A military acquaintance gave us a sketch of what would take place among every group of Army Doctors at the reading of this Report,—the group to be composed of men ranging in rank—say—from a Deputy-Inspector to the most junior Assistant-Surgeon. The *Army* Inspector thinks it unfair that his *Naval* brother should garner more fruit from his labours than himself. A stout old Surgeon-Major, who has a family to provide for and is willing to keep in harness on that account, albeit "his strength is but labour and sorrow," is in high dudgeon at finding that he can add only a shilling or two to his retiring pension by continuing until his age is 55. A Regimental Surgeon, whose remedy for all grievances lies in an earlier and better retirement, cannot conceal his disgust at the offer of five-tenths of his pay as a retiring allowance at twenty years. A Senior Assistant-Surgeon, grown depressed and irritable by the prospect of longer service in his subordinate capacity, longing for promotion, finds 2s. a-day a very poor substitute for the disappointment; and the Junior Assistant, viewing with dismay his position on the list at the foot of some 800 men, and listening to the expressions of determination on the part of the elders not to go before twenty-five years, ejaculates—"Why, I may live and die an Assistant at this rate; and the maximum pay I can get is 17s. 6d.!"

Such is our friend's sketch. He proceeds to analyse the Report and calls attention to the reigning purpose. The recommendations of the Committee are designed—"In view of the proper requirements of the Service, and in order to encourage the coming forward of *a larger number of the most eligible class of candidates, so as to render the competitive examinations really worthy of the name, and such as was contemplated upon its establishment.*"

The first difficulty to be surmounted arises from a slowness, almost amounting to an absence, of promotion altogether for the very junior officers. By what plan was the Committee to induce a really good and superior class of candidates to place their names at the foot of a list of some 800 Assistant-Surgeons?

This has not been attempted by making the promotion more rapid, or by fixing a definite time at which a man should cease to be an Assistant-Surgeon, but by a pecuniary equivalent for the rank of Surgeon. They have recommended the pay for Assistant-Surgeons above 5 years' service of 12s. 6d., in lieu of 11s. 6d. per diem; above 10 years' service, of 15s., in lieu of 13s., or on promotion of 17s. 6d.; above 15 years', 17s. 6d., in lieu of 13s.

These sums are just and reasonable enough, but all increase of pay for that rank ceases after fifteen years. The Committee were confronted by the long list of Assistant-Surgeons of 1854, and they could not get over the difficulty of twelve years and promotion; and so long as the present regimental system remains intact and unmodified this difficulty will remain likewise. The Committee did not grapple with the question of the enormous disproportion between the number of Assistant-Surgeons and Surgeons, and this disproportion must, therefore, still continue.

It seems, too, to have been lost sight of that India absorbs nearly half the Department; the new scale of pay will, therefore, not affect that half at all.

A service can never be popular with well-educated and ambitious students where a man has the certainty almost of spending a large part of his life in the most subordinate position; and, unfortunately, it does not appear to be at all clear at what date a man may expect to be promoted. He will certainly attain the daily pay of 17s. 6d. after 15 years' service, but it is highly improbable he will gain a step in rank at that time, or soon afterwards. At 20 years' he may still remain an Assistant-Surgeon, and he will then be at liberty to retire upon 8s. 9d. per diem. Now, will the *right* men enter such a service while the Indian Medical Department is open to them? In the Navy, the promotion to the rank of Surgeon has been, and is, much quicker; and the Indian Medical Warrant fixes twelve years as the time for promotion. We do not wonder, then, at the rumoured petition of the last batch of candidates to be allowed to exchange to the Indian Service.

It may be said that had a fixed time been adopted for promotion in the Army, the authorities would have had to contend with the difficulty arising from a sudden and great increase in the number of Surgeons. But is there any reason why the presence of two Surgeons in a corps should necessarily entail evils arising from conflicting authority any more than the presence of two majors in a regiment does so; the senior assumes the lead and takes the responsible position in the one case, then why not in the other?

But the Committee, we presume, thought the difficulties insurmountable; and we next turn to another and slower method for accelerating the circulation of promotion—viz., an earlier permissive retirement.

Here the claims of the service and the public purse come into play. A retirement on the completion of twenty years' full-pay service is advised; but, in the language of the *Pall Mall Gazette*, "provisoes are attached to the recommendation which may not be so satisfactory as could be wished." The retiring allowance will be exactly half the pay of which the Medical Officer may be in receipt at the time his twenty years is up. In the case of a fresh candidate, as far as we can see, he will be an Assistant-Surgeon in receipt of 17s. 6d., and entitled, therefore, to 8s. 9d. on going. In the case of Surgeons it will be more, of course; but still only five-tenths of the daily pay. Very few men will leave on such a retiring allowance unless compelled by sickness, and, in that case, a rather better provision is made.

The Committee probably thought that a man of twenty years' service was, by his age and experience, the most useful and best class of officer to retain. If so, it might be expected that some additional inducements would be held out to him to remain. Surgeons-Major, retiring compulsorily at fifty-five years of age, are recommended to be given a retiring allowance of 1*l.* per diem—that is to say, they will receive about 1s. 6d. per diem more than at present, if they are compelled by their age to retire, instead of going voluntarily after twenty-five years' service.

Very few men, indeed, will be fifty-five years of age at the time they will have completed twenty-five years' service. Nearly all of them entered the departments before they were twenty-five, and we suppose this clause must have been introduced to meet the case of those candidates who entered under the late regulations extending the age of the candidates to thirty.

There are recommendations in the way of increased remuneration, which are, good remuneration for the rank of Assistant-Surgeons up to fifteen years; poor for the Surgeons; and none at all for the Army Inspectorial ranks.

The recommendations of the Committee as to relative rank, position at mess and on mixed boards go to confirm the present custom; but to fix that position more plainly and definitely by the alterations suggested to be made in the *Army List*. All the reasonable men will be satisfied, we think, with this part of the report; those possessed of very military notions will not.

THE VENEREAL COMMISSION.

The report issued by the Committee appointed to inquire into the treatment and prevention of venereal diseases in the Army and Navy, and to suggest any practical rules to the authorities whereby the frequency of contagion could be diminished, is a very valuable one. It discloses the astounding fact, in the first place, that as regards the Army "the loss of service arising from them (admissions of men suffering from venereal

diseases) was equal to that of the whole force serving in the United Kingdom for an entire week;" and the statistics of the Navy show that in 1862 "the daily loss from venereal diseases was about 9·9 per 1000," which may be looked upon as equal to the loss of the services of the whole complement of such a vessel as H.M.S *Royal Oak* (iron-clad). The estimated cost of venereal diseases in the Navy in the same year (1862) is reckoned at 32,296*l*. This sum refers to disease in "all ships in commission, and all Naval Hospitals at home and abroad; it does not include the expenses for Marine Infirmaries for the care of seamen and coastguardmen in sick quarters. . . . Nor are the expenses for the conveyance of invalided seamen sent home from abroad included." If these omissions be taken into account, and the term venereal be made to include diseases of vital organs, of special senses, rheumatic and bone affections, "the sum of 32,296*l*. would be better represented by that of 50,000*l*., as the cost of venereal diseases in the Royal Navy for 1862."

The operations of the *Contagious Diseases Prevention Act* would seem to have been successful in a certain degree, but the Committee recommend its more complete development. It would appear that its application fails especially to detect disease in the earliest stages; that it acts with difficulty, and is of slow operation, thus permitting the spreading of the disease for many days before discovery takes place; and that it is not calculated to secure the evidence of existing disease, which is obtained by a kind of chance, either through the spite of companions, or from the occasional knowledge of the police or other possible information; "those prostitutes only against whom information is laid are liable to compulsory examination under the present Act." The Committee recommend the absolute necessity for instituting a periodical compulsory examination of all prostitutes, of separating them from the possible contact with others, and detaining and treating them in Hospitals until cured; and they base this upon the complete success which has attended the operation of such regulations, especially in the Ionian Islands and Malta. At the present time there is nothing to prevent, on the arrival of a ship, all diseased women from infecting the whole crew, and such women could only be reached by a periodical examination, such as suggested. In addition, it is proposed that the system of Lock Hospitals should be very considerably extended, and placed under Government control; that a Surgeon should be appointed in each town with power to send women to these institutions; that penal enactments be instituted for infringement of regulations; that the system of control should be extended to garrison and seaport towns; that loose women should not be allowed residence in public houses, nor to carry on "the open solicitation" in the public streets, and "the scandalous and barefaced immorality" which is spoken of by some of the witnesses as disgracing Portsmouth and other towns of the same class. The expenses attendant upon these changes would be repaid by the greater efficiency of the Service generally. The objections to the regular examination of men are noted.

"However efficiently the regulations as regards women may be carried out, their success in arresting the spread of disease must be very imperfect, unless similar precautions be adopted for preventing the men from carrying infection to the women. The Committee have been led to give much consideration to the periodical examination of the persons of men of both services. The Committee are of opinion that the practice, so far as the soldier is concerned, should be universal throughout the Army, and that it is no less necessary to the health of the sailor whenever he has the opportunity of access to women. Without such a regulation the proposed periodical examination of women must lose half its value."

Suggestions are also made for improving the general condition and tone of men. Dr. Balfour makes a separate report, thinking that the weekly examination would not diminish prostitution, but rather offer increased facilities, and makes some special recommendations of his own. The Appendix contains the experience of Sir H. Storks and Mr. Inglott, at Malta, and the report on prostitution in Paris, and the laws in operation there for its repression, which we cannot enter into here.

The Committee appear to have met the matter fairly; they allow the existence of a great evil, and suggest what appear to them suitable legislation, avoiding as much as possible all encouragement and facility of access to prostitutes.

THERMOMETER IN PHTHISIS.

The statements that have already been laid before our readers have by no means exhausted the information that the thermometer gives us. By means of it we gain the most important information concerning doubtful cases of consumption. All of our readers must have met with cases which have perplexed their skill and resisted diagnosis by the scantiness of the symptoms and physical signs. In such cases the thermometer assists us greatly. It is by both physical signs and symptoms that we learn that a patient is the subject of tubercular deposit in the lungs. Of these, physical signs are the most to be relied upon; but physical signs sometimes altogether fail us, and this is especially the case at the commencement of the disease, at which time most is to be expected from treatment. The following physical signs, situated at the apex of the lungs, are those chiefly to be relied upon in an early case of phthisis—namely, dulness on percussion; weakness of the respiratory murmur; jerking respiration and rhonchus. But jerking respiration is generally absent, and when present, it may be due to hysteria or nervousness, and thus is most important when limited to one apex. It is, indeed, a sign whose presence gives us important information, but whose absence by no means frees the patient from the suspicion of consumption.

Rhonchus, moreover, during the early stages of the disease is mostly absent. Nor can the absence of dulness on percussion be accepted as a proof of the freedom of the lungs from tubercular deposit, for no dulness may be detected, although tubercule even in considerable quantities may be present. If small in quantity, it may fail to impair the percussion note; and even if the deposit be considerable, if it be scattered through the lungs, no dulness may be detected. This is especially the case with children; indeed, with young people the diagnosis of consumption must be often made when dulness on percussion is absent throughout the course of the disease. Again, when there is a considerable amount of deposit in the lungs, and when this is localised in their apices, if some emphysema be present we may entirely fail to obtain any loss of tone on percussion, or the slight loss of tone may be due to former disease which has left the lung impaired, but from which no further bad consequences are to be apprehended.

Weakness of the respiratory murmur is a valuable sign, but it is often difficult to be sure that it is present, as the intensity of the respiratory murmur varies greatly in different people. It is true that the vesicular murmur is heard equally loud under both clavicles, but if both sides be equally affected, we lose this means of comparison.(a)

Thus often the most important of the physical signs are absent, and even if present in a slight degree much doubt must remain as regards the nature of their cause. Indeed, we need not dwell on the insufficiency of physical signs to enable us to make a diagnosis in many early cases of phthisis. We appeal to the experience of those of our readers who are in the habit of making post-mortem examinations in support of our statement.

But if physical signs sometimes fail us, how much more is it the case with symptoms, for the symptom of early phthisis

(a) We can, however, mostly learn if the respiration be weak under the clavicles by comparing the vesicular murmur heard at this part with that heard lower down the chest, for the respiratory sound is as loud under the clavicle as at any other part of the chest.

are by no means characteristic? They are frequently met with as the result of other causes.

The symptoms most relied on are cough, emaciation, night sweats, and frequent pulse; but none of these singly, nor their combination, will enable us to declare the patient to be tubercular.

For emaciation is frequently produced in other ways. It may be due to the influence of bad hygienic conditions of life, to excesses of various kinds, or to mental oppression, the result of grief or disappointment. Nay, more, it must be recollected that phthisis may progress without causing loss of flesh of the patient; that, indeed, under favourable circumstances, the patient may even gain in weight. Profuse sweating is mostly due to two causes, 1st, fever, 2nd, debility; for on the decline of the temperature of febrile patients, sweating almost always ensues. This is well seen on the critical days of various febrile affections, and in the third stage of ague, at which time the temperature is returning from an abnormal elevation to the temperature of health. But weakness is a most frequent cause of sweating, those persons whose health is broken down from any cause often sweat profusely on exertion, from excitement, or during sleep. Persons also present great individual differences in respect of the amount of excretion from the skin; thus profuse sweating is by no means a proof of phthisis.

We may add in passing, that the state of the skin often affords us much information respecting the condition of our patients, and thus becomes an indication in treatment.

When the result of weakness, profuse sweating in non-febrile patients calls for tonics, out-door exercise, and a bracing climate. If it occurs in febrile patients in whom the temperature remains high, it shows want of vigour of the system; and if it occurs at the commencement of the disease it is often of serious significance, and calls for the free administration of stimulants.

How are we to determine whether the sweating be due to a fall of the temperature, or if it be due to weakness? If it be caused by the former of these conditions, it occurs only once in the day, and usually in the evening, as there is only one rise and fall of the temperature in fever in the twenty-four hours, and the fall most frequently occurs in the night; while, on the other hand, if the sweating be due to general weakness, then it may occur at any time, and may be frequently repeated. Thus, on exertion, or from excitement, or from sleep, patients in such a condition perspire freely.(b)

The thermometer gives us a still more certain means of learning to which of these conditions the sweating is due. The sweating resulting from debility is not only profuse, but often of a very offensive smell.

Of the remaining symptoms that we have mentioned, cough is not of itself sufficient to prove the existence of consumption, and we have already seen that weakness may cause the pulse to beat too quickly. Thus, three of the most important symptoms—loss of flesh, a quick pulse, and profuse sweating—may be due to mere weakness, and this condition may be produced by many other causes than phthisis. Hæmoptysis is, of course, a valuable and serious symptom, but it is absent in many cases of phthisis, and when it occurs it may be difficult to learn from the account given by the patient whether it comes from the mouth, throat, or lungs. But we need hardly dwell longer on this part of our subject. All our readers must have but too often met with doubtful cases in which some of the above symptoms and signs were present, and yet were not sufficiently marked to warrant a positive diagnosis, which cases caused them great perplexity and much anxiety. What information does the thermometer afford us in such doubtful cases? *While tubercle is being deposited in any of the organs of the body, the temperature of the patient is preternaturally raised.*

The degree of elevation varies. It, however, mostly reaches 102° or 103° Fahr., and not unfrequently 104° or 105° Fahr. It must be borne in mind that the temperature of tubercular patients is often normal in the morning, but rises in the evening; and thus it is important that the observations of the heat of the body should be made in the evening. Such daily elevation of the temperature may continue for many months.

Thus a patient with some of the symptoms and signs of phthisis, but whose temperature after a careful examination is found to be normal, is not the victim of this serious disease. If, on the contrary, the temperature be elevated, and no other cause can be detected—and in the great majority of cases such cause, if present, can be detected—then it becomes very highly probable that the patient is suffering from tubercular disease.

We now give cases in illustration of these remarks.

A young woman, 24 years of age, had lost flesh for some weeks. She was very pale, and suffered from great weakness. Her pulse was quickened and her breathing hurried, especially on exertion. She had a slight cough with very scanty muco-purulent expectoration. Her appetite was bad and her sleep much broken. She sweated greatly at night. For some months she had been greatly overworked. By a physical examination of her chest nothing was discovered with the exception of some sonorous rhonchus. This was heard over the whole of her chest. It, however, soon disappeared, and her cough improved. She was considered to be the subject of active tuberculisation. Her temperature, however, was always normal. By means of perfect relaxation from work and generous diet she quickly improved, and ultimately recovered. At no time were any abnormal physical signs other than those mentioned detected, though a careful examination of her chest was frequently made.

A young lady suffered from a severe domestic bereavement, which considerably altered her prospects in life. Shortly after this she began to lose flesh. Her appetite was very greatly impaired. She slept badly at night. Her cough was slight and without expectoration. She had never spat blood. She still continued to discharge the ordinary duties of life, and though visibly failing, declared that she felt pretty well. No physical signs indicative of disease could be detected. The temperature was found to rise to 102 and 103. In a few weeks well-marked physical signs indicative of phthisis were developed. She grew rapidly worse, and her life is now drawing to a close.

We need hardly dwell on the importance of an early detection of this disease, for it is at such a time that most good is to be expected from treatment. On the other hand, serious inconvenience may follow a mistake in the diagnosis. Thus, if phthisis be diagnosed when no such disease is present, it may cause the patients to observe useless precautions that may seriously interfere with their future prospects in life.

It has been already stated that the temperature of the body affords us an exact indication of the severity of the cause producing fever. Such is the case with tuberculosis. *The temperature is a measure of the rapidity with which tubercle is being deposited in any of the organs of the body.* The more rapid the deposit the higher the temperature. Hence we possess an easy means by which we can learn the condition of the patient.

In this respect, again, the temperature is superior to the other symptoms, for we have seen that a patient may not lose flesh, but, on the contrary, may gain in weight, while phthisis is progressing; for the weight is dependent on the appetite

(b) It is generally considered that sweating causes much exhaustion of the patient. When due to fever (elevation of the temperature) much weakness is often the result; not, however, from the sweating, but from the increased consumption of tissue that causes the elevation of the temperature. When, however, the sweating does not depend on a previous elevation of the temperature, it must be considered the result, and not the cause, of the exhaustion. Dr. Druitt has observed that sponging of the body of patients who sweat greatly with water as hot as can be borne often checks the sweating for several hours. This treatment would probably be found more useful in checking the perspiration from exhaustion than that due to fever.

and this holds no constant relationship to the severity of the disease. If the appetite remains good, the weight is maintained or even increased, and the patient may linger on for an almost indefinite period. If the appetite fail, they rapidly waste and speedily die. It is a question of demand and supply; of increased consumption of the tissues and sufficient supply of nutritive material, with power to assimilate it. This increased consumption of tissue (in part, at least) causes the fever. If food can be digested, this increased waste is compensated. Hence the prognosis of phthisis must be chiefly founded on the amount of elevation of the temperature—a measure of the amount of tubercle being deposited—and on the digestive powers of the patient. This, indeed, is the case with all febrile diseases.

It must be remembered that the same degree of elevation in different diseases by no means indicates the same amount of danger. The fever (elevation of the temperature) rarely destroys life. Each fever has, in respect of its dangers, its own peculiarities. These dangers are chiefly due to the poison in the blood. This, in addition to an elevation of the temperature, gives rise to various, and often characteristic symptoms. In phthisis (tuberculosis) the influence of this blood-poisoning, apart from the fever it produces, is but slight. Thus, while with typhus fever, unless the fever quickly subside, the patient dies, a phthisical patient may continue to live for months with a temperature equal to that which occurs in a severe attack of the former disease. Thus, in forming our prognosis, we must take into consideration the nature of the disease, the elevation of the temperature, and the amount of food that can be digested.

But to return to our subject. The pulse cannot compare with the temperature as an estimate of the rapidity of the deposition of the tubercle; for this, as we have seen, is accelerated by weakness, and the amount of weakness of the patients is in a great measure regulated by the amount of food they can take.

Nor can we obtain exact information from the physical signs, for much tubercle may escape detection by percussion. It may be situated in the centre of the lung, or the evidence of its presence that it would give may be completely annulled by some emphysema. Moreover, in respect of the increase of the deposition, we can only get information from the physical signs when the examination is made after a long interval has elapsed, as a slight increase in the amount of the tubercle is utterly beyond detection by these means. Hence the temperature of the body affords us the most exact estimate of the rapidity with which tubercle is being deposited in its organs.

THE WEEK.

KEROSOLENE AS A LOCAL ANÆSTHETIC.

A few days ago Sir James Y. Simpson operated in the Edinburgh Infirmary on a case of vesico-vaginal fistula; and for the purpose of producing local anæsthesia he applied, before making the incisions and stitches, the vapour of kerosolene by a spray douche. Afterwards, he applied the spray of kerosolene to the hands, arms, etc., of several students, and showed, that, by its influence, the douched part could be frozen in a very few seconds. To obtain the full effect of the kerosolene —which is one of the cheapest of medicinal agents—it requires to be pure. In various minor operative procedures Sir J. Y. Simpson has used local anæsthesia of late with varying amounts of success, employing vapour of sulphuric ether, according to Dr. Richardson's ingenious method. He believes that a larger apparatus, provided with several jets, like a watering-pan, would be sufficient as an anæsthetic in many smaller operations. As local anæsthetics he has employed the vapour of oxide of amyl (eupion), nitrous ether, the lighter hydrocarburets from the distillation of paraffine oil, chlorocarbon, hydrochloric ether, etc. Some years ago (see *Medical Times and Gazette* for January 22, 1859, page 79) he suggested, in our columns, solid carbonic acid for producing the same effect, observing that it had always seemed to him that solid carbonic acid, applied in a caoutchouc bag or otherwise, alone or mixed with ether, would probably be found the most convenient and best freezing agent for producing local anæsthesia in the practice alike of the Surgeon, Dentist, and Accoucheur.

SEA SCURVY.

An inquiry was held by Mr. Carttar, at Greenwich, on Monday last, on the body of a seaman, who was said to have died of scurvy about ten hours after admission into the *Dreadnought*. The Medical officer of that Hospital, in conjunction with Dr. Duprè (of the Westminster School of Medicine), having analysed the so-called lime-juice provided aboard the ship in which this man was serving, came to the conclusion that it was either a solution of citric acid or very weak lemon-juice and water. Evidence was given to this effect, a verdict was returned in accordance with that evidence, and it is understood that a prosecution will result therefrom, at the instance of the Board of Trade. On Tuesday last the master of the brig *Western Star* was charged at the Thames Police Court with a breach of the Merchants' Shipping Act. In this case the evidence went to prove that the supply of limejuice was not sufficient for the voyage; that two men had died from scurvy; and that nearly all the crew were more or less disabled from the same cause. Mr. Partridge, the presiding magistrate, convicted the defendant in the full penalty of £20, remarking that this was a gross breach of the Act, and one to be viewed in a very serious light. The latter of these inquiries proves but too plainly how very inadequate is the law, as at present constituted, to deal with this question. If official supervision had been exercised before the vessel hauled out of dock on the outward passage, it is not too much to say that this list of deaths and sickness would never have appeared at all. A penalty of £20 is but a wretched mockery, given as a peace-offering for the deaths of two, and the wretched (perhaps permanent) debility of eight men. It is the duty of the Seamen's Hospital Society to keep this matter before the public, and so eventually to obtain measures that will remove this disgraceful malady from the merchant navy.

FEVER AT BUGLAWTON, CHESHIRE.

Last week we quoted an extract from a letter which appeared in the *Guardian* newspaper, giving an account of an outbreak of fever in the village of Buglawton. The writer of the letter, to whom we wish to give all credit for benevolence and good intention, is, we believe, a clergyman of the parish. That good intentions and benevolence are not a guarantee either for good sense or good taste, is too often proved by the proceedings of clerical as well as lay unauthorised dabblers in Physic. This gentleman, in a portion of the letter which we did not quote, hints that the Doctors have been over-physicking and stimulating their patients, and throws out a bait to some stray homœopathist to come and settle amongst them, by stating that there is no homœopathic Physician in the neighbourhood. We have received several Congleton papers containing letters from the same clergyman filled with homœopathic twaddle, from which it appears that the reverend gentleman has been uniting to his spiritual functions those of the quack. The facts of the case are the following:—The sanitary condition of the village is thoroughly bad. The drainage is in a most deplorable state. The water is impure; indeed, many of the inhabitants are drinking river or well water impregnated with the sewage. Under these circumstances, as was to be expected, there has been a well-marked outbreak of typhoid fever; not, however, it would seem, of a very virulent type, for, according to the reverend gentleman's statement in the *Congleton Advertiser* of February 24, the deaths have only

reached the average of eight per cent. This he thinks a large percentage; we should think it a small one for such an outbreak as he describes. We would suggest to the incumbent of Buglawton that his time would be better employed in introducing sanitary reforms amongst his flock, in obtaining a better system of drainage in their dwellings, and a better water supply, than in interfering with and annoying the Medical Practitioners of his neighbourhood by administering homœopathic nostrums to the sick, by asserting openly that some of the doctors have over-stimulated their patients, and advising that their directions should be disregarded. We have heard that one of the Medical Practitioners of the neighbourhood has, in consequence of this unwarrantable interference, felt it his duty to visit his patients, at a distance of a mile and a half from his house, three times a day, to insure the proper amount of stimulants being given. How would a clergyman like his sacred functions to be interfered with by any lay adventurer who might possess sufficient ignorance, temerity, and conceit to undertake to supersede the parson?

CATANIA AS A HEALTH RESORT.

Thanks to increased facilities for travel, a trip in search of health is no longer the terrible undertaking it used to be—frequently postponed until worse than useless. We rarely now see on board the Southampton steamers young men and women whose hectic cheeks already glow with the sunset hues of existence. Modern investigations into the influence of climate on the bodily economy enable Physicians to prescribe residence in certain localities with as much accuracy as any medicine from the shops. Consequently several places have become the regular resort of invalids; several almost forgotten have resumed their old importance, and nearly every year some are added to the guide books.

Of these is the old university town, Catania, long celebrated for historical associations and the salubrity of its climate, but scarcely affording to English men and women those comforts which, both in sickness and health, are so indispensable to them.

Catania is situated on the shores of an inlet of the Mediterranean, on the eastern slope of Mount Etna or Mongibello, which the Greeks who colonised Sicily selected as best adapted for the cultivation of their cereals, olives and vines. A natural mole of lava enclosed a small harbour, and there they established a port, about forty-one miles from Syracuse. The scenery is of extraordinary beauty and variety; the isolated cone of Mount Etna rises to the height of 10,874 feet above the sea level, and its sides present three separate and different zones—an upper, which is the principal crater, covered with perpetual snow, scoriæ, and ashes; a middle, covered with dense pine and oak forests which used to supply timber for the fleets of Syracuse; and a third, the lava region, covered with luxuriant vegetation. From every part of the town can be seen the enormous volcano, its summit sometimes obscured by clouds, at others emitting volumes of smoke, while on its sides are the quiet country villages of the labouring people.

The town of Catania has been repeatedly destroyed by earthquakes and eruptions of lava, but often the inhabitants have built themselves a new city out of the materials which destroyed the preceding one. The present town is almost entirely paved and built of lava, traversed by fine long and broad streets, and surrounded by orchards of vines, olives, almond trees, and mulberries, which cover every rising ground. The population is about 80,000. There are many public buildings and an university, founded in 1434 by King Alfonso of Arragon; a lyceum, and an institute with a naval and technological school; there are besides several good schools for both sexes.

There are also public libraries, museums, a botanical garden, scientific resorts of all kinds, public promenades, and theatres. The archeologist may revel in Grecian and Roman antiquities, remains of temples, the forum, theatres, circus, and amphitheatre.

The Hospital of St. Mark can accommodate 100, Santa Martha 80, the Syphilitic 50 patients. There are lying-in, sick children's, and foundling Hospitals; the Medical Professors of the University give clinical instruction at these institutions.

The Hospital accommodation at first sight seems small compared with the population, but we have it on the highest authority that the average number sick at one time is only 500 in civil practice. This satisfactory condition of the public health is no doubt owing in a great measure to the sober and simple habits of the people, who are industrious, frugal, and religious, together with the abundant supplies of good and cheap food; the markets are always supplied with plenty of beef and mutton, poultry, game, and both salt and fresh water fish. Fruits and vegetables are in great abundance. But much of this unusual degree of health depends upon the situation of the town on a dry slope, moderately elevated above the sea level, and exposed to the bracing north-east wind, an equable temperature, averaging 68·683° Fahr., the wide, well-paved, and carefully-cleaned streets allowing currents of air to sweep through the town, and the plentiful supply of water which is brought into the town for the numerous fountains, public lavatories, and gardens, in addition to more than a thousand wells which contain good drinking water.

The water of Catania is limpid, crystalline, without smell or distinct taste, and leaves no deposit in closed vessels. Chemical analysis shows that it contains, besides atmospheric air and carbonic acid gas common to all waters, traces of the following:—Bicarbonate of lime, bicarbonate of magnesia, bicarbonate of soda, carbonate of manganese, carbonate of iron, chlorate of iron, chlorate of iodine, sulphate of soda, silicic acid, phosphate of lime.

According to a meteorological return from the University Observatory of observations for fifteen years, we find the following:—

Annual Medium.

Barometer (English inches)	29·829
Thermometer (Fahr.)	68·683
Hygrometer (Saussure)	52·203
Cyanometer	18·041
Evaporation (English inches)	2·692
Anemometer (prevailing wind)	E.N.E.
Evaporation (English inches)	4·397

The most common maladies are derangements of the gastric mucous membrane from warm weather or biliousness. An experience of thirty years shows that these form about six-eighths of all cases treated, the remainder being made up of coughs, pleurisy, pneumonia, and other incidental ailments. Phthisis is so rare that the average number of cases in St. Mark's confined to Medical cases is not above two or three. Asthma, gout, and vesical calculus are still more rare. It would seem that the climate of Catania is peculiarly adapted for cases requiring a dry, bracing, mild air, not subject to sudden changes of temperature. Lines of railroad branching from Catania can take the visitor to any of the principal points of interest, and there is a very fair amount of game for sportsmen.

We have said that Catania had not accommodation suitable for invalids, but, fortunately, that objection has been removed by the Grand Hotel de Catania, about 900 feet from the sea margin, in a situation which commands an uninterrupted panoramic view of Etna and the sea. The director of this large establishment, which contains upwards of 100 bedrooms, M. Adolphus Werdenberg, has made it his business to study the great English hotels, and, impressed with the importance to Englishmen of their home comforts, he has fitted the rooms with carpets and fire-places; where even winter is as mild as our spring, of course, the latter are

rarely to be found in ordinary houses. There are also hot and cold baths, a music, billiard, and smoking rooms, not to mention other resorts often wanting abroad. This is an excellent head-quarters, not only for invalids, but for sportsmen and general tourists. M. Werdenberg is an experienced Eastern traveller, and is ready to give advice and introductions to any going on to Egypt, Syria, or Palestine.

One great advantage of Catania is that it is easy of access, and by different routes. Those who do not mind the sea can get in the Peninsular and Oriental steamer to Malta, meet there an Italian steamer which, allowing for a short delay at Syracuse, will bring them to Catania in a few hours. Those who prefer it can go by France or Italy; from all the Italian ports comfortable steamers ply regularly for Messina or Catania. The railroad takes about two hours, and the steamer about six between these towns. There is another advantage: the scale of charges is graduated according to the requirements of the visitor; he can have a room from two shillings upwards, and, as we have seen, food is varied and cheap. M. Werdenberg has so arranged that if visitors choose to let him know when, he can have one of his own servants to look after them and their luggage at Malta.

We have no doubt that to those who by this time know the old sanitaria, Catania would prove a pleasant and beneficial change.

FROM ABROAD.—A BUTCHERS' MICROSCOPICAL SOCIETY—PARIS REGISTRATION RETURNS.

The trichina question is taking on a practical aspect in Germany in the shape of the formation of microscopical societies by pork-butchers. That at Nordhausen, in Prussian Saxony, has just published its rules, stating in the preamble, that, as the microscopical examination of the flesh destined for sale is the only security for the public and the trade, and that as where this has to be paid for it will be apt to be neglected, it has been resolved to form a society which Professor Kützing has agreed to instruct in the art of using the microscope and detecting the trichinæ in their various forms. Those persons who are desirous of being members of the Society must be in possession of a sufficiently good microscope, and have learned the use of it for the detection of the trichinæ. The microscope must be always kept in good condition, and at least three portions of the muscles of each pig must be submitted to examination immediately after slaughtering. The preparations must be kept carefully between glasses for mutual examination and control, under the superintendence of Dr. Kützing. When the microscopes and preparations are not found to be kept in proper order reproof will be administered, which, if not efficacious, will be followed by expulsion from the Society. The Society, moreover, offers to pay, for every pig containing trichinæ delivered up to it, not only more than the market price of the animal, but a premium of fifty thalers. This is, at all events, a good practical attempt at meeting what has become in Germany a great public calamity.

In a recent number of the *Moniteur* it is stated that although *trichiniasis* has never been yet observed in France, the French Government has taken steps to obtain full information upon the subject, having sent Professors Delpech and Raynal into Germany to investigate and report upon the matter, and also requested the Academy of Medicine to report to it upon the facts which have already been published. As it is so much the fashion to say that we are always behind the French Government in this kind of inquiries, we may remind our readers that our Government is already in possession of an elaborate Report upon the subject of trichiniasis from the able pen of Dr. Thudichum, and printed in the last Report of the Medical Officer of the Privy Council.

Dr. Farr, in his preface to the "Summary of the Metropolitan Weekly Returns for 1865," just published, makes the following observations:—

"It is a common notion on the Continent that the publication of weekly tables, such as those of London, may shake the nerves of the people and lead to explosions of terror in times of epidemic; but experience proves that the publication of the facts quiets instead of disturbing the popular mind, and while it reveals the exact extent of danger, robs it of the halo of alarm with which the imagination surrounds indefinite pestilences walking abroad by noonday. The panic in Paris, Marseilles, and Naples from cholera last year had no parallel in London in 1854, and if weekly tables had been published in Paris that city would probably have enjoyed the same comparative immunity as London in 1865; for the London tables, demonstrating the diffusion of cholera by the wells and water companies, led the latter, under legislative pressure, to seek purer sources of supply; while Paris was left behind in this work of improvement, and unnumbered thousands of the people perished."

Although the French authorities have not mustered up enough courage to publish weekly tables of the mortality of Paris, Baron Haussmann has caused to be issued monthly tables for 1865 of a very complete character; and although they are rather late in making their appearance, that for September having only been just published, yet they constitute a very important step in the right direction, and will embrace a complete account of the late epidemic of cholera. They are published in the form of a handsome quarto number of some twenty to thirty pages, and are divided into two sections—the one relating to topography, and the other to the population. In the first are detailed meteorological observations made at the Paris Observatory, tables of rainfall, as observed at eight stations, thermometrical observations made on the waters destined to the supply of Paris, the quantity of these derived from the various sources, and tables of the height and condition of the waters of the Seine. Under the section on Population are tables of births, marriages, and deaths; and detailed tables of causes of death, arranged, however, as it seems to us, upon a very faulty system, under twenty different heads. As an example, we may state that deaths from cholera are entered under the heading "Diseases of the Organs of Digestion." As an appendix to these tables, others are given of the amount of direct taxes and the price of bread in Paris during 1865, During the month of September the total births in Paris amounted to 4402 (2224 male and 2178 female) and that of the deaths to 3512 (1844 male and 1668 female), being an excess in favour of the former of 890. Of the 4402 births, 3139 were legitimate and 1263 natural. Of these infants 313 were either born dead or died within twenty-four hours—viz., 214 legitimate and 99 natural infants. The marriages solemnised during the third quarter of 1865 amounted to 4537. The population of the 20 arrondissements, exclusive of the garrison, is estimated at 1,667,841.

PARLIAMENTARY.—THE CATTLE PLAGUE—ENCLOSURE OF EPPING FOREST—WEIGHTS AND MEASURES—TRICHINOUS DISEASE IN SWINE—POOR LAW RATING OF HOSPITALS AND CHARITABLE INSTITUTIONS—VARIOLA OVINA IN NORTHAMPTONSHIRE.

In the House of Lords on Thursday, February 22, a conversation took place, in which several points in connexion with the Cattle Diseases Bill were referred to, and the continuance in force for a few days of the Orders in Council was recommended, with the view of enabling Parliament maturely to consider the two bills upon the subject.

In the House of Commons,

Mr. Doulton asked a question as to the alleged enclosure of Epping Forest.

Mr. Childers, on the part of the Government, said that there had been a correspondence between a department of the Government and the Metropolitan Board of Works as representing the metropolis on the subject, but nothing had been decided. The Government have under consideration the question of what measure should be adopted; but since the report of the last Committee no fresh instructions have been issued by the Treasury.

Mr. Locke asked whether it was the intention of Her Majesty's Government to introduce any bill into Parliament during the present Session to amend the law relating to weights and measures.

Mr. Childers said it was the intention of the Government to introduce a bill this Session on the subject. The special object of the bill would be to transfer to the Department of the Board of Trade all the duties at present imposed by various Acts of Parliament on the Controller-General of the Exchequer, and to place on a more satisfactory footing the custody of our standards.

In reply to Sir A. Agnew,

Mr. Childers said it would have nothing to do with the coinage.

Mr. Hunt's Cattle Plague Bill passed through Committee, with numerous amendments and with the addition of many new clauses

In the House of Lords on Friday,

Lord Granville stated, in reply to Lord Derby, that the Government did not propose to take charge of Mr. Hunt's Cattle Diseases Bill when it reached the House, but if no peer should undertake the charge the Government would consider whether they should not adopt it.

A conversation followed upon the subject of the Cattle Plague, in the course of which Lord Granville stated that experiments with a view of finding a cure for the disease were still in progress.

In the House of Commons,

Sir J. Walsh asked whether the attention of Her Majesty's Government had been drawn to the appearance of a new disease affecting swine in parts of the Continent of Europe, and not only destroying the animal, but rendering the flesh poisonous and dangerous to human life; and whether they had instituted any inquiries by competent Medical and scientific authorities, with a view to ascertain the nature, extent, and progress of the disease. The hon. baronet explained, in putting the question, that the disease had appeared in France and Germany, and that eggs were deposited by insects in the hide of the animal, which died soon afterwards, or, if promptly slaughtered, could not be eaten with safety.

Mr. Bruce said that in 1862 Professor Gamgee was directed to report upon the subject of diseases in meat, and among the diseases embraced in the inquiry was the one referred to. A German Physician of eminence who had paid special attention to the subject was directed to make a report, and it was published in the last volume of the reports of the Medical Officer of the Privy Council. The report was most exhaustive, supplied a number of illustrations, and gave every possible information upon this and other parasitic diseases affecting animals that were killed for human food.

Mr. G. Hardy called attention to a recent decision of the House of Lords on the Mersey Docks Act, and entered into an elaborate argument to show that if the principles there laid down were carried to their full extent, they would lead to the rating of charitable institutions, such as Hospitals, schools, etc. He discussed the grounds on which such institutions had been originally exempted, contending that they were public buildings in the strictest sense of the word, and showed that in many cases their utility would be hampered by the burden of these rates. He put a string of questions to the President of the Poor-law Board as to the instructions which he had issued on this subject, and as to his intentions with regard to future legislation.

Mr. Villiers asserted that great convenience and public advantage had been gained by this decision of the House of Lords, which had set at rest a question on which, for a long series of years, the Courts had given conflicting opinions, and he argued that the exemptions alluded to had arisen from a wrong construction of a clause in the Act of Elizabeth. In reply to Mr. Hardy's questions, he replied that the Poor-law Board had not issued any instructions to rate this class of buildings, though their law advisers had given an opinion that, after the judgment of the House of Lords, these exemptions were invalid; and with regard to legislation he announced that he had no intention to bring in any Bill on the subject.

In the House of Lords, on Tuesday,

Lord Granville, in answer to questions addressed to him, stated that an inspector had been sent into Northamptonshire to inquire into the outbreak of small-pox among sheep in that county, and that the Custom House authorities adopted the same precautions with regard to sheep arriving from abroad as in the case of cattle imported into this country.

Lord Granville then, in moving the second reading of the Cattle Plague Bill, declared himself unable to defend either its principle or its details. The principle was uniformity of restrictions, but that principle was largely modified by numerous exceptions which, in his opinion, would render the provisions of the Bill less stringent than the regulations now enforced by the local authorities. At the same time he admitted that some of the clauses would usefully supplement the Cattle Diseases Bill, and therefore he proposed the second reading with a view to the details being carefully considered by a Committee. The Government intended to suggest certain amendments which they believed would facilitate the operation of the measure.

After remarks from Lord Berners, the Marquis of Bath, Lord Winchilsea, the Duke of Marlborough, the Duke of Buckingham, and Lord Romney, the Bill was read a second time, and was subsequently referred to a Select Committee.

REVIEWS.

On Some of the Causes and Effects of Valvular Disease of the Heart, being the Croonian Lectures of the Royal College of Physicians for 1865. By Thomas B. Peacock, M.D., F.R.C.P., Physician to St. Thomas's Hospital, etc. London: Churchill and Sons. 1865. Pp. 114.

These lectures are devoted to the consideration of cases of valvular disease of the heart arising from causes other than inflammatory affections, to which last conditions it has been very much the habit of late to attribute it. The causes specially referred to are congenital malformation of the valves, injuries of the valves, and alterations in capacity of the orifices and cavities. The lectures exhibit much research, and are well deserving of most careful study. In a table which we quote, the relative frequency with which the several causes of valvular disease operated is given in regard to 63 cases which have come under the care of the author during life, and in which the hearts were examined after death. Thus, of 26 cases of aortic valvular disease—

9 or 34·6	per cent.	are referred to	malformation
2 or 7·4	,,	,,	injury
6 or 23·07	,,	,,	rheumatism; and
9 or 34·6	,,	,,	various other causes combined.

Of 17 cases of mitral valvular disease—

11 or 64·7	per cent.	are referred to	rheumatism
6 or 25·2	,,	,,	other causes.

Of 16 cases of mitral and aortic valvular disease—

2 or 12·5	per cent.	are referred to	malformation
10 or 62·5	,,	,,	rheumatism
4 or 25·0	,,	,,	other causes.

Cases are quoted both from the author's practice and from other sources to illustrate the several points on which he dwells. Some of them are very interesting, and perhaps more especially four cases which illustrate injury to the valves of a heart, previously sound, during some violent muscular effort. Such cases are very different from those in which valves previously diseased give way under some slight exertion or shock. The following extract supplies something like a summary of the leading features of the classes of cases discussed by Dr. Peacock:—"1. There are cases in which the patients have been delicate throughout their lives, and have specially displayed evidences of defect in the circulating organs; while they have never had rheumatism or any other serious illness, and have never sustained any accident, and in which, after death, the valves display one or other of the forms of defect which have been described. 2. There are other cases in which, after the patients have sustained a severe injury or strain, when previously in good health, symptoms of heart disease manifest themselves and never afterwards wholly subside, and in which on examination the valves are found obviously to have been in some way torn. 3. There are yet other cases in which the patients, without having previously been in impaired health or subject to any symptoms indicating cardiac delicacy, have decided attacks of rhuematism or some other form of acute or chronic disease, in which there is proof that the heart was probably or certainly implicated; and after death the valves are found to present some of those conditions well known to ensue upon endocarditis. In cases like this we can have no hesitation in assigning the valvular disease respectively to malformation, injury, or rheumatism, etc.; but 4. There are other cases of which the causation is very obscure. The valves may have been the seat of some congenital defect, which, though trivial, may have predisposed to subsequent disease; the patient may have sustained an injury, scarcely noticed at the time and nearly or entirely forgotten, yet some portion of

the valvular apparatus may have been strained or torn, so as to interfere with their efficient action, and lead subsequently to more serious defect; or during a trifling rheumatic attack, such as few persons pass through life without suffering, or in the course of some acute inflammatory or febrile affection, the heart may have been slightly affected, and the disease thus first set up may ultimately occasion important changes of structure; or 5, and lastly, the patient may have had an attack of rheumatism or some other acute or chronic disease in which the heart may have been involved; and yet such attack may not have been the original cause of the valvular disease, but may only have called into active operation some defect which had previously existed in a latent state. Questions like these frequently arise in considering the probable causation of valvular affections, and make it extremely difficult to decide to what the original development of the disease is to be assigned."—P. 69.

The subject of Dr. Peacock's third Lecture, on the changes which are produced in the state of the heart itself by the various diseases of which it may be the subject, is introduced by an acconnt of some very important original researches into the weight and dimensions of the healthy heart, in considering which the lecturer takes into account the character of the diseases producing death and the duration of the illness, since "it is evident that the weight of the heart must vary considerably, according to the mode in which death takes place; the organ being heavier when the patient dies after only a short attack of illness and lighter when death has occurred from lingering and emaciating diseases." A great part of this information is given in the form of tables, which will doubtless be extensively consulted in future by pathologists.

