana are widely distributed over the eastern two-thirds of the State, and have an aggregate area of about 39,000 square miles. From a commercial standpoint there are only three important fields in the State. These are, according to production, as follows: (1) Red Lodge field in Carbon County, (2) Bull Mountain field in Musselshell County, and (3) the Great Falls field in Cascade County.

The Red Lodge field comprises an area of about 50 square miles, but the number and thickness of the beds compensate in large measure for the small size of the field. The beds dip to the southwest toward the Beartooth Mountain, from which they are separated by a great fault.

The Bull Mountain field has a known productive area of 630 square miles, being a great synclinal basin lying mainly between Yellowstone and Musselshell rivers. This field has developed since the building of the Chicago, Milwaukee & St. Paul Railway in 1908.

The Great Falls coal field, which contains about 1,500 square miles, is south and east of the town of Great Falls. This field is one of the first to be developed in the State, but owing to the heavy percentage of ash the coal can hardly compete with that from Red Lodge and Bull Mountain.

The Milk River field, in the northern part of the State, as well as the great lignite fields in the eastern part, cover large areas, but are only slightly developed.

#### CHARACTER OF COAL BEDS.

The coal beds of the Red Lodge field vary from 3 to 12 feet in thickness; the coal is high<sub>r</sub>grade subbituminous, slacks readily, and for this reason pillars will soon crush when left standing, and thus allow the roof to fall. The coal about Bridger, a little to the northeast of Red Lodge, is bituminous, but only a little of this coal is mined at present.

In the Bull Mountain field the coal beds occupy a synclinal trough. There are 10 to 16 feet of clean coal; the dip does not exceed  $6^{\circ}$ . The mines are opened by shafts ranging from 137 to 350 feet deep. The quality of the coal is about the same as that mined in the Red Lodge field.

In the Great Falls field the beds are 3 to  $7\frac{1}{2}$  feet thick, with a slight dip to the north. At Sand Coulee, the principal mining center of this field, the beds are flat and about 10 feet thick. The coal is bituminous and intrinsically of higher grade than from either of

14355°—Bull. 115—16——16

the fields so far described, but the heavy percentage of ash detracts greatly from its commercial value, and the field, which up to 1907 held first place in the State's production, has now dropped to third place.

In the Milk River field the roof in most cases is a soft sandstone or carbonaceous shale, making it necessary to leave considerable coal to keep the entries from caving in. Extensive timbering will be necessary when mining is done on a large scale.

#### MINING METHODS.

The mines at Chestnut, Gallatin County, are the oldest in the State, having been opened in 1867, and coal hauled from them long distances by teams. The records show that the production of coal in Montana began in 1880, when 224 tons were reported as mined. In 1913 the production was 3,240,973 tons, of which Carbon County mined 1,187,270 tons. The mines are opened by drift, slope, and shaft, and are mined by the room-and-pillar and pillar-and-stall systems. At Stockett the roof is sandstone, and the coal is mined by machines. Machines are also extensively used at Belt. In 1896 there were 62 mining machines in use in the State, which produced 37.5 per cent of the coal; in 1913 there were 97 machines, producing 33.2 per cent of the coal, whereas 35 per cent was shot off the solid, and 31 per cent was reported as being mined by hand.

#### REPORTABLE ACCIDENTS AND ORGANIZATION OF INSPECTION SERVICE.

The first mine-inspection law of Montana was approved March 14, 1889, and provided for the inspection of all mines where 5 or more men were employed, except mines operated only by the owners or lessees. The inspector was authorized to employ an assistant to act in cases of emergency, as in cases of accidents, or in the absence of the inspector. The assistant's salary was on a per diem basis and his employment was limited to 100 days a year. Mine operators were required to report to the inspector or his deputy all fatal and serious accidents in and about the mines. The inspector was required, whenever possible, to go to the scene of the accident and investigate the cause thereof; and if it was not possible for the inspector to visit the mine, the person in charge was required to obtain written and sworn statements from persons who had witnessed the The inspector rendered annual reports to the governor and accident. enumerated therein all accidents of which he had received notice.

On March 4, 1897, an act was approved directing the deputy inspector to devote his entire time to his official duties. On March 18, 1901, an act relating exclusively to coal mines was approved, and the governor was authorized to appoint a coal-mine inspector. An act approved March 4, 1913, created a department of labor and industry, consisting of a commissioner, boiler inspector, inspector of mines, and coal-mine inspector, and directed that the annual reports of these inspectors should be combined in one volume and published biennially. The authority to appoint the deputy inspector was transferred from the coal-mine inspector to the governor by an act approved March 31, 1913.