The following are some of Dr. Peacock's remarks upon the prognosis in heart disease: "It has generally been considered that the prospects of longevity are greater in persons who labour under affections of the aortic than of the mitral valves. Yet though the various secondary affections more readily occur in the latter than in the former class of cases, I believe that the received opinions as to the relative duration of life in the two forms of disease is erroneous. I have met with cases in which patients with marked signs of mitral insufficiency have survived for many years; and we all know how frequently such cases come under treatment, both in public and private practice, again and again, the local complication being readily relieved, and the patients soon regaining a comparative state of health. On the contrary, in cases of aortic incompetency, we rarely find that the patients derive any very material benefit from treatment, and such cases as we have the opportunity of watching generally prove fatal in no long time. Indeed, notwithstanding the greater frequency of such cases, I am unable to refer to any instance in which life has been sustained for a considerable period. Probably injuries to the aortic valves present the condition under the most favourable circumstances for the prolongation of life, and yet I have shown how very limited is generally the period during which such patients survive. It will be remembered that of the nine cases of injury of the aortic valves to which I have referred, life was maintained for the longest period in two of those which I have myself reported. In one of these the patient died three years after the occurrence of the accident; but as no post-mortem examination took place, the precise nature of the injury is uncertain. In the other, the patient was still living when the last information was received five years after the accident had occurred. In reference to the prognosis in cases of valvular disease, the mode in which death is liable to occur must also be considered. In aortic valvular disease, death usually results from failure of the power of the left ventricle, and hence may take place suddenly and when least expected; and this, not only in cases of very serious defect, but when there is only slight insufficiency or when the valves are quite competent. On the other hand, in cases of mitral valvular disease, death is generally due to the pulmonary engorgement and other secondary affections, or to the progress of the dropsical effusion, and is usually more gradually brought about. It is worthy of observation, that in cases in which the heart is most remarkably enlarged sudden death is yet of common occurrence. Such was the termination of the case which fell under my notice, where the organ, though not the seat of valvular disease, weighed 40 oz. 12 drms.; and in that of Dr. Bristowe, in which there was incompetency of the aortic valves, and the weight was 46 oz. 8 drms. The remarks which I have made as to the duration of life are intended to apply to cases of incompetency of the aortic and mitral valves, not to instances of obstruction at those orifices. In cases of mitral disease, it would often be difficult, if not impossible, to distinguish between simple obstruction and regurgitation; and hence no comparison can be instituted between the duration of life in such instances and those of aortic obstruction. In the latter form of disease, however, we know that, provided the obstruction be not great, life may, under favourable circumstances, be prolonged for many years, and a large amount of health and vigour be enjoyed; and it has been shown that even the most aggravated disease of the valves is compatible with freedom from cardiac symptoms for many years. The case which I have referred to, as reported by Dr. Stokes and Dr. Graves, and still more strikingly one of those which I have myself mentioned—in which the patient died at 76 years of age, and then not of symptoms referable to the heart—may be referred to in support of this assertion."—P. 106.

We must also quote the following opinion respecting the value of digitalis, which has recently been maintained to be a cardiac tonic. Dr. Peacock says:—

"I have not seen any decided proof of the correctness of this opinion; it has several times occurred to me to observe the symptoms of cardiac incompetency greatly aggravated by the use of the remedy, and equally remarkably lessened by its discontinuance. . . . In cases of mitral valvular disease, I believe, however, that digitalis is eminently useful; not by any influence which it exerts over the heart itself, but from its powerful diuretic action, by which it tends to lessen the amount of the blood, to relieve congestion, and promote the absorption of any fluid which may have been effused, and so indirectly to assist the action of the heart."—P. 112.

These lectures embody in a small space the results of a vast amount of laborious research.

A Manual of Minor Surgery and Bandaging, for the use of House-Surgeons, Dressers, and Junior Practitioners. By Christopher Heath, F.R.C.S., Assistant-Surgeon to, and Lecturer on Anatomy at, the Westminster Hospital. Third Edition. London: Churchill and Sons. 1866. Pp. 249.

We are glad to take this opportunity of drawing attention to a new edition of Mr. Heath's "Manual of Minor Surgery and Bandaging." This admirable little book explains the *minutiæ* of Surgical practice—all those niceties of dressing and bandaging upon which the comfort of the patient and the credit of the Practitioner so much depend. In the best interests of our Profession we wish this Manual success. The more it is taken as a guide, the more will the details of Surgical practice be finished and perfected; and are we not learning every day that the safety of patients depends more upon simple means carefully used than upon heroic remedies and great operations?

Man, considered Socially and Morally. By George Sparkes, late Madras Civil Service. London: Longmans. 1865. Pp. 162.

Mr. Sparkes is evidently a man who has a taste and capacity for metaphysical inquiry. He has read largely on the subject, and now he has undertaken to write upon it. The result is, that he has produced a very readable little book, which deals in a short and clear way with many of the most interesting questions relating to the nature of man in its social and moral aspects. When we mention that our author discusses the origin of evil, virtue, and vice; moral responsibility; the races of man; the fixity of species, besides a host of kindred topics, and all in the space of a hundred and sixty-two small pages, it will easily be understood that his book is of a popular rather than of a scientific kind. Still we have derived both pleasure and instruction from the perusal of it. But, in writing a popular book upon such abstract questions as these, we would recommend Mr. Sparkes to be a little more diffuse. A few more examples and illustrative anecdotes would serve to make the subject both plainer and more interesting. Moreover, a work like this ought always to be divided into chapters and sections. Metaphysical subjects, above all others, require to be treated with method and arrangement.

The Third Annual Report of the Peking Hospital, under the care of J. Dudgeon, M.D., for the year 1864. Peking: Printed by James Ly and Co., 1865.

This thin yellow pamphlet is so interesting that we should like to transfer it bodily to our pages if we could. It is the

account of one year's work of a missionary Physician at Peking, and as it appears that one of the Emperor's ten Surgeons has been a pupil at the Hospital, there is some chance of the spread of surgical skill. In fact, there is no *à priori* reason why the Chinese should not make good Surgeons.

A Manual for the Classification, Training, and Education of the Feeble-minded, Imbecile, and Idiotic. By P. Martin Duncan, M.B., Hon. Consulting-Surgeon to the Eastern Counties Asylum for Idiots and Imbeciles, and Wm. Millard, Superintendent of the Eastern Counties Asylum for Idiots and Imbeciles. London: Longmans. 1866. Pp. 191.

This will be found a most useful handbook by those who have the training and education of idiots; and, indeed, it contains many hints which would be of value to those who have the care of perfect children. The authors give some excellent advice as to the qualities which are essential to a good attendant upon the imbecile; and then they proceed to lay down a scheme of education, wherein they recommend that the powers of the body should be strengthened and developed by suitable diet, regimen, and exercise before the training of the mind is attempted. The results which are brought about by this system appear to be most satisfactory; and we would advise all who are interested in the subject of lunacy to study this little book.

GENERAL CORRESPONDENCE.

SUCCESSFUL CANDIDATES FOR THE ARMY MEDICAL SERVICE.

Letter from the Director-General of the Army Medical Department.

[To the Editor of the Medical Times and Gazette.]

Sir,—The Director-General of the Army Medical Department presents his compliments to the Editor of the *Medical Times and Gazette*, and begs to enclose a list of the candidates of Her Majesty's British Service who were successful at the competitive examination in August last, and who have passed through a course at the Army Medical School, showing the combined results of the examination.

Army Medical Department, February 21, 1866.

NYCTALOPIA.

Letter from Mr. Caleb Barrett.

[To the Editor of the Medical Times and Gazette.]

Sir,—The case of "Night-blindness" by Mr. Haynes Walton in your last number reminds me of one which I noticed some years since, and now send for your publication, if you think it will interest your readers:—

A farm labourer, aged 30, applied to me on July 7, 1860. For a week he had suffered from considerable loss of sight every evening about twilight, recovered gradually by candle-light, and entirely in the morning. He had some dull, aching pain about the eyes, but no external sign of congestion; his general health was good. The ophthalmoscope showed some dulness of the vitreous humour, a deeper colour of the retina, and larger size of its vessels. I prescribed for him blisters behind the ears, and purgatives, with a shade for the eyes.

On the 27th I again examined his eyes with the ophthalmoscope, and found the vitreous humour clear, the vessels of the retina still large here and there, but the retina itself, especially near the optic nerve, paler than in health. His sight was much improved. He was advised to use blue spectacles, and take the tinct. ferr. sesquichlor. His sight was quite restored in about four weeks.

In June, 1862, he had a similar but slighter affection.

I am, &c.,

Caleb Barrett, F.R.C.S. (exam.), Surgeon to the Gloucester Infirmary.

5, Barton-street, Gloucester, February 20.

POISONING BY HALF AN OUNCE OF PRUSSIC ACID—POWER OF MOTION AND VOLITION.

Letter from Dr. G. Corfe.

[To the Editor of the Medical Times and Gazette.]

Sir,—I beg leave to forward to you the accompanying brief report of a fatal case of poisoning by hydrocyanic acid, which has recently occurred at our Dispensary, and for which I am indebted to the Resident House-Surgeon.

I am, &c. Geo. Corfe, M.D.

9, Nottingham-terrace, Regent's-park, Feb. 28.

"Western General Dispensary, Feb. 24.

"Dear Sir,—The circumstances attending the death of Wm. Hesketh on Sunday last were as nearly as possible as follows:—About 11¼ a.m. he suddenly opened the door of our sitting-room on the first floor, advanced about two yards or so within the doorway, and said, "Come down directly, I have taken half-an-ounce of prussic acid." He then immediately turned round, and ran very quickly downstairs, leaning on the banister. I and the assistant, Mr. Killingworth, immediately followed him down, and found him standing in the centre of the Dispensary room. He said, "Give me something," and we immediately gave him some ammonia and iron, of which he drank some, and then tried to excite vomiting, by pressing his finger on the back of his tongue. An abortive attempt at vomiting took place, and he then fell on his back, insensible; his face, previously pale, became much congested, and the veins swollen; the pupils were dilated and fixed, the lids half closed. There was very slight stertor with the first respiration or so after he fell, but the respiration became soon fainter, and ceased with frothy exudation from the mouth. Cold affusion, artificial respiration, and the galvanic battery were tried without any effect.

"The post-mortem next day showed engorgement of the venous system with dark fluid blood; left side of heart contracted and empty; right, uncontracted and containing dark blood. All the organs, including the brain, were congested. The stomach contained some grumous material, and smelt of ammonia. Mr. Hillman, who was present at the post-mortem, made subsequently an analysis of the contents of the stomach, and found large quantities of prussic acid. He is now preparing a detailed report of the whole case for publication. As far as I can judge, the period that elapsed from the time at which he came to our room to his death could not have exceeded ten minutes; but, supposing he ran up immediately on taking the poison, the time that elapsed from taking the poison until he became insensible could not have exceeded two minutes. "I am, &c.,

"R. L. Thom."

RINDERPEST AND ITS AFFINITIES.

Letter from Mr. George Gaskoin.

[To the Editor of the Medical Times and Gazette.]

Sir,—A great authority in veterinary science has informed us that Rinderpest is Rinderpest; I presume an *idiopathia* which took its origin among the bovine race; but it is a little too much to affirm of any one species of animals when they happen to be victims of a communicable virus that this infection originated in their blood, and that it is peculiar to their nature. We must place such a conclusion on a par with that which derives syphilis *è fœdo muliere*. The mutual participation of several tribes of animals in the effects of a single morbid poison, and the modification of that poison in its passage through their bodies, as well as the various modes of their subjection to its influence; these form fit subjects for

modern thought, appertain to modern Medicine and to our present stage of civilisation. When a man is accustomed to hold a transplantable virus on the point of his lancet he easily persuades himself that there is something in its origin, independent of the animal that may chance to feel its sting. The transmission of the contagion from England to the Zoological Gardens at Paris, where it committed such great ravages, is a central fact on which to fix our intelligence, and we should never forget that man also is a large animal. I am of opinion, therefore, that we should continue in this same path of thought, notwithstanding the ill success which has attended Dr. Murchison's experiment, whether this reside in defect of method or of principle, noting with scrupulous care all the pathological differences in the various tribes of animals affected, and following in the track of the contagion as the thread which should guide us; for assuredly we stand on the threshold of great discoveries. Whether the idea of vaccination as preventive was original or not, it behoved us to try it in England. It is extraordinary how in the pages of Dionysius of Halicarnassus, and of Livy, we find that plagues of cattle preceded some of the most malignant pestilences recorded as happening to ancient Italy. In the fine poem of Fracastorius there is a beautiful passage, in which a pestilence is described as commencing among the goats in autumn under influence of the south wind; and not till the following year, in spring and summer, did there ensue a plague, which destroyed nearly every head of cattle :—

"Infirmas pecudes, balantumque horrida vulgus
Pestis febre mala miserum pene abstulit omne."

Whether this was the same infection as that he describes in his first book, "De Contagione," as occurring near Forojuolo and in the Venetian and Veronese plains, I cannot say. If the lungs of the goats were affected, the same appears to be the case with the sheep in our cattle plague. This passage of the poem I have seen nowhere referred to.

Writing in the interests of scientific inquiry, I abstain from any deprecation of the poleaxe; but let us not relax in inquiry, for even the poleaxe might fail. Erasmus jokingly proposed to burn the syphilitics; and Phillip the Long of France, in dealing with the lepers, did pursue that plan, but it fell short of success. I am, &c.

3, Westbourne-park, Feb. 14. Geo. Gaskoin.

THE COMMITTEE ON THE ARMY AND NAVAL MEDICAL SERVICES.

[To the Editor of the Medical Times and Gazette.]

Sir,—I do not believe that we have been fairly represented at the late inquiry before the Committee at the Admiralty, or they would never consider the addition of two shillings a day could be an equivalent for promotion. Most men have been deluded in the course of their lives, but no one was ever more deluded than I was when I entered Her Majesty's Army Medical Department some ten or twelve years back. I am convinced that if I had employed that time in private practice anywhere my position would be infinitely better than it now is. I do not envy the man whose name occupies the 700th place on the list of Assistant-Surgeons. He clearly never can be promoted, and as for myself, I may remain—well, never mind; the subject is not pleasant to a man in the best of spirits, and I can hardly be that, seeing I am fresh from the perusal of the Report of the Committee.

I am, &c.,

February 28, 1866. An Assistant-Surgeon.

[To the Editor of the Medical Times and Gazette.]

Sir,—The Committee of Inquiry on Naval and Military Medical Affairs have given in their Report, and, like the fable of the mountain in labour, they have produced a very ridiculous offspring. As yet I have only seen a report of the conclusions at which they have arrived. I have not seen the evidence upon which they based their conclusions. But whether the conclusions be or be not in accordance with the evidence, I am perfectly satisfied that the Committee have failed to appreciate the requirements of the Naval Medical officers, and that the recommendations of the Committee, if adopted, will fail to induce candidates to offer themselves for Assistant-Surgeoncies in the Navy.

I particularly dislike comparative statements, because they are injurious; but I may observe here that the bait of 2s. 6d. a day for the first five years to a Naval Assistant-Surgeon in excess of what the Army Assistant-Surgeon gets is too transparent to be successful in promoting enlistment, and the paltry boon of counting staff time for pay only after eighteen years, and the promise of one pound a day when worn out and unfit for further service, must fail to induce men to serve with any *esprit*.

What is really wanted to make the naval service popular is the abolition in whole or in part of half-pay time, and an increased promotion to the higher grades of the Profession. The abolition of half-pay time would be preferable to any present increase of pay, and the appointment of inspectorial officers to all our Hospitals and flag-ships on foreign stations would be more in accordance with our requirements than the patchwork recommendations of the Committee to which I refer. I am, &c.,

A Naval Medical Officer.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, February 6.

Dr. Peacock, President.

REPORT ON THE NATURE OF THE ERUPTION IN CATTLE PLAGUE.

The following is the report by Mr. Sibley and Dr. Dickinson :

We have examined portions of skin removed from cattle which had died at different periods of the disease; and also through the kindness of Dr. Sanderson, Professor Gamgee and Mr. Duguid we have been enabled to observe the appearances presented during life.

It appears that the cutaneous eruption is by no means a constant character of the disease; whereas the affection of the mucous membrane is always present. We may instance, as an illustration of the former statement, the case of a calf suffering severely from the disease, in which a careful examination of the skin at various periods failed to detect any departure from the natural state.

The eruption when present is generally observed on the third or fourth day, and increases until the seventh or eighth day.

The first change observed, and sometimes the only change, is an irregular injection of the skin observable about the parts least covered with hair, particularly the neighbourhood of the udders. The skin is traversed by a fine vascular appearance almost as if chafed by friction.

The next alteration, that which must be regarded as most characteristic of the disease, is the appearance of a number of small, indurated, and discoloured spots, which are slightly raised above the surface. The skin above them is greasy to the touch, and scurfy in appearance. If one of these hard elevations be examined with the microscope, it is found to consist of scabs of epithelium, more or less mixed with granular matter. The only change in the cutis is that the papillæ are somewhat prominent and injected. The more rare form of eruption, of which we have seen two instances, consists of cream-coloured elevations, varying in size from that of a mustard-seed to the diameter of a third of an inch. It is right to mention that each of these two specimens had been immersed in spirit before examination. The smaller spots are circular in outline; the larger are very irregular in outline and in amount of elevation. The raised part is nearly white and opaque, so that by the naked eye the spots are not to be distinguished from pustules. They are surrounded by a dusky red halo. Some come off as crusts, leaving a disc of cutis exposed and raw-looking beneath, having in its centre some raised and injected papillæ. Six or eight of these prominences existed in a portion of skin six inches square from the neighbourhood of the udders.

We have never observed vesicles.

A section through one of the large elevations described showed that the formation was upon the surface of the cutis, from which it could be easily displaced. The cuticle was separated from the cutis, the interval being occupied by a soft yellow material, solid, very easily broken up. Beneath this the papillæ show a great increase of vascularity. The soft material between the cutis and the outer layer of cuticle consisted of a great accumulation of epithelial scales, in various stages of development, some of which were irregular, granular, and broken up. These were mixed with granular and fatty matter, and with a good many bodies, possibly rather

smaller than pus corpuscles, which, however, some of them much resembled. They were irregular in shape, round or ovoid, and others angular. Some of them were evidently epithelial nuclei, while others had two or three separate nuclei of their own. The latter were such that had they been found in undoubted pus, they would have been regarded as pus corpuscles.

With regard to scars left by the eruption, we have examined two animals recovering from the disease, as well as a portion of the skin of one killed in the seventh week, which was exhibited by Dr. Crisp. In none were any marks present. We were not able, however, to find out what amount of eruption, if any, had existed during the progress of the disease in these animals.

Conclusions.—From these observations we come to the following conclusions:—

1. The eruption in cattle plague is not constantly present.
2. The ordinary form consists of small hard elevations composed of altered epithelium.
3. In a few exceptional cases an eruption is observed, at first sight composed of pustules, but which minute examination shows to consist, like the other, chiefly of altered epithelial formation.

REMOVAL OF A LARGE RECURRENT ENCEPHALOID TUMOUR FROM THE ORBIT, THE PATIENT WELL FOURTEEN MONTHS AFTER.

This remarkable case was brought forward by Mr. Campbell de Morgan, in whose practice it occurred, to illustrate the pathology of malignant disease. The following account was given by Mr. De Morgan:—J. V., 35, a gardener, healthy, and of a healthy family, received a blow on the left eye in August, 1863. Two months after the sight began to fail, and he had deep pain. In February, 1864, he had completely lost the sight of the left eye. On April 20 the eye was removed by Mr. Woolcott, at the Maidstone Eye Infirmary, for a cancerous growth within the globe. The parts healed rapidly, and he went out with his health improved. The lids were closed. In May he had severe darting pain at the back of the orbit, and in a short time after the lids began to open from a tumour protruding from behind. The increase was very rapid, and he lost health and strength. In August the tumour began to bleed, and he continued to lose a considerable quantity of blood. In October a piece as large as a large walnut dropped off. He came to the Middlesex Hospital on November 3, 1864. A large, irregular tumour protruded from the orbit, excavated and sloughy. The margins of the lids can be traced over it above and below; but at the lower part the disease has involved the cheek. Its surface is somewhat flattened and circular, and measures four inches across. It projects nearly four inches from the cheek on the outside, and about two and three-quarters of an inch from the nose. No alteration could be detected in the cranial bones; nor were any diseased glands to be felt. There have been no cerebral symptoms. He was in a wretched state from the continued bleeding and offensive discharge, as well as from severe pain. I removed the tumour on November 23, 1864, by first cutting out the mass from the orbit with curved scissors, then applying freely the actual cautery till the iron could be felt rubbing on the bone, and finally filling the orbit with a pad of cotton wool thoroughly coated with Fell's chloride of zinc paste, as was done in Mr. Moore's case of rodent cancer. There was very little hæmorrhage. He suffered but little after the operation. In a fortnight a larger mass of charred and destroyed tissue was thrown off, with some of the bones of the orbit. Portions of the bony framework of the orbit exfoliated from time to time, exposing the dura mater and the nasal cavity. Healthy granulation soon covered the whole surface. He rapidly regained flesh and strength, and was discharged; but he came every week to see me. One or two little millet seed looking excrescences remained at the inner part of the cavity, but did not seem to grow. From to time, however, I applied the chloride of zinc or the nitrate of silver to them. On my return to town in September, 1865, he came to me, looking and feeling ill, with rheumatic pains in the right hip; he has lost flesh; the pulse was 100. The excrescences on the inside of the orbit were larger—one as large as a small nut. I cut them away, and destroyed the whole tissue from which they sprang and the parts around it, with the chloride of zinc. Healthy granulation soon ensued. He has remained free from any appearance of disease to the present time—fourteen months after the second operation—and is now strong and well.

Mr. De Morgan then added the following remarks:—The interest of this case, which I believe to be almost unique, consists in the light which the rapid recurrence after the first removal of the disease, and the subsequent effectual removal, throw on the local nature of cancer. No class of case was regarded as more effectually proving the necessary return of this disease from original predisposition than that of encephaloid of the globe of the eye. I removed the tumour without a hope of getting rid of the disease beyond a short time. But I thought that the patient's life might be prolonged in some comfort, and that as the disease sprouted it might be kept down by means of caustics. When I found that so unexpected an improvement took place, I began to doubt whether I had made a mistake in the nature of the disease. The mass which I removed had been examined, and pronounced to be medullary with some melanotic deposit; but it had been thrown away. Mr. Woolcott had, however, preserved the eye, and he very kindly presented it to me. It looked as though the whole disease had been removed, save that at one point the sclerotic was a little rough and dull. The optic nerve appeared healthy. Microscopic examination, which Mr. Hulke made carefully, showed that extending between the inner and outer sheath of the nerve were little masses of cancer elements. The same was seen in the meshes of the sclerotic, extending to the dull-looking patch. The disease then had existed in the tissues beyond the seat of operation. Its germs were scattered—sown, we may say—over the surfaces exposed, and quickly sprouted in the soft vascular tissue. In the second operation all the parts were destroyed to a great depth, and probably to a depth beyond the range of the disease. I say probably, for it is by no means sure that the germs of the disease may not extend along the course of the nerve in the cranium. The view of the pathology of cancer which is here indicated should lead Surgeons to early and complete extirpation of the disease, and to the attempt at their thorough removal in apparently desperate cases. Mr. De Morgan added that, in a case by Mr. R. B. Carter, and in the report of cases by Dr. V. Häsuer, of Prague, attention is called to the probable local nature of cancer of the globe. Mr. Moore's paper has more forcibly and more generally drawn attention to the subject.

REMOVAL OF THE LACHRYMAL GLAND FOR EPIPHORA.

Mr. J. Z. Laurence showed a healthy lachrymal gland which he removed under the following circumstances:—The patient from whom it was taken was a man aged 25. Three years ago he was chipping caustic soda, when a particle of it flew into his left eye; violent inflammation ensued, and from that time he suffered from overflowing of tears. When the patient was seen last December at the Ophthalmic Hospital, Southwark, there was no trace of either punctum lachrymale of the left eyelids, and the inner thirds of the lids were united to the ocular conjunctiva by white, fibrous frœna. An ineffectual attempt was made to discover the lower canaliculus by excising a portion of the skin and mucous membrane over its presumed situation; at the same time the frœna were divided. It having been found impossible to restore the excreting lachrymal passages, Mr. Laurence determined to remove the lachrymal gland. An incision about an inch and a quarter in length was made immediately below the outer two-thirds of the supra-orbital ridge, when, upon retracting the parts, and after a little careful dissection, the gland, together with its accessory lobe, came into view, and was, without difficulty, separated from its attachments by the handle of the scalpel and removed. The edges of the wound were united by two points of suture, and cold water applied to the wound. This healed by the first intention. The excessive flow of tears observed previous to the operation had ceased when he left the Hospital four days after the operation, the moisture of the two eyes being the same. The same result was observed a fortnight afterwards. Mr. Laurence suggested whether, in intractable cases of fistula lachrymalis generally, excision of the lachrymal gland might not be practised.

Mr. J. Z. Laurence also showed a

FUNNEL-SHAPED DETACHMENT OF THE RETINA

in an eyeball which he had taken from a female aged 32 years. She attributed the affection of her eye to a bad confinement five years ago. Whilst pregnant with the child she had suffered from epileptiform fits, and for three days during that confinement she was convulsed, and lost a large quantity of blood by flooding. Three months afterwards she experienced for about twelve hours a complete loss of sight, preceded by severe pain in the left side of the head. Similar attacks recurred at intervals of three months up to three years ago, when she began to lose her sight every night, and re-

gain it on the following morning, and a few days afterwards she lost all consciousness, and remained in that condition for a fortnight. Upon again becoming conscious, she discovered that she was stone-blind of the left eye. She had severe pain in and around it; the pupil was widely dilated, and the globe was very hard. She was then admitted into a metropolitan Ophthalmic Hospital, and iridectomy was performed, which was followed by relief to pain, but no restoration of vision. In this state she remained till November, 1865. She then had a severe headache, which lasted two days. She applied a month later at the Ophthalmic Hospital, Southwark. At that time there was a general vascularity of the tunics and congestion of the rectal vessels; the lens was opaque; the pupil widely dilated with coloboma upwards; the globe was quite soft and exquisitely tender. There was also profuse lachrymation of the left eye, and slight photophobia of the right. The patient suffered great pain at the vertex, and along the left supra-orbital ridge. She had no perception of light with the left eye, but with the right her vision was perfect, although it was subject to transient obscurations. Ineffectual attempts having been made to relieve permanently her sufferings by medical treatment, the eyeball was removed. Upon making a section of the globe, a reddish-brown fluid flowed out, which contained an abundance of cholestrine plates. The retina was completely detached from the choroid, and was funnel shaped, the apex of the cone being attached to the optic entrance, its base to the margin of the lens. The removal of the disorganised eye was followed by a cessation of all pain, and of the threatened sympathetic irritation of the right eye.

Mr. Hinton showed a specimen of

EXFOLIATION OF THE TYMPANIC BONE.

It had been discharged from the right meatus of a girl aged five years. A discharge had existed since an attack of scarlet fever at three years old. The deafness in this case was not extreme, and the exfoliation was attended with very little irritation. The membrane of the left ear was also perforated.

DISCONNEXION OF THE INCUS AND STAPES.

In illustration of the remarks made by Mr. Toynbee at a previous meeting, Mr. Hinton exhibited the petrous bone of a man, twenty-four years of age, in which the long process of the incus was reduced almost to a thread, and had no attachment to the stapes. The membrana tympani had fallen in and adhered to the promontary about its central part, lying in contact also with the atrophied portion of the incus and with the head of the stapes, which appeared to be thus maintained in its natural position. The ossicula were freely mobile. In this case, in spite of the disconnexion of the incus and stapes, the hearing, which had been tested shortly before death, was very slightly impaired. There was no history of discharge from the ear.

Mr. Toynbee showed a specimen of

HAIRS IN THE MASTOID CELLS.

Mr. Toynbee said that, according to his own experience, this case was unique. The hairs were firmly embedded in the mastoid cells, and surrounded by masses of epidermis. Dr. Tilbury Fox, who examined them, agreed that the hairs could not have been introduced from without, but were nourished in the cells.

Mr. Toynbee next exhibited a specimen showing

DISCONNEXION OF THE INCUS AND STAPES.

Bearing upon the specimens of disconnection of the incus from the stapes shown at a previous meeting, Mr. Toynbee exhibited a dissection in which he had disarticulated the incus from the stapes in a healthy ear; he showed that so long as the tensor tympani ligament remained healthy, the incus and stapes were retained in contact, and during life doubtless simple disconnexion of the incus and stapes would not be attended by deafness; indeed, so great a power has the tensor tympani ligament in drawing inwards the drum and the chain of bones, that a thin layer of india-rubber placed between the incus and stapes was tightly held there to any one who is tolerably acquainted with the pathology of the ear.

The Secretary then read a communication by Dr. Weber, of Berlin, and exhibited specimens for this gentleman demonstrating the possibility of

INJECTING THE TYMPANIC CAVITIES BY THE EUSTACHIAN TUBE.

There were three petrous bones, into the tympanic cavity of which Dr. Weber had succeeded in introducing ink by the Eustachian tube, after death, the bodies having been placed in an erect posture. These experiments were undertaken in consequence of the statement of Dr. Kramer, that fluids could not be forced into the tympanum through the Eustachian tube while the membrana tympani was perfect—a statement which Dr. Weber thus proved to be entirely incorrect.

In reference to Dr. Weber's specimens showing that fluids can be injected through the Eustachian tube into the tympanum during life, Mr. Toynbee said no one who had any experience in ear diseases could no more doubt the practicability of injecting fluids into the tympanum than they could the practicability of injecting fluids into the bladder. But the question was, first, is such a proceeding safe? and, secondly, is it of any use? Seeing from his own experience that the injection of tepid water into the tympanum was liable to produce long-continued sensitiveness of the organ, seeing that fluids in the tympanum must be applied to the outer surface of the membrana fenestræ rotundæ, within which is the expansion of the auditory nerve; and seeing that death has occurred from merely blowing air into the tympanic cavity, the operation of injecting medicated solutions into the tympanum is surely not a safe proceeding. And, secondly, supposing it to be safe, *cui bono?* For the cure of what pathological conditions of the mucous membrane of the tympanum are these injections to be used? "Such conditions," Mr. Toynbee said, "are unknown to me. The conclusion arrived at is that the operation of injecting fluids into the tympanic cavity is dangerous and useless, and therefore the Profession ought resolutely to set its face against it."

Dr. Duckworth exhibited specimens of

FIBROUS TUMOURS IN THE ILEUM, CAUSING PARTIAL OBSTRUCTION OF THE BOWEL BELOW AND DILATATION ABOVE.

This specimen was taken from the body of a woman aged 43, single, who died after an illness of fourteen days from acute pyæmia. On examining the abdomen the ileum was seen to be greatly distended in part of its course, also contracted below the dilatation. Under the serous coat of the dilated portion several white patches were seen. On opening the intestines these were found to correspond to four tumours, one the size of a large walnut, and three about the size of horse beans. They were firm and elastic to the touch; the mucous membrane passed over them, and on three of them presented the "shaven beard" appearance. The solitary and agminate glands were healthy throughout the intestines. The largest tumour was somewhat constricted about its middle. Seven inches below this mass the dilatation of the bowel was abruptly limited by a strong pyloric-like band of muscular fibres. It appears that this portion of the gut had grasped the largest tumour near its centre, and thus produced a partial obstruction leading to the dilatation of the bowel above this point. These growths were found to arise in the submucous tissue, and a portion of one of them was seen under the microscope to present the characters of typical fibrous tissue. There were no symptoms during life referable to this condition of the bowel. The tumours were not polypoid and not pedunculated.

Dr. Duckworth also exhibited a

SPECIMEN OF GALL BLADDER, WITH OBSTRUCTION OF THE CYSTIC DUCT FROM A BILIARY CALCULUS.

This was removed from the same patient as the last specimen. The gall bladder was enlarged and full of transparent fluid. A large calculus could be felt within it. At the commencement of the cystic duct a calculus the size of a musket-ball was impacted. It had apparently passed some way along the duct, which was commencing to contract behind it. The common duct was free. The fluid was found to consist of thick yellowish mucus, with flaky masses suspended in it. Plates of cholesterine and of columnar epithelium were found it in on microscopical examination. Both the calculi consisted chiefly of cholesterine; that in the gall bladder had four facets upon it. There was a distinct history of occasional attacks of the passage of gall stones, accompanied with jaundice. This patient had been treated at the Royal General Dispensary.

Dr. Hilton Fagge exhibited a kidney showing an

ABNORMAL POSITION OF THE URETER.

The ureter lay *in front* of the vein and artery, and not *behind* them. This is a point, Dr. Fagge remarked, of some importance, because it shows that we cannot, with absolute certainty, distinguish a right from a left kidney. The other differential character which is sometimes made use of—namely, the flattening of the posterior surface—was also absent in this case.

Dr. Conway Evans exhibited a specimen of

ANEURISM OF THE INNOMINATE ARTERY, WITH FRACTURE OF THE STERNAL END OF THE CLAVICLE.

The patient was admitted, under Sir William Fergusson, into King's College Hospital about a year after the accident, with a pulsating tumour reaching from the parotid region to the third rib, and extending over to the opposite side. The symptoms were comparatively slight. The diagnosis which Dr. Anstie made by the sphygmograph was that the subclavian was unaffected. The man died from rupture of the aneurism through the skin, the tumour having greatly collapsed. It remained questionable whether the aneurism had been caused by the fracture, or had previously existed, and had been injured in the fracture.

Mr. William Adams showed a specimen of

LOOSE CARTILAGE REMOVED FROM THE KNEE-JOINT.

The cartilage was removed by subcutaneous incision from a man nineteen years of age. Mr. Adams entered into the theory of the formation of loose cartilages, and detailed the microscopical appearance of his specimen.

Mr. Bryant brought forward

TWO CASES OF RUPTURED FEMORAL ARTERY,

one from disease, the other from accident. In the former case the patient, aged seventy-five, was admitted dying from disease of the heart and arteries. One day he complained of pain in the thigh, and a pulsating tumour was found in the site of Hunter's canal. The artery was tied above the tumour; it was atheromatous, and yielded with a crackling sensation. All pain ceased in the limb. The ligature did not separate; but the man gradually sank and died three weeks afterwards. The ligature was found in position. The whole vessel was blocked up nearly as far as the aneurismal sac, which was composed of the muscles and soft parts of the thigh. In the other case, a patient of Mr. Poland's, the rupture of the popliteal artery was from accident. The limb became gangrenous, and amputation was performed about a fortnight afterwards. Secondary hæmorrhage occurred, for which at first the femoral and next the external iliac artery was tied. He still remains in a very critical state, four days after the last operation. On examination of the leg, the anterior crucial ligament was ruptured, and the posterior was injured. The popliteal artery was completely ruptured, and its ends retracted about an inch. The posterior aspect of the vein showed some traces of rupture, corresponding to the arterial lesion.

[In our report of the last meeting of this Society the name of the exhibitor of the specimen "Mulberry calculus removed from the female bladder by lithotrity" was wrongly printed. Mr. Christopher Heath was the exhibitor].

(To be continued.)

BOOKS RECEIVED.

Capital Punishment is Murder Legalised. By James C. L. Carson, M.D. Pp. 68. London: Houlston and Wright, Paternoster-row. 1866. 1s.

*** Dr. Carson adds to this work half a page "to the reader" explanatory of the preceding sixty-eight pages. He wishes, he says, "to show the tendency and spirit of the age in which we live. A feeling in favour of trifling and inadequate punishments is becoming almost universal." The virtuous are "trampled upon," while the vicious are cajoled, flattered, and encouraged in their evil ways. A startling statement, no doubt, but not necessarily a correct one. Dr. Carson says a man fighting in self-defence kills justifiably, but he seems to forget that capital punishment is but society fighting in self-defence. He desires punishment to be slighter, but surer. What would he do with a convict who murdered his gaoler?

The Modern Practice of Photography. By R. W. Thomas, F.C.S. Pp. 67. London: Harrison, 59, Pall-mall. 1866.

*** Commences with an introductory sketch of the art, followed by five chapters explanatory of how to make the negative, clean the plate, varnish, print, and prevent fog stains and streaks in the negative.

Annali de Medicina Pubblica Hygienica Professionale. No. 20. Firenze. February, 1866.

*** Contains a long article in four chapters on public health generally; treats of Hospitals and public institutions, and of the great Hospital at Milan; a review of the propagation of cholera, with a notice of the Constantinople Conference, at which Professor Bosi, of Bologna, represents Italy. The number is completed with well-selected articles from the *Medical Times and Gazette* and other journals.

Facoltà di Chimica Napoli, addressed to Italians, but especially to Municipalities, Provincial Boards, and Youth. 1866.

*** Is an announcement of the purposes and plans of the thirteen professors who teach chemistry and physics generally, and specially in Naples.

Photographs, Coloured from Life, of the Diseases of the Skin. Second Series. By Balmanno Squire, M.B. London: Churchill and Sons.

*** Portfolios to hold six parts, 3s. 6d. No. 1, 3s. 6d. The number before us is a good representation, beautifully tinted, of Rupial and Lupoid Syphilides, with a handy sheet of letterpress giving the history and present state of the case. This promises to be an important, though very cheap series.

ARMY AND NAVAL MEDICAL SERVICES.

ABSTRACT OF THE REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WHOLE QUESTION OF THE RANK, PAY, AND POSITION OF THE MEDICAL OFFICERS OF THE ARMY AND NAVY.

1. The Committee having met on the 20th November, considered it desirable that the evidence taken before the Royal Commission in 1857-8, "on the regulations affecting the sanitary condition of the Army," under the presidency of the late Lord Herbert, with the report and recommendations of that Commission, and also the evidence and report of a Committee of the House of Commons in the session of 1856 on the Medical Department of the Army, should be laid before them. Those public documents contain much information respecting the position of Army Medical officers at the period of the issue of these reports, and their claims for consideration at the hands of Her Majesty's Government, and explain the grounds on which the Secretary of State for War promulgated the Royal Warrant of 1st October, 1858, which conferred on the Medical officers of the Army "relative rank, with all precedence and advantages attaching to the rank with which it corresponds, except as regards the presidency of courts-martial."

2. It appears that, not long after the issue of that Royal Warrant, some alterations in its provisions were made by a memorandum issued from the Horse Guards in December, 1858, depriving Medical officers of certain advantages which had been conferred upon them by the terms of the Royal Warrant, and in particular excluding them from the presidency of courts of inquiry, of committees, and boards of survey.(a)

The alterations introduced by the Memorandum were embodied in the new Army Regulations of 1st December, 1859, and were confirmed by a Royal Warrant of date 1st May, 1863.

Considerable disappointment appears to have arisen in the minds of the Medical officers of the Army when these alterations in the Royal Warrant of October 1, 1858, became known and their operation practically felt; and the existence of this feeling was brought prominently under the notice of the Secretary of State for War in a memorial addressed to him on July 12, 1865, by the President and Fellows of the Royal College of Physicians, in which they express their great regret "to know that a general and settled feeling of discontent with their condition prevails among the Medical officers of the Army, and they cannot doubt that this must operate prejudicially, not only on the interests of the Medical Profession, but also—and with still more injurious effect—upon the military Service of the country."

3. The evidence adduced before the Committee bears out the statement of the College of Physicians that a feeling at present exists on the part of the Medical officers of the Army that they have been deprived of some of the advantages accorded to them by the Royal Warrant of 1858; and witnesses have stated that they consider their position to be in some respects even more unpleasant now than before the issue of the Warrant which was intended to remedy all cause of discontent, on account of the terms of the Warrant not having been faithfully carried out.

The expression of complaint at being deprived of their position as presidents of courts of inquiry, of committees and boards of survey, is not, however, entirely unanimous. The Medical officers have no wish to be mixed up with questions of discipline,(b) but they consider themselves aggrieved at being disqualified from being presidents of those mixed boards at which, by their Professional education, they are specially fitted to lead an inquiry, and at being obliged to appear only as witnesses when these boards are presided over by combatant officers junior to themselves in rank.

4. Relates to right of Medical officers to preside at boards.

5. To their social position at mess on public occasions.

6. To the more public recognition of their relative rank with combatant officers, it recommends that a general list of their names and ranks should appear in the official list, and that they should be placed in a more important position in the regimental list.

7. That Medical officers ranking with field officers should appear mounted on parade.

In the Appendix No. 24 will be found a return of the number of candidates who have been examined at Chelsea Hospital as to their Professional qualifications between January, 1860, and February, 1865. During this period the candidates who passed were arranged in three divisions or classes, according to the number of marks gained. The result during the period in question was as under:—

1st Class.	2nd Class.	3rd Class.(c)	Rejected.
6	144	199	110

These figures seem to establish the fact that a majority of candidates passed with the minimum qualification required for their admission at all into Her Majesty's Service. But it is further to be remarked that, during the last three years, there has been a gradual increase in the number of candidates who passed in the 3rd class, and simultaneously a considerable increase in the number of those rejected. Thus during 1860, 1861, and 1862, there were passed into the Service—

6 candidates in the 1st class
72 ,, ,, 2nd ,,
45 ,, ,, 3rd ,,

Whilst during 1863, 1864, and the first half of 1865, there were—

0 candidates in the 1st class
72 ,, ,, 2nd ,,
135 ,, ,, 3rd ,,

(a) Also as Warrant of March 28, 1861, negatived clause 16 of the Warrant of 1858, which gave the Surgeons relative rank according to dates of commission, but this Warrant of 1861 was itself negatived by Warrant of May, 1863, and the original clause (16) restored.

(b) In the Army Medical Instructions there is inserted a letter addressed to the Secretary of State for War by the late Lord Herbert, explaining the principles and the changes introduced in the new code. He says,—"In the Hospital Regulations generally we have, in accordance with the opinion of the Royal Commission, liberated the Medical officers, wherever it is possible, from all duties not strictly Professional—a change indispensably necessary for the efficiency of the Medical officers, in order to enable them to devote more time to the higher duties of their Profession, and the better to perform the sanitary duties with which we have now charged them."

(c) It should be stated that 19 of the 3rd division did not enter the Service, owing to there not being a sufficient number of vacancies at the time.

And of 167 candidates for examination in 1860, 1861, and 1862, 25 only were rejected; whilst in 1863, 1864, and 1865, of 319 candidates, 99 were rejected, that is to say, 15 per cent. failed in the examination in the former period and 30 per cent. in the latter. To which it may be added that at the last examination, in August, 1865, of 31 candidates, 17 were passed and 14 rejected, or at the rate of more than 45 per cent.

It is manifest, therefore, that there is at present a considerable deficiency of candidates of that higher class of Professional attainments which it was hoped would have presented themselves as competitors for Her Majesty's Service, and which it is on every account so desirable to procure.

In endeavouring to find the reasons for this deficiency, the Committee have been led to the conclusion that it may be referred to several causes, some intrinsic to the Service itself, and some extraneous to it.

The alleged causes of the unpopularity of the Army Medical Service, arising from the so-termed grievances of the officers, have already been sufficiently adverted to. The following reasons, extraneous to the Service, accounting for the dearth of well-qualified candidates, have been brought to the notice of the Committee:—

(1.) That, although the number of Surgical Diplomas from the Colleges of London, Edinburgh, and Dublin would appear to have increased during the last ten years, it appears by evidence to be the general impression that the actual number of Surgical students has decreased, or not kept up with the increase of the population;(d) whereas a far wider field for the Medical Profession has been opened out in the emigration ships, and in the service of the large steam navigation, mining, and other companies, and in the colonies.

The consequence is, that Her Majesty's Service is brought into a more severe competition than formerly with the other demands upon the Medical Profession.

(2.) In further explanation of the comparatively small number of English candidates, and as showing that at present the Army Medical Service is not sought by a very large number of Medical students, whom it would be desirable to induce to become competitive candidates, it has been stated by the Professors at Netley, and by other competent witnesses, that few of the numerous students frequenting the London Medical Schools can at present be induced to come forward at the examinations. The number of English students who now present themselves is so small as to be out of all proportion with the number of Medical men educated in England, as will appear from the circumstance that, out of the last 490 candidates for admission into the Army Medical Service, 264 were educated in Ireland, 89 in Scotland, only 89 in England, and 48 in mixed or foreign schools. Of those 490 candidates, 347 were received into the Service—viz., 168 Irish, 71 Scotch, 71 English, and 37 from mixed schools.

It appears also that a late Chelsea examination, of 77 successful candidates, 47 were from Irish, 18 from Scotch, and only 8 from the English Medical Schools; so that practically at the present time the list of candidates at the competitive examination receives but a very scanty addition from the numerous class of English students, and the Medical Service of the Army derives but little benefit from the immense field of instruction afforded by the great Schools and Hospitals of the metropolis.

In addition to what has been shown above with respect to the position taken by the majority of the candidates who have passed at the Chelsea examination, and the large proportion of those who have been rejected, it should be remarked that in the classification there given only the strictly Professional qualifications are regarded; but besides this several witnesses have stated, and the Committee are of opinion, that it would be highly desirable, if possible, to secure for the Medical Department of the Army the services of men not only Professionally qualified, but also of better general education and information than would appear to be possessed by many amongst those who have presented themselves for examination.

Scale of Pay Proposed by the Committee for Army Medical Officers.

	Rank.		
	Assistant-Surgeon.	Surgeon.	Surgeon-Major.
Under five years' service:—	s. d.	s. d.	s. d.
Present rate	10 0	—	—
Proposed rate	10 0	—	—
Above five years' service:—			
Present rate	11 6	—	—
Proposed rate	12 6	—	—
Above ten years' service:—			
Present rate	13 0	15 0	—
Proposed rate	15 0	17 6(e)	—
Above fifteen years' service:—			
Present rate	13 0	18 0	—
Proposed rate	17 6	20 0	—
Above twenty years' service:—			
Present rate	—	—	22 0
Proposed rate	—	—	24 0(e)
Above twenty-five years' service:—			
Present rate	—	—	25 0
Proposed rate	—	—	27 0
Above thirty years' service:—			
Present rate	—	—	—
Proposed rate	—	—	—

10. The Committee also consider that the prospect of optional retirement at an earlier period than at present permitted would prove a further inducement to young Medical men to enter Her Majesty's Service; they therefore recommend that Army Medical officers should be permitted to retire after twenty years' service upon full pay; but, at the same time, with a view to guarding the interests of Her Majesty's Service, they are of opinion that the rate of half-pay awarded to officers so retiring should not exceed five-tenths of their full pay, and that officers with this service should be permitted to retire on the present half-pay of their rank, if, after one year on half-pay, they are reported by a Medical Board to be permanently unfit for further service.

11. The Committee further recommend that, as a special reward to officers of long and good service who, owing to the comparatively small numbers of the inspectorial ranks, have not been promoted to any higher position than that of Surgeon-Major, such officers of the rank of Surgeon-Major as have served for twenty-five years on full pay should, on being compulsorily retired at 55 years of age, receive the half-pay of £1 a-day, but such officers retiring voluntarily under 55 years of age should only receive seven-tenths of their full pay. And that all Medical officers who may be found unfit, by a Medical Board, for further service, in consequence of illness contracted in and by the Service, shall be allowed to retire on the rate of half-pay to which they may be entitled by service, according to the rates at present allowed. Surgeons-Major of twenty-five years' service so retired to be grauted £1 a-day.

We have now to recommend—

1. That at all boards upon which Army Medical officers may be summoned as members, they should sit and take precedence according to their relative rank, and should preside, if senior in relative rank to the combatant officers, with the exception of courts-martial and courts of inquiry on military offences.

It is, however, suggested for the consideration of the authorities, whether it is not advisable to establish regulations for referring all necessary questions to Medical officers, for their opinion and report, and to discontinue all mixed boards.

2. With the view of preventing misunderstanding as to relative rank at mess,—that invitations sent by the colonel or officer commanding, in the name of himself and the officers of a regiment, be considered official, and that the senior combatant officer present should always preside; and that when a second position is formally assigned on such occasions, such position should be determined by relative rank, as defined by the Queen's Regulations and Warrants. We consider, however, that no second place should be recognised.

3. That in the Monthly Army List the names of the Medical officers of each regiment be inserted above those of the other regimental staff, with a heading, "*Medical Officers;*" also that a general list of all Medical officers in the Army be inserted in the Monthly Army List, and that in such list the relative rank of each class of Medical officers, with the corresponding rank of combatant officers, should be clearly stated, thus:—Inspectors-General of Hospitals (ranking with majors-general); Deputy-Inspectors-General (ranking with colonels), &c.; and that opposite the name of each officer should be the number of his regiment or the station on which he is serving. That Medical officers should be replaced in the list of the regimental staff in the classification of officers in the Queen's Regulations, and it is submitted for consideration whether the Medical Department should not be placed immediately after the lists of combatant officers in the Army List.

4. That Medical officers, ranking with field officers and being allowed forage, should be ordered to provide a charger and to appear mounted on parade.

5. That increase of pay and earlier retirement be granted as defined in paragraphs Nos. 9, 10, and 11.

(Signed) A. MILNE,
W. PAULET, A.-G.
DOUGLAS GALTON.
J. B. GIBSON, D.-G.
A. BRYSON.
W. O. MARKHAM.
GEORGE BUSK.

(d) So far as can be gathered from the Medical directories, the number of Practitioners in the United Kingdom has very slightly increased in the last five years; and the number of Medical students registered in the English schools has diminished during the same period. The number of Surgical Diplomas granted by the Royal College of Surgeons of London during the fifteen years ending December 31, 1849, was actually slightly in excess of the number granted in the last fifteen years.

(e) A proposal to increase the pay of the inspectorial ranks was made, but the Committee, being divided in opinion, do not make any recommendation.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 28th ult.:—

Josiah Sarjant, L.R.C.P. Edin., Limehouse, diploma of membership dated February 23, 1859; Henry Rickard, L.R.C.P. Edin., H.M.S. *Wellesley*, Chatham, December 6, 1859; Frederick Mastyn Rickard, Stoke Plymouth, May 9, 1865; Richard Pugh, Llandovery, South Wales, July 25, 1865; and David Anderson Moxey, M.D. Edin., Turnham-green, November 16, 1865.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 22, 1866:—

Thomas Franklin Lloyd, 42, Finsbury-circus, E.C.; Edward Matthew Owens, Sutton, Surrey, S.; Robert Wyllie, Robin Hood's Bay, near Whitby; Walter Smith, Bognor, Sussex; John Haigh Tadleton, Birmingham; Christopher Smith, Paris.

As an Assistant:—

Alfred Kent Laslett, Canterbury.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BABINGTON, BENJAMIN G., M.D. Cantab., has been appointed Hon. Consulting Physician to the Hospital for Diseases of the Throat, Golden-square.

GOWING, B. C., M.R.C.S. Eng., has been appointed House-Surgeon to the Whitehaven and West Cumberland Infirmary.

HOARE, WILLIAM P., M.R.C.S. Eng., has been appointed Medical Officer to Dartford Union Workhouse.

ROBERTS, FREDERICK T., M.B. Lond., has been appointed Lecturer on Botany at the Liverpool Royal Infirmary School of Medicine.

Tuckwell, Henry M., M.D., has been elected Physician to the Radcliffe Hospital, Oxford.

Woodhouse, Thomas J., M.D. Lond., has been appointed Physician to the Royal Hospital for Incurables, West-hill, Wandsworth.

BIRTHS.

Bond.—On January 25, at Southampton, the wife of Francis T. Bond, M.D., of a daughter.

Bullock.—On February 24, at Spring-grove, Isleworth, the wife of Henry Bullock, F.R.C.S. Eng., of a daughter.

Coleman.—On December 29, at Iquique, the wife of Dr. Coleman, of a daughter.

Cowell.—On February 25, at 112, Piccadilly, W., the wife of Thomas W. Cowell, M.R.C.S., Eng., of a daughter.

Cowie.—On February 24, at 10, Bridge-road, Finchley-road, the wife of Alexander J. Cowie, M.R.C.S. Eng., H.M.'s Bengal Medical Staff, of a son.

Elin.—On February 21, at Hertford, the wife of George Elin, M.D., of a daughter.

Jones.—On February 24, at 201, Queen's-road, Dalston, the wife of John D. Jones, M.D., of a son.

Maclean.—On February 9, at Ville au Roi, St. Martin's, Guernsey, the wife of Dr. Maclean, of twin sons.

Madge.—On February 26, at 32, Fitzroy-square, the wife of Henry M. Madge, M.D., of a son.

Muriel.—On February 23, at 71, St. Giles-street, Norwich, the wife of Charles E Muriel, M.R.C.S. Eng., of a son.

Nutt.—On February 16, at Sherborne, the wife of Horace Nutt, M.R.C.S. Eng., of a daughter.

Rawlins.—On February 24, at Stoke Newington, the wife of Frederic W. Rawlins, M.D., of a son.

White.—On February 17, at Frome, Somerset, the wife of William A. White, M.R.C.S. Eng., of a son.

Wood.—On February 19, at 54, Upper Harley-street, W., the wife of Dr. W. Wood, of a daughter.

Worthington.—On February 21, at Worthing, the wife of Dr. Worthington, prematurely, of a daughter.

MARRIAGES.

Sutherland—Dunbar.—On January 15, at St. Andrew's Church, Calcutta, Dr. Robert Sutherland, Assistant-Surgeon, H.M.'s 5th Lancers, to Elizabeth Hannah, second daughter of William Dunbar, Esq.

DEATHS.

Boyd, Henry, M.D. Glasg., at Argyle-street, Glasgow, on February 18, aged 54.

Fosbroke, William, M.M., M.D. Edin., at Veranda House, Old Kent-road, on February 15, aged 50.

Hewett, William, Surgeon, at Sidney-terrace, Reading, on February 23, aged 72.

Jeffery, Edward, Surgeon R.N., at Sandwich, on February 20, aged 75.

Lucas, W. Owen, M.R.C.S. Eng., at 9, Taunton-place, Regent's-park, on February 25, aged 78.

Gillett, William E., L.R.C.P. Edin., at Paul's House, Taunton, on February 24, aged 67.

McWhinnie, Andrew M., F.R.C.S. Eng., of the Crescent, Bridge-street, Blackfriars, on February 27, aged 58.

Taylor, James, M.D. Glasg., at Barnhill, Glasgow, on February 16, aged 22.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Chertsey Union.—Dr. J. H. Blount has resigned the Windlesham District; area 6099; population 2361; salary £40 per annum.

Rochford Union.—Dr. Arthur C. White has resigned the Great Wakering District; area 16,934; population 3614; salary £52 per annum.

Weobley Union.—Mr. Edward Crickmay has resigned the Dilwyn District; area 20,103; population 3701; salary £78 per annum.

Wincanton Union.—Mr. Wallis has resigned the Castle Cary District; area 9613; population 4108; salary £75 per annum.

APPOINTMENTS.

Birmingham Parish.—Lucius Warrilow, M.R.C.S.E., L.S.A., to the Fourth District.

Gainsborough Union.—Charles F. George, M.R.C.S.E., L.S.A., to the Blyborough District.

Neath Union.—John Russell, M.R.C.S.E., L.S.A., to the First Central District and the Workhouse.

Tonbridge Union.—Edward Leeds, M.R.C.S.E., L.S.A., M.B. Oxon, to the Sixth and Seventh Districts.

Cambridge.—Dr. Humphry has been elected Professor of Anatomy, and Mr. Alfred Newton Professor of Zoology and Comparative Anatomy.

Greenwich Hospital.—Pensions to Naval Medical Officers.—Friday's *Gazette* announces that in the distribution of the Greenwich Hospital funds, there is to be one pension of £80 per annum allotted to the rank of Deputy Inspectors-General of Hospitals and Fleets, and fourteen pensions of £50 to those of Staff-surgeons and Surgeons. The service afloat required to render officers eligible for these pensions is in each case nine years.

University of Cambridge.—At a congregation on the 22nd inst., Mr. Edward James Augustus Trimmer, of Jesus College, and Secretary of the Royal College of Surgeons of England, had the Degree of "M.A." conferred on him.

Disinfection in Cattle Plague.—The Royal Commission on the Cattle Plague have issued a series of minute recommendations for the disinfection of sheds, lairs, trucks, etc. The principal chemical disinfectants on which they rely are carbolic acid, cresylic acid, sulphurous acid gas obtained by burning sulphur and chloride of lime.

Testimonial.—A handsome epergne, accompanied by an illuminated address, has been presented by the officers and attendants of the Cheshire Lunatic Asylum to Dr. Brushfield, their late Medical superintendent, who has been recently elected to the superintendency of the Woking Asylum.

A Relic of the Mammoth.—A tusk, measuring ten feet two inches in length and twenty-two inches in circumference at the thickest part, has been found ten feet below the surface in excavating for gravel for the Spalding and March Railway at the pits at Deeping St. James. It is in a good state of preservation.

Hæmorrhage after Division of the Frænum Linguæ.—Simple as this operation usually is, it may, when the frænum is very thick, unavoidably give rise to a hæmorrhage, which in young infants may not be without its danger. Various means of arresting this have been proposed, but that employed by M. Binaut is one of the most simple, consisting in the seizing the bleeding part by the ordinary dressing forceps, and keeping up compression as long as necessary. The duration of this compression must vary in different cases, and in the one he relates it was continued for three hours.—*Gaz. des Hôp.*, February 20.

The Poor-Law Board and the Bethnal-green Guardians.—On February 27 Lord Enfield, M.P., the Secretary of the Poor-Law Board, communicated to the guardians of Bethnal-green the Board's decision in the inquiries which were held relative to the sudden deaths, under peculiar circumstances, of two pauper inmates of the workhouse. The following paragraph in the Secretary's letter refers to the Medical officer of the workhouse:—"As regards the Medical officer of the workhouse, the Board think it would be a more satisfactory arrangement if this officer, or an assistant Medical officer, were required to reside in the workhouse. The Board also direct me to point out that the regulations in force for the arrangements of the workhouse do not admit of the duties of the Medical officer being delegated to a deputy, but require that those duties should be performed by him personally, subject to the appointment of a legally qualified Practitioner, to whom application may be made in the absence of the Medical officer."

Dr. Charles A. Lee, Professor of Hygiene in the University of Buffalo, gives the following summary of preventive measures against the cholera:—

"1. Quarantine relations cannot be too strict nor too rigidly enforced.

"2. The most thorough sanitary measures must be enforced and carried out in all places offered to the invasion of the disease, especially in large cities, where every effort should be used to have all houses, streets, allies, privies, drains, cesspools, etc., thoroughly cleansed and disinfected.

"3 All intercourse with places infected with the disease must be absolutely prohibited, or at any rate, guarded with the greatest care and precaution.

"4. Should the disease unfortunately be introduced into a place, cholera stools should never be emptied into necessaries and water-closets in common use.

"5. The police should be instructed to pour into every privy and water-closet suitable disinfectants or furnish the same for this purpose."

Mr. Worms' Treatment of the Cattle Plague.—The following is Professor Simonds' Report as to the condition of Baron Rothschild's cattle on February 22:—"*Result of Inspection of Baron Rothschild's Cattle.*—No. 1, attacked, February 9; died, February 12—This animal was first seen by Mr. Leper, veterinary surgeon, Aylesbury. She was placed under Mr. Worms' care the day succeeding the attack. Nos. 2 and 3, alleged attack, February 10; attacked, February 19—These animals were subjected to Mr. Worms' treatment on February 10. They were seen by me on February 14 and 17, and found to be unaffected with cattle

plague. They are not serious cases. No. 4, alleged attack, February 12; Nos. 5, 6, 7, 8, and 9, February 13; Nos. 10 and 11, February 14—These animals were first seen by me on February 14, and again on the 17th, and found to be free from cattle plague. They still continue well. Were treated by Mr. Worms, and reported to me as cases of cure and convalescence. Nos. 12 and 13, alleged attack, February 15—Neither of these animals are suffering from the cattle plague. Seen first by me February 17, and reported as convalescent. No. 14, alleged attack, February 16; attacked February 20—Is rapidly sinking from the disease; was under Mr. Worms' care from February 16. No. 15, alleged attack, February 17—This animal still continues to be free from any symptoms of the cattle plague. No. 16, attacked, February 16; died February 19. Nos. 17 and 18, attacked, February 16; died, February 20. Nos. 19 and 20, attacked, February 17—Neither of these are severe cases. No. 21, attacked, February 20—This animal is rapidly sinking. No. 22, attacked, February 20 - Sinking, but not so rapidly as No. 21. No. 23, attacked, February 20—Not a severe case at present. No. 24, attacked, February 20—Gradually sinking. No. 25, attacked, February 21; died, February 22. *Summary of the Twenty-five Animals.*—11 are unaffected; 5 are not severe cases of plague; five have died; four are sinking under the attack; total, 25.—James B. Simonds."

Prevention of the Diffusion of the Cattle Plague Poison.—Mr. White, M.R.C.S., of Finchley, in addition to the Disinfecting and Ventilating Porch described in the *Medical Times and Gazette* for February 17, has suggested a Cattle-shed Emanation Disinfector, or apparatus for ventilating and disinfecting the air issuing from cattle-sheds in general, and especially from sheds in which plague-stricken cattle are kept, and from slaughter-houses of diseased cattle. "Insert," says Mr. White, "a fire or flame in a flue in or near the top of the cattle-shed, and the greater part of the infectious effluvia will thus be drawn up out of the shed and be destroyed by the flame, and the means of contagion consequently be diminished. Let the flue, *e.g.*, be of fire-clay brickwork or of iron, and have in the lower part of its interior bars on which to place fuel (thrown in at the top of the flue) and an ash door, and let the flue be either on the top of the roof or in an elevated part of the side or the end of the shed, and facing the entrance to it." Mr. White gives the right of his above invention for the above purpose for the free use of the community. By adopting conjointly with this plan Mr. White's Cattle-shed Disinfecting and Ventilating Porch (a gratuitously offered plan), no infectious effluvia can escape out of the shed into the open air. A description of the Cattle-shed Emanation Disinfector may be obtained from Mr. Weir, Agricultural Engineer, 142, High Holborn.

The following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked.			2. Result of reported Cases from the Commencement of the disease.

Duties and Dangers of a Military Surgeon.—Speaking of the war at Waiapu, a correspondent of the *Hawke's Bay Herald* says, in reference to the Pukemaire affair:—"Owing to the roughness of the ground, and the great difficulty of conveying the wounded to the rear, the Medical officers were well up with the attacking party, and all hands speak well of them for their kindness and attention on this and other occasions. Dr. Grace might be seen in the thickest of the fight, taking charge of a poor fellow who was badly wounded, when, having dressed his wounds, he hurried back to the trenches with a surgical instrument in his hand somewhat resembling a revolver."—*Nelson Examiner, Nov.* 23, 1865.

The following account of a casual ward and its inmates at Peking, extracted from Dr. Dudgeon's Report, may be a source of comfort to the guardians of the poor at Lambeth:—"In no other place in the world, perhaps, Rome, Naples, and Lisbon not excepted, is there to be seen regularly such a collection of filthy, unwashed, ragged, and naked people. It is not at all wonderful that skin diseases, and particularly scabies, should exist to a large extent. On account of their filthy habits, unwillingness to wash themselves, and inability to cleanse their cotton-wadded garments, the cures are neither rapid, permanent, nor numerous. I lately visited the yang-chi-yuen, an establishment for the support of the destitute, outside the western gate of the Chinese city. It was set apart for the purpose by the Emperor Kang-hsi, 180 years ago, and a marble tablet resting on a tortoise has been set up to that effect. The design was, that the destitute from all parts of the empire, on visiting the capital, might experience the imperial bounty and favour outside the city, just, as it were, before entering the celestial city. The age of this and similar charitable institutions, both here and in the south, is significant. They are not traced, as far as I know, to a period prior to the introduction of Christianity by the Jesuits, and therefore there is good ground for the notion that Christianity gave origin, impetus, and spirit to such institutions. During each winter there are upwards of 1000 beggars quartered here. They are distributed through the various courts of the building, with some reference to their circumstances; those having no clothes or money; the able-bodied men for whom there is no work in winter; cripples and diseased persons. Each room has two kangs, each about 12 feet long and 9 broad, The kangs are covered with mats and heated Upon these sit the beggars, men and boys, some completely naked, others nearly so, generally in rows to the number of forty or fifty. Each room has thus about one hundred inmates. The recumbent position is never obtained; they sit closely huddled together, each bolstering up his neighbour. In the centre of each room is a large brick stove where hot water is served out. Each room has a manager and a cook. One of the best behaved of the beggars is appointed foreman and is responsible for the good conduct of those under his charge. These overseers keep quietness, peace, and order, and prevent fighting, brawling, and confusion. The beggars are not allowed to speak; disobedience to this law brings a bucket of cold water about them. The windows and doors and all chinks are carefully papered. Some sanitary and Medical improvements were suggested, which they promised to carry out. The air of these rooms is almost insupportable. The mortality is very great—from forty to sixty per month. In one of the large rooms, used as a kitchen, are several large cauldrons, in which several hundred pounds of millet are cooked at one time. In the centre of the kitchen is a large cauldron full of heated charcoal, around which the beggars congregate, where they are supplied with their rations, which is two meals of millet per day, at the expense of the imperial exchequer. When the place is very crowded their allowance is diminished. They usually get about half-a-pound of millet and one ounce of vegetables. After the morning meal they are permitted to leave the premises to cater through the city, each one bearing an earthenware dish in which he carries some charcoal, or in which he receives the rice that may be given him. The cripples usually have theirs suspended to a rope which is thrown round their necks. At this establishment there is not, as at some places, a coverlet suspended from the roof which is let down upon them at night, with a view that all may equally share in its distribution and none may be able to carry it off. Ulcers, tumours, favus, porrigo, and scabies are very prevalent. I was recognised by some who had been patients at the dispensary, and numbers rose from their kangs to exhibit their sores. One court was appropriated to women, of whom there were about fifty. At this institution I recognised the patient mentioned in last year's report with the fractured femur, who had attempted to strangle himself; who had been in the Hospital for a long period, and who was resolved to live and die in it. His friends were found, and it was ascertained that he had been in a mandarin's suite; had been guilty of thefts; had broken his thigh in some such excursion, and had disappeared. He was a nuisance in the Hospital from his filthy habits and threats to kill himself, so as to give the Hospital the expense of his interment, a mode of revenge not uncommon in China."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

J. M., Leith.—We always publish the official lists of the College.

T. M.—Bence Jones's translation of Mulder.

T. W.—St. Bartholomew's, St. Thomas's, and the Consumption Hospitals. Write to the Registrars.

We may advise our sanitary readers to petition in favour of Mr. M'Cullagh Torrens' bill for promoting the building wholesome houses houses for artisans and the labouring classes.

A public meeting will be held on Saturday (this day) at Willis's Rooms, at 2 p.m., under the presidency of the Earl of Carnarvon, to promote the views of the Association for the Improvement of the Infirmaries of London Workhouses.

Associate, King's College.—In the interesting memoir of Sir Wm. Fergusson in the *Illustrated London News*, it is stated he displaced Mr. Hawkins on the Council; it should have been Mr. John Bishop.

Lithotomist, Exeter.—The "Gentleman's Magazine" for 1733 states that Mr. Paul, a surgeon at Stroud, extracted from the kidneys of a woman, by an incision through her back, a stone as large as a pigeon's egg, and made a "perfect cure."

A Registered Practitioner.—The Council of Medical Education and Registration publish a black list of the names of those members who have been struck off the Register, with the reasons assigned for the proceeding.

Bibliopole, Sheffield.—Cornarius died in 1558. He was fifteen years employed in translating the works of the Greek Physicians. William Cunningham was a lecturer at Surgeons' Hall in 1563; he wrote a work on syphilis, called "*Chamæleontiasis,*" from the supposed resemblance between persons affected with it and the chameleon.

Aspatria, Carlisle.—We will endeavour to supply the information next week. At present all we can inform you is that the first-named gentleman committed suicide some years ago at Brighton. William Woodville, M.D., was Physician to the Small-pox Hospital, and wrote a "History of Inoculation." He died in 1805. Of his portraits, there is, we think, one prefixed to his "Medical Botany." John Leake, M.D., died in 1792. There is an engraved portrait of him by Bartolozzi, printed on satin. It may be seen in some private collections, and also in those of the College of Surgeons and Medical and Chirurgical Society. Consult Wadd's "Mems, Maxims, and Memoirs."

Since the French Government, after due inquiry, has accepted the results of my researches as correct, I feel that by having demonstrated that every case of cholera is *invariably* preceded by a diarrhœa for a few hours, or for a few days, or for a few weeks, and that if this diarrhœa is promptly cured, the developed stage—that of vomiting, severe purging, spasms, etc., etc.—is prevented and life is safe: I feel, I say, that I have placed the information within the reach of every one how to protect himself against an attack of developed cholera; that I have thereby done what no constituted Medical authority or private Medical Practitioner has done to benefit the human race; and that for myself I enjoy the conviction that, relative to cholera, my life has been useful to my fellow-men; that whatever fate may have in store for me, that my name, in connexion with cholera, will go down to posterity as a benefactor to the human race.—*From Dr. Macloughlin's last Pamphlet on Cholera.*

The Report of the Commissioners on the Public Medical Services.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The report of the Commission on the Army and Naval Medical Services which has lately been published is a thoroughly English document. It is a capital example of our mode of getting over difficulties, and in this respect shows the stamp of the national genius as strongly as does our Established Church or our Constitution, or to come to modern instances, as clearly as must any Reform Bill which is to have the ghost of a chance of passing. Its characteristics may be summed up in a word—compromise. I am not going now to discuss the recommendations of the Commission on the important subjects of pay, retirement, and promotion, though it is evident that the increased rates of pay recommended are intended to counterbalance the omission of all reference to the sore subject of slow promotion. But look at the way in which the Commission got over the points at issue in connection with relative rank and precedence at boards of inquiry and mess. It is easy to see that the weight of evidence brought forward by the Army Medical officers completely established the justice of their claims, and it is also easy to see that the Commission have felt it their duty ostensibly to ratify these claims in every important particular; but it is equally clear that to carry justice into practice would scarcely be palatable at the Horse Guards; neither, probably, would it seem convenient to the Adjutant-General, Lord William Paulet, and Captain Galton, who had seats on the Commission. Accordingly the representatives of both parties have come to the conclusion that it will be wiser quietly to shelve the points at issue. The bones of contention are, in fact, to be dropped. The Commission acknowledge that Medical officers have the right to preside at mixed Boards on the principle of seniority laid down by the Royal Warrant. But they think it would be better to do away with mixed Boards altogether, and that the Medical officer should only be appealed to for his advice on scientific or Professional questions. Again, on the "important subject" of the second place at the regimental mess, which lies between the Surgeon and Major, they think it wiser to do away with the "vice" than that the Doctor should have to assert a right which on the score of seniority the Royal Warrant certainly gives him. "It is not advantageous to the service that there should be a second recognised place." This perhaps is the most delicate reproof to both parties which the Commission could have administered, at the same time it is the solution which common sense would suggest. It is clear that it must be most advantageous for the service that the best carver should be the Vice-president, and if my brother Medical Officers have the skill popularly ascribed to them, there need not be for the future any fighting for the arduous post. A nice exercise of judgment in the distribution of the turbot's fin would constitute a paramount claim. The fact is, Sir, that the better part of the Medical Officers of the army would be glad to see these trumpery squabbles set at rest. For one, although I could pick a good many holes in the Commissioners' Report, I think that in the main it does great credit to their common sense. A fair compromise is the best termination to any dispute, and leaves the smallest residuum of heart-burning. A Medical Officer who is a gentleman will receive respect and courtesy in any regiment. If he is not a gentleman, a hundred Commissions would not prevent his being tabooed. At least, that is the experience of Yours, &c., Vielle Moustache.

The Griffin Testimonial Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following subscription has been further received on behalf o the above fund:—Christopher Tayler, Esq., Trowbridge, 5s.; amount previously announced, £134 0s. 3d.; received at *Lancet* office, £10 19s.

I am, &c.

Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, February 28.

Corrigendum.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In the *Medical Times and Gazette* of February 17, under the head of Poor-law Medical Service, page 187, is:—

"*Walsingham Union.*—Mr. Damant has resigned the Fakenham District; area, 12,539; population, 4655; salary, £52 per annum."

I beg leave to state I have held the Fakenham District for the last fourteen years and have not resigned, nor is it my intention to do so. I will therefore thank you to contradict it in your next. I am, &c.

Thos. Wm. Damant, M.D., M.R.C.S. Eng.

Fakenham, Norfolk, February 26.

Gordon's Splint for the Treatment of Fractures of the Radius.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In your impression of the 17th inst. appears an interesting communication from Mr. Lawson Tait on the treatment of fractures of the radius at the styloid process, by means of Gordon's splint. Mr. Tait, however, very inaccurately ascribes to me the authorship of the eminently practical paper on Gordon's splint which appeared in the *Dublin Quarterly Journal* for February, 1865. The paper in question is from the pen of my esteemed friend and colleague in the Meath Hospital, Mr. Porter. From my own experience, I can fully indorse all that Mr. Porter and Mr. Tait have stated with regard to the efficacy of Dr. Gordon's splint in the treatment of fractures of the radius. I am, &c.,

Dublin, February 19. William Stokes, Jun.

*** We have also received a note from Mr. Lawson Tait requesting us to correct the error Dr. W. Stokes points out.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Mr. Lawson Tait's description of Mr. Gordon's splint for the treatment of Colles' fracture of the radius is so interesting and practical, that I am sure it would be acceptable to the Profession if he would name some instrument maker from whom the splint may at first (as a pattern) be obtained. I am, &c.,

Leominster, February 22. Samuel Barnett.

Condition of the First Stomach in Cattle Plague.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—An overlooked fact connected with the treatment of the cattle plague is, that the first stomach is so loaded with vegetable matter that no remedy given in the ordinary way has a chance to enter the system of ruminating animals, not even to bombard with onions, assafœtida, &c. It has been observed that, in all cases in this neighbourhood, the cattle (to use a common expression here) are maw-bound—descriptive of the mass of food found in the magnus venter. A landed gentleman, who has been most active in employing anything likely either to prevent the disease or to do good sent the following account to me lately, viz.:—"Two animals have been opened under my direction. Their livers were gone and the food and medicine were found in the first stomach." Cannot the stomach-pump be used to move this mass one way or other, and medicines made to effervesce in the first stomach, so that the hindrance to proper remedies may be removed in order to combat a disease so ably described by Professor Gamgee? I am, &c.,

Pocklington, Yorkshire, February 24. J. Watmough, M.D.

On Flour of Mustard as a Therapeutic Agent in Reference to Cooper's Sinapine Tissue.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—It is well known that the activity of mustard poultice depends upon the development of a volatile oil—sulphocyanide of allyl—which does not exist in the flour of mustard until it is mixed with water to form a poultice, it is then formed by the action of an albuminous principle—myrosin—upon sinapisine or myronate of potassa. Although the poultice thus produced is almost universally used as a rubefacient, it is, nevertheless, accompanied with many disadvantages, such as the variable quality of mustard, hot water not being at all times readily obtained, and the difficulty of forming with linseed meal or with flour a homogeneous compound. A perfect substitute for it, therefore, must be a valuable addition to our remedies. Cooper's sinapine tissue has appeared hitherto to be all that is required; it is permanent, light, portable, most readily

applied, and produces a uniform effect—as it is merely a piece of thin paper lightly glazed on one side with the stimulant composition, it is evident, therefore, it does not depend upon the essential oil of mustard for its activity. The composition contains a transparent crystalline substance, having many of the properties of sinapisine, also an uncrystallisable substance (myronic acid), together with the principle of capsicum (capsicine). The principles of mustard enter more largely into its composition than capsicine; from this circumstance, I am informed by Mr. Cooper, that he named it "Sinapine Tissue." I have myself used it continually for more than twelve months without having perceived anything objectionable in its effect; in short, it appears to me to be every way superior to the old poultice, and from testimonials received by Mr. Cooper from numerous Physicians and Surgeons of high standing in various parts of the country, it would appear that it has gained for itself a reputation upon a sound basis; it may, therefore, be considered a great acquisition to us as a topical remedial agent. I applied a piece of the tissue last week which has remained upon my table since January, 1865, and it appeared not to have diminished the least in activity.

I am, &c., George Down, M.D.

*** Our criticism is confirmed by Dr. Down so far as it affirmed that *capsicine* is an ingredient in the paper.—Ed.

Poor-law Medical Reform.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall feel obliged by your finding space for the names of the following gentlemen who have forwarded subscriptions to the Association during the past week.

I am, &c. Richard Griffin.

12, Royal-terrace, Weymouth, February 24, 1866.

Subscriptions received by Mr. Griffin:—Olivey, H. P., Taunton, 4s.; Cooper, W., M.D., Thingoe, 10s.; K. J., 4s.; Westell, J., Cookham, 20s.; R. J., 11s.; Morris, G., Hereford, 5s.; Thomason, R., Hereford, 5s.; Hanbury, G., Hereford, 5s.; Lane, J. C., Hereford, 5s.; Saukey, F. H., Bridge, 10s.; Norman, G. B., Basford, 10s.; Simpson, R., Settle, 5s.; Dobson, T., Windermere, 5s.; Holme, W., Kendal, 5s.; Hope, 5s.

Subscriptions received by Mr. Prowse:—Thompson and Felce, Launceston, 21s.; Marshal, J. T., York, 10s.; Williams, W., and Son, Guilsborough, 10s. 6d.; Mann, C. T., Boxford, 5s.; Jones, T., Ross, 10s.; W. S. Roots, Ross, 10s.; Dowson, A. H., Orford, 5s.; Furber, G. H., Maidstone, 5s.; Smith, R. L., Clare, Suffolk, 5s.; Williams, T., Pontypool, 10s. 6d.; Hughes, R., Bala, 10s. 6d.; Cogan, C. C., Greenwich, 5s.; Kingdom, A. S., Combmartin, 5s.; Yeoman, J., Whitby, 10s.; Vise, A. B., Holbeach, 10s.

Mr. Griffin has forwarded to those members of the Association who have subscribed during the last twelve months a pamphlet of 52 pages and the following letter:—

"12, Royal-terrace, Weymouth, March 1st, 1866.

"Dear Sirs,—The accompanying pamphlet is intended to be sent to each Member of Parliament so soon as we can get some gentleman to undertake the introduction of a Bill into the House of Commons. It is possible the proposed Bill may not meet with the entire approval of all, but it must be borne in mind that it is almost impossible to meet the views of every one, and much will depend upon the member who introduces the Bill as to the exact clauses that shall be retained.

"I intend to apply to one or two members about bringing in the Bill, but as it is possible they may not accede to my request, I hope each of you will consider that it devolves upon you individually to find a member; by adopting this course we shall be sure of success; should any of you require a pamphlet to send to a member to whom you may write, I will supply you with it. I regret I can only send pamphlets to the Medical Officers who have subscribed within the last twelve months, as the present subscriptions will only about cover recent expenses; I therefore trust that if any of your colleagues intend to subscribe, they will do so without loss of time, in order that the printer may strike off the requisite number of copies, as the type of so large a pamphlet cannot be re-set without great expense. It may possibly be said that much of the present pamphlet is merely a transcript of former ones, which I admit—indeed, I only view it as a rearrangement, with some additions, of much that has been written before; but had I not adopted this course, a majority of the present House of Commons would know nothing of the matter, and would take it for granted that the late Select Committee on Poor Relief (England) had fully gone into the subject, and from the evidence laid before them had decided that there was no need of fresh legislation; whereas now they will see that the subject was not fully gone into by the Select Committee, and that the evidence of a Poor-law Inspector had grossly misled them.

"I am, Dear Sirs, sincerely yours,

"Richard Griffin.

"To the Subscribing Poor-law Medical Officers of the last twelve months."

An Army Surgeon on the Report of the Commission at the Admiralty.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—We who have grown grey in this world's experience well know that the anticipations of evil or happiness have far greater influence over men's minds than the reality of either one or the other, and thus it was that when I cast my eyes over the Report of the Committee on the grievances of the Medical officers of the two services, I felt my heart sink with a sickening feeling of disappointment as I perused the recommendations which we, within the charmed circle of military Medical life, had fondly hoped would be the means of rendering us a happy and contented class. The wish was most probably father to the thought, but I believe that most men were in accord that both our military and social position would be improved by the inquiry that has lately taken place. Alas! how futile 'tis to put faith in men, for from the tenor of the recommendations that have been published our hopes have been sadly dashed. The appiness we anticipated has resolved itself into the minor degree of atisfaction that our incomes are likely to be increased by two shillings a day whilst we are actually serving, and into the lowest depths of depression that our pensions on retirement are to be little affected, and that the retirement we have so longed for, although conceded, is to be obtained at such a sacrifice that none but those whose private means are good can possibly take advantage of it. I have struggled on year after year upon an income only just large enough to supply my family with the plainest necessaries of life, and hence I know only too well the value of an addition to my means of £36 per annum. But yet I know also that however acceptable such an addition will be, yet that it will be totally insufficient to enable me to fulfil one of my highest duties—that of insuring my life, in order to make a reasonable provision for my family—let alone give me the means of allowing myself and them such trifling luxuries as I find every one of my moderately successful Medical brethren in civil life are well able to obtain. It was, therefore, with the hope that a liberal scale of retiring pensions would be recommended that I buoyed myself up, for I have looked anxiously forward to a time, not, I hoped, far distant, when I trusted to be placed in such a position as would enable me to work honestly at my Profession in civil life, and obtain that provision for my family which I find I am powerless to provide for them whilst serving. But by the recommendations of the Committee I am shut out for years from all such hope, for if I take my retirement after twenty years' service, I shall have to give up at once £219 a-year in money alone—a sum that might, indeed, be most easily made by many, but which I am not wise enough to think I could realise as a certainty until I had been a considerable time practising my Profession in civil life. There are other points, of no value whatever, such as the precedence of our names in the Army List, and such like trivial distinctions—dear, indeed, to the hearts of men who shine alone by the light reflected from the gold lace on their own and neighbours' coats, but worthless as true advantages to us, either as individuals or as a class; whilst in respect to that social position which is dear to the heart of every true gentleman—his perfect equality with whom he is in daily communion—we are positively and distinctly degraded, for the beardless cornet is now recommended by the Committee to take a position at the dinner-table which is denied to one who might very easily be his father. These phases of the question, I am free to confess, are selfish ones; but still they go home to one, and will, I think, sadly influence that which, in the eyes of the Government, should of course be the major consideration—viz., the welfare of the State. And now, from a brief review of the Report in reference to such, it cannot be denied that the best goods are the cheapest in the end, if they are required to last a reasonable time; and as the recommendations of the Committee are based upon the advisability of holding out such inducements as shall enable the State to secure the services of the most educated young Medical men, the question naturally arises, Are the inducements held out sufficient to tempt such men to enter the Medical service of the Army?

I abstain from touching upon the recommendations as they affect the Navy, though to my mind they are liberally framed in most respects, but I cannot do otherwise than endorse the honourable and clearly-put protest of Sir James Gibson in respect to the injustice done to the administrative ranks of the Army Medical Service by the ignoring of all claims on their part to any improvement in their position; whilst those of the sister service are materially advantaged. This, however, by the way, and let us hope that a Liberal Government will see the justice of treating both classes in an equal spirit, and not allow the higher grades in the Naval Service, who are, as a rule, almost stationary at home stations, to reap advantages unshared with those of their military brethren, whose servitude extends over the whole world.

But is it to be supposed that the *elite* of our schools will be tempted with the bait of a fair—nay, liberal—scale of pay upon first entering the service, and even for some few years afterwards, when the simplest sum in division must tell them that they cannot possibly be ever anything else than an Assistant-Surgeon—or, at all events, that they must remain in such a subordinate position twenty-six to thirty years! Add to this the fact that should they remain so long they cannot obtain more than 17s. 6d. a day, and 8s. 9d. a day pension, and I think the calculation will convince the most sanguine. The sum is an easy one, for it is but to divide 800—the number, or thereabouts, of the Assistant-Surgeons now serving—by 30, the number of average promotions per annum! It remains to be seen whether the simplicity of this test will take effect on the minds of men who are of a studious and thoughtful temperament, and whether they will shun a service that holds out to them no hope of distinction, but will ever keep them at the lowest round of the Professional ladder! And if these men will not come forward, as it is absurd to think they will, our ranks will be filled, and that, too, to overflowing, by a class of men who, to escape the honest hard work of a noble calling, will rush to the Army, in the hope that when gazetted they will be enabled to put off for ever and aye all that relates to their Profession except its name, and lead a life of idleness and dissipation. Too many there are already in the service who answer to this description, whose avowed intentions of doing as little as possible are as openly expressed as their ordinary walk in life shows their sincerity in this respect to be without deceit. Such men I have been in a Professional and official capacity intimately associated with, and hence I speak from neither speculative nor hearsay data when I prophesy such a result in the lamentably slow rate of promotion which the absence of recommendations of a liberal scale of retirement to the senior ranks will necessarily produce, unless remedied by the independent action of the Minister for War before such recommendations are embodied in the anticipated new Warrant on the subject. Such a scale of retirement may in a money point of view appear expensive, but it does not take a John Stuart Mill to prove that such an expenditure would be anything but a blot upon the political economy of the present day.

I am, &c.

February 27. A Grey-headed Medical Officer.

The late Professor Schroeder van der Kolk.

The following letter, addressed to the editor of the *Reader*, appears in that journal for February 3:—

"7, South Anne-street, Dublin, January 16, 1866.

"Sir,—My attention has been called to the following passage, which appears in your impression of the 23rd December, 1865, p 714:—

"'C. Schroeder van der Kolk, son of the great anatomist, has just published a work entitled "Soul and Body" (Seele und Leib), in which he endeavours to prove that what is called soul is simply the manifestation of brain, just as digestion is the function of stomach. He says, memory, imagination, reason, and even volition, are but the result of physical actions, or electro-molecular, excited by the operation of perception—the contact with the outer world.'

"It is true that Dr. H. W. Schroeder van der Kolk, son of the late distinguished anatomist and physiologist, and now Professor of Physics at Zutphen, in Holland, has edited essays entitled 'Ziel en Ligchaam' (Soul and Body), and that a German version of this work has recently been brought out by Vreweg, but the essays are from the pen, not of the son, but of the late Professor himself. I am assured that these essays, however, contain no theory of the action of the brain; what is stated in the paragraph I have quoted from your pages refers clearly to the "Handboeck van de Pathologie en Therapie der Krankzinnigheid" (Manual of the Pathology and Treatment of Insanity), a fragment published after the author's death, and subsequently translated by Theile into German. But neither are the views contained in this work correctly stated in the above paragraph. The words 'just as digestion is the function of the stomach,' strongly recall expressions of Vogt, but are not to be found in the writings

of van der Kolk. As it fell to my lot to translate some of the works of the late distinguished Professor, and as I was privileged during the editing of my translations to enjoy a lengthened correspondence with him, I am enabled to say that he held opinions the very opposite of those implied in the passaage just brought forward. I hope it will not occupy too much of your space to allow me to quote, in support of this statement the following passage from my translation of S. van der Kolk's work on 'The Minute Structure and Functions of the Spinal Cord,' a translation (published by the New Sydenham Society, London, 1859) which was carefully revised and corrected by the Professor himself. The author, speaking of the harmonization of movements, says, at p. 74 :—

"'Some, as E. Pflüger, observing such phenomena, have been misled into assuming a sort of voluntary power or mind in the spinal cord, an error attributable solely to want of examination of the ingenious arrangement of the tissue and of the structure of the cord, in which all these harmonized movements appear to lie hidden, pre-arranged in the several combinations of the groups of ganglionic cells, and ready to be excited by any stimulus, whether voluntary or reflex, so that they are produced just as the harmonic tones of a piano under the fingers of the player. Such a view is sufficient to excite amazement at the ingenious nature of all these arrangements and wonderful combinations, but, it is conceivable, and in my opinion not so difficult to imagine : while the idea of volition in the spinal cord, without consciousness, with the entire rejection of the existence of a soul, as Pflüger suggests, is an absurdity not to be thought of. On the contrary, the deeper we penetrate into the knowledge of the mechanism of our body, the more we shall be convinced that the whole is arranged as a perfect minister of our spirit and of our will, in which both the amazingly correct insertion, size, and combination of the muscles, and certainly not less the combination of the ganglionic groups, whereby these muscles are harmoniously and suitably moved, are calculated with incomprehensible wisdom and fulness of purpose.'

"The sentiments expressed in the foregoing quotation will, I trust, be sufficient to defend their author from the imputation of any leaning towards materialism. I trust, therefore, Sir, you will allow me, as the friend and constant correspondent, during many years, of the late Professor Schrœder van der Kolk, to show by an example what the real tendency of his writings and teaching was, as it is possible that a contrary inference might be drawn from the paragraph which found its way into your number of the 23rd December last.

"I have the honour to be, Sir, your obedient servant,

"William D. Moore, M.D., Dublin, M.R.I.A."

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·865 in. The barometric pressure rose to 30·20 in. on Wednesday, and fell to 29·54 in. on Friday.

The general direction of the wind was W.S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864 ; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 38·9°.

APPOINTMENTS FOR THE WEEK.

March 3. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m. ; St. Thomas's, 9½ a.m. ; King's, 2 p.m. ; Charing-cross, 1 p.m. ; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Rev. G. Henslow, "On Systematic and Structural Botany."

5. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m. ; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

Epidemiological Society, 8 p.m. Dr. Thudichum, "On Epidemic Outbreaks of Trichiniasis (spiral flesh-worm disease)."

Medical Society of London. 7 p.m. : General Meeting for Election of Officers and Council. 8½ p.m. : Clinical Discussion. Dr. Macpherson, "Case of Threatened Elephantiasis of Scrotum in a European."

Odontological Society, 8 p.m. Meeting.

Royal Institution, 2 p.m. General Monthly Meeting.

6. *Tuesday.*

Operations at Guy's, 1 p.m. ; Westminster, 2 p.m. ; National Orthopædic, Great Portland-street, 2 p.m. ; St. Peter's Hospital for Stone, 3 p.m.

Anthropological Society of London, 8 p.m. A. Higgins, Esq., Hon. For. Sec. A.S.L, "On the Orthographic Delineation of the Skull." W. H. Wesley, Esq., F.A.S.L., "On the Iconography of the Skull." Dr. Paul Broca, "On a New Goniometer, for the Measuremeut of the Facial Triangle." C. Carter Blake, Esq., F.G.S., F.A.S.L., "On Certain Supposed Simious Skulls, Ancient and Modern, with Reference to a Skull from Louth, in Ireland."

Pathological Society, 8 p.m. Meeting.

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

7. *Wednesday.*

Operations at University College Hospital, 2 p.m. ; St. Mary's, 1½ p.m. ; Middlesex, 1 p.m. ; London, 2 p.m. ; St. Bartholomew's, 1½ p.m. ; Great Northern, 2 p.m. ; St. Thomas's, 1½ p.m.

Hunterian Society (Council, 7½ p.m.), 8 p m. An open meeting.

Obstetrical Society of London, 8 p.m. Dr. Routh, "Fibro-cystic Disease of the Uterus." Mr. Baker Brown, "On the Use of the Actual Cautery in Ovariotomy." And other Papers.

8. *Thursday.*

Operations at St. George's, 1 p.m. ; Central London Ophthalmic, 1 p.m. ; Surgical Home, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m. ; West London Hospital, 2 p.m.

Medical Society of London. Anniversary. 5 p.m. : Oration ; 6½ p.m. ; Dinner.

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

9. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Sir John Lubbock, Bart., "On the Transformation of Insects."

MAW'S CATALOGUE.

A NEW EDITION OF

S. MAW AND SON'S

PRICED CATALOGUE OF

SURGEONS' INSTRUMENTS AND APPLIANCES,

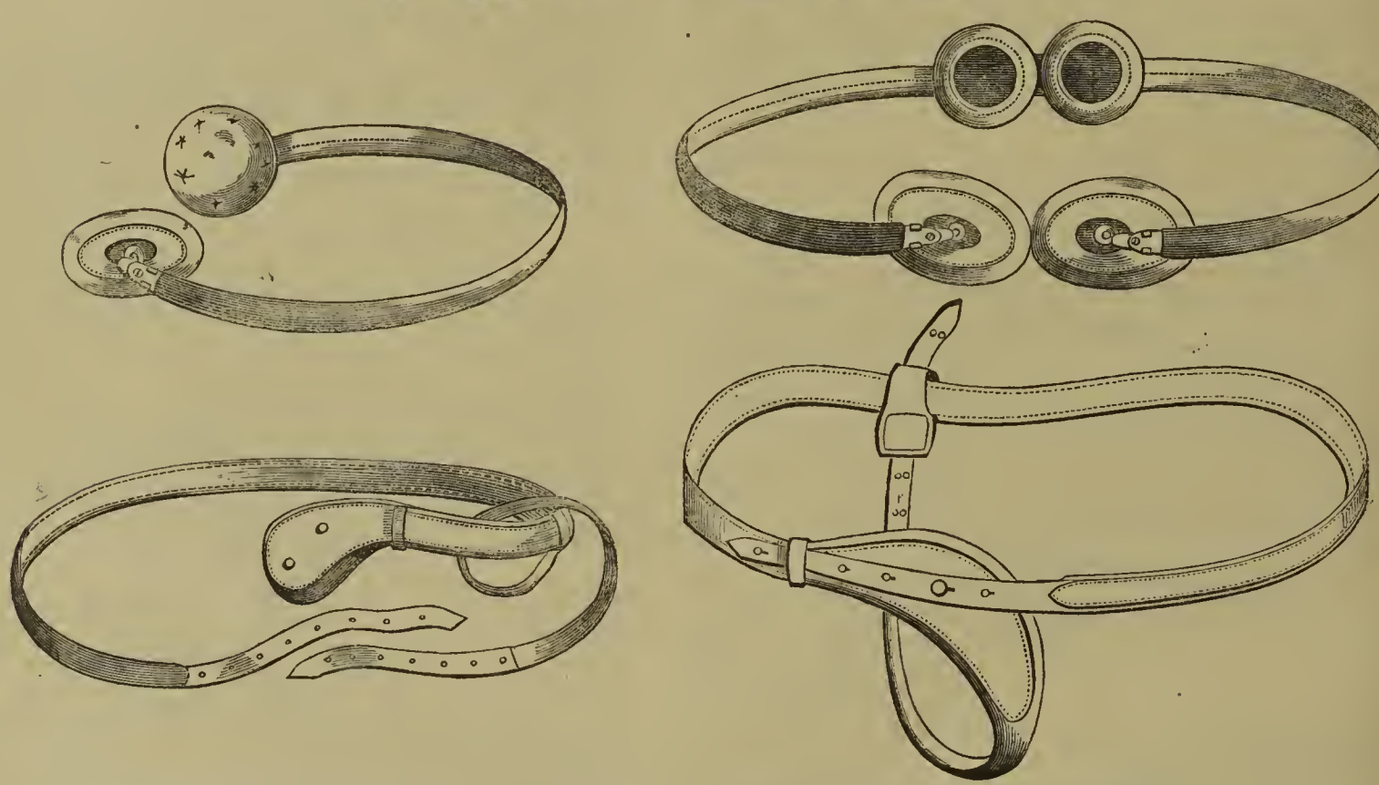
Greatly enlarged, and profusely illustrated, is now ready, and may be had gratis by members of the Medical Profession on application at 11, Aldersgate-street, London, E.C.