Mine operators in Montana report to the inspector only those accidents causing at least 14 days' disability, and these are published in the inspector's annual reports. Accidents causing disability for less than 14 days are not considered serious.

#### ACCIDENTS.

Tables 111 and 112 show the number of fatalities in and about the coal mines in Montana, classified by causes and calendar years since 1889, as compiled from the State mine inspector's reports. The years 1896 and 1899 are left blank, as reports for these years were not available. Continuous records for 1900 to 1913, inclusive, show that 159 men were killed in and about the coal mines in Montana,

FATALITIES IN MONTANA COAL MINES, BY PRINCIPAL CAUSES, DURING THE YEARS 1900 TO 1913, INCLUSIVE.

COAL-MINE ACCIDENTS IN MONTANA IN WHICH 5 OR MORE MEN WERE KILLED

|              | Date.             | Name of mine. | Location of mine. | Neture of accident. | Number<br>killed. |
|--------------|-------------------|---------------|-------------------|---------------------|-------------------|
| 1906<br>1908 | June 7<br>Nov. 20 | Red Lodgedo   | Red Lodgedo       | Mine firedo         | · 8<br>9          |

representing a fatality rate of 3.89 per 1,000 men employed. Of this number 55.34 per cent were killed by falls of roof and pillar coal and 14.47 by mine cars and locomotives. Montana has been free from disasters due to gas and dust explosions. The production per fatality was 186,276, or there were 5.37 fatalities per million tons of coal

mined. There have been two mine fires, in which 17 men were killed.

The 8-hour day prevails in Montana and the time element is, therefore, taken into consideration for comparison with other 8-hour and with 10-hour States (Table 40). The total number of hours worked per year is 1,930, as compared with 2,447 for Virginia or

2,255 for Alabama. The total number of hours of labor performed has been converted to a 2,000-hour basis and fatality rates shown in Table 41, for comparison with other States. The fatality rate on the actual number of men employed during the 10-year period 1903 to 1913 (except 1909) is 4.08, as compared with 4.23 fatalities per 1,000 on the basis of 2,000-hour workers. The tables of statistics for the State of Montana follow:

### NEW MEXICO.

# AREA AND DISTRIBUTION OF COAL FIELDS.

The coal fields of New Mexico comprise about 13,000 square miles but most of this large area is undeveloped and the producing districts are small and widely scattered.

The most important field, both as regards quality of coal and amount produced, is the Raton field, which is the southward continuation of the Trinidad field of Colorado. It extends about 40 miles south of the State line to the Cimarron River, and from the base of the Rocky Mountain Range eastward about 50 miles. Its area is about 960 square miles.

The largest area is the San Juan River region in the northwestern corner of the State. Its area is about 10,000 square miles, but only two small districts in this great field are developed at present. These are Gallup, on the Santa Fe Railroad, at the southern end of the field, and Monero, or Lumberton, at the north end. The coal at Gallup is subbituminous, and at Monero bituminous. The Los Cerrillos field, in the central part of Santa Fe County, contains about 35 square miles, and is noteworthy as the only western field outside of Colorado that is producing anthracite. Operations in the White Oaks field of Lincoln County are small, and the production is limited to local consumption. Mining on a small scale is also carried on at Carthage, in Socorro County, in a small isolated field containing bituminous coking coal.

# CHARACTER OF COAL BEDS.

Practically all of the coal mined in the Raton field comes from a few large mines working the lowest bed of coal. This bed varies from 4 to 12 feet thick. There are at least four other coal beds thick enough to be of economic importance, although comparatively little development has been done on them. The second bed from the bottom, known as the Sugarite coal, has been opened east of Raton at the Sugarite mine, and the third bed has been developed to some extent at Yankee, and is believed by some to be the same as the coal bed opened at Brilliant, which is situated in Dillon Canyon, northwest of Raton. No producing mines have been opened on the higher coal beds. The coal beds in the Raton field lie nearly flat, and mining is not particularly dangerous, except for gas in some of the mines.

In the Gallup district the coal beds, as a rule, lie nearly flat, except on the rim of the basin, 3 miles east of Gallup, where they sharply upturn. There are five coal beds in this district, ranging in thickness from  $2\frac{1}{2}$  to 7 feet. The coal beds of the Los Cerrillos field dip about  $18^{\circ}$  east. There are three important beds, varying in thickness from  $2\frac{1}{2}$  to 7 feet with the higher grade of coal in the northern part of the field. The northern part also contains some anthracite coal which has been produced by an intrusion of igneous rock, and which gradually merges into coking and semicoking coals to the south.