Parties at a distance will be supplied on furnishing name and address, either through any respectable Chemist, or free by post on receipt of four stamps.

S. M. and Son, in order to consult the convenience of the Profession, and to obviate the multiplicity of small accounts, have made such arrangements that Instruments of their manufacture may be obtained through most Chemists throughout the United Kingdom at their list prices.

11, Aldersgate-street, London, E.C., Feb. 1st, 1866.

TRUSSES.



COMMON SINGLE TRUSSES, Circular Form, covered with Basil and Chamois Leather, warranted best springs	per dozen.	£1	0 0
Do., do., covered with Red Leather or Stout Calf, and lined with Jean	per dozen.	1	10 0
COMMON DOUBLE TRUSSES, Circular Form, covered with Basil and Chamois Leather, warranted best springs	per dozen.	2	0 0
Do., do., covered with Red Leather or Stout Calf, and lined with Jean	,,	2	14 0
SINGLE PATENT TRUSSES, on Salmon and Ody's expired patent principle	,,	2	0 0
Do. do. do.	,,	3	18 0

These Trusses are capable of being lengthened or shortened, and are furnished with an extra spring to increase the strength if necessary.

Truss for Scrotal Hernia, with elongated pad—Single, 5s. each; Double, 10s. each.

S. M. and S. have made such arrangements that members of the Medical Profession, not having accounts with them, will be able to obtain Trusses of their manufacture at the advertised prices through most respectable Chemists, or they will be forwarded, on receipt of a remittance, direct from

S. MAW & SON, 11, Aldersgate-st., London, E.C.

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

Injuries to the Head and Neck of the Humerus.—We will classify fractures of the humerus near to the shoulder-joint not into those at the surgical neck and those at the anatomical neck, but into those *below the tuberosities* and those *through the tuberosities*. Respecting the latter, I have now to ask your attention to a most important practical point, and one which you will find scarcely mentioned in books. A few months after a fracture through the tuberosities, or, what comes to the same thing, a separation of the epiphysis, it is very likely that all the appearances of a dislocation will be assumed. Owing to the altered form of the neck of the bone, the head is gradually displaced downwards, until a hollow is caused under the acromion, and the aspect of things is exactly like that of a dislocation. You may even feel the head of the bone in the axilla, though not so low down, nor so distinctly as in a true dislocation. It often happens that a patient in this stage of things consults another Surgeon, and is told that a dislocation has been overlooked, or, still more frequently, a Surgeon discovering this state in a patient whom he has himself treated, is led to the belief that he has made an almost disgraceful mistake. Sometimes this deceptive appearance is present from the first, but more usually it is produced when the patient begins to use his arm, and if present at first it always increases. I have seen this often, and have seen reduction attempted not unfrequently. A boy, aged 14, was brought to me by a Surgeon, who believed that he had overlooked a dislocation. The deformity was very considerable—a hollow under the acromion, the head of the bone felt in the axilla, the fibres of the deltoid stretched. Two months had elapsed, and the Surgeon who brought him expressed himself as certain that the symptoms now present were not there at first. I detected irregularity and thickening about the line of the epiphysis, and I found also that by pressing the arm straight upwards I almost fill up the subacromial hollow. I convinced myself and my friend that the accident had been a separation of the epiphysis, and that there was no reason to reflect upon the treatment. The most conclusive example of this condition, however, came under my notice nearly twenty years ago, when I was a student. Being at an autopsy on a lunatic who had died in asylum, I observed deformity in one shoulder, and remarked that it must be dislocated. The Medical superintendent remarked that he had treated the man a year ago for fracture of the neck of the humerus, and that he felt confident that there was no dislocation. He willingly gave me permission to remove the bones, although expressing his fears that I should expose some bad Surgery. We found on dissection that there was a fracture through the tuberosities, and the head of the bone had travelled down to a new articular facet just below the glenoid cavity. This specimen is, I believe, now in St. Bartholomew's Hospital Museum.

When the appearances of dislocation are present in a case of fracture from the first, they are due to displacement inwards of the upper end of the lower fragment, and the higher the line of fracture the more deceptive they will be. At this stage, however, we have the symptom of crepitus to help us, and it is decisive. The hollow under the acromion is also never so definite as it becomes at a later stage. At the latter, when the bone is consolidated, it is often exceedingly difficult to form a decided opinion.

From this clinical fact two corollaries arise—first, that we should be exceedingly careful in giving opinions respecting old cases which have not been under our own care from the first; and secondly, that when we have to treat such a fracture we should clearly explain to the patient what the result will be. In one case recently in the Hospital we had all the appearances of dislocation, with the most positive crepitus in the neck of the bone. At the end of a month, when the bone was united and the swelling had disappeared, we had yet more deceptive appearances, and explained to the man that, should he ever be examined by another Surgeon, he might very likely be told that a dislocation had been overlooked, and I offered him a written statement of what the nature of his injury had been. I may repeat that in the first stage the diagnosis is not difficult; the abnormal mobility, the crepitus, and the ease with which the elbow may be brought down to the side all point to fracture.

It is possible that dislocation and fracture may occur simultaneously. Two or three times I have suspected this complication, but I have never had an opportunity for proving it, or of examining a dissected specimen. It is *à priori* very improbable that such lesions should be produced together. When the neck of the bone snaps by violence there is no longer any agency by which the head of the bone, now discontinuous with the shaft, should be displaced, and on the other hand, if once the bone has been dislocated it would be exceedingly difficult by any continued violence to break it. I suspect strongly, therefore, that in most of the cases in which we hear of dislocation and fracture together, are really instances of fractures unusually high up, and in which, as I have just explained, the appearances of dislocation are subsequently simulated.

In any case of separation of the epiphysis in which the two fragments should be thoroughly liberated from each other, the epiphysis itself would in all probability be displaced by the three muscles attached to it (sub-scapularis, supra-spinatus, and infra-spinatus) in such a direction that its under surface, instead of looking downwards, would look directly outwards. There is nothing whatever to counteract these muscles. The appended sketch (Fig. 1) illustrates this hypothetical state of things. I have often suspected its existence, but have had no opportunity for dissecting a specimen. Should it occur, no Surgical art could bring the epiphysis down again, and the shaft of the bone would unite to it at an angle. Thus the neck of the humerus would come to resemble in form the neck of the femur of a young subject, and subsequently the elevation of the arm by the deltoid would push the head of the bone lower and lower in the glenoid cavity, and gradually produce the appearance of dislocation to which I have adverted.

Fig. 1.

Fig. 2.

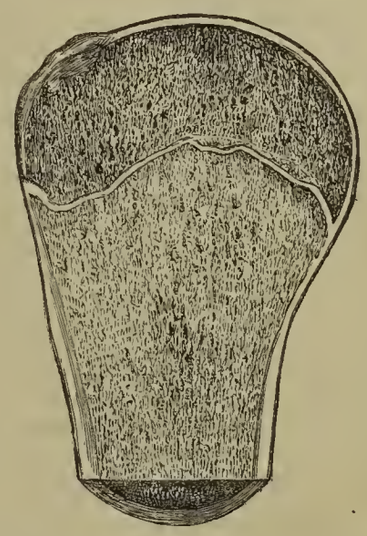


Fig. 1.—Detachment of the upper epiphysis of the humerus, with displacement of it by the action of the muscles inserted into the tuberosities. The black line through the Surgical neck shows the direction of the line of fracture in a case alluded to below.

Fig. 2.—Section of the head of the humerus from a boy of 14, showing the line of cartilage at the junction of the epiphysis.

I show you a sketch of a section of a young humerus that you may refresh your memories as to the direction of the epiphysal line. You must recognise clearly that a separation of the epiphysis is a quite different lesion from a fracture through the anatomical neck. The epiphysal line passes through the base of the tuberosities, and leaves the muscles inserted into these to act upon the upper fragment (the epiphysis). In all separations of epiphysis the periosteum is, I believe, stripped off from the upper end of the distal fragment, and left attached as a dense cup to the lower edge of the proximal one. This circumstance leaves the epiphysis with still more muscular fibres attached to it than would have

been the case were a clean section made through periosteum and all. Thus, in the case of the humerus, the teres minor is inserted below the epiphysal line; but I suspect that it usually remains with the cup of detached periosteum in connexion with the upper fragment.

Dislocations of the humerus are very rare in children and young persons. Separations of the epiphysis and fractures below the tuberosities are not very uncommon. I have seen five or six cases in which the diagnosis of separation of the epiphysis seemed clear. In one instance it was remarkably definite, for the lower fragment was displaced forwards, and when the swelling had disappeared we could put the finger in a flat ledge of bone a third of an inch wide, looking directly upwards, and presenting the irregularities characteristic of an epiphysal surface. The patient was a lad aged fourteen, who had not been under my care in the first instance, but who was brought to me on account of the deformity described.

I possess a specimen of fracture below the tuberosities (see Fig. 2, in the preceding page) from a boy aged ten years, in whom, of course, the epiphysis was not united. In this instance the displacement was unusual, the lower fragment being external to the upper and drawn upwards behind it. In this position it was firmly held by the bands of detached periosteum, through which it had escaped, and which prevented its being brought even on the post-mortem table into accurate apposition with the other fragment. For the same reason we had found it difficult during life to produce crepitus. I have no specimens of separation of the epiphysis of the humerus, nor have we one in the London Hospital Museum.

Mr. Herbert Spencer, who was House-Surgeon to the London Hospital in 1863, now of the Bradford Infirmary, Yorkshire, once showed me a lad in whom it seemed probable that both upper and lower epiphyses of the right humerus had been detached. In the left arm there had been separation of the lower epiphysis, and he had besides had a fracture of one clavicle. These complicated injuries had been sustained in a fall from a ship's mast. The right humerus was much shortened, partly by arrest of growth and partly by union with displacement.

As regards the treatment of injuries to the neck of the humerus, we may note that in the majority of cases there is little or no displacement, and that the fragments are locked or impacted together. The higher up the injury and the thicker the bone at the site of fracture the more likely is this to occur. In such cases it matters little what plan of treatment is adopted. If there be displacement, it will probably be that of the lower fragment inwards, and to counteract this we must employ extension and put a large pad in the axilla. It may be sufficient in some cases to employ the plan of a large axillary pad with the arm bandaged across the chest. On the whole, however, I prefer to use a single long splint, well padded and pressed into the armpit, on which the arm and forearm may be extended with great efficiency. The only plan which would be likely to remedy the displacement which has been just described in reference to separation of the epiphysis would be by carrying the limb directly outwards at right angles with the patient's trunk. I have never tried this, and it would probably be very inconvenient in practice. In any case in which decided displacement existed despite extension in the straight, I should be inclined, in spite of the inconvenience, to try abduction of the arm, keeping the patient in bed and using plaster of Paris.

You will see that in discussing the treatment of these fractures we have to take notice quite as much of the extent of displacement as of the direction of the fracture. In many cases, whether of fracture through the tuberosities or separation of the epiphysis, there is only incomplete displacement of the fragments one from the other, and they still remain in apposition at parts. In such cases the fragments, by their mutual locking and pressure, prevent the muscles from effecting the characteristic distortion. The thicker any given bone is at the part where broken, the more likely it is that the displacement will be incomplete.

Then we must also recollect that in many cases the displacement will not be according to the direction of muscular action, but will be influenced rather by the position assumed by the bone at the moment that violence was applied. Very often the original displacement, although contrary to muscular action, is from some wedging of fragments, or more frequently from the intervention of tense bands of periosteum or fascia, never afterwards altered. Thus we know beforehand what the typical displacement is when the fragments are free to move under the influence of the muscles, but we cannot predicate of any given case what it will be, since it may be modified by other conditions.

(To be continued.)

NO HEALTHY OR MORBID ACTION DUE TO PHYSICAL AND CHEMICAL CHANGE ONLY(a).

By LIONEL S. BEALE, M.B., F.R.S.,
Physician to King's College Hospital.

Of those who accept the now popular mechanical and chemical theories advanced to explain the changes occurring in fully-formed living beings many do not assent to the conclusion that the phenomena of development can be explained by physics and chemistry. They probably entertain the opinion that *development* is conducted upon principles totally different to those in operation in the fully-formed tissue, and that the phenomena regarded as peculiar to development operate only during the earliest periods of life. But although it has not been generally admitted that embryonic matter is present in the textures at every period of existence, it is, nevertheless, quite certain that textures are being developed in the adult, and that new tissue is produced even in advanced age, from living germinal matter which no one could distinguish from that existing at the earliest periods of embryonic existence. Not only so, but every one familiar with disease knows that new tissues may be formed and structures produced in old age, manifesting a power of growth as remarkable as that exhibited early in life. The facts of the case do not permit us to assume that there exists any differences in the essential nature of the formative or nutritive operations in the embryonic and fully-formed state of the tissues.

There is, however, the greatest difference with regard to the performance of *work* in the embryonic and fully-formed state. But *work* and the process of *formation* are two very different things. *Work* depends upon the *destruction* of that which has been already formed. The destruction of matter is doubtless due to physical and chemical changes; but it has never been shown that the matter destroyed was *formed* without the occurrence of *vital* changes. Work does not commence, force is not exhibited until the formation of the material to be destroyed is complete. The processes of nutrition, and growth, and multiplication are essentially the same at all ages and in all living things, but far more active in the embryo than in the adult; while, on the other hand, the amount of *work* that may result from the disintegration of material that has been *formed* is greater in the adult than in the child, and in the latter than in the embryonic condition. The phenomena of nutrition, growth, and multiplication enable us to draw a *sharp line and very positive distinction* between things *living*, at any period of life and under every condition of existence, and things *inanimate*.

It is not a little significant that those who assert in the most decided manner that the changes going on in living things are of the same nature as those occurring in the inorganic world, have not even attempted to explain any of the special phenomena peculiar to living beings. They content themselves with the most general assertions, and avoid in the most careful way the discussion of the particular phenomena occurring in a single cell, or, indeed, of any individual matter which would bring them and their opponents to a distinct issue. I have more than once begged chemists and physicists, who deny the existence of purely *vital* actions in living beings, to explain by physics and chemistry the movements which occur in a single living amœba, a pus corpuscle, or a white blood corpuscle, and have asked them to tell us how simple food becomes converted into the living moving matter, and why this matter divides and subdivides and thus gives rise to new separate masses, which grow like the first and give rise to others; but they neither explain nor admit that they cannot do so. They deny the existence of any peculiar force or power in things living which does not influence lifeless matter, and yet they are quite unable to account for the phenomena, peculiar as well as common to every living particle, by physical force. They will not discuss the matter in detail because,

(a) Part of a lecture delivered during the course of Physiology and General and Morbid Anatomy at King's College, London, 1865, with additions.

I fancy, they perceive that the fallacy of some of their arguments would be exposed. In one way it is a safe course to assert and reassert of things living in general what no one dare assert of any single mass of living matter in particular.

Not a particle of tissue nor the red matter of a single blood corpuscle is formed without matter passing through the living state; and of the phenomena occurring in this living state chemists tell us nothing. They argue as if food might simply pass into the blood, and get oxidised there; but food, as food, does not pass into the blood. It is changed, and by pre-existing living matter. Neither can food be oxidised; but the matters oxidised result from changes occurring in matter that was living. This temporary living condition is really the important state to study, and this is the state which is ignored by many altogether. Every cell contains this living, formless matter, and without it the cell could not be nourished, or appropriate nutrient matter. It could not form tissue or secretion. It could not grow or give rise to other cells like itself.

Not only is it erroneous to teach that all, or nearly all, the actions going on in the living body are physical and chemical, but it is not true that any action characteristic of a living thing can be accounted for by what is yet known of physics and chemistry. The idea of disease comprises something more than mechanical defect or chemical alterations. If we may correctly speak of chemical and mechanical diseases, surely it is not incorrect to talk of the diseases of a steam-engine or the pathological phenomena of a spinning jenny. Any one who has studied and thought over the formation of a common abscess, or the occurrence of any simple, acute, or chronic inflammation, must have convinced himself that the changes comprehend phenomena which cannot yet be included under Physics or chemistry.

Fermentation not a Catalytic Action.—Much has been said about *fermentations* and *contact actions* or *catalysis*, and by some they have been considered to be closely allied, if not of the same nature; but recent investigations, and especially those of Pasteur, have led us to restrict the term *fermentation* to the changes effected by *living organisms alone*, and *catalysis* to the phenomena due to mere contact and surface action.

No true fermentation, and according to Pasteur, no putrefaction, can occur without the presence of *living particles*. Catalytic actions, on the other hand, may be induced by perfectly lifeless matter like platinum. Unless, therefore, it can be distinctly proved that fermentation is a mere contact action, independent entirely of the *vital* changes occurring in the living and actively growing organisms constituting the "*ferment*," we must admit that there is a great difference between *fermentation* and *catalysis*.

The old notion which attributed some of the most important changes occurring even in the organism of man and the higher animals to *catalysis* has been recently revived, but so long as it remains completely unsupported by observation and experiment, it is not likely to gain favour among scientific men at this time, more especially as many important facts recently ascertained in connexion with cell-nutrition render it still more improbable than it appeared when first advanced, if they do not prove it to be altogether untenable.

A very little consideration will show that there is little analogy between *catalysis* and the phenomena which occur in connexion with *living cells*. The lifeless catalytic matter never multiplies; the living always does. The lifeless passes through no definite stages or states of being; the living invariably does so. The lifeless catalytic body does not necessarily alter in chemical composition during its action; the living one is always undergoing change in its active state. The first cannot be said to *form new material*; the last always exhibits this property. Neither the assimilation of food, nor the conversion of food into blood, nor the conversion of blood into organ or texture, can be correctly spoken of as due to catalysis or contact action, for in these processes not only are certain elements of the pabulum taken into the very substance of the matter which is the catalytic agent, but these become a part of the agent itself. In no case does the food directly become blood, or the blood undergo direct conversion into organ or texture, but both food and blood pass through a transition stage during which neither the compounds existing before nor those which are to be produced can be detected.

If the catalytic platinum could take up and convert the materials around it into *platinum* and give rise to something differing in composition and properties from itself as well as from the matter around it which it had taken up, an analogy would exist between the phenomena above mentioned and catalysis. If it could be shown that in assimilation, in the conversion of food into blood, and blood into tissue, the pabulum became changed while the cells, like the platinum in catalysis, underwent no change, then it might be correct to regard living cells as catalytic or contact agents, but it has been distinctly proved that nothing save that which is alive can effect changes like those occurring in connexion with living cells, and that "*living*" comprehends more than mere chemical, mechanical, and catalytic changes, or all these together.

ORIGINAL COMMUNICATIONS.

FURTHER NOTES ON THE NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA.

By BENJ. W. RICHARDSON, M.A., M.D., F.R.C.P.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE PRINCIPLE AND THE PRACTICE.

The new method of producing local anæsthesia which I had the pleasure of introducing to the Profession in the pages of this journal on the 3rd of last month has created an interest which, at the most sanguine moments, I did not anticipate. This success is due in a great measure to the simplicity of the process, its readiness of application, and its determinate and demonstrative action; but the most important element in the success is, that the new process supplies a want long felt in every class of the Profession—namely, a ready means of removing pain arising from Surgical operations or other causes without the risk of sacrificing life.

The short paper I now write may be considered as an answer, in a general sense, to the various questions and suggestions that have been addressed to me since my last communication. For convenience, I may classify this series of answers under four heads. 1. The principle of the new process of local anæsthesia. 2. The instrument to be used. 3. The fluid to be used. 4. The mode of application.

The Principle of the Process.

The principle of the new anæsthetic process consists in directing on a part of the body a volatile liquid having a boiling point at or below blood heat, in a state of fine subdivision or spray, such subdivision being produced by the action of air or other gaseous substance on the volatile liquid to be dispersed.

When the volatile fluid, dispersed in the form of spray, falls on the human body, it comes with force into the most minute contact with the surface upon which it strikes. As a result there is rapid evaporation of the volatile fluid, and so great an evolution of heat force from the surface of the body struck, that the blood cannot supply the equivalent loss. The part consequently dies for the moment, and is insensible, as in death; but as the *vis a tergo* of the body is unaffected, the blood, so soon as the external reducing agency is withdrawn, quickly makes its way again through the dead parts, and restoration is immediate. The extreme rapidity of the action of this deadening process is the cause of its safety. The process can suspend life without causing disorganisation; if I may use the expression, it produces syncope of the part—temporary death—but not necessarily destruction. When we produce general anæsthesia we virtually extend this mere local action to the body altogether—*i.e.*, we check the evolution of force at the centre, and produce an approach to temporary death of the whole of the organism.

The Instrument.—Improvements.

The instrument by which the volatile fluid is dispersed is described at length in my paper published in this journal on February the 3rd of this year. It consists of a spray-tube and bottle worked by Dr. Andrew Clark's hand bellows. The tube differs from all other spray-tubes in that the volatile fluid is brought up for dispersion by air pressure produced by the same motion as that which causes the dispersion. The instrument also provides a means for regulating the current of fluid; it allows the ether to be carried along tubes of any convenient length and curve; and, lastly, it enables us to construct a *compound* instrument by which the effects may be multiplied to any reasonable extent for large operations.

In my original paper, referred to above, I described simply the single dispersion-tube. Since then, I have made a large number of tubes to answer various powers and purposes. I

have a tube in which there is a bulb enlargement at the end with perforated side, or side and central jets. This tube is exceedingly useful for the cavities of the body, such as the vagina or rectum. It distributes the fluid in the same manner as a syringe with several perforations at its point. In practice, I find that the dispersion of the fluid delivered from one fine tube by a series of jets is not so efficient, proportionately, as when it is delivered by one jet: the fluid, that is to say, requires a certain degree of concentration to ensure success.

In order to multiply the anæsthetic producing power, I have other instruments constructed which may be called compound. In these cases the bottle holding the volatile fluid either receives a common central tube of large size communicating with a number of terminal jets, or each terminal jet has a separate jet running into the fluid. By this means I have a brush of jets, which may be circular, or long, or flat, as required. For this compound tube a six-ounce containing bottle for the fluid is necessary, and additional bellows power. The present small hand bellows will only work a compound jet of two elements with efficiency. I have tried to meet this difficulty by using a bellows worked by the foot, but not as yet to my full satisfaction. To get the air pressure I have tried various plans so as to do away with the hand bellows. I have used carbonic acid compressed into an iron bottle, and have applied the gas in its escape so as to act in the same manner as the air from the bellows. The apparatus complicates, and the pressure of gas cannot be nicely regulated. I have modified this plan also by trying to get force by generating carbonic acid gas at the time; also by generating hydrogen from zinc and dilute sulphuric acid, and using the pressure of the gas as the distributing agency.

Again, I have tried water pressure, as in the common gas holder; and I think in the dentists' room this plan would succeed well, if the preliminary expense were no obstacle. But taking all in all the hand ball bellows are as yet the most practical and most ready; they carry in the pocket, and one can go with them to the patient and commence anæsthesia at once—a great consideration. In many small operations, requiring only one or two strokes of the knife, the whole may be done painlessly, while the patient thinks that the preparations are merely being made—much, of course, to his gratification.

Several suggestions for the improvement of the jets offer themselves for consideration; the fish-tail gas-burner, the Argand burner, the conservatory water engine, and many other mechanical contrivances similar in kind will occur to every one as worthy of imitation, and as quickly as they can be made they will be produced and tested.

The Fluid to be Used.

I still continue to use absolute ether for operations, and now, as Mr. Robbins has produced an ether of specific gravity 0·720 of negative effect on the tissues, and having a boiling point of 92° Fahr., a better fluid can hardly be demanded. Many other fluids have been suggested by various readers of my original paper—viz., methylic ether, amylene, monochloretted chloride of ethyle, pure chloric ether, nitrite of ethyle, a volatile hydrocarbon derived from the manufacture of portable gas, chloroform, rectified turpentine, and numerous compounds and mixtures. As regards these I may state that they have all been under my careful consideration, but that as yet none of them, taking their qualities all in all, are equal to absolute ether. Some are open to rejection at once from their boiling point being too high; others are unpleasant, and would not admit of being used in operations on the mouth or teeth; others cause irritation of skin; others in their pure state are so extremely volatile that they could not be kept in the surgery for any length of time—this is specially the case with methylic ether and nitrite of ethyle, both promising substitutes for ether; lastly, a body too volatile would somewhat affect the operator during the operation if it were diffused in the pure state. Nitrite of ethyl is open to this objection not so much as the nitrite of amyl would be, but to some extent.

In time we may, perhaps, by experiment get a compound volatile mixture which being as negative as absolute ether in its effect on the body shall boil a few degrees lower.

Before leaving this topic, let me state that the mere alteration or change of the volatile fluid used is no change of the principle of the present anæsthetic process. Ether itself is only a local anæsthetic on being employed according to this principle. This is important to be borne in mind, otherwise a principle may become confounded with a detail, and every fluid with a low boiling-point and the other necessary physical qualities, as I have described them, for producing insensibility will be dubbed a local anæsthetic. By a slip of the pen, indeed, this error was committed in the *Medical Times and Gazette* of last week, a short leading article having been headed "Kerosolene a Local Anæsthetic." Kerosolene—a body very impure, unpleasant, and of unsteady but low boiling-point—when applied by my method acts like ether, because it resembles ether physically. But kerosolene is no anæsthetic *per se*, although it would serve as a substitution agent for one part of the anæsthetic process, in the same manner, and in none other, as an earthenware bottle would take the place of the graduated glass bottle in which the volatile liquid is commonly retained.

Dr. F. D. Fletcher, of Southport, has suggested to me the employment of liquid carbonic gas, and, as will be seen by last week's *Medical Times and Gazette*, Sir James Simpson has had carbonic in view for some years. I believe the first physiologist who actually tried to apply the reducing agency of carbonic acid for the production of anæsthesia was the late Dr. Snow. He went to great trouble and expense to experiment on the gas in the solid state, and he applied it in that state to his own skin. Singularly enough, the insensibility produced was slow and imperfect, but the worst feature was that a slough was always produced on the part where the acid had been applied. Snow, therefore, gave up the effort, convinced that carbonic acid in the solid form could never be made applicable in actual practice, and that if it could it would not be a safe agent.

I myself moved for a time in a similar direction by using carbonic acid in the liquid form. Mr. Robbins supplied me with the gas reduced in a three-pint iron bottle under pressure. When the stop-cock was opened and the carbonic was liberated through a fine jet, an intense cold was produced; but I utterly failed in attaching a conveying tube that would be applicable for operations. The pressure, in a word, was unmanageable, and for ordinary practice, dangerous. In one experiment, while the jet was being directed on the back of my hand, the nozzle of the tube became set free, and, being projected with violence, injured me severely. I, therefore, like Snow, gave up carbonic acid as a body that would not submit to guidance, and as impossible to use in Surgical practice.

We need not, fortunately, trouble ourselves on this subject. I have shown that by the dispersion of fluids of low boiling points we can get a degree of cold which answers the required purpose without employing fluids or gases under pressure. If we want more than absolute ether, chemistry can furnish us with fluids which boil even at below 70° Fahrenheit, which fluids, dispersed as vapour, would fill the purpose of carbonic acid with only one disadvantage—that of being difficult to keep in store during many months of the year.

Next week I shall take up the subject of practice; shall relate my own successes and failures with the new anæsthetic process, and shall offer a few simple rules and suggestions for those who would employ the process.

ON THE

TEMPERATURE OF THE BODY

AS A HELP TO DIAGNOSIS IN TUBERCULAR, CANCEROUS, AND OTHER FORMS OF CONSOLIDATION OF THE LUNGS.

By SYDNEY RINGER, M.D., and WALTER RICKARDS, M.D.

Cases not unfrequently occur where many of the symptoms and physical signs common to consolidation of the lungs from tubercle, cancer, and other growths are present, while those symptoms, etc., by which they may be distinguished are absent. The diagnosis in such cases is often impossible.

These observations were made with the hope that some information might be gained by which the consolidation from tubercle may be distinguished from that due to cancer and other growths. It has been shown by one of the authors of this paper that the temperature of the body is always preternaturally elevated while tubercle (a) is being deposited in any of its organs. If, therefore, it should be proved that cancerous and other growths in the lungs fail to elevate the tem-

(a) This statement applies both to tubercle and to scrofulous pneumonia. The product of scrofulous pneumonia was formerly considered to be infiltrated yellow tubercle.

perature, we shall possess a ready means of distinguishing between the above-mentioned diseases.

These cases, though not numerous enough to settle this question, point to this conclusion. The difficulty of diagnosis mentioned, of course, occurs only when the growths affect the apex of the lung. Physical signs only indicate physical conditions, that is, increased rarefaction or consolidation of the lungs, or the presence of fluid in the pleura. Therefore if the growths be limited to the lungs—if there be no mediastinal tumour to aid the diagnosis by producing symptoms of pressure on the various organs situated in the mediastina—the physical signs are very much the same, for in consolidation from tubercle and from cancerous and other growths we have in the early stage of the disease merely the signs of consolidation —that is, dulness on percussion under the clavicle, lessened expansion of the same part of the chest walls, increased vocal fremitus, with harsh bronchial or diffused blowing breathing. These are the signs of consolidation of the lung, and are consequently common to the diseases mentioned. Symptoms, moreover, are not sufficient to separate these diseases. It is true that the further progress of the disease often clears up the diagnosis. Thus the absolute limitation of the disease to one lung, especially if this be on the right side, extreme and extensive dulness, without evidence of breaking up of the lung (from either cavernous breathing or the presence of rhonchus) and the character of the expectoration may point to some growth in the apex of the lung, and prove that the consolidation is not due to tubercle.

But even when the symptoms have advanced to such a degree, the diagnosis is often difficult except by an expert in thoracic diseases. For it is often difficult to be sure that no disease is present in the other lung. There may be well marked cavernous or tracheal breathing (and the latter is difficult to distinguish from cavernous breathing), with well marked pectoriloquy. Nay, further, if any bronchitis be present, it may produce some submucous rhonchus at the apex of the lung. How are we, then, to distinguish between these diseases? In case of cancerous or fibro-plastic infiltration of the apex of the lung, the cavernous breathing (unless the lung tissue has broken down—an uncommon occurrence in this disease) is conducted by the infiltrated lung from the trachea or bronchi, and thus the cavernous breathing is best heard over or immediately by the side of the sternum, whilst cavernous breathing produced in cavities due to tubercular softening is mostly heard earliest and the best developed at the outer part of the infra-clavicular region of the chest. But this distinction, though often of service, can perhaps scarcely be alone relied on. It is on the evidence of the presence of mediastinal tumour indicated by the pressure symptom mentioned, and by the dulness it causes over the upper part of the sternum, that we chiefly rely. It is in doubtful cases where these symptoms or signs due to a mediastinal tumour, are absent, and where the diagnosis is so difficult, that we hope to show that the temperature of the body affords us a means of distinguishing these diseases. We now proceed to give a short account of the cases :—

Recurrent Fibro-Plastic Tumour.—The victim of this growth was a woman, aged 27. The tumour, which was situated to the right of the umbilicus, had been noticed for two years. It had been removed, and did not return for six months. After the interval it again appeared in the cicatrix of the wound. It had grown rapidly. While under observation the tumour rapidly increased, and was consequently removed, but it immediately reappeared in the wound and again rapidly increased. There were evidences of great consolidation of the apex of the right lung. Thus the expansion under the right clavicle was almost *nil*. Vocal fremitus was much diminished. The percussion note was absolutely dull as low as the third rib, below which it was excellent. The breathing was cavernous over and close to the sternum. This character of the respiration diminished on passing outwards and also downwards, so that it was scarcely heard at the acromial angle, and disappeared below the second interspace—indeed, in this interspace it was only heard over the inner half. There was distinct pectoriloquy close to the sternum over the second rib. There was no rhonchus. There was some dulness over the right apex posteriorly as low as the angle of the scapula, but this was by no means marked. The breath sounds were weak. As far as physical signs could be relied on, the left lung was healthy. The dulness of the right side extended to the middle of the sternum. There were no pressure symptoms, and the patient had never spat blood. The heart beat in its usual place. Post-mortem.—The large tumour was found in the abdomen. The chief part of the upper lobe of the right lung was converted into an encephaloid-looking mass, and throughout the rest of this lung and the whole of the left there were innumerable small tumours which varied greatly in size, from a walnut downwards. These tumours had common characters. They were soft, and easily broke down; they gave no milky juice, and had a brittle fracture. Dr. Wilson Fox was of opinion that the tumours were of the nature of fibro-plastic growth. The temperature was taken daily from March 14 to April 25. This varied from 98 to 100. On two occasions it rose to $100\frac{2}{5}$. It was mostly below $99\frac{3}{5}$.

Scirrhus of Breast.—This patient was 44 years of age. The tumour had been present for two and a-half years. During the nine months before her admission into Hospital it had grown rapidly. When she came under treatment, the tumour occupied the entire breast. The skin over the tumour was shiny, tense, and adherent to the growth beneath. The nipple was retracted. The tumour was of stony hardness. There was an enlarged gland in the axilla. Her temperature was taken daily in the axilla for eight days. The highest point reached was 99° Fah.

Scirrhus of the Breast.—The female was 42 years of age. The tumour was of the size of an orange, and had been present twelve months. It occupied the middle of the mamma, and the nipple was situated over the centre of the growth, to which it was adherent. The skin over the rest of the tumour was moveable. There were no enlarged glands in the axilla. The tumour was pronounced to be schirrus by the Surgeon in attendance. Her temperature was taken for two days. The highest point reached was $98\frac{4}{5}$.

Carcinoma of Stomach.—This occurred in a man, aged 60. At the post-mortem there was seen a growth occupying nearly the whole of the pylorus, and infiltrating the tissue of that part. It had the appearance of schirro-encephaloid. It was nodulated and highly vascular. The temperature was taken night and morning for the fourteen days preceding his death. It never rose higher than $99\frac{1}{5}$.

Malignant Tumour of Buttock.—This growth occurred in a boy, 4 years of age. It was of four months' duration. It had grown rapidly, and had reached the size of a large cocoanut. While in the Hospital, he was attacked with convulsions, in which he died. The tumour was found, after death, to have all the naked eye characters of an encephaloid growth. The lungs were crowded with secondary deposits, varying in size from a nut to a walnut. The temperature was observed for the six days previous to his death. Its highest temperature recorded was $99\frac{4}{5}$.

Tumour of Cerebellum.—The patient was a boy of 11 years of age. The tumour was situated in the left side of the cerebellum, and had reached the size of a hen's egg. It was found to be composed of cells that were in no way characteristic. His temperature was taken for thirty-eight days. On two occasions it rose to 100; at all other times it was below this, and was often as low as 96 and 97.

Mediastinal Tumour.—John C., 53. He is still in the Hospital. There is a very extensive tumour occupying the mediastinum, and infiltrating or displacing a great part of the left lung. The nature of this is uncertain. It is certainly solid, and is not an aneurism. His temperature has been noted for seven days. The highest point it reached was $99\frac{2}{5}$.

Tumour in Neck.—This was of nine months' duration; it was of rather considerable size. It was supposed to be malignant; as, however, the patient left the Hospital alive, this diagnosis is uncertain. His temperature was taken during eight days, and marked as its maximum $99\frac{1}{5}$.

Malignant Tumour of Face.—Sarah J., aged 13, was admitted with a large tumour on the right side of her face. This had displaced the right eye and the nose. It also involved the gums and a large ulcerated growth occurred in the mouth. It lasted in all seven months. Its growth was irregular; sometimes it increased with great rapidity, and at other times its growth appeared to stop. A large abscess formed in the tumour, which burst and continued to discharge for some time. The tumour at last extended down the neck and into the mouth. It so far disfigured the child that her friends could not recognise her. At the post-mortem the tumour was found to possess all the characters of an encephaloid cancer. It was firm and rather fibrous in the centre, but much softer at its circumference, at which part it broke down readily. It was highly vascular, and gave an abundance of milky juice; it infiltrated and softened the bones, so that they could be cut with ease. Her temperature was taken daily

from March 17 to June 12. During the whole of April the temperature was considerably elevated, rising daily to 103° and 104° Fah.; on the bursting of the abscess the temperature fell, and remained afterwards normal.

Epithelioma of Face.—The temperature of this woman was taken for seven days before the tumour was removed. It varied between 99 and 99⅘.

We have here tumours of various kinds,—some of comparatively slow growth, others of very rapid growth. Some remained local to the end, in other cases very numerous secondary formations in the lungs were developed, and yet in only one case was the temperature elevated. In this it was most probably due to the abscess that formed in the tumour, as on the bursting of this the temperature fell to that proper to health, and remained so to the end of the life of the patient.

The views respecting the nature of cancer have of late been considerably modified. The definition has been so considerably limited that many growths that were formerly, and still are, clinically considered cancer are now referred to other species of formation. But, adopting the older views, some of these tumours were scirrhus, some encephaloid, some scirrho-encephaloid, and some simply fibro-plastic, and one epithelioma. Hence, as far as we are justified in drawing conclusions from so limited a number of cases, it would appear that these growths do not cause a preternatural elevation of the temperature of the body. One of the authors of this paper has already published one case of cancer of the lung where the temperature was normal.

Thus the observations at present made for the solution of the question put at the beginning of the paper render it probable that by the aid of the thermometer we are enabled to diagnose between consolidation due to tubercle and that due to cancerous and other growths.

Occasionally, moreover, much doubt exists in the mind of the Practitioner whether a swelling be due to a solid growth or whether it be due to pus. This can in most cases be decided by the help of a small trocar, yet sometimes this fails to clear up the doubts that exist, and, indeed, sometimes leads to an erroneous conclusion. Abscesses always at one part of their course cause a considerable rise in the temperature, and very often this continues till the pus is discharged. Whether there be such an elevation from the presence of a "cold abscess," the authors are unable to say. As far as one is justified in judging from the absence of all febrile symptoms, we may conclude that fever is not present in such cases; and, should this be the case, while the absence of fever will not prove that a tumour cannot be an abscess; on the other hand, if fever be present, will it not be probable that the swelling is not due to a solid growth, but to the presence of pus?

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

TOWN'S HOSPITAL, GLASGOW.

CASE OF APOPLEXY WITH GREAT HYPERTROPHY OF THE HEART, BUT WITHOUT VALVULAR OR ARTERIAL DISEASE.—STATE OF SENSATION, SPEECH, THE REFLEX FUNCTION, AND THE IRRITABILITY OF THE PALSIED MUSCLES.

(Communicated by Dr. Alexander Robertson.)

S. C., aged 46, miner, was admitted into Hospital in the forenoon of the 25th of last January, suffering from hemiplegia of the left side, and in a state of apparent insensibility. He could, however, be partially roused by loud talking, and then appeared to have an indistinct understanding of the questions addressed to him, as he attempted to reply, though in a confused, muttering manner. His power of articulation was impaired, but not greatly, most words being pronounced so as to be understood individually without much difficulty, although they were somewhat incoherent in their connexion. Both eyes were shut; but, on raising the right eyelid and touching the conjunctiva, there was an instant contraction of the orbicularis muscle, whereas the same stimulus, when applied to the left eye, produced no effect; the eyelid just fell slowly over the eye as if by its own weight. The pupils were slightly contracted, the right being more so than the left; they were but little sensitive to light. The tongue was protruded towards the palsied and the face was twisted towards the sound side. The paralysis of the motor power in the left extremities was complete; there was not the least movement, either voluntary or involuntary. The sensory function appeared to be as completely lost as the motor. Thus, when the left arm or leg, or that side of the body, was pinched or pricked with a needle, there was no indication of sensation; but, when the right side was tested in the same way, the evidences of pain were unmistakable. The power of deglutition was impaired; he could swallow liquids, but, after a few mouthfuls, the glottis seemed to be imperfectly closed, and a paroxysm of coughing resulted. The urine was passed involuntarily, and it was found, on the action of purgative medicine, that he had no control over the sphincter ani. The irritability of the muscles was tested by galvanism. A *weak*, continuous current was passed down both arms, producing contractions equal both in respect of strength and rapidity in their respective muscles. Pulse 92, weak; head rather hot; coughed occasionally.

From the time of his admission till his death—which was somewhat sudden, four days afterwards—the symptoms varied very little in their character, except that on the day before he died the pulse was increased in frequency and fulness, and he complained of pain in the right side of his head.

The treatment consisted principally of purgatives, with sinapisms to the extremities, in the first instance, and afterwards leeches to the temples, blister to the neck, and evaporating lotion to the head when inflammatory action appeared to be threatening.

Before death the person with whom he lodged called at the Hospital, and it was ascertained from him that patient had left his home on the day previous to his admission here, apparently in his ordinary health, which he considered to have been excellent; in fact, he believed him to be a healthy, strong man. His acquaintance with him, however, had not been of long duration, and he could give no reliable information as to his habits.

Autopsy.—Pia mater and brain were greatly congested, and the sinuses were distended with dark blood. In the substance of the right corpus striatum and thalamus opticus was a clot, about the size of an ordinary hen's egg, dark and of considerable consistence. These centres were quite broken down, except that the wall of the lateral ventricle was not injured. Both ventricles contained dark serous fluid—the right about six drachms, the left about half that quantity. External to the effusion, to the depth of not more than a quarter of an inch, the brain substance was softened and deeply discoloured, and a yellowish tinge, gradually fading as it receded from the clot, evidently caused by the colouring matter of the blood, extended considerably farther. The arteries showed no indication of morbid change. The specific gravity of a section of the cerebral substance, taken from near the effused blood and including softened brain, was 1043, whereas a corresponding portion of the opposite hemisphere was 1046. No other abnormal condition was observable either in cerebrum or cerebellum. The heart was greatly hypertrophied, particularly on the left side. It weighed 23 oz. The wall of the left ventricle measured one inch in diameter at the base, and three-quarters of an inch near the apex. All the cavities were enlarged, though not proportionately to the hypertrophy of the walls. The diameter of the aorta was increased, and its muscular coats thickened, but they were soft and elastic, and appeared to be of normal structure. The valves were all healthy. The muscular tissue of the heart was of natural colour and consistence, but when examined by the microscope some of the fibres were found to have undergone a fatty metamorphosis, whilst others were evidently quite sound. Both lungs were greatly congested, and the lower lobe of the left one, except its anterior margin, was hepatised, sinking like a stone in water. The cortical substance of the kidneys was also, to a slight extent, the seat of fatty degeneration. There was a large amount of fat on the body generally, and there was more than usual on the surface of the heart. The voluntary muscles were fully developed, and had a thoroughly healthy appearance.

Remarks by Dr. Robertson.—The association of apoplexy with hypertrophy of the left ventricle, and without valvular disease, is well known to be of not infrequent occurrence; but along with these conditions it is usual to find distinct evidences of morbid change in the arteries of the brain. In the case described these vessels, so far as could be observed, were quite healthy. They must, however, have been subjected to an abnormal strain from the increased propelling

power of the ventricle; and when the pneumonia occurred, involving a large portion of one of the lungs, the return of the blood from the head would necessarily be retarded, increasing the pressure upon the cerebral vascular system: hence, in all probability, the occurrence of the apoplexy.—The cause of the great enlargement of the heart is not so clear. There was no valvular disease to account for it. Some years since, Dr. S. Kirkes (*Medical Times*, 1835, page 515) directed attention to the occasional association of apoplexy, renal disease, and cardiac enlargement without valvular obstruction, regarding the renal as the primary affection and causative of the cardiac hypertrophy. But in his cases the kidneys were in an advanced state of degeneration, and the cerebral arteries were also the seat of morbid change, whilst in mine, the kidney disease was not great, and the arteries were healthy. As already stated, no reliable information was obtained as to the patient's previous habits, so that we may conjecture that possibly the abnormal state of the heart was due to augmented action caused by alcoholic or other stimulus.—The loss of sensation is worthy of note, as it has been thought by some that in apoplexy from sanguineous effusion in the central parts of the brain, it is but little involved. Indeed, Mr. Hutchinson, in a recent number of the *Medical Times and Gazette* (February 3) advances the supposed immunity of sensation in apoplexy of the central parts as a means of diagnosis from injuries of the superficial parts of the brain, where, he states, both motion and sensation are affected. This alleged escape of the sensory function in ordinary apoplexy does not consist with my own experience of many cases in which I have noticed its condition. I have found that sensation is generally impaired, though not so severely as motion. The mistake has probably arisen from the rapidity with which, in most instances, it is at least partially restored, even where there is not the least recovery of the motor power.—There was complete loss of the reflex action of the orbicularis palpebrarum muscle. This is not usual even in severe cases of hemiplegia. Generally, even though voluntary power over the eyelids no longer exists, if the conjunctival membrane is touched, greater or less contraction of the orbicular muscular fibres occurs. Thus, in another case which has been under my observation since the occurrence of the one described, and in which there was total unconsciousness, and palsy of one side, terminating fatally in a few hours, owing to a very large effusion of blood on the surface, and into the substance of one of the hemispheres, the same stimulus applied to the conjunctiva produced distinct though feeble contraction of the orbicular muscles of both eyes.—The presence, even though a little impaired, of the faculty of speech, including language and articulation, where the hemiplegic symptoms were so severe, gives negative support to the view advanced by M. Broca, and which has given rise to so much discussion, that loss of speech is associated with right hemiplegia alone. Since the publication of that observer's remark, my attention has been directed to the point in numerous cases which have been under my care in this institution, and certainly it must be granted that the association of these two conditions is very general. I have, however, notes of several patients where left hemiplegia and impairment of speech were conjoined, but in none did the latter symptom exist to a marked degree.—The comparative irritability of the muscles of the palsied and those of the sound side, as tested by galvanism, has been the subject of considerable difference of opinion. Dr. Marshall Hall considered that the palsied muscles were always more easily affected; but this view has by no means received unqualified support from succeeding observers. In my own case no appreciable difference was observed between the two sides.—The diminished specific gravity of the cerebral substance in the vicinity of the effusion is worthy of note, and is probably to be accounted for by the fact that the portion examined was partially softened.

Singular Inquest at West Hartlepool.—Under this head the local papers detail the particulars of an inquest held on the body of a seaman, named Stemberg, who died somewhat suddenly before Medical assistance arrived. The symptoms detailed by the non-professional witnesses might have been those of strangulated hernia or of poisoning. No Medical evidence, it appears, was called. The policeman who saw the body stated that he saw no marks of violence upon it, but that it was emaciated and diseased! This seems to have satisfied the jury, who returned a verdict of "Found dead from inflammation of the stomach."

SATURDAY, MARCH 10.

THE REPORT OF THE COMMITTEE AT THE ADMIRALTY.

No one can read this Report without perceiving that there must be something very defective in the relations of the central Medical with the executive authorities. Such appears to have been the impression on the mind of one at least of the civil members of the Committee, and this Report affords much corroboration of it. Whether this has arisen from want of power, or want of energy, on the part of the Medical authorities, we cannot say; but there is something very wrong somewhere in the working of the Medical Services. There does not appear to be any—or, at any rate, any adequate, representation of Professional feeling.

For the last four or five years men have been appealing through the public press for a redress of many minor matters, which might have been adjusted by half-an-hour's conversation between the official Medical representatives and the executives of the Horse Guards and Admiralty. Instead of this, things were allowed to take their course and acquire strength by doing so. Medical officers ought to repose the same confidence in their own administrators as the combatant officers repose in the Horse Guards and Board of Admiralty; but this is unfortunately not the case. There was no uniformity of regulation, and consequently no uniformity of action and custom. Warrants so loosely framed as to be capable of almost any interpretation; regulations, which ought to have been expressed with perspicuity, contradicting one another; and official memoranda at variance with all the rest! A Medical officer might find himself in *this* position to-day, and in *that* to-morrow, according as he had a different commanding officer. Such a state of things strikes at the root of all discipline, and the combatant officer must often have been as fairly puzzled as the Medical, how to guide his course aright. No one knew, apparently, who or what was right; and the consequence was, that matters were always "cropping up" every bit as distasteful to the executive as to the Medical officer. Then, again, no end of very small difficulties and disagreeables were accumulating, of no earthly interest to one set of officers, but productive of injury and serious discontent to another. Had the representation of our Professional instincts, feelings, and interests been more firmly carried out, we must think the authorities would never have pursued so dangerous and suicidal a policy. If this has not been done, then the official representation is very ineffective.

This inquiry was not set on foot until grave injury had been done to the State. The end has been that the Executive and Medical members of the Committee are unanimous in their Report. We learn that the Admiral presiding entered into and met all the grievances in a most considerate manner; and the other Executives conducted the investigation in as

fair and impartial a spirit as was consistent with the interests they represented and had to protect.

Of course the Report is a compromise; but it is not the worse on that account. In dealing with the Army part of it, we could not avoid hitting off such a blot as the absence of promotion for the juniors. We were not singular in this, for almost all the witnesses examined represented the long continuance in a subordinate position as *the* grievance of the junior officers.

In the Naval Service it is different. Promotion has been, and must continue to be for some time, much quicker. Still the Naval Medical Officers undoubtedly were worse off than their Army brethren. The contrast between the two services in respect of rank, pay, allowances, and position was very unfair. The Report gives a good summary of those points of difference which were to the disadvantage of the Naval Medical Officer, and the Committee have endeavoured to rectify these, with so large a measure of success as to have called forth a strong protest from Sir James Gibson against the peculiar favour shown to the Navy. Unquestionably there are a great many personal and social discomforts attending a seafaring life, and the Naval Service is thus placed at a disadvantage in the competition with the Army. It is not every Medical man that loves the sea, and our Army friends must not grudge those who make the sacrifice a few extras by way of a "set-off."

Of course, it is impossible to please every one, and the Recommendations of the Committee for the Naval Medical Service will appear insufficient to some. All the major evils have been removed, and with regard to the rest, "the Committee being divided in opinion, we cannot offer a decided recommendation." The employment of Staff Surgeons instead of Deputy-Inspectors in foreign flag-ships is thought by some a defect; but they admit that there are many reasons to be urged on the other side.

We have gone through the Recommendations with some care, and we venture to express the hope and belief that all *reasonable men will be contented.* The pay is liberal for the junior ranks; the prospect of promotion very satisfactory when compared with the Army; and in all other respects the Committee appear to have been guided by an honest determination to put things upon a fair and good footing. The protest to which we have alluded ought at least to prove to our Professional brethren afloat that they no longer labour under relative disadvantage.

We were glad to see that Lord C. Paget is evidently disposed to adopt the Report of the Committee; and this reminds us that Sir J. Pakington did not lose the opportunity of saying a good word for that Department whose interests he has never lost one opportunity of protecting.

THE VENEREAL COMMITTEE.

It will be remembered that one of the members of the Venereal Diseases Committee, Dr. Balfour, has dissented from his colleagues as regards that portion of their Report which relates to the prevention of syphilis. The objections taken by Dr. Balfour express the feelings of not a small number of the community. It is imagined that the scheme of compulsory weekly examination, if it necessitate the adoption of a plan of registration, would afford facilities for intercourse with prostitutes, that it would be, in other words, a *protective* and not a *repressive* measure. If a certificate of health were granted doubtless such would be the case. Dr. Balfour believes, also, that the weekly inspection would be degrading to the feelings of the respectable and married men, especially the petty officers, and thinks that "the proper course would be to order all men who contract disease, however trifling, to show it at once to the Surgeon, and in neglect of their doing so, to punish them for disobedience of orders."

The Committee, generally, are of opinion that compulsory measures would be less necessary if it were possible to compel or induce men to confess to the existence of disease, by modifying existing rules, so as to throw greater responsibility on the men for not at once reporting to the proper official the first signs of illness. Dr. Balfour is disposed to extend the details of the present Act but slightly; he would not allow prostitutes to loiter about for hire, nor to assemble together in public or night houses; he would make it an offence on the part of keepers of brothels to harbour a diseased woman; he would give a magistrate the power to send a suspected or loose person to the Lock Hospital for examination and detention, and provide ample room for all voluntary applicants, who may likewise be detained by order of the magistrate, if need be; he further allows that all men, save married men and sergeants, going on furlough should be examined, and again on their return to camp or quarters, thus recognising in fact the principle of compulsory examination in a partial manner. With regard to married men a difficulty arises, in so far that they are by no means infrequently diseased, conveying the mischief to their wives, who may in turn hand it on to others. It is worthy of notice that Sir Henry Storks, no mean authority, is an advocate for the inclusion of the married as regards preventive measures.

The compulsory system has been very successful when fully carried out, as appears from the report of Mr. Inglott, the Comptroller of Institutions at Malta, who writes:—

"The Malta law, you will observe, does not involve a system of legal recognition of public prostitution; it does not licence females to the unlawful occupation, but simply places those who practise it under a kind of surveillance, with the view of obtaining a sanitary advantage by enforcing a measure which tends to mitigate or prevent the awful consequences of neglected syphilitic affections. Besides periodical inspections, the Malta law also enjoins the establishment of lock Hospitals, without which the good results I have described would not have been obtained."

In the case of islands, the law such as obtains in Malta can be fairly and effectually applied, because all sources of access of diseased women can be cut off or guarded against, but under other circumstances, a great difficulty crops up. Take Gibraltar, for instance; it is there found impossible to prevent Spanish women coming into the place and infecting men freely enough. Such would be our case.

If the Government should determine to carry out the recommendations of the Committee—and these recommendations should be successful in garrison and sea-port towns—the public must expect further legislation in reference to the community at large.

A good deal has been said about the control of prostitution in Paris, but the working of police regulation there is much misunderstood. In France they deal only with what may be termed "notorious" prostitutes, and do not touch the details of clandestine prostitution. In reference to legislative enactments, it must be remembered that the class of prostitutes which infect our soldiers and sailors belongs indeed to the same category as that to which the Parisian police regulations are applied. Registered women in Paris are "subjected to such regulations as should disgust them with their position and induce them to make every effort to escape it." They certainly are compelled to keep with them a quasi-certificate, indicating their name, address, and the date of the last inspection, which perhaps is open to objection, but in addition they are obliged to afford information at any time to the police, to present themselves for inspection each fortnight, not to leave home until dusk, and to return to their homes before 11 p.m.; they dare not congregate, walk together, be accompanied by men or frequent public places; their dress must be simple—at least, not conspicuous; they cannot sport themselves in any open vehicle, nor show themselves at their windows. Should they infringe in any of these particulars they are punished. The French make their notorious and ill-behaved women act decently under pain of retribution. There cannot be a question that it would be a very great boon if the horrible and open de-

bauchery and the licentious manners of many of our own prostitutes could be similarly regulated; it would then be possible for the respectable members of society to frequent many places which are now wholly given up to the possession of loose women.

French administration, it is affirmed, does not create tolerated houses, but exercises the most strict supervision over them, making the mistress of each house responsible to the fullest extent. All women, when diseased, are sent to the Hospital for treatment. Such are the statements contained in the Appendix of the Report of the Commission.

Diseased prostitutes should be regarded as public nuisances and dangers, and it is the duty of the Legislature to devise proper means for remedying the evils they produce, without giving encouragement to immorality.

Prostitution is equally a crime whether syphilis is present or absent in those who practise it. It is possible to legislate for the accompanying syphilis alone. The great and all-important thing to avoid—that, indeed, which would afford actual assistance to the spread of prostitution, is the granting of *anything* approaching the character of a certificate of health—in fact, a licence to prostitute. Adopt only the plan of detecting and detaining every diseased woman until she can by no possibility syphilise men, and lessen the chances of such an occurrence by the periodical examination (with the view of detecting the earliest signs of misehief) of those who expose themselves to the risk of disease.

DIETARIES OF THE POOR IN THE METROPOLIS.

Amongst the numerous anomalies consequent on our charming system of local self-government, not the least appears to be the variety of diets adopted for paupers in the Workhouses of the metropolis. The means of securing a uniform scale of diet for the poor—such a scale as should not be so tempting as to offer a premium to the idle, nor so meagre as to operate harshly upon the deserving poor—would be to throw upon the Poor-law Board the responsibility of fixing the quantities and quality of the food. Under the existing arrangement each Board of Guardians or Directors follows its own sweet will in this respect, and, subject to the sanction of the Central Board,(a) regulates the degree in which it will starve or stuff the occupants of its Workhouse.

It will not be uninstructive to observe, from the following table, the allowances given in some of the metropolitan workhouses. These cases have been selected as showing the extremes of (pauper) luxury and parsimony:—

Scale of Dietary for Able-bodied Men, per week.

	Parish or Union.			
	Hampstead, St. John.	Bethnal-green, St. Matthew.	Chelsea, St. Luke.	Fulham.
Bread .. .. ounces	118	92	84	96
Meat .. .. ,,	10	15	15	15
Potatoes .. ,,	16	24	1½	32¼
Cheese .. ,,	11	8	8	8
Pudding .. ,,	14	28	14	14
Gruel .. .. pints	10½	10½	10½	—
Soup .. .. ,,	4½	3	4½	4½
Broth .. .. ,,	1½	4½	4½	4½
Totals:—				
Solids .. ounces	169	167	122½	165¼
Liquids .. pints	16½	18	19½	9

It is true that the Medical Officers have, by the Poor-law Regulations, a finger in the composition of the pauper pie; but, when we have before us recent examples of the treatment experienced by them when interfering on behalf of the poor under their care, it becomes unnecessary to point out the small chance they possess of amending the diet in Workhouses governed by Boards of Guardians who have in view no higher object than the depression of their poor-rate. It is, of course, undesirable to feed a pauper better than the struggling artisan who can barely pay the rate which defrays the cost of the Workhouse rations. Surely, however, it is about the worst possible thing for public morality that the convicted felon should be dieted better than either the ratepayer reduced to the Workhouse, or the honest workman straining every faculty to keep the wolf from the door.

To realise the actual state of facts in this particular, take the ordinary diet for a week at Portland Prison, as stated in 1863. It was, in ounces—Bread 150, cooked meat 39, potatoes 115, oatmeal 14, cocoa 2¼, milk 14, treacle 5¼, flour 16½, barley 3, suet 2¼, tea ½, sugar 3—giving a total of 364¾ ounces. Compare this with the diet allowed to the able-bodied at the Workhouse of St. Luke's, Chelsea, as before set forth, or put the allowance at the Portsmouth Convict Establishment—which gave a weekly total of 397 ounces—in contrast with the allowance at the Workhouse of the Fulham Union, and little room will be left for doubt as to, at least, one of the causes which, session after session, bring before Recorders gangs of the dissolute able-bodied, who receive with glee the sentence which sends them to fatten at the public expense for a further term, or to grow plump while working out a *punishment* (?) which they can do (to use their own expressive words) "on their heads."

(a) Some places, under Local Acts, are not subject to this restriction.

THE DAILY LIFE OF A NAVAL SURGEON.

The daily life of a naval Surgeon is spent in the performance of so many and such varied duties that it is not easy to describe them. It must vary with the station, with the size of his ship, and the causes which influence disease ashore and afloat. In addition to strictly Professional duties he has to perform or superintend the secretariat of his department, and devote a good deal of time to the winding of that red tape which seems so intimately interwoven with all English affairs. The Assistant-Surgeon in a large ship acts also very much as a clerk, and enters the name, age, and quality of each complainant in the "Rough Journal," adding the more prominent symptoms, from the dictation of his superior. The Assistant-Surgeon turns out at an hour Mr. Pepys would call "mighty betimes," and with the Surgeon has seen the sick and has breakfasted by shortly after eight o'clock. He then makes out two lists of the sick, one for the commander and another, called the "binnacle list," for the convenience of those officers who have to direct the police of the ship. The Surgeon has to make morning reports to the captain and to keep returns and a journal of practice, which are forwarded quarterly to head quarters.

By midday these duties have to give way to an inspection of the patients' dietary, dispensing Medicines, and attending to those casual cases which must daily present themselves in a large ship. At sea the wardroom officers dine at two o'clock, but for some reason or other when in harbour they satisfy the *sacra fames* with luncheon at that hour and dine at six. Another visit to the sick and further reports are made between four and six p.m., in order that the executive officers may know the exact number of effective men in the ship before arrangements for the night are made. To the land Practitioner all this seems extremely tiresome, and he shudders at such routine in the small compass of even a line-of-battle ship; fancy being obliged day after day to visit any one room of your house and put an entry to that effect in your note-book; that the housemaid has odontalgia, and the atmospheric electricity has affected the beer so necessary for the due performance of her duties. Let the shore Practitioner contemplate having his valuable time occupied not only in prescribing for patients inside his own house, but feeding, nursing, and writing biographical notices of them, bearing every great and little responsibility which the circumstances peculiar to life on board a ship add to the cares common to his calling. Moreover, the hardest-worked land Doctor can, at all events, feel himself his own master when his work is over for the day, "his mind to him a kingdom is," and no other may "tithe or toll in *that* dominion;" while the naval Medical man is, perhaps,

unavoidably the servant of many masters, and liable to vexations which can hardly tend to cheerfulness. In short, the naval Surgeon is at great disadvantage in the treatment of cases. A civil Practitioner might be very severely taken to task if his instrument case was limited to the meagre supply we find in the case "fitted in accordance with the Admiralty regulations;" thus: two silver catheters and two gum elastic catheters. Considering that the former are liable to break, and the urethras of mankind are not of the same calibre, that gum catheters are certain to wear out very soon, and that vesical embarrassments are very common among all persons exposed to the vicissitudes of weather, the idea of the Admiralty "ordaining" that the Medical attendant of some four hundred men should have two silver catheters is astounding; especially as he must have *twelve lancets* and *six pewter syringes*. The list has not been revised for thirty years, but general Surgery has, and the man fresh from Moorfields may feel some surprise that there are no ophthalmic instruments supplied him with which he may deal with the eight hundred eyes for whose safety he is responsible. Adhesive plaisters and pills are made on board by the Assistant-Surgeon as they are required; both are troublesome things to do and must occupy hours that might be spent by a man with profit to himself and country, and all his opportunities for study are interfered with. Even the great naval Hospitals, Lisbon, Haulbowline, Nova Scotia, Cape of Good Hope, etc., can do the naval Surgeon but little good until they and all flagships are provided with inspectors having full administrative powers over the naval hygiene wherever they may be stationed.

Most of the cases occurring afloat are Medical, but in the event of battle, and even men of war *occasionally* are exposed to such a danger, the Surgeon may search among his lancets and pewter syringes in vain for an aneurism needle, so much more careful is the Admiralty to guard against the effects of the *prælia veneris* than the blows of Mars. Of course naval Surgeons provide themselves with necessary instruments, but they do so at their own cost, and are without them at their own peril; for they might be severely blamed if any life were lost through the absence of some appliance for which not even the six syringes would be an efficient substitute. The remedies for all this are surely very simple, and highly necessary, for, although the men and boys entering the Navy are so carefully selected, there is a mortality of fifteen per thousand, while more than double that number break down on active service and are invalided. This is curiously shown in p. 28 of the Statistics for 1862, when the naval population amounted to "58,870 and the total number of cases of disease and injury came to 88,661, making nearly *three entries* on the sick list for every *two* men in the force. The total number of men either temporarily or permanently rendered unfit for active service (*i.e.*, invalided) being 1944; the deaths 902. The days on the sick list were 1,230,120 (p. 301). Now, surely we have said enough to show that the method of working our Profession on board ship is cumbersome and inefficient. The naval Surgeon seems to have no power Medically or Surgically; cramped in what Johnson calls "a prison with the chance of being drowned;" he combats with diseases of low vitality which he can explain but cannot cure; his patients meet with accidents, and the chances are he has not the necessary appliances, and if things go wrong his conduct is blamed, while the future promises but few rewards for a youth of self-abnegation.

England seems keenly alive to the necessity of an efficient navy; each year the old complaints about a scarcity of sailors are repeated. One means of improving matters would be preserving the material she already has, and if she does go through the form of having Medical attendants for her sailors, let these be provided with the powers and appliances which are necessary under all circumstances for the efficiency of Medical men, and let them have that encouragement to exertion and consideration which human nature requires and which no one gives more freely than John Bull to those who deserve well of the Commonwealth.

THE WEEK.

THE MEDICAL COUNCIL.

We understand that the Medical Senate of the United Kingdom is summoned to meet on the 17th of May. It is in vain to prophesy what amount of legislative work may be done this year; but we suspect that whether the Council succeed or not in obtaining from Parliament any amendment of the Medical Act, some very important results may be obtained though the use of "moral force," or, in other words, from the accurate knowledge of facts, and the plain inferences which common sense may draw from them. It is rumoured that a confidential report has been received from the members of the Council deputed to visit the examinations of the several licensing bodies, and that the tenour of this is such as to cause discomfort and alarm to the institutions whose short-sighted policy it is to dispense diplomas and titles to register upon the system of easy examination in one single branch of the healing art.

THE CATTLE PLAGUE.

Our Parliamentary intelligence gives information only too precise and positive as to the spread of the cattle plague, and as to the failure of Mr. Worms' well-meant medicine. It disposes also, summarily, of the ungenerous slander which had been cast at Professor Simonds by the quackery-supporting papers, to the intent that he had refused to acknowledge that any of Baron Rothschild's cattle which recovered under the Worms' system had really had the cattle plague. Alas! the poor beasts settled this themselves, for after being cured of what the Wormsites said was cattle plague, though Professor Simonds said it was not, they did really die of the disease of which they had been said to have been cured. Meanwhile, it is a significant fact, that by an Order in Council, dated March 3, the Cattle Plague Commissioners are authorised and enjoined to save from the poleaxe and reserve any animals at their pleasure for experimental treatment.

WORKHOUSE INFIRMARIES.

The meeting of the Association for the Improvement of the Infirmaries of Workhouses, which took place at Willis's Rooms on Saturday last, is at least an evidence that the public are fully alive to the necessity of reform in the Hospital management of the sick poor. It was attended by an Archbishop, several members of the Peerage and of the lower House, and by a large number of influential persons. We are glad to see that the subject is receiving the attention which it merits, and we should rejoice at the erection of infirmaries for the treatment of pauper patients, and at the appointment of adequate staffs of Medical officers and inspectors. But we doubt whether the London public are prepared to be taxed especially for this end, and we very much question the probability of the weak Government at present at the head of affairs venturing to impose a new Metropolitan rate. Whilst we earnestly wish that the Association may be successful in obtaining a better system of attendance and nursing for the sick poor, we would strongly advise them not to waste their energies in devising schemes too large to be realised.

THE LATE DR. CONOLLY.

In another column will be found an obituary notice of this distinguished Physician and philanthropist, from one whose pen is tinged with the affection produced by the closest ties. We cannot, however, let pass the opportunity, on the part of the proprietors and conductors of this journal, of expressing their profound respect for the memory of one whose communications have so often given value to our pages. Amongst friends he was one of the most genial, kindly, and social of mortals: what Dr. Johnson would have described as "a clubable man;" and trivial though it seem,

the possession of qualities which make a man beloved in society is no slight addition to the more substantial excellences of human character. In Professional life we need hardly say that he was much consulted, especially on maladies of the nervous system, and that few Practitioners met him without deriving pleasure and instruction from the interview.

THE UNIVERSITY OF LONDON CALENDAR FOR 1866 AND THE B.S. DEGREE.

This calendar contains a notice of several important alterations in the Regulations relative to examinations for degrees. These shall be noticed next week. Meanwhile, we desire to call attention to the new degree of "Bachelor of Surgery," the preparations and qualifications for which leave nothing to be desired by those who demand that the Surgeon should not be a mere "one qualification" man, representing the ancient handicraftsmen, but that he should be a thoroughly instructed General Practitioner, with special knowledge of Surgery superadded. Every candidate for the B.S., must already possess the M.B., and must have attended a special course of Operative Surgery on the dead body. The examination will constitute a practical test of the candidate's knowledge in Surgical Anatomy, operations, diagnosis, and treatment. Students must bear in mind that this is not yet a *registrable qualification;* the possession of the B.S. would not yet entitle a man to register as having a recognised Surgical qualification, with its attendant privileges. But never mind. It remains to be seen whether the mere Membership of the College of Surgeons will *go to the wash* (as old women say) and whether its claims will stand. A B.S. + M.B. must be worth more some day than a M.R.C.S., which requires in its fortunate possessor no examination in Medicine, Materia Medica, Chemistry, and Botany.

THE REGISTRAR-GENERAL'S WEEKLY RETURNS IN LONDON AND PARIS.

It is an old and too true saying that we are apt to overlook the immense labour required to get any work done smoothly and punctually when that work requires many hands for its accomplishment. We in London are accustomed to look out for the Registrar-General's Weekly Returns every Wednesday morning, just as one would for the price of the funds, or the latest telegrams; and we see, as a matter of course, how many have died, from what causes, in every corner of that "province covered with houses" which we call London. But we ought not to forget that some praise is due to the authors of a system by which returns from so many officers are received, recorded, and tabulated, and the results published so unerringly and so promptly. All over London, day by day, the district Registrars are receiving entries of deaths—in the small and better districts perhaps from two to six; in the larger and worse districts from twenty to forty per week. On Sunday just as much of the entries as concerns the statistician and sanitarian is copied on a convenient sheet and put into the post, directed to the Registrar-General, at Somerset House. No *names* are copied into this sheet; but merely the fact of death, with time, place, cause, sex, and age. On Monday these are tabulated and printed, and on Tuesday the Weekly Return is ready for distribution to the newspapers. Then all who take an interest in social and sanitary questions can see at a glance the death-rate, its causes and varieties, in every one of the 135 subdistricts; and thus it is quite impossible that any groundless panic should arise with reference to any alleged wholesale poisoning, whether from epidemic or other sources. Nor does the benefit rest here; for whilst the public is disabused of any unreal fear, the original Returns for the Registrars are forwarded every Wednesday to the Medical Officers of Health for each respective district, and these functionaries are thus able at once to cause visitation and purification of any houses in which deaths from contagious disease have really occurred.

Here we may express our thanks to Mons. the Sénateur Haussmann, Prefect of the Seine, for his kindness in sending us copies of the *Bulletin de Statistique Municipale*, relating to the city of Paris, from January to October, 1865. This bulletin is directed by an official ordonnance to be published monthly, and contains the number of births and deaths, the causes of death in each arrondissement, and an account of the meteorology, besides any other statistical matter which may arise from time to time. It is a quarto publication, extremely elaborate, with diagrams of the temperature of air and water for each day of the month. The causes of death, the number of deaths in private houses and institutions, of newly-born infants, etc., are all detailed with a completeness and precision such as might have been expected from French officials. But, if we may do so with courtesy, we would venture to point out to M. le Baron Haussmann that the smaller and less elaborate sheet of our Registrar-General, by the fact of its publication *weekly*, is really of more practical use as a means both of consoling the public mind and of averting real danger; and we suggest that the publication of such a *weekly* record in every capital of every European country, and especially in Paris, as being *par excellence* the capital of Continental Europe, would be a march of real progress in the history of civilisation.

REGISTRATION OF DEATHS IN SCOTLAND.

Our readers are aware that a considerable injustice is enacted by the law of registration of deaths in Scotland. The Medical certificates of the cause of death, which in England and Ireland are supplied as a free-will public service by the Medical Profession, in Scotland are wrested from the Medical Practitioner under the threat of the infliction of serious penalties. To say nothing of the grossly unconstitutional character of a law which compels a Profession to render unrequited service to the public by an enactment of penalties and confiscation, the insult which the law fixes upon the Physicians and Surgeons of Scotland is worse than the injustice which it inflicts. We are very glad that the Glasgow Medical Association are not content to sit down quietly under such a flagrant grievance. At a meeting recently held at the Trades' Hall, it was announced by the Council of the Association that they were about memorialising every Scottish member of Parliament, together with the Colleges of Physicians and Surgeons, in order to obtain their co-operation in an effort to obtain a repeal of the obnoxious law. One argument used by the Association is, that although penalties are thus imposed, in practice they entirely fail to extort the information required. It was stated at the meeting by Mr. Walker "that the Returns issued from the Registrar-General's office for Scotland were not worth the paper on which they are printed; and that no Medical man acquainted with the facts put the least reliance on the document." This is just what we should expect. An unjust tax is always paid grudgingly, and evaded if possible. It is to be hoped that this shameful anomaly will not be allowed to continue law. The whole influence of the Profession in the three Kingdoms ought to be exerted for its revocation.

POLITICO-MEDICO-MILITARY MATTERS.

We could not discover that Lord Hartington, in moving the Army Estimates on the 5th inst., gave any promise that the recommendations contained in the Report of the late Committee at the Admiralty would be embodied in an authoritative document. It surely cannot be that the Government is going to defer action until the result of the next competitive examination at Chelsea is known? Prophets are not wanting who still declare that nothing will be done for the Army Medical Officers; but we cannot believe them.

The Late Hong Kong Affair.—At the same debate this subject was touched upon by many members. General Peel

*

remarked, on the saving effected by the removal of a regiment from China, that he was afraid there were very few more of that regiment to withdraw, in consequence of a total neglect of all the warnings of Medical men. Several other members adverted to the same subject, and it will be fully investigated before long, Colonel North, the member for Oxfordshire, having taken up the matter.

We were very glad indeed to see that Colonel P. Herbert adverted to the very costly fittings of some of our recently-constructed military Hospitals. The plate-glass, handsome chandeliers, and such like extravagances are ridiculous in such buildings. They answer no end as far as the health and treatment of the soldier are concerned, and we have been assured that these unfortunate men stand in constant dread of "breakages" and "barrack damages." Whatever ministers to health, cleanliness, comfort, and Hospital administration is all very well; but we heartily assent to a remark made, we believe, by the Commander-in-Chief, one day whilst visiting one of these kind of Hospitals, that such fittings were as grossly unfair to the private soldier as they were unnecessary.

A Cold Blast.—In the obituary column of the *Times* of the 6th inst. we noticed the following record of deaths:—eight over 60 years, six over 70, four over 80, and two over 90 years of age. If the sudden accession of cold weather is terribly fatal to the aged, it is, at any rate, some "set off" to see that some of us have a good chance of dying old.

BURIAL ALIVE.

The abundance of other topics hinders us at present from saying a few words on the conditions under which there may be real danger of burial before life is quite extinct. Now we will only reproduce the cases reported by Cardinal Archbishop Donnet in the French Senate, in the discussion on a petition that the time between death and burial should be lengthened. We will add one instance, which we have heard on the best authority:—About thirty years ago, a young woman of 18, daughter of a Madame Laligand, living in the Rue des Tonnelliers, at Beaune, in Burgundy, was supposed to have died. The ordinary measures were taken for interment. The body was put into a coffin and taken to the church, the funeral service was said, and the *cortège* set out for the cemetery; but on the road between the church and the cemetery, the supposed dead recovered power of motion and speech, was removed from the coffin, put to bed, recovered, married, and lived eighteen years afterwards. She said that she had retained her consciousness during the whole of her supposed death, and had counted the nails that were driven into her coffin. Statements such as these, and such as those made by the Archbishop, will surely be subjected to the ordeal of a French scientific commission, and we may suspend our judgment for the present. To return to his Eminence. He said that he had the very best reasons for believing that the victims of hasty interments were more numerous than people supposed. He considered the rules and regulations prescribed by the law very judicious; but, unfortunately, they were, particularly in the country, not always executed as they should be, nor was sufficient importance attached to them. In the village he was stationed in as assistant-curate in the first period of his sacerdotal life he saved two persons from being buried alive. The first was an aged man, who lived twelve hours after the hour prescribed for his interment by the municipal officer. The second was a man who was quite restored to life; and in both cases a trance more prolonged than usual was taken for actual death. The other instances, says the *Times'* correspondent, I give in the words of the Archbishop:—

"The next case that occurred to me was at Bordeaux. A young lady who bore one of the most distinguished names in the department had passed through what was believed to be the last agony, and as apparently all was over, the father and mother were torn away from the heartrending spectacle. As God willed it, I happened to pass by the door of the house at the moment, when it occurred to me to call and inquire how the young lady was going on. When I entered the room the nurse, finding the body breathless, was in the act of covering the face, and, indeed, there was every appearance that life had departed. Somehow or other, it did not seem to me so certain as to the bystanders. I resolved to try. I raised my voice, called loudly upon the young lady not to give up all hope; that I was come to cure her, and that I was about to pray by her side. 'You do not see me,' I said, 'but you hear what I am saying.' My presentiments were not unfounded. The word of hope I uttered reached her ear and effected a marvellous change; or, rather, called back the life that was departing. The young girl survived; she is now a wife and the mother of children, and is this day the happiness of two most respectable families."

The Archbishop mentioned another instance of a similar revival in a town of Hungary during the cholera of 1831, which he had heard that day from one of his colleagues of the Senate as they were mounting the staircase. But the last he related is so interesting and made such a sensation, that it deserves to be repeated in his own words:—

"In the summer of 1826, on a close and sultry day, in a church which was excessively crowded, a young priest who was in the act of preaching was suddenly seized with giddiness in the pulpit. The words he was uttering became indistinct, he soon lost the power of speech, and sunk down on the floor. He was taken out of the church and carried home. All was thought to be over. Some hours after the funeral bell was tolled, and the usual preparations made for the interment. His eyesight was gone; but if he could see nothing, like the young lady I have alluded to, he could hear, and I need not say that what reached his ears was not calculated to reassure him. The Doctor came, examined him, and pronounced him dead; and after the usual inquiries as to his age and the place of his birth, etc., gave permission for his interment next morning. The venerable bishop in whose cathedral the young priest was preaching when he was seized with the fit came to his bedside to recite the *De Profundis*. The body was measured for the coffin. Night came on, and you will easily feel how inexpressible was the anguish of the living being in such a situation. At last, amid the voices murmuring around him, he distinguished that of one whom he had known from infancy. That voice produced a marvellous effect and superhuman effort. Of what followed I need say no more than that the seemingly dead man stood next day in the same pulpit. That young priest, gentlemen, is the same man who is now speaking before you, and who, more than forty years after that event, implores those in authority, not merely to watch vigilantly over the eareful execution of the legal prescriptions with regard to interments, but to enact fresh ones in order to prevent the recurrence of irreparable misfortunes."

MEDICAL OFFICER TO THE POOR-LAW BOARD.

Without reflecting for one moment upon the value of the body of gentlemen at present acting as Poor-law Inspectors,—who, we have reason to know, have almost all had at various times opportunities for improving the position of Medical officers, of which they have in many instances availed themselves,—it will be generally admitted that, in addition to, and in concert with, the general supervision exercised by those Inspectors, the mode of administering relief to the *sick* should form the subject of special inspection—inspection entrusted to men possessing peculiar aptitude for the work—to men, therefore, who have received an education of which each step has had immediate reference to the abnormal conditions of human health—inspection, in short, by Medical men. In the year 1865 Dr. Edward Smith was appointed as a Poor-law Inspector. This was the first instance in which the post was held by a Medical man: barristers had held it; baronets had adorned it; country gentlemen had disported themselves therein. It remained, however, for Mr. Villiers to appoint a Medical man as Inspector. The appointment of Dr. Smith gave general satisfaction apart from any Professional question. To us, however, it seemed to be an approach to the Medical inspection of which we have spoken above, and was, therefore, hailed as a good omen. Our anticipations have proved correct

—Dr. Smith has been appointed as "Medical Officer to the Poor-law Board," in addition to holding the appointment of Poor-law Inspector, and Medical officers have now a right to hope that the Board, when assisted by his advice, will have better opportunities for appreciating the difficulties and troubles of the Profession to which he belongs than they have hitherto appeared to possess. There can be little doubt that the future progress of Poor-law Medical relief will justify Mr. Villiers' selection—a selection made, doubtless, only after careful deliberation.

FROM ABROAD.—BRUSSELS REGISTRATION RETURNS—"PROFESSOR" HOLLOWAY IN ITALY—TREATMENT OF CARBUNCLE.

M. Janssens has published the registration returns of Brussels for 1865, and we give here some of the figures. The population of the city, which amounted to 187,155 on the 12th January, had, by the 31st December, increased to 189,337, viz., 92,805 males and 96,532 females; the augmentation having, therefore, been during the year 2182 inhabitants, of whom 1347 were males and only 835 females. During the year there were 6021 *births* registered; of these 3118 were males and 2903 females. Of the 6021 births, 4572 (2371 males, 2201 females) were legitimate and 1449 (747 males and 702 females) illegitimate. During the year 168 twin children were born, 98 male and 70 female—36 being illegitimate. There were 1730 *marriages* solemnised during 1865 and 15 divorces decreed. The *deaths* amounted to 5853 (2960 males and 2893 females), comprising in that number 318 infants born dead. The number of deaths for the first six months of the year amounted to 3117, and of the last six months to 2736; the maximum monthly number (567) occurring in July, and the minimum number (394) in September. The month of November, which, with March, is usually the most fatal month of the year, only this year produced 396 deaths, 533 occurring in March. Among the deaths 1453 occurred in hospitals, hospices, or prisons, while 1830 indigent persons died *à domicile*. Among the principal causes of death the following may be specified:—Phthisis, 860; bronchitis and pneumonia, 545; organic diseases of the heart, 415; enteritis and diarrhœa, chiefly in children, 539; variola, 236; tubercular meningitis, 274; croup and diphtheric angina, 211; apoplexy and ramollissement of the brain, 193; mesenteric disease, 212; scarlatina and measles, 220; convulsions in children, 213; puerperal deaths, 79; deaths from accidents, 76; typhoid fever, 98; cancer, 61; suicides, 41 (24 during the first and 17 during the last six months of the year); alcoholic delirium, 21. Of the total number of deaths, 5535, obtained by excluding the infants born dead, 1404 took place under one year of age and 1148 between one and five years of age, *i. e.*, about one-half of the entire mortality, occurring before the fifth year. Between five and twenty there occurred 370 deaths; between twenty and forty, 792; between forty and sixty, 840; and above sixty, 985 deaths. The following are the returns of the four principal Hospitals:—On the 1st of January, 1865, there remained 1262 patients, and 15,530 were admitted, making a total of 16,792 persons treated during the year. Of these 14,256 were discharged, 1367 died, and 1169 remained in the Hospitals.

The question of admitting non-Medical advertisements into Professional periodicals has been often discussed; and sometimes our French *confrères* have been rather severe in their remarks upon the somewhat heterogenous assemblage which gains admission to our own and contemporaries' covers. Whatever views may be entertained on the matter, few, we believe, would ever suppose that the illustrious "Professor" Holloway would succeed in invading the pages of any Medical journal in any part of the world; but sure it is that he has obtained a conspicuous place on the cover of a well-known Italian periodical—the *Gazetta Medica di Torino*, of seventeen years' standing, and edited by Professor Borelli. Whether deceived by the assumption of a title or tempted by large payment, certain it is that the two "Professors" seem to have joined heart and hand; for not only is a long advertisement concerning the pills and ointment admitted, with a suitable graphic illustration, but Professor Borelli announces the gratifying fact that his journal may be read gratis at the central establishment in the Strand, where also advertisements and subscriptions are received.

M. Gosselin read a report on a memoir on subcutaneous incisions in carbuncle, by M. Alphonse Guérin, sent into the Academy some two years since, and since amplified and published by its author in the *Dictionnaire di Médecine et de Chirurgie Pratiques*. The procedure consists in plunging the narrow blade of a straight, probe-pointed bistoury into the centre of the carbuncle, and then, having turned it on its flat side, insinuating it beneath the skin to beyond the tumified margin. Having reached this point, the Surgeon, directing the cutting edge towards the deep-seated parts, incises from without inwards until he feels the sensation of resistance overcome. This incision is followed by three others, each radiating in the same way from the centre. M. Gosselin agrees with M. A. Guérin as to the danger of producing erysipelas and purulent infection by the ordinary incisions of anthrax, and he has in his own practice discontinued them for some time past. When the anthrax is small, he leaves it to itself, and a spontaneous cure is always the result; and when it is large he practises a great number of punctures, with the object of relieving the strangulation. M. Gosselin has only had the opportunity of trying M. A. Guérin's mode of procedure five times, and that when the anthrax had reached an advanced stage; so that he is unable to judge of its advantages when employed at an early stage. In his cases no erysipelas followed.—M. Velpeau, without adverting to M. A. Guérin's plan, which stands in need of yet more evidence in its favour, cannot agree with M. Gosselin in stigmatising free and open incisions. As erysipelas is, at certain times, whether in Hospital or private practice, induced by the most trifling circumstance, even the bite of a leech, it must be very difficult to determine how far an erysipelas which may complicate anthrax has been due to the incisions employed. His experience does not correspond with that of M. Gosselin as to the frequency with which erysipelas follows incision of carbuncle, as in very many cases such is never observed—unless, indeed, the erysipelas be prevailing epidemically. He feels convinced that incisions in carbuncle are useful in proportion to the number that are made. A small anthrax, which is, in fact, only a large boil, may heal without them; but when it reaches a large size, parallel incisions should be performed, at a centimetre's distance from each other, these being also carried pretty deeply and sufficiently long to reach beyond the affected parts on both sides. There should be no fear in making as many as are required, even from 15 to 20, if necessary, the patient, if he dread the pain, submitting to anæsthetics. This is the most certain and the least dangerous remedy, and so efficacious that M. Velpeau feels no temptation to change it; and M. Nélaton, who had once renounced incisions, has found it necessary to recur to them. How mere punctures can suffice for the treatment of large carbuncle M. Velpeau cannot imagine; and although small anthrax will get well of its own accord, yet even here multiple incisions will abridge the cure and render it more assured.—M. Guérin, sen., observed that he had long remarked that the very painful incisions in anthrax favour the development of erysipelas and purulent infection. So in the case of tumours, ablation by the knife much more frequently is followed by erysipelas than when caustics are employed—the mouths of the divided vessels under the operation of these last not remaining patent and apt for the absorption of the altered liquids. So in anthrax, spontaneous opening renders the occurrence of erysipelas less possible than when this is effected by incision, organic changes having obliterated the vessels

and rendered absorption less active. The method now proposed by M. A. Guérin must, in fact, be rather regarded as a means of effecting *debridements* under the skin than as an example of the subcutaneous method, properly so called, which has for its object the prevention of the occurrence of suppuration, which in anthrax is already present. Still, incisions so made are certainly preferable to large incisions, open to the air.—M. Michon observed that M. Gosselin could not, when he spoke of punctures in anthrax, which, like M. A. Guérin's incisions, are mere means of *debridement*, have had in view the formidable form of anthrax which keeps increasing in size, and for which the large incisions mentioned by M. Velpeau are alone efficacious. Little matters whether they are crucial or parallel, providing that they are sufficiently extensive. No large anthrax is ever cured spontaneously; and M. Nélaton has abandoned the opinion he once held on this point, as well as that the affection is always fatal to the aged. M. Michon has seen an anthrax as large as the crown of his hat completely cured by free incisions, in an aged gentleman. He believes also that erysipelas more easily complicates carbuncles that have not been effectually incised than those which have been treated by large incisions. M. Cloquet also insisted upon free incisions, which will only prove efficacious on the condition of their being made deep and extending beyond the limits of the part affected. He has only met with erysipelas after incisions that have been made too small.—M. Larrey likewise believes that it has been the practice of making the incisions too superficial that has brought this mode of treating carbuncle into disfavour.

PARLIAMENTARY.—THE CATTLE PLAGUE—VOTES TO THE NAVAL MEDICAL ESTABLISHMENT—METEOROLOGICAL OBSERVATIONS—DISINFECTANTS FOR THE CATTLE PLAGUE: M'DOUGALL'S POWDER—MR. WORMS' TREATMENT: REPORT BY PROFESSOR SIMONDS—CAPITAL PUNISHMENT.

In the House of Commons on Thursday, March 1,

In answer to Mr. Sandford,

Mr. T. G. Baring said the Third Report of the Cattle Plague Commissioners would, in all probability, give an account of the experiments as to the cure of the plague.

Votes of £57,368 for the Naval Medical establishments, and £75,664 for Medical stores for the Naval Service were agreed to.

On Friday, March 2,

Colonel Sykes asked the President of the Board of Trade whether any and what arrangements were making for taking systematic and permanent meteorological observations either at the Board of Trade or at the Greenwich and Kew Observatories, for British objects, and whether foreign Governments would be invited to co-operate, by causing simultaneous meteorological observations to be made with a view to arriving at a knowledge of the physical laws which cause atmospheric changes.

Mr. Milner Gibson: After the death of Admiral Fitzroy it was thought desirable to refer the question of the future arrangements for the conduct of the business of the Meteorological Department to a Committee of Inquiry, the members of which should be named by the Admiralty, the Board of Trade, and the Royal Society. This has been done, and the Committee are on the point of making their report. Until this report has been received and considered it is not possible to give a satisfactory reply to the question of my hon. friend.

On Monday, March 5, in the House of Lords,

Lord Granville announced that he should propose on Thursday that the Standing Orders be suspended, in order that the Cattle Plague Bill might pass through all its remaining stages on that day.

In the House of Commons,

Mr. W. Miller asked the Secretary of State for the Home Department whether he is aware that the Cattle Plague Royal Commission, in their endeavours to discover the best disinfectant, referred the question only to a single individual—namely, Dr. Angus Smith, who reported in favour of carbolic acid, or M'Dougall's powder, of which preparation he himself is co-partner with Mr. M'Dougall, and which is generally believed by chemists to be no disinfectant at all.

Mr. Baring said that the question was one which ought to be put to the member for Calne (Mr. Lowe), who was a member of the Commission. Dr. Angus Smith was annoyed at the reference to himself, and he wished that the question should be deferred until the report he prepared had been made and presented to Parliament. He had, however, given him the following information on that part of the question:—"I never had any interest, profit, or advantage from the sale or manufacture of M'Dougall's powder, or of any other substance made by him, or by anybody else." Dr. A. Smith added:—"I do not recommend M'Dougall's powder as the best disinfectant." And upon the third point he said:—"Carbolic acid is not M'Dougall's powder, but a liquid not manufactured by M'Dougall." With regard to the second branch of the question, he had received the following from Mr. Montagu Bernard, the Secretary to the Commission:—"Dr. Angus Smith was the person employed by the Commissioners to report on disinfection and disinfectants. He is an eminent chemist, as every one knows, and had previously turned his attention to the subject. After a long series of experiments on a great number of substances he reported in favour of chlorine, muriatic acid, sulphurous acid, and the two tar acids (otherwise called carbolic and cresylic acids). On a consideration of his report, the tar acids were deemed by the Commissioners most likely to be efficacious and best suited for general use. They then instructed a younger, but distinguished chemist, Mr. W. Crookes, F.R.S., to go to a district where the disease was raging to test in several ways the efficacy of the selected substances, and to ascertain by personal experience the best and simplest modes of using them. Mr. Crookes has been for some time at work, and the accounts received from him are very satisfactory. M'Dougall's powder is a preparation containing carbolic acid, with sulphites of magnesia and lime. It was among the many substances tested by Dr. Angus Smith, and he recommended it as useful in some ways, making no secret of the fact that it had been first produced by himself, together with Mr. M'Dougall, ten years ago."

In answer to the latter part of the hon. member's question, he had to state that the Home Office had no means of forming an opinion in regard to disinfectants, but when the Cattle Diseases Act was passed the Secretary of State for the Home Department directed a letter to be written to the Royal Commissioners, asking them to furnish him with the best plan for disinfecting premises, etc., from the contagion of the cattle plague. That information was supplied, and it had been circulated throughout the country. From the constitution of the Commission, and the manner in which they had directed the experiments to be made, it was impossible to suggest any body of persons better qualified to come to a proper conclusion on the matter.

On Tuesday in the House of Lords, Earl Granville read the following report by Professor Simonds on Mr. Worms' treatment of the cattle plague:—

"Veterinary Department of the Privy Council-office,
"Princes-street, March 3, 1866.

"Sir,—I have the honour to report that, acting on your instructions, I have to-day visited Mentmore for the fourth time, for the purpose of ascertaining the progress of the cattle plague in Baron Rothschild's herd, and the results of the treatment adopted by Mr. Worms. Since my last visit, February 22, the disease has made rapid progress, and I regret to add that the fatality has kept pace with its advance. It appears that, in consequence of the deaths which had occurred up to February 22, and the number of animals which were then sinking more or less rapidly from the disease, it was determined to give trial to Mr. Worms' remedy as a prophylactic as well as a curative agent, and, accordingly, all the remaining animals of the original 119 were dosed on succeeding days with the mixture. With a view also to limit the number of cases, the unaffected animals were taken out of the straw yards and placed in small lots in nine different yards, distant from each other, and temporarily fitted up on the south side of one of the plantations. The location of these yards and the manner of their construction were well suited for the required purpose. Before describing the state of things as now existing, it will be necessary shortly to refer to my former reports of February 15, 19, and 22, in which the particulars were given of the first 25 animals which had been removed from the herd and put under Mr. Worms' treatment. In the first of these reports it was stated that ten animals, which, at the time of my examination, gave no evidence of disease, were being treated by Mr. Worms, and that one—the original animal attacked—had succumbed to the malady. In

my second report I stated that four other unaffected animals had also been taken out of the yards for treatment, with five more which were the subjects of the cattle plague. In my third report I stated that in the interim three of the animals which were unaffected at my first and second visits had been attacked with plague, and in addition to these other cases had also occurred. A summary was attached to this last-named report, which is here repeated:—February 22, 1866—Unaffected, 11; affected, but not severely, 5; died, 5; dying, 4—25. On my visit to-day I found that the whole of the 11 animals referred to in the summary, and which had been regarded by Mr. Worms as having been cured, had been attacked, and that nine of them had died. Under the peculiar circumstances of the case, it may be as well to add the result of the treatment of these 25 animals as distinct from the rest of the herd. Numbers 1, 3, 4, 5, 6, 7, 10, 12, 13, 14, 15, 16, 17, 18, 20, 21, 22, 23, 24, and 25 are dead, and numbers 2, 8, 9, 11, and 19 are convalescent. Passing from these cases, I have now to describe the general state of the remaining portion of the herd, the disease, as previously stated, having made fearful havoc among the animals since the 22rd of February. In the sheds were five heifers rapidly sinking from the disease. In contiguous yards were lying 13 cows and heifers which had been shot, some on the previous evening and the remainder on this morning, all having been so severely affected as to be beyond all hope of recovery. A bull and a heifer were about to share the same fate just as I arrived on the premises, but were allowed to live until my inspection was completed. I may here remark that none of these animals were destroyed by the orders of the local authority. In No. 1 extemporised yard were 24 cows, 10 of which were dying, and the remaining 14 were all more or less affected. In the eight other yards were 35 heifers, all of which were affected. Several were dying and three were dead. The general state of these animals was such that in a few days scarcely one of them may be expected to be alive; and so great has been the mortality, and so rapid the progress of the disease, that I was informed by the bailiff that all treatment had been abandoned for some few days, and the animals left to their fate. Graves were being prepared as quickly as possible, and all the requiremonts of the law were being properly carried out. The almost total destruction of this herd will, it is to be feared, be followed by a serious loss among the dairy cows on the estate. On Feb. 24 the malady unfortunately made its appearance among them, and on my inspection to-day I found that two had died, six been slaughtered, and two others were dying. Two bulls and seven calves were also rapidly sinking. The entire stock on the dairy farm consists of twenty-nine cows, twenty-four calves, and four bulls, all of them being animals of great value. In concluding this report I cannot refrain from expressing my sincere regret that another supposed means of arresting cattle plague by Medical treatment should have proved abortive.

"I have the honour to be, Sir, your obedient servant,

"The Clerk to the Council. "Jas. B. Simonds."

In the House of Commons,

Mr. Hibbert asked leave to bring in a Bill to permit capital punishments to be carried out in the interior of prisons, under certain regulations, of which he gave a brief explanation.

Sir G. Grey, in acceding to the motion, intimated that a Bill was being prepared in the Home Office to give effect to the recommendations of the recent Commission on this subject.

Trichiniasis.—Outbreaks of this terrible disease keep occurring from time to time in Germany. One has recently occurred in Zittau, in Saxony, but unaccompanied by fatal cases, although as many as fifty-seven persons were affected after partaking of ill-prepared sausage-meat. Dr. Küchenmeister having no faith in benzine, recommends, in recent cases, equal parts of turpentine and sulphuric ether, with what effect remains to be seen. In two of these cases the trichinæ were detected by harpooning, and, as in other epidemics, children suffered least, while in several women menstruation was precipitated. In Görlitz, in Silesia, there has also been an outbreak, eighty persons being affected, but only one dying. All over Germany, either through the agency of the butchers themselves, whose trade is threatened with extinction, or more often by decrees of the various Governments, means are everywhere being organised for an effectual microscopical examination of the pork before delivery for sale

REVIEWS.

The British Army in North China and Japan: Peking, 1860; *Kagosima*, 1862. By D. F. Rennie, M.D., Senior Medical Officer of the Force in the North of India, late Surgeon to her Majesty's Legation, and to the Legation of his Majesty the Emperor of the French. London: John Murray. Pp. 408.

When it was determined in 1860 by the British Government that an expedition should be sent to China, Dr. Rennie volunteered his services, and this volume is one very agreeable result of their having been accepted. Arrived at Hong Kong, he was soon actively engaged, at first among the military Hospitals, and subsequently as Surgeon to the Legation. It is impossible to do more than to select a few of the strictly Medical observations, for every page contains anecdotes of great value as illustrating Chinese men and their habits, fighting scenes worthy of "our own correspondent," and all told with a freshness quite exceptional in diaries.

Dr. Rennie seems to have been surprised to find in the Moray Barracks *every one* of those sanitary defects, besides others of a totally local character, which had been shown a few years before by the Army Sanitary Commission to exercise so destructive an influence on the health and the longevity of the soldiers in England, and concluded that climate was often blamed for the results of defective Hygiene. Subsequently he seems to have found other causes—*e.g.*, on December 7 there had been a marked deficiency of ozone, and with it an increase of cases of neuralgia and ague. "December 9.—During the night a great increase of ozone had taken place, and as suddenly the neuralgic patients grew suddenly better; many quite well. March 7.—The electricity was coming down in an unbroken stream, and it appeared to exercise an injurious influence in several cases of sickness. In one chronic case there was great nervous disturbanee, which disappeared when the atmosphere recovered its normal condition. Undoubtedly the English soldier is rendered very susceptible to any morbid influence; loaded with ammunition so disposed as to require tight strapping over the chest, spleen, and liver, he suffers all the bad effects of tight lacing; sharing at night, with thirteen others, a bell-tent, which when occupied holds only 400 cubic feet of air, and living on a diet unsuited for the climate; while a residence in malarious localities, though not the special exciting cause, makes the soldier afterwards susceptible of certain atmospheric influences, subject to paroxysms of periodic disease. Another instance of atmospheric influence is given when the soldiers were at Tang-Koo, eating fruits and raw vegetables, and in an atmosphere of foul odours." Some very limited choleraic influence passed over the neighbourhood, and two soldiers separated from to three miles fell victims to it. Heat apoplexy, called *coup de soleil*, takes place chiefly at night or in cloudy days. When fever broke out among the coolies on the *Winifred* transport, the Chinese Doctor blamed "too muchee piecee men; too muchee piecee hot:" this is "pigeon" English, *i.e.*, business English. The Chinese seem apt phonetic scholars; Joss is the Portuguese Deos; and the scrawl on poor young Bowlby's coffin lid when read sounded Bo-bee. They seem to be expert apothecaries, and can powder camphor. They sell fish in the street preserved in three inches of ice; they steal the pots and pans up the chimney before the cooks' eyes, and we advise our readers to study their ways in Dr. Rennie's delightful narrative.

The second portion of the book is on Japan. From Shanghai Dr. Rennie proceeded to Japan in July, 1863. He gives a most pleasant account of this beautiful and little-known island, where the married ladies dye their beautiful white teeth black and gentlemen sit naked at their cafes; where shampooing is the monopoly of the blind, who shave their heads and wear a Doctor's dress, only they walk the streets ringing a bell, seeking employment, ready to use the *minimum*, *medium*, or *full power*. Dr. Rennie seems to have found both the first hard to bear, but they removed all sensations of fatigue. Tattooing is also a profession. Here Dr. Rennie had further proofs that cholera depends not upon worms in the stomach, as the Japanese think, but upon an electro-chemical change caused by atmospheric electricity coming in collision with some special condition of the electricity of the human body; in other words, the decomposition of the blood by the electrical agency transmitted from the atmosphere through the nervous system. Both parts of this compact volume are full of acute observation and suggestive remarks.

Researches on the Medical Properties and Applications of Nitrous Oxide. By George Ziegler, M.D., Physician to the Philadelphia Hospital, etc. Philadelphia: Lippincott. 1865. Pp. 66.

This pamphlet gives such an extravagant idea of the properties of nitrous oxide that men of more sober minds will probably be deterred from investigating its medicinal uses. It is, in fact, a laughable little book upon the laughing-gas. Not that the author intends to be amusing—far from it; but when a man tells us that nitrous oxide is a remedy for almost all diseases, he makes himself ridiculous.

Dr. Ziegler considers the uses of nitrous oxide under four heads—(1) Therapeutic and Hygienic, (2) Revivifying, (3) Antidotal, (4) Anæsthetic; and an unprofessional person, after reading a few pages, would suppose that at last an universal remedy had been discovered. What do our readers think of the following extract, which is taken almost at random?—"In comprehensive terms, nitrous oxide is a direct, potent, and permanent chemico-organic, arterial, nervous, cerebral, and general stimulant, secernent, depurant, aphrodisiac, and antitoxic, having a special tendency to the blood, brain, nervous system, and genito-urinary organs." The book abounds with such high-flown sentences as this. But, strange to say, this extravagant praise is not supported by any statistics; and only two cases are detailed, and those were cases wherein the use of nitrous oxide, as an anæsthetic, was followed by fatal results! Has Dr. Ziegler been experimenting upon himself, and was he still under the influence of the laughing-gas at the time he wrote this little book?

GENERAL CORRESPONDENCE.

THE TREATMENT OF CHOLERA IN INDIA.

Letter from Dr. Howard B. Montgomery.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have this day perused with the most marked surprise and regret an attack upon the Professional abilities of the Indian Medical Service as regards the treatment of cholera, and I solicit your permission to protest against it as at once unjust and unjustifiable.

The attack to which I allude is under the authority of Dr. G. Johnson, Physician to King's College Hospital, and Professor of Medicine in King's College. It may be found at page 165 of the *British Medical Journal*, published on Saturday last. Dr. Johnson says—"One effect of the theory, that collapse is a result of the drain of liquid from the blood, has been to change—nay, almost to reverse—the treatment of cholera in India; and the consequence of this change of treatment has been a great increase in the percentage mortality from the disease. Thus it appears from a Report on the Public Health of Bengal, referred to in a leading article in the *Times* of February 12th, that whereas in 1818 'not one-third of the cases of cholera proved fatal, we now find three-fourths beyond remedy.' This increase of mortality is attributed to the increasing virulence of the disease; but surely change of treatment has had great influence. In 1818, and for many years after, purgatives were very generally given by the Indian Practitioners, and the practice of venesection was common; while of late years, under the influence of pathological theory, purgatives and bleeding have been almost entirely discontinued, and brandy and opium have been largely substituted."

The writer of the foregoing sweeping censure is himself the author of a very remarkable (and, I believe, very erroneous) theory as to the pathology of the disease in question; but this does not in my opinion justify him in imputing to the implied ignorance or obstinacy of the Indian Practitioners such wholesale slaughter of human beings as is here indicated. It is, of course, to be regretted that any one should fail to meet Dr. Johnson's views as to the treatment of this and every disease; but I would respectfully suggest that Indian Medical Officers are not as incompetent as he imagines, nor am I, as one of them, disposed to sit silently under a censure the most sweeping and insulting that could be offered to a body of gentlemen whose abilities are thus denied in this assertion of their alleged malpraxis.

Dr. Johnson's statistics are vague, and by no means convincing; and although I am prepared to accord entire credit to the intended accuracy of all reports of the Bengal Sanitary Commission, yet, as I have not had an opportunity of examining the grounds upon which their quoted conclusion is based, I personally am of opinion that 750 per mille is largely in excess of the rate of mortality observed in cases treated by European Practitioners in India generally.

I may remark that Bengal is the least healthy of the three Presidencies, and that it has witnessed epidemics of cholera of exceptional intensity (*e.g.*, that at Mean Meer); it may be, therefore, that actual numerical accuracy may give rise to erroneous conclusions if taken to be universally applicable.

As to comparisons between statistics of 1817-19 with those of 1864-65, I hold them to be utterly useless. In the first panic of a new disease many analogous affections are likely to be confounded with it and wrongly classified, while increased experience will draw the line of demarcation more distinctly, and, in such a case as that of cholera, admissions will bear a smaller excess over casualties when diagnosis is more accurate. This explanation may possibly account for the very marked difference shown in the following table of Dr. Ewart's, which exhibits a decrease in admissions and an increase in mortality of persons attacked in the three Presidencies subsequent to 1835, 1836-37, and 1838 respectively: the ratio of deaths to strength, however, in Madras, is somewhat lower subsequent to than before 1838:—

Presidency.	Periods.	Percentage of admissions to strength.	Percentage of deaths to strength.	Percentage of deaths to admissions.
Bengal .	1818-35 . .	3·25	0·85	26·36
,, .	1836—53-54 .	2·62	1·04	29·75
Bombay .	1818-19—35-36 .	2·96	0·64	21·64
,, .	1836-37—53-54 .	2·44	1·003	41·11
Madras .	1829-1838 . .	2·7	0·74	27·10
,, .	1842—1851-52 .	1·2	0 64	50·2

Now, none of these returns give any support to the assertion of the high rate of mortality alleged as now existing in India. Without, however, questioning the general statement attributed by the *Times* to the Bengal Sanitary Commission, I may justify my own individual opinion by referring to a few more recent statistics regarding stations and troops under the Madras Presidency and elsewhere in India. Dr. Ewart (an Indian authority, and consequently, I suppose, in Dr. G. Johnson's eyes, incompetent) gives the following results regarding the mortality of Europeans from this disease (condensed from his "Vital Statistics," p. 147):—

Presidency.	Periods.	Admissions.	Deaths.	Percentage.
Bengal .	1818 to 1853-54	14260	4806	33·70
Bombay.	1818-19 ,, 1853-54	6781	2206	32·53
Madras .	1829 ,, 1851-52	4243	1478	34·83

The rates of admissions to strength were in the same order—2·87, 2·64, and 1·98. Bengal, therefore, ranks highest in frequency, and is the mean in mortality of the three Presidencies, according to these returns, but these tables do not include any returns later than 1854. But it would be idle to deny that cholera has almost universally been considered to show a tendency to prove more fatal during recent than in former years. One of the possible causes of this I have before alluded to, but a careful analysis of further facts will prove, possibly, a better means of fixing the cause accurately. Active service in the field, ill-ventilated barracks, bad drains or no drains at all, intemperance, and the like, all act as against the common soldier's recovery. Non-commissioned officers, officers, women, and children, show a less rate of per-centage of deaths to admissions than do the soldiers generally, and much less than that of the unmarried residing in barracks. From statistics now before me upon the experience of eight years, ending in 1854, it is plain that of every 1000 officers treated only 166·6 died, or 16·66 per cent., or about half the average mortality of troops from 1818 to 1854.

Now, these officers were treated by members of the Medical Profession in India, who have declined to bleed and purge their patients, and yet the mortality is far below that prevalent in 1818. Again, between 1838 and 1853 the average per-centage of deaths in the European General Hospital at Bombay, all the year round, was little more than 55 per cent. of admissions, and a less ratio obtained in a similar institution at Calcutta, from 1842 to 1852; and I believe European Hospitals in India have the worst class of cases ever seen.

But perhaps it would be a still fairer test of practice in India to select other exemplars of the results of practice of more recent date, so as to refute the sweeping and unjust condemnation of it pronounced by Dr. G. Johnson. I have hastily compiled from the records of the *Madras Quarterly*

Journal of Medical Science several tables showing the mortality, in Southern India and in Burmah, from cholera treated by European Medical officers. These returns comprise different classes, Europeans and natives, as may be seen from the column of Remarks. I may add that they are all in reference to cases occurring since 1857, and may be taken to represent modern treatment during epidemics of cholera by various methods.

Authority.	Admissions.	Deaths.	Percentage of deaths.	Remarks.
Dr. Griffiths .	7	3	42·8	Europeans, men, women, and children, 1863.
Dr. Sutcliffe .	44	26	54·5	21 Europeans and 5 natives died, in same proportion to those attacked of each class, 1863.
Mr. McTavish.	33	19	57·5	
Mr. Balfour .	196	80	40·8	Soldiers, native and European, 1857 to 1862.
Do.	292	159	51·3	Native prisoners, 1858 to 1863.
Do.	48	23	47·9	Gaols (native), 1862 and 1863.
Total . .	620	310	50·0	

The foregoing figures fall far short of the 750 per mille of the Bengal Sanitary Commission.

It would be useless to multiply statistics, if it did not seem desirable that, to vindicate the loudly-condemned ability of Indian Practitioners, I should quote from varied sources of recent information ; and some of the following returns show a state of mortality which I do not think likely to be reduced by even bleeding and purgatives in the hands of any one. The cases are chiefly those of natives in regiments and gaols :—

Authority.	Admissions.	Deaths.	Percentage of deaths.	Remarks.
Mr. Evezard .	17·	1·	5·8	Condy's disinfecting fluid, internally, stimulants, and counter irritation and nutrition.
Dr. Mackay .	6	0	0	Ditto.
Dr. Doyle .	46	15	32·6	Ditto, with astringents.
Mr. Fry . .	35	15	42·8	(Not known.)
Mr. Morgan .	131	67	51·1	Ditto.
Total . .	235	98	41·7	

Now, it is to be remembered that these are all cases of natives, and that the people of the Madras Presidency are more fatally affected than those of Bengal or Bombay, and the mortality among them from 1828 to 1838 averaged 45·1 of admissions ; it fell between 1842 and 1851 to 42·0, and it is here shown as 41·7. This is somewhat opposed to a progressive increase, as generally believed.

I will only add one further fact to show the results of treatment by the internal administration of turpentine, as recommended by Dr. Mudge, of the Madras Army, and as adopted by me when succeeding that officer in charge of a Civil Hospital in the city of Madras. The total number of cases treated by us amounted to 69, of the worst form of epidemic disease. Of these, 42 recovered and 27 died, or 30·9 per cent. It would be needless, however, on the present occasion to do more than sum up the results of the foregoing, which certainly show that a very much fairer estimate of actual average mortality would be 50 per cent.

But be the mortality what it may be, let our efforts be crowned with comparative success or eventuate in our worst discomfiture in the battle with disease, in the name of all that is just and Professional let us be henceforward free from such an attack as that against which I protest. We are not prone in India to abandon any line of treatment once adopted unless we find good reason to do so. Nor do we continue to pursue any line of treatment that we know to be unsuccessful. And, I may add, we are equally slow to adopt visionary ideas unsupported by argument and not based upon undoubted facts. We value life as highly in India as any at home can possibly do, and we spare no exertion to save it for our patients. The accusation that for thirty years or so we have been killing our patients from a change of practice is as hard to bear as a social insult, as it is a grave Professional error utterly without foundation. The hard lot that many of us have to bear through life there will not be lightened by such accusations as this one, for men accused are half condemned.

In order, however, to appreciate the utility or otherwise of treatment in any disease, it is essential that we should be informed what rate of mortality has been witnessed where no treatment, or treatment confessedly erroneous, has been alone resorted to.

The usual impression is, I believe, that of cases not treated 50 per cent. only will die, and if this were correct, then we should be compelled to acknowledge that European Physicians were singularly unfortunate in the results of their practice in India. But I believe that the foregoing estimate of mortality is far below the mark. The following is the only instance that I can find of such a state of things, and it is strongly confirmative of my own views, which are not recent, on this point.

At a village called Nuthum, epidemic cholera appeared, and was treated only by native Practitioners. The result was that 63 persons were attacked, and of these 50 died, or 79·3 per cent. Now, previous facts have demonstrated that practice in Madras shows a general average mortality of not more than 50 per cent. of deaths to admissions, so that Madras treatment exhibits in this instance a decrement of 29·3 per cent. of deaths to attacks. Perhaps no better illustration than this could be afforded that treatment does *some* good: that it does not do all we could wish, and that it still allows—or is powerless to prevent—a high rate of mortality, are and must continue to be painful facts. But even they do not justify such an imputation as that to which I have now replied.

May I venture to suggest to Dr. Johnson and others who, like him, are disposed to deny merit to all save their own immediate disciples, that Indian Medical officers are not quite so incompetent as he imagines, and that we can show a death-rate that is not indicative of any remarkable stupidity on our part? I find that in 1864 the total mortality of the Bombay Army was 13·36 per 1000 ; that of 1863 only 12·0, including in the former case 21, and in the latter 7, from cholera ; and the average mortality in this army for some years back falls below that "hoped for" if sanitary reform was efficiently carried out. The death-rate in the Bombay Army is that of an army 12,000 strong. (These figures relate only to Europeans.) Similarly in Madras, with a standing army of Europeans numbering about 14,000 men, the actual mortality from all causes is reported as follows :—

1860	19·17 per thousand.
1861	14·66 ,,
1852	17·09 ,,
1863	16·52 ,,
Average . .	16·86

It would prolong this paper too much were I to enter upon any discussion of Dr. G. Johnson's theories. My object is to protest against his extraordinary and unseemly attack upon a large body of gentlemen, his equals in position, and, I trust, his superiors in good taste, and to appeal to you, Sir, for some more generous estimate of Indian Practitioners than is revealed in the sweeping condemnation I have named, in which on insufficient data there is levelled against them an accusation of ignorance and incompetence that I know to be unjust and I believe to be untrue. I am, &c.

Howard B. Montgomery, M.D.,
Surgeon Madras Army.

16, Durham-terrace, Westbourne-park, W., Feb. 21.

P.S.—Since the foregoing was written, I have discovered that I have accidentally omitted the statistics of a very remarkable and fatal epidemic in the native gaol at Calicut, reported by Dr. Pearse. If this epidemic be considered, and the returns by Dr. Mudge, and some by Dr. Shortt, we get the following additional data :—

Authority.	No. of admissions.	Deaths.	Percentage.
Dr. Mudge . .	69	27	30·9
Dr. Pearse . .	140	91	65·0
Dr. Shortt . .	25	10	40·0

If these figures be added to those in a previous table regarding native patients, the average of the whole would approach very nearly the 50 per cent. estimated by me.

I cannot, however, omit to state that Dr. Pearse suggests, and I think with propriety, that the high rate of mortality at Calicut may in part be due to the fact that few trivial cases occurred at the end of the epidemic in consequence of what I may call arrestive measures having been adopted—viz., the removal of the great bulk of the prisoners from the infected locality, their consequent non-exposure to contagion, and the improved sanitary condition of the gaol (previously much overcrowded) as regards those continuing to inhabit it.

Preventive and *arrestive* measures are, in my opinion, the great points to which we should look; and if Indian Practitioners can show that the percentage of deaths to strength is steadily decreasing, they are giving evidence of a far greater usefulness to the State than any apparent lessening of the rate of mortality in those attacked would of necessity indicate.

That this was done in Madras between 1842 and 1852 I have already shown the proportionate deaths to strength being from 1829 to 1838 0·74 per cent., and from 1842 to 1852 only 0·64. But in 1862 it had fallen in the European force to 0·350 percentage of strength, and in 1863 to 0·309; while, among natives, the proportion was very much smaller.

So long, therefore, as a diminution in the net percentage loss of life and of admissions, as compared to strength, occurs, one grand object of our exertions is amply fulfilled; and if a progressive improvement can be carried out, it will in time extirpate the disease.

February 28.

ON THE DOSES OF ACTIVE MEDICINES.

Letter from Dr. C. R. Bree.

[To the Editor of the Medical Times and Gazette.]

Sir,—It is a very thankless office to find fault. More particularly is this the case when those with whom you differ are men in an eminent position. I am now, however, going to appeal to all practical men in the United Kingdom. The subject with which I am about to deal is posology, and the men with whom I am going to find fault are the editors of the new abridged edition of Dr. Pereira's "Materia Medica and Therapeutics."

Every one knows how great was the outcry when the new Pharmacopœia was published without a posological table. We have now got one by the editor of the Pharmacopœia, Senior Physician to St. Bartholomew's Hospital, and Lecturer on Materia Medica, assisted by the President of the Linnean Society, one of the first botanists of the age, and Mr. Warington, a distinguished pharmaceutist and chemist.

Such an array of names must carry great weight with those who put faith in names. At all events, their posological table comes before the Medical world, and is thrown into the hands of the young Practitioner, chemist, etc., with the stamp of authority. It ought to be unexceptionable. I believe it to be very faulty. The chief objection I find with it is, that the minimum doses are, in a great number of important cases, too large, and cannot be prescribed in practice as such without danger, even in one or two instances to life. I will quote some cases in proof of what I say:—

1. Acid. hydrocyanicum dilutum, min. iij. to vij. There are many people in whom three minims of this acid would produce symptoms of poisoning.

2. Aloe barbadensis, gr. iij. to v. A much smaller dose than 3 grains will act as an active aperient. In the preparation introduced by Dr. Christison into the British Pharmacopœia, viz., the Pil colocynthidis et hyoscyami, and of which the dose is given in the posological table as gr. viij. to xx., I have found a 2-grain pill usually quite sufficient. I have never given more than gr. iv., and this was Dr. Christison's practice. In this pill the pil. coloc. co. is made of Barbadoes aloes, the only way to take which drug is to unite it with the extract of henbane. Did any of the editors ever take three grains of Barbadoes aloes?

3. Aloe socotrina, gr. iij. to v. A very effectual purgative may be made by adding gr. $\frac{1}{4}$ of ext. nux vomicæ to gr. iss. of socotrine aloes. Three grains, as a rule, is too large a dose to begin with.

4. Ammoniæ carbonas, gr. v. to gr. xv. Two or three grains is a most useful remedy in some forms of dyspepsia.

5. Argenti oxydum, gr. $\frac{1}{2}$ to gr. ij. A quarter of a grain will, in nine out of ten cases, do as well as a larger dose, and with less risk of colouring the skin, which results from this preparation as well as the nitrate.

6. Atropia, gr. $\frac{1}{30}$ to gr. $\frac{1}{10}$! Minimum dose very much too large.

7. Capsicum, gr. v. to x. Minimum dose too large.

8. Ext. aconiti, gr. j. to ij. Ditto.

9. Ext. belladonnæ, gr. j to ij. Ditto.

10. Ext. hyoscyami, gr. v. to x. Ditto.

11. Ext. opii, gr. $\frac{1}{2}$ to ij. Ditto.

12. Ipecacuanha as an expectorant or sudorific, gr. j. A sixth of a grain will often answer every purpose.

13. Liq. morph. hydrochl., ♏xx. to ʒj. Minimum dose much too large.

14. Liq. strychniæ, ♏vj. to ♏xxx. Minimum dose gr. $\frac{1}{20}$ too large. It ought never to be more at first than $\frac{1}{40}$th of a grain.

15. Lobelia as an emetic, gr. x. to xx. Tinct. lobelia, tinct. lobelic æther, f ʒj. to ʒij. This medicine ought never to be given as an emetic, and the dose of the tincture is dangerously large.

16. Tinct. colchici seminis, vin. colch., f ʒss. to f ʒij. Minimum dose much too high. The maximum dose has been known to cause death.

17. Tinct. opii, ♏x. to ♏xl. Much good is often done by a much less dose than ten minims.

18. Zinci sulphas (as a tonic), gr. ij. to gr. x. Minimum dose too high. Maximum dose too low.

I am, &c.

C. R. Bree, M.D., Senior Physician to the Essex and Colchester Hospital.

February 14.

P.S.—Were I an examiner in the Practice of Medicine I would pluck any man who told me that he would use medicines in the doses given as minimum ones in this table.

AN EASY METHOD OF REDUCING ORDINARY DISLOCATIONS OF THE SHOULDER JOINT.

Letter from Mr. W. E. Porter.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the observations relative to "Reports on Fractures," etc., in your number for January 6 last, you say suggestions will not be unwelcome to you, I therefore send you the following:—

While a student at the London Hospital a dislocated shoulder was brought in, which great force failed to reduce. On pausing for a short time before adopting other means, one of my fellow students picked up the arm and gently manipulated it; while doing so the bone slipped into its place—how, none could say, but the dislocation was reduced. I thought of it a great deal, and came to the conclusion that the humerus, without the exhibition of great force, was a sufficiently powerful lever, when used as one to reduce an ordinary dislocation of the shoulder. Not long after I left the Hospital, and had to wait some time before I had an opportunity of testing my plan.

While acting as House-Surgeon to the Dorset County Hospital in 1856, a dislocated shoulder was brought in; it was a stock case, that is, it came frequently; but it must have been troublesome to reduce, as they always used pulleys for it, and the Hospital porter began getting them in order; I thought, however, I would try my plan first.

The patient was a moderately muscular man, at about the middle period of life, and having undressed him I laid him on a mattress on the uninjured side; kneeling behind him, I placed the palm of one hand firmly on the head of the scapula and the fingers in the axilla under the head of the humerus; with the other hand I grasped the condyles and pressed the arm to the side, then drew it backwards and thus got a better hold with the fingers engaged at the head of the bone; by the next movement I slid the arm forwards and depressed the elbow, at the same time rotating outwards, and lifting the head of the bone it immediately slipped into its place.

Since I have been in practice I have tried the plan three times on healthy, muscular young men, all first dislocations; in two I succeeded quickly and easily, and failed in one which had been done three days; the old way of the heel in the axilla was in this case after some difficulty successful.

I am, &c.,

Lindfield, Sussex, March 3. Wm. Elliott Porter.

GREENWICH HOSPITAL OUT-PENSIONS FOR NAVAL MEDICAL OFFICERS.

[To the Editor of the Medical Times and Gazette.]

Sir,—I perceive by a memorial from the Lords Commissioners of the Admiralty to the Queen, dated the 14th ult., that they have thrown aside the sectarian feelings which actuated them on the passing of the Greenwich Hospital Bill last Session, and appear disposed to distribute out-service pensions in a more catholic spirit.

You may remember that the noble and gallant Secretary of

the Admiralty resisted every effort that was made to have the claims of Medical officers recognised, and, notwithstanding the indefatigable exertions of Mr. Hennessy, Sir John Pakington, and others, he was successful in his resistance for the time.

Under pressure of a blank list of candidates for Assistant-Surgeoncies, the Admiralty have re-considered the subject of Greenwich out-pensions, and are now prepared to give to Medical officers a moderate participation in the same.

I shall not now criticise the very peculiar allotment of pensions to the different classes of officers, or the very exceptional privileges attaching to the ten pensions allotted to Flag Officers. Mindful of the great kindness shown to the Medical Department of the Navy by the *Medical Times and Gazette*, I am unwilling to trespass further on your space than by asking you to bring to the recollection of your readers Mr. Hennessy's services to our Profession in the last Session of Parliament.

I am, &c. A Naval Surgeon.

CONCUSSION OF THE SPINE.

[To the Editor of the Medical Times and Gazette.]

Sir,—When a boy about 14 years old, I was trying with others as to who could jump farthest from a waggon, backwards-way. In making a spring my feet caught, and I fell heavily upon the broad of my back on to the hard ground.

With a boy's impulse, I strove to rise, and succeeded in reaching, somehow, a stone that I could sit on—barely a yard from where I fell. On it I sat, unable to speak or to move a limb, and I could read, in the horror of my brothers' faces, how ill they thought me looking.

The fun was suspended barely for a minute, when the cry arose "Here's your father coming!" I could only turn my eyes to see how far he was off, and I shall not soon forget the mental process I went through, as to what could be done in about a minute and a half. I must either succumb—go to bed—have a Doctor—take some horrid jalap and black draught, or I must appear as sound as usual. I elected to man myself, and just as my father came up to us I rose and joined the group: all kept my secret; and "Tom, you look pale; is anything amiss?" was all I heard. My reply was simply that I had fallen and hurt myself, but was better now; and then with the party I proceeded, and to walk for a considerable distance, every minute improving my condition.

I have often looked back to this accident, and to certain others I have since met with and read of,—notably, the murderous attack of Mr. —— upon Captain ——, near Hungerford-market, and asked myself—"What does the Doctor mean by "spirits?" I remember how in Fitzjames' case—

——— "To his heart
The life-blood went with thrilling start,"

yet how he

"Manned himself with dauntless air,
Returned the chief his haughty stare."

I can recal the horror of the sight of blood, so common amongst young Surgeons, and the vigorous efforts I made to prevent myself from fainting. I can recollect how fear has seemed to paralyse my muscles until the strong effort of "will" not to be overcome has forced them to obey my orders. Thinking of all these points has led me to the conclusion that there is the same difference in the "spirit" of men as there is in the "blood" or "breed" of horses and dogs. That some men, women, and children when knocked down, mentally or bodily, will lie till they are picked up by somebody; that other men, women, and children won't be knocked down at all if they can help it without instantly rising again. What the power of "will" is—how it comes, how it operates, how it is to be cultivated—must be understood ere we can form trustworthy opinions respecting the result of railway or other accidents, or understand the effects of fright, etc.

Had I been a "soft" fellow, had the family Doctor been a pleasant one, had I wished to escape school, I might truthfully have made out my case, as above, to have been a very bad one. A person may appear an impostor, or hysterical, simply because he has not the desirable amount of

Pluck.

Dr. Dauglish.—This gentleman, who was distinguished as the inventor of a peculiar process in the manufacture of bread, has lately died intestate, leaving personality to the amount of 25,000*l*.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ANNIVERSARY MEETING.—March 1, 1866.

James Alderson, M.D., F.R.S., President.

The President declared the ballot for the election of officers and Members of Council for 1866-7 open for one hour, and nominated Dr. Markham and Mr. G. Gaskoin scrutineers.

The Auditors' report was then read.

Dr. Webster moved the adoption of the Auditors' report. He said the financial condition of the Society was most satisfactory, and remarked on the minuteness with which the accounts were kept. There was an item of 8s. for fines, and one of 10s. 6d. for old brass. Dr. Webster spoke with approval of the fact that half the expenditure for books was for foreign books.

Mr. Partridge seconded the motion.

Dr. Pitman said that Dr. Webster had probably forgotten that comparatively little was spent on English books because (from the liberality of Authors) many were presented to the Society.

The Report of Council was then read. After congratulating the Society on its prosperity, and on the unusually large number of Fellows elected, the Report gave an account of the present number of Fellows, stating changes by death, elections, and resignations. The financial condition of the Society appears to be very satisfactory. The Society has funded £500, and has carried £190 to next year's account. The sum now standing in the names of trustees is £4816 11s. 5d. There have been large additions to the library,—350 books, exclusive of continuations—182 presented, 168 purchased; 191 of these were English, 159 foreign. Dr. Ashburner had given sixty-one volumes on the early and later history of Mesmerism. Mr. Curling, who, to quote the words of the Report, has repeatedly laid the Society under similar obligations, had presented a rare and beautiful medallion executed in ware in 1788 of Dr. Joseph Black, the Professor of Chemistry in the University of Edinburgh. The thanks of the Society were due also to Sir Rutherford Alcock for a portrait of his father—an oil painting by Haydon—and for an oil painting by Mr. Inskipp, a portrait of Sir Rutherford himself. After speaking of special additions to the library, the Report says:—"The librarians, however, report with regret, and in the hope that this notice may attract the attention of the Fellows, that very few additions have been made to the Society's collection of photographic portraits of its Fellows and to the photographs of pathological specimens." Two committees had been appointed—one to report on the subject of "Hypodermic Injections," and the other on "Electricity in the Treatment of Disease."

The result of the ballot for officers and members of Council was then announced by the President:—*President*—James Alderson, M.D., F.R.S. *Vice-Presidents*—*Patrick Black, M.D.; *Henry Bence Jones, M.D., F.R.S.; *Prescott Gardner Hewett; *Charles Hewitt Moore. *Treasurers*—Henry Alfred Pitman, M.D.; *George Busk, F.R.S. *Secretaries*—*Henry Hyde Salter, M.D., F.R.S.; *George Green Gascoyen. *Librarians*—Alexander Patrick Stewart, M.D.; *Charles Brooke, F.R.S. *Other Members of Council*—Andrew Whyte Barclay, M.D.; Edmund Lloyd Birkett, M.D.; *John Clarke, M.D.; *Patrick Fraser, M.D.; *Richard Quain, M.D.; *James Dixon; *Edwin Humby; *John Abernethy Kingdon; *John Marshall, F.R.S.; Alfred Poland. Those gentlemen to whose names asterisks are prefixed were not on the Council, or did not fill the same office, last year.

Mr. Charles Hawkins moved the adoption of the Report. He said that, unlike Dr. Webster, he was not enamoured of large balances, and did not think that the present members of the Society should save money for people who came after them. After taking away the sum received for letting lodgings, there was a balance of five hundred pounds for books. He thought more ought to be laid out on English books, and he added the Society was quite rich enough to buy them. He thought the library ought to be not simply a Medical library, but that it should also contain books on Science, and books bordering on scientific subjects. Again, he could see no reason why the present members should remain stewing in

that room in order that those who came after might find a large balance. In latter years, Mr. Hawkins, said the Anniversary Meeting had been held in the evening; he thought it would be better to hold them, as they used to be held, in the afternoon. It was only fair to do this, in order to insure a proper attendance as a compliment to the President.

Dr. Fraser, in seconding the resolution, said that he quite agreed with Mr. Hawkins that the Society was rich enough to buy English books, and ought not to depend on the generosity of authors.

The President remarked that the observations of the speakers would be borne in mind by the Council. He added that a small balance would prevent the Society from ever leaving its present room, as the sum asked for a larger place was much greater than their present balance.

Dr. Pitman then moved the alteration of one of the bye-laws, the resolution being "That the words *Fellows, Members, and Licentiates* be inserted in the place of the words *Fellows and Members*." The law, as it stood, excluded Licentiates, and the object of the resolution was to enable them to be proposed as members.

The resolution was seconded by Dr. Barnes.

Mr. Partridge asked if the rule thus altered would not include those who might be licentiates in special branches only, as for instance licentiates in Dental Surgery, Midwifery, etc.?

Dr. Pitman said it was not contemplated to include those who were licentiates in special branches merely.

Dr. Sankey asked if Masters in Surgery were included?

Mr. Charles Hawkins thought such an alteration ought to have been brought forward by the Council, and that the law should be worded so as to include all legally qualified Medical men. He remarked, too, that he thought the rule limiting the number of General Practitioners to one-third should be abrogated. He thought any one on the Register should be allowed to be a candidate.

Mr. Partridge would second Mr. Hawkins' proposal.

Dr. Pitman said that many Medical men did not think it worth while to register, and that there were many Fellows of the College of Physicians whose names were not registered. Mr. Hawkins' proposal, therefore, would exclude some properly qualified candidates.

Mr. Hawkins meant to say that any one, either properly qualified or registered under the Act, should be eligible. He thought, however, that Dr. Pitman's motion might be taken as a step.

Dr. Pitman's motion was then carried.

THE PRESIDENT'S ADDRESS.

The President said he had first to fulfil the melancholy duty of speaking of the Fellows who had died during the past year. He selected the more prominent characters and grouped them, so as not only to bring forward their merits, but to deduce lessons from their career which might be useful to the living. He mentioned especially Dr. Ferguson, Physician Extraordinary to the Queen, his extensive practice and his general accomplishments, which made him welcome in the best society. Somewhat as an antithesis, he mentioned Dr. King, of Eltham, who was also a highly successful Practitioner and who was the object of the deepest attachment, and was satisfied with no more brilliant reward. Among the the honorary Fellows he particularly mentioned Mr. William Hooker and the greatly lamented Mr. Brande, and concluded his notice of the departed by referring to the obituary, paying a tribute to those whose less prominent career may not have been less useful and less happy and their loss not less deeply regretted. He then referred to the Congress to be held at Constantinople to inquire into the circumstances connected with the introduction of cholera into Europe, and trusted that the investigation might throw some light on the epizootic now present, and proceeded as follows:—"Many will be sorry to observe how this visitation is being treated under a sort of panic by the Legislature, with less regard than might have been desirable to the amount of knowledge which we already possess, or to the sensible deductions thence to be derived. I have no doubt that you, the Members of this Society, are too enlightened to fall into the peculiar notions adopted by the general public about this cattle disease, or plague, as they are pleased to call it; that you all perceive the futility of hunting for specifics, of trying to identify it with diseases of the human constitution, and of believing in its importation and propagation by contagion as the only cause. All these fallacious views seem to blind the Legislature as well as the public to facts which are clearly established. These facts are, that the cattle disease, like cholera, follows a certain course, which is undeviating in its direction, though the visitation skips over some localities; that the disease also, like cholera or any other epidemic, abides only for a certain period in each locality, and that it is most virulent and unmanageable at the beginning of each outbreak, and becomes amenable to simple treatment, or any treatment not positively injurious, towards the end of its presence in each place, whilst the ultimate cause of the disease and the law of its progress are unknown to us. All these facts display the fallacy of pretending to stop or exterminate—that is, in the presumptuous phraseology of the day, 'to stamp out' the disease by means of preventing contact; and the same facts testify to the sad want of judgment in sacrificing stock, and adding inconvenience to the farmers' loss, in order to obtain an end which, according to the knowledge which we possess, is obviously impossible. None will, of course, deny that there is a certain amount of power to communicate the disease by what is termed contagion or infection, and that moderate precautions to avoid needless contact are wise and good; but it is plain that when the best is done in this direction the laws of transmission and duration will defy all Orders in Council and all Parliamentary enactments either to obtain immunity or to effect 'stamping out.'" The President then congratulated the Society on the success of the past session, and on the character of the communications, as well as of the discussions which followed—discussions which had been conducted with the utmost amenity as well as advantage to Medical knowledge. He expressed a hope that more papers would be introduced on scientific subjects collateral to Medicine, and hinted that many of those which were laid before the Royal Society would find a more appreciating audience in the Society he was addressing. He concluded by referring to the Committees established in 1862, and on the valuable matter contained in the Reports of those of 1862 and 1864. He did not doubt that the two now sitting would be equally successful; that the records of these Committees would prove enduring memorials of the Society's vitality. He congratulated himself on having the honour of being President of a Society which is animated with the true spirit of inquiry, and follows out its object with willing and united feeling.

Mr. Curling moved a vote of thanks to the President for his able paper, with a request that it should be printed. To one point Mr. Curling said he might be permitted to refer. The President had spoken of the reputation of the late Mr. James, of Exeter. For his (Mr. Curling's) part he should have pointed out the present Mr. James, the father of the Mr. James lately deceased, as the Surgeon whose reputation had made the name James famous.

Mr. C. H. Moore cordially seconded Mr. Curling's motion. He remarked on the genial personal influence of the President in the Council as well as in the Society.

Mr. Brooke proposed, and Dr. Gibb seconded, a vote of thanks to the retiring Hon. Secretaries—Dr. Fuller and Mr. Birkett.

Dr. Fuller said the work had been a labour of love; they had both endeavoured to do their duty. He was pleased to be able to refer to the flourishing state of the Society. In leaving his office he wished to bear testimony to the very valuable services of the Sub-Librarian. It would, Dr. Fuller said, be very difficult for the Secretaries to get through their work were it not for the efficient aid of Mr. Wheatley.

Mr. Birkett had had great pleasure in performing the duties of the post he was about to leave. There was one point on which he would take the opportunity of commenting. He thought a little change was required in the manner of conducting the meetings of the Society. He thought it would be well to hold exhibitions of instruments. This would encourage instrument makers to send instruments.

The Italian Parliament.—The Chamber of Deputies of the present Italian Parliament numbers ten Medical Practitioners among its members, and the Senate seven—in all, therefore, seventeen members. The Italian Medical journals congratulate themselves upon this accession of strength, believing that all questions relative to Hygiene, public education, and the penitentiary system will have a much better chance of being thoroughly discussed; while the hard conditions which the Municipal bodies, especially the Tuscan, make with their Medical *employés* will be thoroughly inquired into.

OBITUARY.

JOHN CONOLLY, M.D.

EARLY in the morning of Monday, March 5, there passed to his everlasting and long-desired rest, after a few hours of illness, one whose name will always be identified with a great and noble work. JOHN CONOLLY, to whose earnest convictions, faithful perseverance against all difficulties, and zealous labours, the modern humane treatment of the insane mainly owes its practical origin and its consummate triumph, is henceforth only a name in history. But if there is a good title to the gratitude of mankind in the alleviation of infinite human suffering—if there is a title to immortal fame in the faithful performance of a great and good work of reform, the memory of which must last as long as human sympathies endure, then his is a name which the world will not let die, and his a glory of which nothing ever can bereave him. He made the best part of a life having many vicissitudes a noble part of human progress: by his death individual ties and sympathies, virtues and foibles, all fall away, and the greatness of his life, standing more clearly out, becomes the concern, as it is the gain and honour, of mankind.

The late John Conolly, M.D., was born at Market Rasen, in Lincolnshire, his mother being of the name and family of the present Laureate. His father dying when he was only a few years old, he was early sent from home to school; and often and earnestly in after life did he revert to the dreary misery of that period, in which the semblance of learning was mechanically imparted by aid of frequent punishments. That he had obtained by stealthy purchase some volumes of the *Spectator* and a copy of the "Pilgrim's Progress" were gleams of bright reminiscence of that dark period; and he read and re-read the essays of Addison with a delight to which he ever loved to recur, and which we may well understand in one who wrote as elegantly and correctly as he always wrote. It may well be, indeed, that the influence of Addison's easy and graceful style contributed to the formation of his own correct taste in composition; for to the last scarce anything more offended his refined sensibility than coarseness and slovenliness in the expression and structure of a sentence.

Soon after leaving school, and when not yet eighteen years of age, he entered a Militia Regiment as ensign, and was stationed at different places both in Scotland and Ireland. The life of thoughtless pleasure and reckless excitement, common at that time amongst the officers of a regiment, could not fail to be for a time attractive to a young ensign of lively and impulsive temperament, with a passionate love of genial social intercourse; but it marks the superiority of his mental culture, as well as the skill of the pen which has often pleased and instructed the readers of this journal, that other officers used commonly to have recourse to his help to compose their important letters. Not long after leaving the regiment, and when only 22 years of age, he married, and went with his wife to France, where in a beautiful cottage near Tours, afterwards occupied by the poet Béranger, he passed in unheeding enjoyment the happiest year of his life. But at the end of a year, and when a child had been born, it became necessary to think seriously of adopting some profession or other regular means of livelihood. After consulting friends, one of whom was the amiable Dr., now Sir Arnold Knight, he resolved to commence the study of Medicine at Edinburgh. Leaving, then, behind him, with natural reluctance, his beautiful cottage and the unmingled poetry of life, he set forth with his wife and child to Edinburgh, and began in earnest the work of a Medical student. It was a great and dreary change, but its weight was lightened by the friendly hospitality of many of the illustrious men who at that time adorned the northern capital, and who were attracted to the student by the amiable disposition, courteous manners, and refined culture which distinguished him through life.

On graduating as a Doctor the subject of his thesis was "Insanity;" his attention being thus early occupied with the subject which was to be the field of his future labours and triumph. It will be erroneous, however, to suppose that he then foresaw the future scope of his work, or that he had any definite aim which he proposed to himself to work for. No man who has done anything great in the world of practical activity ever had such pre-determined aim, though he might think so afterwards; there is much blind struggling, amidst shifting uncertainties and untoward circumstances, before the appointed man and his work come together; and it is that which lies deep in his nature, that which is beneath will and beneath consciousness, and of which he can give no account; that unconsciously impels him on his course, and inspires him with the faith necessary to success.

On leaving Edinburgh, Dr. Conolly first went to Lewes, with the object of there settling in practice, but moved after three months to Chichester, where, about the same time, the late Sir John Forbes established himself. Their short rivalry was the foundation of a lasting friendship, and they were afterwards associated together as joint editors of the *British and Foreign Medical Review*, and with Dr. Tweedie in the production of the *Library of Medicine*. But Chichester was not equal to the support of two Physicians, and Dr. Conolly, after residing there a year, removed to Stratford-on-Avon, where he practised successfully for several years, and accomplished much literary work. Here, too, he enjoyed the friendship of the great Whig scholar and champion, Dr. Parr, the severest of schoolmasters, but the most kind-hearted of men. Leaving Stratford-on-Avon to assume the Professorship of the Principles and Practice of Medicine at University College, London, he established himself in Gloucester-place, and was during the time of his residence in London one of the most active members of the "Society for the Diffusion of Useful Knowledge." But as practice did not come sufficiently quickly, and as divisions existed in the councils of the college, and bickerings and heart-burnings within its walls, while no Hospital had yet been built, he resigned his appointment, after holding it for three years, and returning to the neighbourhood of Stratford, settled at Warwick. It was after he had been there six years that the office of Resident Physician to the Hanwell Asylum became vacant, and that he applied for the appointment; being defeated only by the casting vote in favour of Dr. Millingen. But a year afterwards the office was again vacant, and his second application was happily successful. And now at last, after many wanderings and much suffering, he had found the true sphere of his labours: he was appointed Resident Physician in June, 1839, and in September of that year every form of mechanical restraint had been banished from the Asylum. It was some time before the non-restraint system was generally accepted as practicable; much opposition had to be encountered and overcome; but the experiment made on so large a scale in an institution containing nearly a thousand patients, suffering from every variety of insanity, proved beyond all question not only the entire practicability, but the great benefit of the humane system of treatment. The complete record of its progress is contained in the admirable Reports of the Hanwell Asylum from 1839 to 1844. In the latter year Dr. Conolly resigned his appointment at the Asylum, but continued to devote his energies to the promotion of every good scheme having for its object the improvement of the condition of the insane. In conjunction with the late Dr. Reed, he was an active promoter and the constant supporter of the Idiot Asylum at Earlswood; and his warmest desires were fixed on the establishment of long and sorely needed public asylums for the poor insane of the middle classes.

Though it may justly be thought, perhaps, that one who did so much for the world was not adequately rewarded by it, when others who have not deserved so well have received great rewards, his services were not entirely unrecognised. A magnificent testimonial, consisting of a massive silver group of allegorical figures, together with his portrait, was presented to him in 1852 by public subscription; and in the same year the University of Oxford conferred upon him the degree of D.C.L. But his highest testimonial is the noble work which he has accomplished, and his highest honour will be in the grateful recognition of foreign lands and of future ages.

Of his literary works we cannot speak at length now. They are well known both in this and other countries; his book on the "Construction and Management of Lunatic Asylums" is a standard work of authority, and his little work on "Hamlet," published two years ago, is one of the most graceful, learned, and philosophical essays that has ever proceeded from any pen. His extremely polished style, the careful construction of his sentences, the elegance and precision of his language, make whatever he wrote most interesting to read.

During the last few years of his life he had, in consequence of failing health, gradually retired from active practice; and daily occupied in the study of classical authors, English and

Latin, he awaited with equanimity the great change. He had so lived that when the summons came he could meet it, not in fear and trembling; but, sustained by the consciousness of a good work well done, he willingly approached his grave as one who, the long day's task over, "wraps the drapery of his couch about him, and lies down to pleasant dreams." His end was sudden, as he had ever prayed that it might be; and his intellect was perfectly unclouded until close upon the fatal termination, as he had hoped with an exceeding earnest hope that God would grant it might be. A sudden attack of hemiplegia was followed by severe unilateral convulsions, and in a little more than two hours he entered on his everlasting rest. He was 71 years of age.

"After life's fitful fever he sleeps well."

WILLIAM OWEN LUCAS, ESQ., M.R.C.S.

Death has just closed, at the age of 78 years, the career of a man whose loss will be widely felt. Mr. Lucas breathed his last on Sunday, the 25th ult., at his residence, Taunton-place, Regent's-park, from a sudden attack of epileptiform apoplexy, resulting from albuminuria. He was suddenly seized in church at the conclusion of the service, and never recovered consciousness.

He terminated a bright career of honourable and exemplary usefulness; and it is consolatory to his friends to reflect that the last act of an upright and unsullied life was that of prayer and thanksgiving in the temple of God. He was a man especially remarkable by his high tone of Professional conduct and feeling, and well worthy of the intimacy he enjoyed through life with most of the leading members of our Profession in London.

His manly and independent character, and genial manners, together with a thorough practical knowledge of his Profession, secured to him an extensive practice. While in private life he won the esteem of all who knew him—kindhearted, generous, and sympathising—he was always to be found foremost where any good was to be done, combining the integrity and courtesy of the gentleman with the kindness and affection of a friend.

"For worth he had ever a hand and smile,
And for poverty his purse and a tear."

BOOKS RECEIVED.

Transactions of the Obstetrical Society of London. Vol. VII. For the Year 1865. With a List of Officers, Fellows, etc. Pp. 335. London: 1866.

*** This society continues to flourish, and the papers contained in the volume before us testify to its practical value. Dr. W. S. Playfair gives notes of a case of extra uterine fœtation. The tumour occupied the left hypogastrium. Potassa fusa was applied with the view of forming an aperture through which the fœtal structures might possibly be extruded. The patient, however, died. A cyst was found full of adipocere, studded with portions of fœtal bones. Mr. Wills, of Totnes, Devon, gives a case of double monstrosity, with account of the delivery. Two *left* feet protruded. Mr. Wills, assisted by Mr. Owen, placed the patient under chloroform and extracted two male children, attached face to face. The mother made a good recovery. E. Parson, M.D. Lond., gives a case of embolism of the pulmonary artery after ovariotomy (*embolism* means, entomologically and by usage, not the formation of a clot, but its being cast off and deposited in a vessel), beginning soon after the operation and causing death on the fourth day. Mr. Parson considers that the slowness of death was due to the clot being tubular and allowing blood to pass for a time to get into the lungs. He considers this might have been diagnosed before death. Albert Napper, Esq., of Cranley, describes a case of amputation of the upper arm under chloroform in the seventh month of pregnancy. The woman made a good recovery, and was subsequently delivered safely. This case is very valuable to practical Surgeons, as the question of operating during pregnancy is often a difficult one to decide. The annual address of the President, Dr. Henry Oldham, contains much of importance to Accoucheurs, especially his remarks on the necessity for an improvement in sick nurses. Dr. Greenhalgh exhibited a polypus of unusual size, and insisted on the desirability of cutting them away *in situ*. Dr. Bathurst Woodman, specimens of fibroid tumours, illustrative of the connexion between unfruitful sexual excitement and these growths. He also describes a case of chancre on the os uteri. The patient died of anæmia: the post-mortem appearances are carefully given. Mr. I. B. Brown recommends the actual cautery as a means of arresting bleeding from the pedicle as likely to lessen the dangers of ovariotomy. Dr. Snow Beck considers that the phenomena of puerperal fever may be produced by poisons introduced into the general system; that the uterine secretions would supply the poison, and the open sinuses of an imperfectly contracted uterus would admit it. He gives two cases to prove these deductions. Gives an able sketch of the present position and duties of the obstetrician. From New Zealand Mr. John Rouse sends the recovery of a still-born child, with a marking of the skin simulating the effects of an injury over the larynx, which might, under other circumstances, have been suspicious; it was covered with unbroken vernix caseosa. Mr. A. Harris, Camborne, Cornwall, gives a curious account of a membrane expelled from uterus a few days before delivery at the full term. Dr. Graily Hewitt and Dr. Meadows, after examination, consider the only explanation is that the woman has a partial or complete double uterus. Dr. Roper, of the Maternity Charity, has been led to the conclusion that labour in primiparous women late in the reproductive period of life is not so difficult as most obstetricians seem to believe. Dr. Alfred Meadows endeavoured to relieve a case of imperforate bowel by operation, but though the knife was passed up for an inch or more, it failed to reach the gut, and the child died. Mr. W. Gayton describes minutely a case of monstrosity born in the eighth month. Dr. Braxton Hicks contributes two cases of mento-posterior face presentation. Dr. Marion Sims figures a new curette for uterine fungoid granulations, made by Mr. L. Mayer, with a moveable joint in the shaft, which is a great improvement. Mr. King Pierce, a description, with a graphic illustration of a fœtus lacerated transversely at birth; also an elaborate report on the same by Drs. Meadows and Harley. Mr. Hammet Harley, F.L.S., figures an anencephalic infant who lived for seven hours. The mother had been frightened by an erotic idiot. Dr. Rash gives a case of œdema of the lower half of the body after a fall during pregnancy. Mr. Lawton's erectile tumour in the sheath of the funis is interesting. An engraving from Professor White, U.S., at p. 217, of the section of a pelvis, does not resemble the pelvis of females in Europe, and is calculated to mislead students. Dr. Greenhalgh's careful description of a distorted pelvis contrasts well with it. Dr. Aveling has a good case of ovariotomy, with remarks on the treatment of the pedicle. Dr. Uvedale West describes and figures very beautifully a form of battledore placenta. Professor Berry gives remarks on two cases of obstructed labour. The volume ends with an elaborate paper by Dr. Greenhalgh, on the Cæsarian Section and Craniotomy, and a catalogue of obstetric works in the Society's library.

The Medical Record: a Scientific Monthly Journal of Medicine and Surgery. No. I. New York, March I, 1866. Four dollars per annum. W. Wood and Co., Publishers, 61, Walker-street, New York.

*** Contains original communications from W. H. Van Buren, Gordon Buck, Austin Flint, Alfred Port, E. Williams, and other men of great ability. May we ask our Professional *confrères* in America why they do not discountenance the wholesale kleptomania of their booksellers? Why should the works of English authors be appropriated without consent and remuneration? Americans who travel say that it is because of the profligate and disreputable class who attain political powers; but surely a learned Profession should be above such a practice. If an American Physician or Surgeon wants a book by Syme, or Tanner, or Hughes Bennett, why not get an authentic edition, and refuse to countenance piracy?

Bulletin de L'Académie Royale de Médéeine de Belgique, Année 1865. Deuxieme Serie. No. 10. Bruxelles, 1855. Pp. 922.

*** With the public register appended. Begins with an address by M. Warlomont, on the Duties of the State towards the Widows and Orphans of Medical Men who have fallen Victims to Duty in Cholera Epidemics. A Paper on Pleuro-pleumonia in Cattle, by M. Maire, and several other papers.

Journal de Médécine Mentale, etc., etc. Par M. Delasianne. Tome VI. No. 1. January, 1866. Paris: Masson and Son.

*** A paper on Mental Pathology; one on Medical Jurisprudence, by M. Pegrat; and on Suicide by Dr. Lemclaigne.

The Negro in Jamaica. By Commander Bedford Pim, R.N. Pp. 72. London: Trübner and Co., 60, Paternoster-row. 1s.

*** Consists of two parts; one, the African considered ethnologically, full of interesting and important research. Part II.—The African in the New World, which considers the Negro's position as a man fairly and rationally, and a clear and philosophical paper. Part III.—On the Past and Present Condition of Jamaica, worthy of the deepest attention of all persons in that beautiful, unhappy island.

A Dictionary of Science, Literature, and Art, comprising the Definitions and Derivations of the Scientific Terms in General Use, etc. Edited by W. T. Brande, D.C.L., and the Rev. G. W. Cox, M.A. London: Longmans. Part VIII., completing the Second Volume.

ARMY AND NAVAL MEDICAL SERVICES.

ABSTRACT OF THE REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WHOLE QUESTION OF THE RANK, PAY, AND POSITION OF THE MEDICAL OFFICERS OF THE ARMY AND NAVY.

(Concluded from page 240.)

Medical Officers of the Navy.

The Committee having met to consider the rank, pay, and position of Naval Medical Officers, the Chairman stated that Captain Henry B. Phillimore, R.N., had been appointed a Member of the Committee, and would attend in the place of Lord W. Paulet, K.C.B., on the inquiry respecting the Medical Officers of the Navy.

The Evidence and Report of the Royal Commission in 1840 on Navy and Army Promotion; and

The Evidence and Report of the Committee of the House of Commons on the Navy Estimates in 1848;

were added to the other papers already on the table.

A memorial addressed by the Royal College of Physicians, dated the 12th July, 1865, to his Grace the Duke of Somerset, First Lord of the Admiralty, pointing out the "general and settled feeling of discontent with their condition which prevails among the Medical Officers of the Navy;" and "that it is highly desirable that the Medical services of the Army and Navy should be assimilated as closely as their relative nature will admit in rank, pay, position, and retirement," was read; also three letters respecting that memorial, from Dr. Bryson, C.B., Medical Director-General of the Navy, to the Lords Commissioners of the Admiralty.

At the commencement of the inquiry into the condition of the Naval Medical Service, the Committee was informed by Dr. Bryson that he experiences the very greatest difficulty in obtaining young men to join the service; and that at present he has only three candidates on his list, while upwards of forty Assistant-Surgeons are required to supersede Surgeons employed in lieu of Assistant-Surgeons, to fill up vacancies, and to provide for the common exigencies of the Service.

Deeply impressed with the gravity of this condition of the service, the

Committee have in the first place endeavoured to discover the reason for so great a deficiency of candidates, and from the evidence brought before them have come to the conclusion that it may be referred chiefly to the following causes :

1. The Committee was informed that when the Royal Medical Warrant of 1st October, 1858, became known to the Lords Commissioners of the Admiralty, they obtained an Order in Council, dated 13th May, 1859, and in the same month issued a Circular Order conferring rank, pay, and retirement on Naval Medical Officers, on the same terms as were granted to Army Officers.

It is alleged that the non-fulfilment of this Order in Council in some of its provisions has acted prejudicially to the interests of the service, by deterring Medical candidates from entering the Naval service, and that the professors at the various schools have dissuaded students from doing so.

The existence of this alleged grievance, and the unfavourable impression produced by it upon Medical teachers and students, and consequently its prejudicial effect upon the service, appears to be fully established by the evidence before the Committee, and it is also confirmed by Dr. Bryson in his letter of the 9th August, 1865.

2. A second reason may be sought in the fact that, although the number of Surgical diplomas from the Colleges of London, Edinburgh, and Dublin has apparently increased during the last ten years, the general impression of Medical gentlemen is that the actual number of Medical students has decreased or not kept up with the large increase of the population.

3. A third reason for the deficiency of Medical candidates for Her Majesty's Service, and one which would seem to be of great force when taken in conjunction with the foregoing, is the wider field which of late years has been opened for Surgeons, both in this country and abroad, in emigrant ships, and in the service of the large steam navigation, mining, and other companies, and in the colonies, etc.

Her Majesty's Service therefore is necessarily brought into a much more severe competition with the general public demand for Medical men than was formerly the case.

Exclusive, however, of these considerations, the Committee are led to believe that a general opinion prevails at the Medical schools that the Naval service does not hold out the same inducements, nor the same prospects as the Army Medical service; that, independently of the personal and social discomforts which are inseparable from a sea life, and which are especially experienced by young men on their first joining the naval service, the pecuniary and social advantages are in favour of the military service; and that young men, in the choice of a profession in which their future prospects are so materially involved, naturally prefer that service which appears to them to hold out the greatest advantages. That this is the case appears to be confirmed by the fact that, whilst the army obtains as many Medical officers as are required, the navy does not secure the requisite number of candidates for the service, and many young men resign their appointments to seek other employment.

The contrast between the two services with respect to the relative rank, pay, allowances, and position of the respective Medical officers is shown in the following statement of particulars; and from returns which appear in the Appendix it was ascertained that, although the full and half-pay and retirement are the same, there are certain differences in pecuniary and other allowances between the two services disadvantageous to naval Medical officers.

1. For instance, by the Royal Warrant of October 1, 1858, and the Order in Council of May 13, 1859, it is stated that there shall be four ranks of Medical officers, namely :—

Inspector-General; Deputy Inspector-General; Surgeon, who after twenty years' service shall be styled Surgeon-Major in the Army, and Staff-Surgeon in the Navy; Assistant-Surgeon. But in the Army the Surgeons-Major have not only been put on a separate list, but promotion to that list has been made by Royal Warrant, virtually establishing "Surgeons-Major" as an additional or fifth rank.(a)

In the Navy no such distinction has been made, either in respect to a separate list of Staff-Surgeons, or a distinct rank, the Order in Council only admitting of the four ranks. This difference of practice gives the army service an advantage.

2. The Assistant-Surgeon of the Army counts all the time he serves on full pay towards his future promotion, advanced pay, and retirement.

The Assistant-Surgeon of the Navy, although his full service counts towards increased pay and retirement, can only count ten years of his service towards his promotion as Staff-Surgeon.

3. The Army Surgeon is always on full pay, except in cases of reduction, consequently all his time from his entry into the service is available continuously for future advancement.

With the Navy Surgeon it is different; he is placed on half-pay so soon as his ship is paid off, and may not be again employed for one, two, or more years, all of which time is lost to his future advancement and retirement; and from the evidence as well as the return it appears the Naval Surgeon on an average has to be about twenty-four years in the service before he can complete twenty years' full-pay time.

4. Although the Order in Council of May 13, 1859, established the same rates of full and half-pay and retirement to Naval Medical Officers as were given to the same rank of Army Medical Officers by the Royal Warrant of October 1, 1858; yet the pecuniary and other allowances have not been equalised; for instance :—

5. At the military Hospitals at home, Army Medical Officers and Naval Medical Officers at the Royal Marine Infirmaries, in addition to their full pay, are allowed servants, or an allowance of one shilling a day for each, and the number of servants is fixed according to relative rank. They are also granted fuel and candles, or money allowance instead, also barrack furniture (abroad 1s. 6d. for servants).

The Naval Medical Officers at Hospitals above the rank of Assistant-Surgeon have no allowances of any description whatsoever; they have only the full pay of their rank, but on foreign stations have allowances in lieu of provisions.

6. The pecuniary travelling allowances for army officers are fixed according to relative rank.

The naval allowances are not fixed according to relative rank, but at a lower rate according to a classified scale (see Admiralty Instructions pages 235-6).

7. By the Royal Warrant prize money in the army is to be shared according to relative rank.

In the navy the distribution of prize money by Royal Proclamation is not classified in the same manner as in the army, and is consequently not shared according to the principles of relative rank.

8. Military officers when serving in India, and also in some of our colonies, receive pecuniary allowances of a local character.

The naval officer, unless when serving on shore, does not benefit by these regulations.

9. The senior Medical officer serving on a foreign station has an allowance according to the number of the troops on the station (see Article 9, of Medical Warrant).

The Naval Medical Officer has no such advantage.

It has been stated to the Committee, in the course of the evidence given by Naval Medical Officers, that, independently of the differences which exist in allowances granted to Army Medical Officers from which Naval Medical Officers are excluded, there are several other causes for complaint on their part in respect to their position, which they consider should be remedied.

10. They consider that they are entitled from their relative rank to the choice of cabins, in the same manner that army officers are entitled to choice of quarters, with the view of obtaining a cabin between decks for some period of their service instead of being always in the cockpit.

11. That the claim of Assistant-Surgeons to cabins should be more clearly acknowledged, as the existing Admiralty Order is sometimes not carried out or is evaded.

12. That Staff-Surgeons from their rank are entitled to more consideration than at present, in respect to servants.

13. That in the army, with nearly the same number of Medical officers above the rank of Assistant-Surgeon, there are seven Inspectors-General, and twenty-six Deputy Inspectors-General on full pay, whilst in the navy there are seven Inspectors and only fifteen Deputy Inspectors, three only of the former and thirteen of the latter being on full pay, and they request consideration as to an increase of these few rewards for long and meritorious service, either by appointing Deputy Inspectors to flag-ships, in place of Surgeons, or otherwise as may be thought fit.

14. That the periods of retirement by age should more nearly correspond with the Army Regulations, in order to advance promotion.

15. That more opportunities for shore or home appointments should be open to Naval Medical Officers by limiting such appointment to five years.

16. That they should have equal consideration in the award of honorary distinctions under the statutes of the Order of the Bath as Army Medical Officers.

17. That extra pay, lodging money, and compensation for losses to Naval Medical Officers should be determined according to relative rank.

18. That Naval Medical Officers should participate in the advantages of Greenwich Hospital pensions.

19. That when Surgeons are required by the exigencies of the service to perform the duties of Assistant-Surgeons they should enjoy all the advantages of the higher rank.

20. That from the difficulty of keeping up their Professional knowledge when at sea, Assistant-Surgeons should be allowed leave of absence to attend a Medical school to enable them to qualify for their examinations.

21. That Staff-Surgeons, in order that they may be placed in their proper position according to relative rank, should rank with Commanders by date of Commission, and that the wording of Articles 3, 4, page 40, of the Admiralty Instructions, and the last clause paragraph 9, of the Circular of May, 1859, require reconsideration as affects the position of Medical officers.(b)

22. That the full pay should be increased, as an inducement for those qualified candidates to apply for admission into the service, who now seek other and what they consider to be more advantageous employment.

1. The Committee have given careful consideration to these various subjects of complaint with respect to the service itself and to the circumstances which appear to be efficient causes of the dearth of Medical candidates, and impressed with the reasonableness of some of the alleged complaints, and with the propriety and justice not only of placing the Medical officers of the navy in the same position in regard to all advantages as those of the army, but in view of the circumstances which naturally render the naval the less popular service of the two to men who enter it at a mature age, they are of opinion that, so far as is practicable, such additional advantages should be held out to Naval Medical Officers as may in some degree compensate for the less favourable nature of the naval service; and particularly for the difference which exists between the two services in the matter of forced loss of time upon half-pay.

2. They are further of opinion that in order to meet the increased competition with other fields of employment open to Medical men in civil life, it is necessary to increase the pay and prospective advantages of the service in order to obtain a due supply of well and liberally educated candidates.

In fulfilment of these objects they have resolved to submit the following recommendations to the consideration of the Lords Commissioners of the Admiralty.

Recommendations.

1. That Staff-Surgeons be placed on a separate list, and considered as a distinct rank, and that promotion to that rank (although twenty years on full-pay may not have been completed) should be open to officers for distinguished or special service.

(a) In May 1865, Dr. Cogan, Surgeon of the 2nd Regiment, was specially selected for advancement to Surgeon-Major after only fourteen years' service, in consequence of meritorious service at Bermuda during the epidemic of yellow fever in 1864-65.

(b) On the subject of relative rank, it appears that on the promulgation of the Order in Council of May, 1859, the rank of Naval Medical officers became advanced, and they were placed in the same relative position as the Army Medical officers. The Naval Surgeon, from being junior to all lieutenants in the navy, become equal in rank with commanders, in accordance with the dates of their respective commissions; and when he became a Staff-Surgeon, he ranked with, but junior to, a lieutenant-colonel in the army, or a captain of the navy under three years' standing, and senior to all commanders. An Order in Council, in April, 1861, defined the relative rank of naval officers with officers of the army; by which the commander of the navy was raised in rank from major to lieutenant-colonel, but junior—the rank then held by Staff-Surgeons. In June, 1863, a further Order in Council was obtained, defining the relative rank between naval officers of the military and civil branches of the service, etc, ; in which the Staff-Surgeon was stated to rank with commanders, but junior of that rank. It is this clause which is said to place the Staff-Surgeon in a subordinate position ; for although his relative rank with the army officer is the same--namely, lieutenant-colonel, but junior,—he considers himself, from his position in the naval service, to be below his proper rank with the Army Medical officer.

2. That the whole time an Assistant-Surgeon serves on full-pay should be allowed to qualify for the rank of Staff-Surgeon, provided he passes his examination for Surgeon before he completes ten years' service.

3. To compensate the Naval Surgeon for loss of time, by his being placed on half-pay and unable to obtain employment, the Surgeons' and Staff-Surgeons' full-pay should increase by periods of four years instead of five years as at present.

4. That Naval Medical Officers be granted the same allowances at Hospitals at home and abroad as the Army Medical Officers, in respect to servants, fuel, furniture, or pecuniary allowances in lieu.

5. That the scale of travelling allowances, extra pay, lodging money, and compensation for losses, be fixed for Naval Medical Officers according to relative rank.

6. With respect to the question of prize money, the Committee, owing to the present principle on which the Prize Proclamation is drawn, are unable to agree upon a special recommendation, but are inclined to the opinion that the share of Medical officers should, after the officer in command of the ship, be regulated by relative rank.

7. That in regard to cabins, while the requirements of the service renders it necessary that the senior executive officer and the staff-commander or master should have the cabins placed most advantageously for their special duties, Medical officers should, after them, have cabins more in accordance with their relative rank in the service, and that cabins for all Assistant-Surgeons should be specially ordered, to prevent future difficulties or neglect of the existing Admiralty Order.

8. That a Staff-Surgeon, ranking with commander, be allowed a servant.

9. That a Staff-Surgeon should be appointed to all flag-ships bearing the flag of a commander-in-chief on foreign stations, with an allowance of 5s. a day in addition to his established pay.

10. That the periods of retirement by age be fixed for

Staff-Surgeon, Surgeon, or Assistant-Surgeon, at . . 55 years
Inspector-General and Deputy-Inspector-General . . 65 ,,

but this regulation should only apply to new appointments.

11. That Naval Medical Officers be considered equally eligible to honorary distinctions as Army Medical Officers.

12. That they should have equal consideration for Greenwich Hospital pensions with other officers of the service.

13. That Assistant-Surgeons, after completing their time for examination for the rank of Surgeons, be granted two months' leave of absence on full pay, on the condition of their resuming their studies at a Medical school or Hospital.

14. That in order to place Staff-Surgeons on an equality in rank with Surgeons-Major in the army, they should rank with commanders by date of commission; but we are of opinion that officers in command of H.M. ships must on all occasions be considered senior in rank and precedence to all officers placed under their command, and that a ship, as a regiment, must always be represented by an executive or combatant officer, after whom all officers should take precedence according to the relative rank conferred on them by Royal authority. (See Clause 10, etc.)

15. That the pay of the Naval Medical Officers be increased in accordance with the following scale:—

Scale of Pay proposed for Naval Medical Officers.

Rank.	Under 5 years' service.		Above 5 years' service.		Above 10 years' service.		Above 14 years' service.		Above 18 years' service.		Above 22 years' service.		Above 26 years' service.		Above 30 years' service.	
	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
Assistant-Surgeons	10 0	12 6	11 6	12 6	13 0	15 0	13 0	*17 6	..	..	..	..	..	..	..	..
Surgeons	..	..	..	..	15 0	17 6†	18 0	20 0	18 0	22 0	..	..	..	..	..	..
Staff-Surgeons	..	..	..	..	..	..	..	..	22 0	24 0†	25 0	27 0	25 0	27 0	..	..
*Deputy Inspector-General of Hospitals and Fleets	..	..	..	..	..	..	..	..	28 0	30 0†	30 0	32 0	30 0	35 0	34 0	37 0
*Inspector-General of Hospitals and Fleets	..	..	..	..	..	..	..	..	..	..	40 0†	45 0	45 0	47 0	45 0	50 0

* Provided he passes his examination before ten years' service. † Or on promotion.

16. That, as the prospect of optional retirement at an earlier period than at present permitted would prove a further inducement to young Medical men to enter Her Majesty's service, Naval Medical Officers should be permitted to retire after twenty years' service on full pay; but at the same time, in order to guard the interests of Her Majesty's service, the rate of half-pay awarded to officers so retiring should not exceed five-tenths of their full pay, and that officers with this service should be permitted to retire on the half-pay of their rank, if, after one year on half-pay, they are found, on Medical survey, to be permanently unfit for further service.

17. That as a special reward to officers of long and good service, who, owing to the comparatively small numbers of the inspectorial ranks, have not been promoted to any higher position than that of Staff-Surgeon, such officers of the rank of Staff-Surgeon as have served for twenty-five years on full pay should, on being compulsorily retired at 55 years of age, or retired on Medical survey, receive the half-pay of £1 a day.

We further recommend that competitive examination for admission of Medical officers into the navy be established at Greenwich Hospital, after the plan adopted in the army, at Chelsea, and that Professional instruction by a course of lectures and attendance at Haslar be given to Medical officers on first entry, in some measure on the system adopted at Netley Hospital.

Some of the Medical witnesses have stated that it is desirable that naval boards of survey should be made purely Medical boards, as they are in the army; on this question, however, the Committee are not agreed, and therefore offer no opinion.

APPENDIX.—PROTEST FROM SIR J. R. GIBSON.

In signing these reports, I feel called upon to record my dissent from those recommendations in which the Committee suggest a different rate of pay for the officers of corresponding rank in the respective services, and a different period of service as qualifying for an increase of pay.

I do not think that the inspectorial officers of the navy are subject to more unfavourable conditions of living than those of the army. I fully concur in the augmentation of pay recommended for the former, but I am clearly of opinion the claims of the latter to equal consideration have been as fully established.

The proposal to give the Medical officers of the navy an increase of pay after four years' full pay service, while the same advantage is only attainable in the army after five years, is still more objectionable. Full pay service in either department is equally valuable to the State, and so long as the rate of pay is regulated by length of service, no distinction as to the duration of the periods qualifying for the increase should be made.

When Medical officers of the navy are unavoidably placed on half-pay while still effective, and when, in consequence of such reduction, they are deprived of an opportunity of completing the full pay service necessary to entitle them to the highest rate of retired pay, before being retired, under the superannuation clause of the existing Warrant, their case might be met by giving to all officers so superannuated the highest rate of retired pay for which they are by rank eligible, without reference to their full pay service, and their compulsory retired service might be allowed to count for increase of pay on their re-employment. Such a measure would be but just to those whose cases form the grounds of the Committee's recommendations, and it would remove all cause of complaint, without provoking discontent or affecting injuriously the interests of the Army Medical service, and, through it, of the army.

(Signed) J. R. GIBSON, Director-General.

Army Medical Department, February 8, 1866.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 1, 1866:—

William Smith, Gorton, near Manchester; Henry Marten Body, Cheriton Fitzpaine, Devon; Abraham Robt. Verity, Bridgend, Glamorganshire; George Arthur Rogers, 32, Queen-square; Charles Thomas Dalley, Leicester; Allen Fennings, St. Ann's-road, Notting-hill.

The following gentlemen also on the same day passed their First Examination:—

George E. D'Arcy Adams, King's College; John Canning Wilkins, University College.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BAILEY, Mr. I., has been elected Dispenser to the Radcliffe Infirmary, Oxford.

BRADLEY, JOHN, M.R.C.S. Eng., has been appointed House-Surgeon to the Northern Hospital, Liverpool.

FARRELLE, WILLIAM K., L.R.C.P. Edin., has been elected House-Surgeon to the Belfast Union Infirmary.

HICKS, Dr. J. BRAXTON, F.R.S., has been elected Honorary Fellow of the Berlin Obstetrical Society.

NICHOLS, WILLIAM P., F.R.C.S. Eng., has been elected Mayor of Norwich.

PEIRCE, W., M.D., has been appointed Second Assistant Medical Officer to the Dorset County Lunatic Asylum, Dorchester.

SMITH, ALFRED R., M.D. Edin., has been elected one of the Physicians to the General Infirmary, Hereford.

SPEARING, ANDREW, M.D. Glasg., has been elected Medical Officer to the Antrim Union Workhouse.

WARD, JOHN, M.R.C.S. Eng., has been appointed Medical Officer to the Penistone Union Workhouse, Yorkshire.

BIRTHS.

ANNESLEY.—On March 3, at Devonport, the wife of Francis C. Annesley, M.R.C.S., Deputy Inspector-General of Hospitals, of a son.

BENNIE.—On February 24, at Lympstone, Exeter, the wife of A. Bennie, L.R.C.P. Edin., of a daughter.

BLAGDEN.—On March 4, at 2, Rowcroft, Stroud, the wife of Robert Blagden, L.R.C.P. Lond., of a son.

CADDY.—On March 4, at Watcombe, Torquay, the wife of Dr. Caddy, R.N., H.M.S. *Ganges*, of a son.

CRESSWELL.—On March 1, at Dowlais, Glamorganshire, the wife of Pearson R. Cresswell, M.R.C.S.E., of a daughter.

PUDDICOMBE.—On February 16, at Silverton, Devon, the wife of E. M. Puddicombe, M.R.C.S. Eng., of a son.

SANDERS.—On March 4, at Chigwell, Essex, the wife of Dr. Charles Sanders, of a son.

SARELL.—On February 17, at Pera, Constantinople, the wife of Richard Sarell, M.D., of a son.

SOMERVILLE.—On February 11, at Gosforth, Whitehaven, the wife of W. Somerville, M.D., of a daughter.

THOMAS.—On February 21, at St. Clear's, Carmarthenshire, the wife of J. L. Thomas, M.R.C.S. Eng., of a son.

MARRIAGES.

HOLMES—ARROW.—On March 3, at the Cathedral, Manchester, Frank Holmes, M.R.C.S., to Annie Elizabeth, second daughter of the late Henry Arrow, Esq.

LYALL—ROWE.—On February 22, at St. Thomas's, Haverfordwest, David Lyall, M.D., Staff-Surgeon R.N., to Fanny Anne, only daughter of George Rowe, Esq.

PRICE—HAVERSON.—On March 1, at All Saints' Church, Upper Norwood, William P. Price, M.D., to Annie Eliza, eldest daughter of J. P. Haverson, Esq.

RING—MILLER.—On March 3, at Willesden Church, John Ring, M.D., to Louise, youngest daughter of the late Reader Miller, Esq.

TAYLOR—SWANN.—On March 1, at St. Mary Magdalen, St. Leonards-on-Sea, John Taylor, M.R.C.S., to Elizabeth, elder daughter of H. T. Swann, Esq.

DEATHS.

LAW, Dr. J. D., at Liverpool, on February 12, aged 33.

M'NISH, W., M.D., at Warriston-crescent, Edinburgh, on February 16, late Surgeon, 63rd Regiment.

SANKEY, WILLIAM, F.R.C.S. Eng., at Guildford Lawn, Dover, on March 5, aged 76.

WATSON, JOHN, M.R.C.S. Eng., at Regent-terrace, Newcastle-on-Tyne, on February 11, aged 30.

WATTERS, HENRY B., L.R.C.P. Edin., at 110, Islington, Liverpool, on March 1, aged 31.

WILLIAMS, JOHN M., M.R.C.S. Eng., at Bridgend, Glamorganshire, on March 1, aged 89.

WYBER, Dr. JOHN, at the London Fever Hospital, recently, aged 26.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Bradford (Yorkshire) Union.—Mr. Samuel Brown has resigned the Horton East District. Remuneration by case.

Bridge Union.—Mr. Robert Tassell has resigned the Third District; area, 4248; population, 2409. Remuneration by case.

Hastings Union.—Mr. Skinner has resigned the Third District; area, 8144; population, 1552; salary, £40 per annum.

Louth Union.—Mr. W. D. Ditchett has resigned the Grimoldby District; area, 17,217; population, 2854; salary, £40 per annum.

Poplar Union.—Mr. Robert Webb has resigned the Western District; population, 26,168; salary, £75 per annum.

Walsingham Union.—Dr. Thomas W. Damant has not resigned the Fakenham District.

Wem Union.—Mr. Edward Gwynn has resigned the Wem District; area, 12,196; population, 3526; salary, £70 per annum, including the workhouse.

APPOINTMENTS.

Alton Union.—Charles Hammond, M.R.C.S.E., L.R.C.P., to the Bentley District.

Bourn Union.—James L. Pritchit, L.S.A., to the Castle Bytham District.

Halifax Union.—Thomas Henry Turney, M.R.C.S.E., L.S.A., to the Sowerby District.

Stockport Union.—Thomas Moore, M.R.C.S.E., L.S.A., to the Marple District.

Taunton Union.—Albert L. Peacock, M.R.C.S.E., L.S.A., to the Churchstanton District.

Thorne Union.—Henry W. Pullan, M.R.C.S.E., L.F.P. & S. Glas., to the Belton District.

THE NEW PROFESSORSHIP OF ZOOLOGY AND COMPARATIVE ANATOMY AT CAMBRIDGE.—At the late election Mr. Alfred Newton and Dr. Drosier were the only candidates. Mr. Newton received 110 votes, and Dr. Drosier 82.

PRIZE QUESTION.—For the subject of the prize of 1600 francs instituted by Madame Aubanel, the Paris *Société Medico-Psychologique* proposes the following question:—"Remissions, Intermissions, and Lucid Intervals in the Various Forms of Insanity, considered in a Medico-Legal Point of View." Essays to be forwarded to the Secretary, M. Brochin, 7, Boulevard St. Michel, before March 31, 1867.

MR. WORMS' TREATMENT OF CATTLE PLAGUE.—Mr. J. Banks Stanhope asserts in the *Times* of Saturday, March 3, that Mr. Worms' plan of treatment has been fairly tested on his farm at Revesby, and has proved a failure.

THE LEVÉE.—At the *levée* on Wednesday the following presentations to the Prince of Wales on behalf of the Queen took place:—Mr. James Pattison, Cromarty, Civil Surgeon, Tavoy, British Burmah, by the Earl de Grey and Ripon; Dr. Dumbreck, C.B., on appointment as Honorary Physician to Her Majesty, by Sir J. B. Gibson, K.C.B., M.D.; Sir James Brown Gibson, K.C.B., on appointment as Knight Commander of the Bath, by the Duke of Cambridge; Dr. Leonard, Inspector-General of Hospitals and Fleets, by the Duke of Somerset; Dr. Logan, C.B., on appointment as Companion of the Bath, by Sir J. B. Gibson, K.C.B., M.D.; George Pain, Surgeon, 11th Prince Albert's Own Hussars, by the Earl of Cardigan. The following gentlemen attended the *levée*:—Dr. Arthur Farre, M.D.; and Mr. White Cooper.

MR. E. R. LANKESTER, of Downing College, Cambridge, who has been elected to the Physical Science Scholarship at Christ Church, is the eldest son of Dr. Lankester, the Coroner for Middlesex.

MAGDALEN COLLEGE, OXFORD.—There will be an election at this College in April next to a Demyship in Natural Science of the value (room, rent, and tuition included) of 75*l.* per annum, and tenable for five years from the day of election. The examination will commence on April 17. Particulars relating to the examination may be obtained by applying to the President or Senior Tutor.

TESTIMONIAL TO DR. LOBB.—A valuable testimonial, consisting of a silver salver and a tea and coffee service, accompanied by a handsomely-illuminated volume, containing the names of the subscribers, was presented at the Albion Tavern, on the 3rd inst., to Dr. Lobb, of Aldersgate-street, by several of his friends and patients, on his retirement from practice, in which he had been actively engaged for upwards of 40 years. After the presentation, Dr. Lobb was entertained at dinner; Dr. C. Brodie Sewell, the treasurer of the Testimonial Fund, presiding.

ON the evening of Feb. 28 Mr. R. V. Tuson, Professor of Chemistry, was invited to attend a meeting in the theatre of the Royal Veterinary College, at which he was presented by by his pupils with a testimonial "as evidence of their esteem, as well as a slight recognition of the able and energetic manner in which he has laboured in their behalf, and of his uniformly kind and gentlemanly behaviour towards them." The testimonial consisted of an address signed by seventy-two students, and of one of Smith and Beck's binocular microscopes, with numerous appliances. We have reason to believe that Professor Tuson's popularity amongst the students is well deserved.

CONTEST FOR A CORONERSHIP. — SUCCESS OF THE MEDICAL CANDIDATE. — On Saturday the Under-Sheriff for Yorkshire made the official declaration of the poll for the Coronership of Yorkshire (Doncaster district), for which there had been a severe contest on the preceding Thursday between Dr. Guy, the Deputy Coroner for the Borough of Doncaster, and Mr. Edward Nicholson, the clerk of the peace. The numbers were—for Dr. Guy, 582; for Mr. Nicholson, 377; majority for Dr. Guy, 205. Voters were brought from a distance of seventeen miles, as far as from Crowle, on the borders of Lincolnshire. The freeholders, 110 in number, of Thorne, where Dr. Guy had been Union Medical Officer for fourteen years, and where he had gained a very distinguished reputation for skill, energy, and kindness, voted unanimously for him.

COMPENSATION FOR RAILWAY ACCIDENTS.—The Metropolitan Railway Company have presented to Parliament a Bill asking for additional powers, and containing a clause limiting the company's liability for injury by accident on the railway to cases in which notice of the claim is given to the company within two months. The Board of Trade suggest if such an alteration of the law be made, it would be more convenient that it should be by a general Bill than by special Acts of railway companies creating exceptional immunities in their favour. One or two companies are also applying this Session for Bills which if passed as presented will create an exception in their favour in regard to liability to make compensation for injures to third-class passengers. The liability has been limited to 100*l.* in relation to passengers by certain morning and evening trains which various companies ere compelled to run at extremely low fares for the accommodation of the working classes; one company now desires to have this limited liability to third-class passengers applied to all its Parliamentary trains.

A Strike at the British Museum.—The *Athenæum* says that the chief officers and their assistants, including Professor Owen, Dr. J. E. Gray, and Mr. J. W. Jones, have presented a memorial to the Government asking for an advance of pay.

The Profession in Islington and the Coroner for Central Middlesex.—At a numerously-attended meeting of the Islington Medical Society, specially convened to consider the subject, the following resolutions were carried unanimously:—1. That it is the opinion of this meeting that when a charge is made against a Medical man before the Coroner, it is unjust that any vote of censure should be passed by the jury without the accused having an opportunity of defending himself. It is, therefore, a matter of regret that the Coroner for Central Middlesex should not have borne this principle in mind in certain recent cases. 2. That the preceding resolution be published in the following Medical journals:—*Lancet*, *Medical Times and Gazette*, and *British Medical Journal*.

Royal Institution of Great Britain.—At the general monthly meeting on Monday, March 5, 1866, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S. President, in the chair, Charles Joseph Hyde Allen, Esq.; George Acland Ames, Esq.; John Boyle Barry, Esq., M.R.C.S.; Edward Ladd Betts, Esq.; John Conolly, M.D., D.C.L.; Mrs. Katherine Sophia Elizabeth Foote; James Park Harrison, Esq., M.A.; Mrs. Elizabeth Mary Hopgood; John Mortimer Hunt, Esq.; Sir James Lacaita; Sir Charles Nicholson, Bart.; Brinsley de Courcy Nixon, Esq.; J. Bertrand Payne, Esq., F.R.G.S.; Joseph Payne, Esq.; Sir Samuel Morton Peto, Bart., M.P.; David Trail Robertson, Esq.; Pandeli Ralli, Esq.; James Graham Stewart, Esq.; Daniel Charles Stiebel, Esq.; and William Castle Smith, Esq., were elected Members of the Royal Institution. The special thanks of the members were returned to the donors of the following additions to "The Donation Fund for the Promotion of Experimental Researches:"—Captain Douglas Galton, C.B., £10; Harry Mackenzie, Esq., third donation, £10 10s.; Samuel Reynolds Solly, Esq., F.R.S., fourth annual donation, £20; Adam Murray, Dsq., second donation, £5 5s. The decease of Wm. Thomas Brande, Esq., D.C.L., F.R.S., L. & E., etc., Honorary Professor of Chemistry in the Royal Institution, was announced from the chair. [Mr. Brande was elected Professor of Chemistry in 1813, and Honorary Professor in 1852.] The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

Illegally Receiving a Lunatic.—At the Oxford Assizes on Saturday, March 3, Richard Harris and John Aries were indicted for illegally receiving a lunatic into their respective houses for profit without a licence, contrary to the statute 8th and 9th of Victoria, cap. 100, section 90; and also for ill-treating the lunatic, contrary to the statute 16th and 17th of Victoria, cap. 96, section 9. Mr. Huddleston, Q.C., and Mr. J. O. Griffits were for the prosecution; Harris was not defended by counsel; Mr. Harrington was for Aries. Harris pleaded "Guilty" to the charge of receiving the lunatic for profit without a licence, but stated he was ignorant of the law; Aries pleaded "Not Guilty." It was then stated that the prosecution was at the instance of the Commissioners in Lunacy, and that the lunatic was a woman named Elizabeth Sims. Harris was a gardener, earning from 12s. to 13s. a-week; Aries was tenant to the mother (a widow) of the lunatic, and farmed forty-two acres at Marston, and the defendants had received the lunatic at the request of her mother. Aries received 16s. a-week with her. At his house the lunatic was seen by Mr. Hitchings, a Surgeon, who found her in a room destitute of furniture, the door of which was secured by a chain, but there was no evidence of any cruelty or neglect. It was then agreed by the learned counsel, with his Lordship's sanction, that a verdict of "Not guilty" should be taken as to both prisoners on the counts of the indictment charging cruelty, and that Aries as well as Harris should plead "Guilty" to the rest of the charge. His Lordship then ordered the defendants to be discharged on their own recognisances to come up for judgment when called upon.

Workhouse Infirmaries.—The Association for the Improvement of the Infirmaries of Workhouses held a public meeting at Willis's Rooms on Saturday last, the Earl of Carnarvon in the chair. There was a very full attendance of noblemen, members of Parliament, members of the Medical and clerical Professions, guardians of the poor, and the general public. The first resolution was proposed by the Archbishop of York, and seconded by Mr. T. Hughes; it was "That the present management of the sick in the Metropolitan Workhouse Infirmaries is highly unsatisfactory; that the buildings are inadequate and unhealthy, the Medical attendance insufficient, the nursing merely nominal, and the general system of administration radically defective." Mr. Ernest Hart moved:—"That, with a view to the humane and efficient treatment of the sick paupers, it is desirable to consolidate the Infirmaries of the Metropolitan Workhouses, to support them by a general Metropolitan rate, and to place them under uniform management in connexion with the Poor-law Board." The motion was seconded by Mr. W. H. Smith. Mr. Davenport Bromley, M.P., moved:—"That in order to give effect to the foregoing resolutions, it is necessary that immediate steps should be taken to introduce a fitting measure in the House of Commons, and that a deputation be appointed to wait on the President of the Poor-law Board to ascertain whether he will be willing to bring in a Bill for the purpose." And "That, in the event of the President of the Poor-law Board declining to take charge of this question, the Committee of this Association is requested to take independent means to bring forward an appropriate measure in Parliament during the present Session." Sir J. Kay Shuttleworth seconded the resolution.

Injection of Perchloride of Iron in Varicocele.—M. Maisonneuve laid before the Academy the results of his trials of the injection of perchloride of iron in varicocele. Encouraged by the successful treatment of varices by this means, he extended its operation to varicocele, employing the Pravaz syringe used for hypodermic injections. A single injection of from twenty to twenty-five drops has always proved sufficient to induce the obliteration of the whole varicose mass, owing to the numerous anastomoses which exist among the veins of the cord, and their termination in one common trunk.—*Gazette Médicale, January* 20.

Medical Ethics.—May I venture to touch on a subject of Professional obliquity, if not misconduct, which is truly lamentable? May I lay bare a wound which cankers in our body, and which, like all sores, may be the better for being exposed? Is it possible to explain favourably the conduct of a man who, too readily, appears as a prosecutor, or on the side of the prosecution, against a fellow Practitioner for so called malpractice? In the majority of cases it is tolerably certain that no good ends are to be gained either by the public or Profession, and it is clear also, that much harm accrues to both; under these circumstances, it would be well to put an end to such a practice, and this is to be attained by our own efforts. If all men refused to appear in court against a Medical brother—except in cases of a criminal nature, when all Professional relations should cease to influence—these actions of malpractice would disappear, and this great blot upon our order would be erased. Should such a case come before you, and your opinion be asked by the legal adviser of the prosecutor, apply at once to the Medical man who was in attendance, for a full and complete account of the case submitted to you, and then having mastered it, give your judgment. In all probability it will dispel the errors with which the case was surrounded, and put the question in the right light, thus tending to stay the process, and arrest the action. At any rate, your part in the proceeding will be honourable, and, whatever the issue, your conscience will be clear. . . . There is yet another practice into which some men have fallen, and which needs only to be mentioned to be condemned; it has special reference to those who act as Medical advisers of a railway company. Is it consistent with the Medical man's true position, to become the agent of such a company in any extra-Professional capacity? Is it right that he should avail himself of the facilities open to him as a Medical man, for gathering information extra-Professional? Without doubt, such breaches of Professional faith do much harm in disturbing that healthy confidence in our discretion and honour which the public so generously repose in us. I say it is derogatory to our Profession and humiliating to our honour to do such things. When employed by a railway company, give your Professional opinion fairly and honestly upon the case before you as it stands, but never be led into any attempt to entrap a patient into an admission with a view of its being legally used against him, and to the benefit of your employers. Never use, or allow to be used with your sanction, any information given to you in confidence as a Medical man for other purposes than those for which it was given. Never assume duties which are unconnected with your Professional capacity, nor allow yourselves to be used as means for the adjustment of claims which it is clearly the business of others to determine.—*Introductory Address at Guy's Hospital, October* 2, 1865.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending February 24.	Week ending February 17.	Week ending February 10.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.
1. Metropolitan Police District . .	12	16	23	7569	3193	3464	333	579
2. South Eastern Co. .	16	26	24	4966	1537	2775	442	212

NOTE.—281 Inspectors have not reported this week in time for this return. Among these, and belonging to the county of Salop, is one Inspector; to Staffordshire, 5; to Cheshire, 5; to York, 5 not reported, and one received, but unintelligible; to Cumberland, 2; to Flint, 1; and to Scotland, 16. These Inspectors returned 2847 cases last week; and the apparent decrease of the disease is probably more due to the absence of these reports than to any real diminution of attacks. In Cambridgeshire, one Inspector has returned five fresh outbreaks and 151 cases; but this information was received too late to be included in this return. This increased work necessarily entailed in carrying out the provisions of the Cattle Disease Prevention Act may, in many instances, account for this delay.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

An obituary notice of the late Mr. McWhinnie will appear in our next number.

Reviews of the following works are in the printer's hands:—"Statistical Report of the Health of the Navy for the Year 1862."—"A Practical Treatise on Urinary and Renal Diseases, including Urinary Deposits." By W. Roberts, M.D.—"Peking and the Pekingese." By D. F. Rennie, M.D.—"Report on the Sanitary Condition of Edinburgh."—"Text-Book of Mental Diseases." By Dr. Max Leidesdorf.—"Recent Anthropological Publications."

"*Dr. Wilson.*"—The drawings of Sir Charles Bell have been removed to the Military Hospital at Netley.

A Studious Reader.—Will you send the paper, with your name, for inspection?

Hexham.—Royle's Materia Medica, edited by Dr. Headland; Squire's Companion to the British Pharmacopœia; Waring's Therapeutics.

Rahere, Ely-place.—The first Hospital for sick persons was founded at Canterbury by Lanfranc, Archbishop of that diocese, in 1070.

Petros, Worksworth.—Lithotomy was first attempted in Paris in 1474.

B. B. should have received a private letter if he had sent his name and address. We can assure him that no part of the reports of societies is intended to be omitted, and we shall be glad to publish anything he may send us on the very interesting subject which he refers to.

Aspatria, Carlisle.—You will find a pencilling of Dr. Addison by "*Probe*," in the *Medical Times and Gazette*, vol. IX., p. 108, and a memoir published immediately after his death in the same journal, for July 7, 1860. The will was sworn under £60,000. Mr. John Addison, of Brook House, Cumberland, was one of the executors. There are photographic portraits of him to be obtained. Consult "Men of the Times," and Wadds' "Mems., Maxims, and Memoirs."

In the *Medical Times and Gazette* of December 15, 1860, will be found the description of an instrument I invented for forming artificial pupil in the centre of the iris by the aid of suction. The tubular arrangement in this instrument is essentially the same as in that used by Mr. Teale for the removal of certain forms of cataract, which instrument he described and figured in the Royal London Ophthalmic Hospital *Reports*, vol. iv., part ii., between three and four years after the first appearance of my invention. Both instruments were made by Weiss; and the same description, as far as it related to the suction apparatus, answers for either.—*Mr. Greenway, of Plymouth, in "Brit. Med. Jour.," March 3, 1866.*

Dr. W. Marsden, of Quebec, publishes a very elaborate and complete system of quarantine against the invasion of cholera. He says:—

"The following plan of quarantine for Asiatic cholera is the result of a special study of the etiology and pathology of the pestilence which five distinct visitations have afforded me during the last thirty-four years. It is no part of my present design to touch the *vexata questio* of contagion or non-contagion, the proposed plan being founded on the principle that Asiatic cholera is a portable, controllable, and communicable disease; and like the plague, may be transmitted and communicated both by persons and effects. The basis of the plan is therefore absolute non-intercourse for a short period with persons from abroad suspected of being infected and a thorough disinfection of personal effects. I assume the principle propounded by Kennedy in his 'History of the Contagious Cholera,' that the peculiar variety of cholera that has visited various parts of the world during the past half-century is identical with that which broke out in India in 1817, and 'assumed a contagious property which there is no evidence to prove it ever before possessed.' My opportunities of investigating facts connected with the disease on this continent have been extensive and ample, and I have been enabled from personal observation and inquiry to trace the introduction of the disease into this country on each occasion to importation from infected places. Its subsequent diffusion throughout the British provinces and the United States has also been strongly marked by the ordinary characteristics of infection, notwithstanding the statement of individual writers to the contrary."

The Guardians of St. Pancras and their District Medical Officers.—In a report presented to the St. Pancras Guardians, it was stated that during the past three months the cost of the cod liver oil disposed of by the District Medical Officers to out-door sick poor was £3 2s., and of quinine dispensed by them £3 12s. 10d. The total cost was £6 14s. 10d., being an average expenditure of about 2s. per week by each District Medical Officer. The value of Medical extras supplied during the period was £89 13s. 4d., showing a decrease of £4 7s. 4d., compared with the preceding quarter. The result was considered in the report as "highly satisfactory." There was, however, an increase of £2 7s. 4d. as to cod liver oil and quinine. It was also stated in the report that the supplying of nourishments by the relieving officers, instead of by the Medical officers, had been attended with good results, and the system is found to answer well. In proof of this, it was stated that "during the thirteen weeks ended February 23 last, the number of Medical orders issued was 4097, which was a decrease of 534 as compared with the thirteen weeks ended December 1, 1865." Having regard, therefore, to the superior administrative powers of the relieving officers, the report concludes by recommending "that in cases of great emergency only that may occur during the hours the relief offices are closed the Medical officers be authorised to give an order for meat in the first instance only, and that such cases shall be afterwards referred to the relieving officer to be dealt with in the usual manner. Also that the District Medical Officers shall furnish to the Stores Committee every Monday a return of the meat so ordered, setting forth the name, residence, and nature of the illness of each patient, and the date and hour on which the meat was ordered." There is also a further check placed on the Medical officers in order to avoid extravagance on their part. Cod liver oil and quinine are to be supplied to them at the Workhouse Infirmary only. The quantities to be supplied at any one time to each District Medical Officer are one Winchester quart of cod liver oil and one ounce bottle of quinine, and they are required to be particularly careful to report weekly the quantities they supply to each patient. After a discussion the report was unanimously adopted by the Board.

SWELLING OF THE TONGUE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We have all met with individuals who suffer from urticaria on taking certain (to them) known articles of dict, of which fish is the commonest. I have notes of its occurrence after eating strawberries, fresh figs, and cocoanut. The latter is an ingredient in most curry powders, and two friends of mine cannot take curry in consequence, for in them it produces great swelling of the tongue, lips, and throat, with an eruption of urticaria on the face, neck, and extremities. Dr. Downie's case of swelling of the nose is a parallel instance of the effect of irritant injecta on the pneumogastric producing reflex excitement in the nerves of the skin, and other nerves in more direct relation with that nerve.

I am &c.

11, Craven-hill-gardens, March 3. J. BRENDON CURGENVEN.

THE TREATMENT OF CATTLE PLAGUE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If the fact brought forward in your last impression by Dr. Watmough in reference to the condition of the first stomach of cattle suffering from Rinderpest in his neighbourhood hold good in other parts of the country, would it not be advisable to introduce something by the hypodermic method? As no rational treatment has yet proved successful, a list of the more powerful agents might be drawn up, and these agents tried *seriatim*.

No doubt Dr. Richardson could give some very useful hints as to what agents would be most likely to be of service. I see that he has succeeded in reducing pyæmia poison to the state of an extract or powder; and no doubt by this time he has discovered something that will destroy its power out of the body. If so, why not in the body also?

Surely, then, by using solutions of the most powerful agents, separate and combined, some antidote might possibly be met with. If permanganate of potash suffices to destroy the poisonous matter of Rinderpest in articles that are saturated with it, the injection of this, or some other agent, into the areolar tissue of the body may, perhaps, be followed by good effects. Is it not worth a trial? I am, &c.,

March 5. JAMES TAYLOR, M.R.C.S. Eng., etc.

MR. CALEB BARRETT'S CASE OF NYCTALOPIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I cannot help thinking Mr. Barrett has found a mare's nest in his case of nyctalopia narrated in your last number. What is there remarkable in a patient's vision becoming impaired in the evening about twilight, improving when the candles were lighted, and becoming restored in the morning? Mr. Barrett goes on to say, "The ophthalmoscope showed

some dulness of the vitreous humour, a deeper colour of the retina, and larger size of its vessels." Twenty days later Mr. Barrett "found"—"thought he found" would be nearer the truth—the "vitreous humour clear, the vessels of the retina still large here and there, but the retina self, especially near the optic nerve, paler than in health."

As the patient "recovered his sight entirely in the morning," I think we may fairly ascribe Mr. Barrett's "observation" of "dulness" in the vitreous humour to his own imperfect focal adjustment of the ophthalmoscope. The "larger size" of the retinal vessels—we are not told larger than what—and their being "still large here and there," would be a more precise observation if we were told whether the enlargement affected the arteries, the veins, or both. But what are we to think of Mr. Barrett's knowledge of ophthalmology when he begins talking about the "colour" of the retina? The retina is a transparent and generally invisible membrane, through which the colour of the choroid is seen. If Mr. Barrett had, however, stopped at the statement that the retina was of a "deeper colour," I could have understood that he meant to say it was turbid from some infiltration or deposit, but when he says that "the retina itself" was "paler than in health" he involves himself in error beyond any hope of redemption or escape, and displays an innocence of the very alphabet of the ophthalmoscope and of the most elementary anatomy of the eye.

I regret to have had to criticise Mr. Barrett's evident inexperience in the use of the ophthalmoscope; but when he comes forward in the character of an expert he invites such criticism, and anything is preferable than that others should be misled by wonders which have no real existence but in the imaginative mind of their exponent.

I am, &c.

A Metropolitan Ophthalmic Surgeon.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Mr. Caleb Barrett favoured us last week with some particulars of a case of night blindness, in which there was turbidity of the vitreous not impairing vision in the daylight; and where there was a coloured retina, that, chameleon-like, changed its hue. Mr. Barrett's eye "in fine frenzy rolling" may, with the aid of his magic mirror, have seen visions denied to common men. To some of these "airy nothings" he has given "a local habitation and a name" in the fair pages of the *Medical Times and Gazette*. But common men will think that a turbid vitreous will impair vision by day as well as by night; and sceptics will disbelieve the existence of that which they will never see, and have now heard of for the first time. He will deem the coloured retina—another Ariel—the creature of a fond imagination, and the turbid vitreous, a Caliban of an imperfect focus.

Many wonderful discoveries have been made with the aid of the ophthalmoscope, and learners have a happy knack of finding mares' nests. But to Mr. Barrett is due the credit of being the first to record the finding of such a nest with two fine eggs.

I am, &c.,

M.R.C.S. (Not a Surgeon to any Hospital.)

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·331 in. The barometric pressure was 29·71 in. on Sunday, and it fell to 29·41 in. on Wednesday.

The general direction of the wind was N.E. & S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 36·2°.

APPOINTMENTS FOR THE WEEK.

March 10. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Rev. G. Henslow, "On Systematic and Structural Botany."

12. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

13. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Ethnological Society of London, 8 p.m. Sir John Lubbock, Bart., and Fred. Lubbock, Esq., "On the True Assignation of the Bronze Weapons, etc." Rev. F. W. Farrar, "On the Adaptation of Races of Man."

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

Royal Medical and Chirurgical Society, 8½ p.m. Meeting.

14. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Microscopical Society, 8 p.m. Annual Meeting.

15. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Dr. Meredith, "On the Duality of Venereal Ulcers."

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

16. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Balfour Stewart, Esq., F.R.S., "On the Evidence of the Existence of an Ethereal Medium Pervading Space."

ORIGINAL LECTURES.

ON GENERAL AND LOCAL CHEMICAL DISORDERS ARISING FROM MODIFIED PEROXIDATION,

AND ON THE MECHANICAL DERANGEMENTS THEY PRODUCE.

By H. BENCE JONES, M.D., F.R.S.

Part III.—Lecture X.

On Fermentations and Fevers.

(Continued from page 221.)

Treatment of Ammoniacal Urine.

The treatment of ammoniacal urine resolves itself into keeping the urine acid and stopping the inflammatory action; and as the alkalescence by its chemical action keeps up the inflammation, the stoppage of the formation of carbonate of ammonia in the bladder becomes the main object to be attained.

Usually, as the urine comes into the bladder, it is acid; as soon as it gets there it finds some ammoniacal urine there already; this not only neutralises the acid that comes from the kidney, but sets up decomposition of the urea, and forms fresh carbonate of ammonia; so that the removal of the ammoniacal urine that remains in the bladder is absolutely necessary, unless sufficient acid can be made to come from the kidney to neutralise it.

Vegetable acids far more quickly run off in the urine than mineral acids, of which sufficient cannot be taken to pass in quantity through the kidneys. Of all the acids lemon juice is perhaps the best which can be used. Many years since Mr. Witt made the following analyses of lemon juice for me (see *Quarterly Journal of Chemical Society*, vol. vii., p. 44):—One ounce (480 grs.) of lemon juice contains only 1·728 grs. of inorganic constituents; of which potash, sulphuric and carbonic acids constitute three-fourths; phosphoric acid, soda, and lime, with traces of silica, and iron and magnesia, constitute the other fourth. Hence water and citric acid constitute by far the largest part of the lemon juice, the citric acid being, on an average, about 40 grs. to the ounce of juice.

It is highly probable that citric acid and other vegetable acids have an anti-inflammatory action (lessening the oxidation that is going on) wherever they are carried, and they not only pass to the kidneys, but probably diffuse into every part of the mucous membrane of the bladder; to a small degree lessening the alkalescence of the textures in which the peroxidation is going on.

The citric acid must not be taken in such quantity that it irritates the stomach and bowels, nor should it set free uric acid in the urine. So that the highest limit can be easily recognised by the bowel symptoms. The lowest limit is so much as will just make the urine acid. This cannot always be reached. Three, four, five, ten lemons or more daily will not neutralise the alkali in the urine, and will not so stop oxidation and nutrition that the body will become feeble and wasted. Before this effect is produced some other way of removing the ammonia must be tried. Taking away the alkaline urine by the catheter so frequently that a smaller quantity of lemon-juice will keep the water acid is easy when the passage of the catheter does not cause mechanical irritation to take the place of the chemical irritant. The catheter must be used more or less frequently, according to the reaction of the urine. If drawing off the water at night whilst taking lemon-juice or other acid keeps the urine feebly acid, this is all the mechanical means required; if not, then, twice, thrice, four times daily the water must be drawn off; and even, in extreme cases, the catheter must be kept in the bladder, so as to free the urine continually without the irritation of the passage of the instrument; but the presence of the foreign body in the bladder, except when perfect rest is observed, often causes so much irritation that it is an aggravation of the disease. Moreover, by washing the bladder with small quantities of hydrochloric or acetic acid and water, after the urine is drawn off with the catheter, the ammonia may be easily neutralised, and a very small quantity of feebly acid fluid may be left in the bladder to counteract the decomposition of the urea, and to make the surface of the bladder itself less foul. How frequently the washing should be repeated, and what the strength of the acid injected should be, ought to be determined by the reaction of test-paper or the smell of the urine. Whatever you do, remember that the object is to get rid of a chemical irritant, and that if by rough handling of the catheter, by its too frequent use, or by too strong an injection you mechanically or chemically irritate the bladder more than it is irritated chemically by the ammoniacal urine, no good will come from your treatment.

When you have removed or can prevent the ammonia of the urine, then balsamic remedies, as in bronchitis, are often useful. These pass from the kidneys and also directly from the blood to the mucous membrane. Buchu, cubebs, copaibæ, turpentine, eau de goudron (purified tar water), all these may be useful; remembering here, also, that if the stimulant be too great, harm may be done by setting up fresh action. Astringents, as any preparation of gallic acid, tannic acid, uva ursi, rhatany, catechu, matico, alum, lessen the secretion of pus and mucus by contracting the textures.

Tonics also often are useful when the acute symptoms subside—as quinine, biberine, pereira brava, and other bitters.

On Fevers; or Qualitative and Quantitative Errors of Oxidation.

The term zymotic disease, which implies a chemical action, is now, thanks to Dr. Farr, in ordinary use. This term means that different vegetable or animal ferments, living or dead, albuminoid substances in certain states of chemical change, can be formed within or can pass from without into the body, and, taking part in the actions going on there, can produce different diseases. Usually fermentation may be considered as a peculiar oxidation in which carbonic acid and water and heat are produced; but instead of the dual action of oxygen on organic substance, fermentation consists in the natural action of three substances—namely, oxygen, the organic matter, and the ferment. These third substances interfere not only in the chemical actions of oxygen, but also in those of nutrition; so that a long list of substances might be formed, beginning with the spermatozoon and passing through torulæ, until we come to pepsine, which are capable in health or in disease of so increasing or altering the chemical actions of oxidation and nutrition in the body that quantitative or qualitative results are obtained which would not have been reached by the ordinary actions without the intervention of the third substance.

It will only be possible for me in this lecture shortly to bring before you one or two of these diseases of fermentation; and on account of the intensity of the ordinary action which occurs I shall class them together as diseases of modified peroxidation. Among these I place small-pox, scarlet fever, measles, typhus fever, as the most striking examples; typhoid fever, yellow fever, ague, are lower in the same class; whilst syphilis and cancer are highest in the class in which there is modified chemistry of nutrition, but no distinct evidence as yet of increased oxidation.

Of all the modified peroxidations that can occur in the body, small-pox is the most definite, because the poison can be got apart, and the quantity necessary for producing the action can be fixed, and through the most glorious discovery of vaccination it can be set in action whenever we please. We can almost see it passing from the cellular tissue into the blood, and from the blood into every particle of every texture, rendering it incapable of undergoing the same action again.

Let us look a little closer at this action of small-pox poison. If the minutest particle of substance, a little dried albuminoid substance, in a peculiar chemical state of action, on a lancet, or in the dust of the air, is put into the cellular tissue or is inhaled into the lungs, it passes on to the blood, and through it into every texture. In a few days the chemical actions of oxidation and nutrition throughout the body are altered, and the particle of matter has reproduced itself immeasurably. The violently increased chemical action, the peroxidation, is shown by the increased heat of the body, the violent fever. The altered nutrition is evident not only in the eruption of pustules in the cellular tissue under the skin, but in the altered condition of the blood and in all the textures of the body; each particle of substance being rendered incapable of undergoing the same process again, and by assimilation every future particle that takes the place of every modified particle is also generally incapable of being modified again.

Throughout the course of the general peroxidation, and more especially at the end of the fermentation, local peroxidations frequently come on in any part of the body. Inflammations of the eyes, the ears, the mucous membranes, the joints, the serous membranes, the parenchymatous tissues, anywhere, an unmodified peroxidation is ready to begin, and this easily gives rise to suppuration or causes obstructions which the feeble circulation cannot overcome.

The most striking facts concerning this small-pox ferment are, first, the very small quantity of substance that produces so much effect; secondly, the immeasurable increase of the poison in the body, each pustule having the same property as the original ferment; thirdly, the period of incubation during which the poison must at first slowly increase in every texture, and there give rise to the modified peroxidation and altered nutrition which constitute the attack.

The poisons of scarlet fever, of measles, and of typhus, though less tangible, are not less substantial than the small-pox ferment. Like it, they can most probably be dried and carried from place to place and pass into the mouth with the dust which we each moment inhale or swallow. In chemical composition scarlet fever, measles, and typhus ferments most probably resemble albumen in complexity, and, like albumen, they may be altered in composition and action by heat, alcohol, arsenic, tar acids, and many metallic salts. As soon as they reach any spot where they can oxidise, they set up an oxidation and reproduction in each contiguous particle of albuminous substance. From the cellular tissue, the air passages, or the stomach or bowels, the contact action spreads into the blood, and there it multiplies, whilst it is carried into all the capillaries, and through them into every texture of the body; then the increased oxidation and formation of ferment becomes most violent, and fever to a greater or less degree is present. Long after the strongest action is reached, a slower action continues, and at any time or in any part or texture of the body, whilst the specific chemistry is going on, an ordinary local peroxidation may be lit up, and a more or less acute inflammation may be added to or follow the fever which the ferment had produced.

During the height of the fermentation in typhus fever, the heat may rise to 5, 6, or even 10° Fah. above the ordinary temperature; and when the fermentation is ended, the albuminous textures of the body are so changed that they are incapable of going through the same process again. Between these two results there are innumerable other products of chemical change, varying with the kind and degree of fermentation. In typhus fever it is said that urea is increased and carbonic acid diminished. To these and a multitude of other chemical questions regarding fermentation chemistry will give definite answers; but above all questions, one of the most difficult to answer and yet one of the most important, is the amount of oxygen that is consumed in the different kinds and degrees of peroxidation which can take place within us.

In each organ, according to the intensity of the action set up by the ferment, altered functions may arise, and these may be still more altered when an ordinary peroxidation at the same time takes place. Thus the brain, heart, lungs, kidneys, liver, or any texture composing these organs may show by more or less wrong mechanical results the effect of the ordinary or modified peroxidation; and the effects of the fever and of the inflammation may be so mixed that neither during life nor after death may any accurate separation be possible.

Closely related in chemical composition to these violent ferments are the less active ferments of ague and typhoid fever. There is so little difference in the chemical composition of animal and vegetable substances, that the distinction between animal and vegetable poisons is no longer possible. Vegetable albuminous matter undergoing change may produce almost, if not quite, exactly the same poison as animal albuminous matter. Hence, probably, the resemblance between ague poison and typhoid fever poison, and the possibility that sometimes one and sometimes the other of these poisons may be formed from the same changing matter under different circumstances.

Ague ferment is probably a highly complex nitrogenous substance, capable of being dried and carried by the wind far from the place where it was produced. It enters by the mouth with the dust, and, like animal or vegetable alkaloids, it passes from the blood into every texture of the body, and acts on each much or little according to its chemical properties. Probably it acts most strongly on the nerves that regulate oxidation, causing for a time contraction of the arterial vessels and consequent suboxidation everywhere. The increased obstruction of the small arteries reacts on the tension of the blood, and this produces increased contraction of the heart, which continues to increase until the obstruction yields and a state of peroxidation is set up by which the poison is partially destroyed. During the remission, probably the poison is reproduced until sufficient, in from one day to three days, is formed to go through the same action again.

This theory of ague admits of a reasonable explanation of the action of quinine and arsenic in stopping the paroxysms of the complaint. On the ague poison itself quinine and arsenic may have no action, but they pass into every texture from the blood, and, combining with the nervous substance on which the ague poison acts, they form a compound on which the ague poison is incapable of producing an effect before it is oxidised and destroyed.

The ague poison, unlike the small-pox or typhus fever ferment, instead of protecting the body by making it incapable of undergoing the same action again, makes the nerves more ready on the slightest renewal of the poison to undergo the same action again; so that it has been said that the ague poison may lie dormant for years. It is far more probable that a much smaller quantity of the poison can produce the return of the symptoms than that the original ferment should retain its properties for months, or even for years, after its first action had passed by. In this respect, and in some others, the action of ague poison proves that it is a very peculiar ferment, and hence, though I have placed it near to the typhoid ferment because of its origin, I must shortly point out to you the different effect which the true typhoid ferment produces.

The typhoid ferment is probably formed out of vegetable or animal albuminous substance. In sewers, in drains, in ditches, possibly even in the drains of the human body, a substance may be formed which is not volatile in itself, but by foul gases or currents of air can be carried into the mouth, and in some period between a few hours and fourteen days it sets up a modified peroxidation. More slowly absorbed and less rapidly reproduced and changed than typhus ferment, it passes into the blood, and from it into each texture; whilst some of the poison has a local action on the glands of the small intestine, and produces increased action, effusion, obstruction, and retrograde action, causing ulceration, sloughing, and even perforation, by which mechanically the contents of the bowel may escape and an uncontrollable simple peroxidation may be set up. The poison that has passed into the tissues acts on each organ more slowly than the typhus poison; still, like it everywhere, it gives rise to altered functions, and everywhere local peroxidations are ready to occur; bronchitis, pneumonia, peritonitis, tubular nephritis, cystitis—any of these and many other inflammations may be set up at any time during the course of the fever. Probably the substances produced by the increased chemical action in typhus and typhoid fever will be found to be very similar. There may be the same amount of heat, the same excess of urea, the same excess of antecedent substances from which the urea is formed; possibly the same consumption of oxygen when the same temperature in each fever occurs; but in the properties of the ferment formed in the body a distinct difference of diffusibility must exist, the typhus poison passing with greater ease into neighbouring bodies; whilst the typhoid poison rarely, if ever, is communicated by infection.

On the Mechanical Disorders that arise out of the Chemical Errors in Fevers.

In all fevers the loss of mechanical power is quite as remarkable as the increase of chemical action. The chief amount of energy liberated by the action of oxygen in the body seems expended in the production of heat, so that far less than the ordinary amount of power remains to be employed in the production of mechanical motion. The muscles may be considered as machines made for the conversion of chemical force into mechanical motion. How this is done cannot be explained in the present state of our knowledge of the mechanical, chemical, or electrical actions in the muscle; but that the muscular force arises from some equivalent force, and sooner or later must come from the chemical force in oxygen, hydrogen, and carbon, opens an immense field for investigation, and is easier of belief than that force should be each moment created and destroyed. The amount of sugar and fat present in any muscle would soon be used up if in the working of the muscle itself fresh fuel was not produced. The action of oxygen on the syntonin in the muscle may be direct, and may give rise to the force required; but it is more probable that the syntonin splits into substances of two classes, one ending in urea, which is incapable almost of combustion, the other in inosit, which would immediately give water and carbonic acid.

In fever the poisonous ferment in the muscle probably determines a different chemical action from that which takes place in the muscle in health. The increased heat and increased urea mark the increased action, but loss of motor-power in the muscles shows that the conversion of chemical into mechanical force does not take place.

This mechanical disorder becomes by its action on the muscles of respiration or circulation the source of complications and dangers in fever to which I must shortly allude. Gradually in the course of fevers the sounds of the heart may be found to become more and more feeble, and the respiration without any wrong in the lung, becomes shallow and weak from the diminished power in the muscular tissue. The diminished tension in the arteries has a direct effect upon the circulation through the capillaries, and the motion in the veins is more or less stopped; hence congestion of blood in the venous system occurs, hæmorrhages, effusions, and coagulations in the veins may take place anywhere. The imperfect action of the muscles of respiration produces the same mechanical effects in the circulation through the lungs; imperfect oxygenation takes place in the lungs from the stoppage of blood in the pulmonary veins; without any inflammation, œdema of the lungs, hypostatic consolidation may occur. The circulation through the lung is so feeble that even the force of gravity acting on the blood in the lungs cannot be counteracted and accumulation takes place in the most dependent parts.

The muscles of the bladder are also so weakened that the urine accumulates, and frequently external muscular pressure is required after the catheter has been passed to cause the urine to flow.

In another large class of zymotic diseases the qualitative and quantitative errors of oxidation are scarcely detectable, whilst the qualitative and quantitative errors of nutrition chiefly mark the action of the poison.

Of these diseases true syphilis may be taken as the type.

It can scarcely now be doubted that the actions of two poisons have been included under the term syphilis. The first, like impetigo, is capable of being communicated, and often repeated because it exists only locally or passes up to the nearest lymphatic glands; whilst in the true syphilis the poison from the local sore enters the blood and passes from it into each texture, where it multiplies and produces changes of nutrition, and partly unchanged, and partly changed in composition passes out perhaps in each secretion.

This true syphilitic ferment resembles very closely the small-pox ferment in the universal diffusion of the poison, and in the consequent protection it gives from another attack by rendering a second similar change in each texture impossible. The protective power of the alteration is to a slighter degree extended to the progeny through the germ and spermatozoon; so that a race partly protected by inheritance may suffer less from these diseases than a purer race, whose textures are free to undergo the full change which constitutes the disease. Both persons give rise to increased cell growths, effusions, oxidations, congestions, and ulcerations; and these may take place in any part of the body, for the poison exists everywhere.

True syphilis differs, however, altogether from small-pox in its definiteness of course as to time. Syphilis produces no fever to terminate the fermentation in a definite period, and it may consequently remain active or dormant in the textures for years.

It is vain now to ask what circumstances at the end of the fifteenth century produced the first modified albuminoid matter which gave rise to the first true syphilitic poison. In cancer, which bears a distant resemblance to syphilis, although the spontaneous generation of the first cancer cell is daily occurring in some predisposed texture, yet we are as yet quite unable to say what produces the first modified particle of matter which multiplies and communicates its composition to adjacent predisposed textures by contact, and is carried by lymphatics and blood vessels to every part of the body, and affects the nutrition of each part with which it comes in contact, provided the textures are in a condition to propagate the cancer cells.

Another instance of spontaneous generation of a poisonous ferment is presented to us in rabies; and with this poison also unless a peculiar condition of system exists the ferment when inserted has no action; and here also our knowledge is at present unable to say what circumstances determine the formation of the first particle of poisonous saliva; except by its effects, the peculiar change in the albuminoid matter of the saliva in the present state of chemical knowledge could not be recognised.

Bethlem Hospital.—Dr. Williams was duly elected the Resident Physician to the above institution on Tuesday last in the vacancy created by the decease of Dr. Phipps.

ORIGINAL COMMUNICATIONS.

FURTHER NOTES ON THE NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA.

By BENJ. W. RICHARDSON, M.A., M.D., F.R.C.P.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE PRACTICE.

In effecting local anæsthesia by my process the Surgeon, according to the nature of the case, may either produce entire blanching of the surface to be operated on, or may stop short of that extreme result, and only induce a superficial anæsthesia. In my first experiments, made with the ordinary ether of the shops, I employed the second form of anæsthesia alone, and even now when a mere puncture through the skin or mucous membrane is required, I still resort to this method, reserving the extreme action for cases where deep-seated parts have to be divided.

For producing the deep anæsthesia with superficial whiteness it is necessary to use absolute ether, and to direct the spray in brisk current at a distance of about an inch from the part. To induce the less determinate condition the ether may be diluted. This may be done by mixing alcohol with the ether, or better still chloroform. Two mixtures of this kind are very useful; one contains six parts of ether and two of chloroform, the other seven of ether and one of chloroform. In using pure ether, or the mixture, differences of time are required. To cause insensibility with the simple fluid—ether—from fifteen to fifty seconds only are necessary. To produce insensibility by the mixture of ether and alcohol, or of ether and chloroform, from four to five minutes are demanded. The sensation felt by the patient also differs. When pure ether is used little if anything is felt until the moment when the part becomes white: then there is a sharp, pricking, burning sensation. When the compound or mixture is used, the sensation, very prolonged by comparison, is that of numbness and aching. On the whole, I have found patients generally prefer the more rapid procedure.

The nature of the operation will, to a large extent, determine the method to be resorted to. For opening an abscess, for incising a small carbuncle, for tying a nævus, for removing very small tumours, for applying nitric acid, and for operations of a similar kind, the mixture of ether and alcohol, or of ether and chloroform, answers every requirement. I should myself also use the mixture in an operation for hernia, because the tissues would not be rendered hard, and the dissections could be carried on with delicacy. But for deeper operations, such as removal of the nail, of portions of bone, of fingers, and the like, the complete action of the anæsthesia requires to be brought into play. For teeth extraction the pure ether also answers best—it acts rapidly and deeply, and there is no great accumulation of fluid in the mouth. By practice, the two degrees of action I have named may be obtained by the employment of ether alone: I mean, the degree of anæsthesia from the spray of absolute ether can be determined by the distance from the part at which the spray is directed: by removing the jet three inches from the part, a moderate effect is produced, nearly equivalent to the dilution of seven parts of ether with one of chloroform. The condition of the patient generally ought likewise to be considered. Aged and weak people become anæsthetic very readily, and for them the milder process is most applicable.

I had intended this week to supply the particulars of experiments on a large number of fluids, simple and compound, which I have tested; but the inquiry is not so exhaustive as I could wish. The substances experimented with are numerous, and the analysis of their respective qualities is a task demanding judicial care. I reserve the subject, therefore, for my next chapter.

The Cholera Conference.—Constantinople, March 7.—A proposal made by the French representative at the Cholera Conference to stop the sea communication between Hedjaz and Egypt; in the event of another epidemic, has been adopted. The Porte, however, will not accept or enforce the measure, fearing an insurrection among the pilgrims. Reinforcements have been sent to Schumla pending the decision of the Conference now being held at Paris.

WHEAT PHOSPHATES.

By TILBURY FOX, M.D. Lond.

Several years ago I became aware that Dr. Hake had suggested to Messrs. Bullock and Reynolds the production of a preparation containing the organised chemical products residing in the outer layers of the wheat grain, believing that they probably would be found to possess peculiar nutritive qualities. In the year 1862, in a paper read before the Obstetrical Society of London, I drew particular attention to the good effects observed to follow from its use. During the last few years I have continued to prescribe the *wheat phosphates*, as the preparation is named, with great success, and feel so confident of its virtues that I strongly recommend it to the Profession in general.

Whilst the subject of infants' food has, on account of prolific inventions and suggestions, become rather a bore, the tendency of refinement has been in the wrong direction, and very nice looking products, pleasing to the eye, but useless for nutrition, have been obtained. The various forms of infants' food are in the great majority of instances simply and purely starch, the central portions of the cereals consisting entirely of the latter product; these foods do not deserve the name of, and *are not, flours;* to call them flours is nothing more or less than *fraud*. Now, inasmuch as the starchy element is not the assimilative nor the flesh forming, but the heat and fat producing principle, all our past efforts in securing a nice white flour have been antagonistic to the possession of nutritive material, and actually the very desirable part of the grain contained in the bran—viz., the organised phosphates and other principles, have been deliberately rejected. Seconds flour makes a much more wholesome bread than that of the first quality.

The importance of a due supply of phosphates in health and disease has been fully recognised at the present day, and as a result we now possess various pyro-, super-, and hypophosphates and phites.

My experience teaches me that there is something essentially special in the organised phosphates—those, in fact, *which have been formed by passing through a living organism* (in Nature's own laboratory)—as compared with artificially-prepared phosphates. It is not the amount, but the kind exhibited that produces the good result. No simple mixture is in any way a substitute. It is not at all unlikely that the cerealin, of which little is known, but which is associated with the phosphates in the bran, and has an action similar to pepsin, may conduce to the beneficial result. A similar kind of action is observed in those cases where quinine fails, but decoction of bark instantly succeeds. The organised phosphates I speak of aid the assimilative function, and I find that ordinary foods are digested, and even medicines—for example, iron when given in combination—act most efficiently after they have previously failed alone. The same is the case with ordinary food in weak digestions. Many of the "foods" recommended are really animal in character—such are the extracts of meat. Nature distinctly points to the agent now under notice as a preferable aid, in virtue of its vegetable origin. The wheat phosphates, too, contain the desirable properties of brown bread without the objectionable ones—viz., the cuticle and husk.

The mode of preparation is simply to make a decoction of well-selected bran, carefully evaporate in a water bath, mix the residue with sugar, and reduce to powder. It may be used in the place of sugar, a teaspoonful or less being added two or three times a-day to the child's food. The cases in which its use is chiefly indicated are those amongst the young, in whom the assimilative function is at fault. I can speak very strongly in cases which belong to my own particular specialty—diseases of the skin. Eruptive diseases of the scalp in infants are most frequently associated with faulty assimilation. Here the wheat phosphates act marvellously well. But in rickets, in marasmus, chronic diarrhœa, and impaired nutrition of all kinds, I believe them to be most invaluable adjuncts. Pallid children pick up tone, colour, and flesh; worms disappear; intestinal irritation subsides; the secretions become healthy; and disease goes. I lay great stress on the phosphates under notice in their character as *organised products* as greatly helping assimilation of food and medicinal agents, and believe them to be the most preferable form of phosphates, especially for the young.

43, Sackville-street, W.

ON SOME FORMS OF DYSPHAGIA (a),

WITH SPECIAL REFERENCE TO NEW METHODS OF TREATMENT.

By MORELL MACKENZIE, M.D. Lond., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat.

(Concluded from page 222.)

The paralytic forms of pharyngeal dysphagia may be due, 1st, to disease of the brain; 2nd, to disease of the spinal cord; 3rd, to disease of the nerves of the part.

1. In the first form, the dysphagia is associated with hemiplegia, and the difficulty of swallowing affects only one side of the food tract. Such cases are very rare, but I had lately a hemiplegia patient under my care who could only swallow whilst lying on his healthy side. Romberg has called attention to this form of dysphagia, and to the fact that the patient can generally swallow whilst lying on the healthy side.

2. That form of pharyngeal dysphagia dependent on disease of the spinal cord cannot be combated locally. It is quickly followed by spasm of the diaphragm.

3. Local weakness of the nerves and muscles is by no means an uncommon source of pharyngeal paralysis.

It is due to many remote causes, hysteria, nervous irritability, anæmia, chlorosis, &c. In these cases I have found the local application of electricity most serviceable; one pole(b) should be applied internally to the mucous membrane of the pharynx, the other to the neck externally; the internal pole must be applied higher or lower according as the paralysis appears to be situated in the upper or lower part of the throat. In these cases there is probably some impairment of the muscular structure of the pharynx as well as the nerve force.

I have had several very severe cases under my care. In one the loss of power was of fourteen years' duration; in two others the impaired power of deglutition had lasted five years.

The lady whose case was of the longest duration—fourteen years—recovered her power of swallowing entirely under a course of treatment of three or four months' duration. In her case the pharyngeal dysphagia was complicated by a slightly impaired action of one side of the epiglottis, and the advance and elevation of the larynx was very slowly performed, probably from loss of power of the elevators of the hyoid bone. The following is the account of the symptoms as described by the lady's husband:—

"In the spring of 1848, about three or four months subsequently to our marriage, Mrs. L. began to complain of constant uneasiness in the throat, the description she gave of it being that it felt as if it were lined sometimes with stiff muslin, and at other times with wet sponge. The sensation was for some months one rather of severe inconvenience than of pain, and no difficulty was experienced in either eating or drinking. The only explanation that ever occurred to us of the origin of this state of things is, that the time referred to we were living in a very damp house, and my wife was in a feeble state of health. Shortly after the appearance of this symptom Mrs. L. suffered from a somewhat serious attack of tendency of blood to the head, and during six months was under constant medical treatment. The first instance of pain and difficulty in swallowing occurred in the winter of 1849, when as she was suckling her infant her Medical adviser had directed her to drink stout. Upon one occasion while so doing she was seized with an apparent spasm in the throat, followed by symptoms of choking so violent that the nurse thought she was in a fit. Previously to this, Mrs. L. had rarely drank anything but tea or coffee and cold water. Since that time until within the last few weeks—a period of fourteen years—she has suffered excruciating distress in consequence of her inability to swallow any liquids naturally. During the greater portion of this time she has been only able to sip drop by drop, and this has been done with great dread of the process, her horror of liquids amounting almost to the descriptions I have read of hydrophobia. The depression of spirits she has suffered has been intense, and at times alarming. During the whole of these fourteen years Mrs. L. never but once has taken a mouthful of liquid at one time, this exception occurring in 1855, when, in the pains of parturition, she drank one cup of tea naturally. All sorts of expedients were adopted,

(a) This paper was originally read before the Medical Society of London.

(b) For applying electricity in these cases I have had an "Œsophageal galvaniser" constructed on the principle of my laryngeal galvaniser, though thicker and longer than that instrument. The electric current does not pass beyond the handle of the instrument until the point reaches the desired spot, when a spring is touched and the shock given.

both externally and internally, but without the slightest mitigation of the evil. Change of air was repeatedly tried, but the only benefit was exceedingly slight and transient. At the first, Mrs. L. suffered nothing while eating, but subsequently to the birth of the infant in 1855 she became so weak in the throat that solid food caused her very great trouble. So much was this the case that from mere insufficiency of food she wasted to a shadow. Under the advice of her Doctor, she now resorted to the use of stimulants before taking food, and until the time of consulting you the ability to swallow has only been maintained by carefully drinking, drop by drop, a glass of wine or a small quantity of spirits and water. By half an hour or three-quarters of an hour thus spent she would be prepared to eat dinner or supper. The effort to take anything early in the morning has been so great that she has quite as frequently dispensed with breakfast altogether as she has adopted the alternative of swallowing a spoonful or two of tea drop by drop. The advice of several Physicians has been obtained, and most of them have dismissed the case as one of nervous delusion, stating that there was nothing the matter with the throat; others assigned it to hysterical causes; but the treatment in every instance was a painful failure, throwing the poor patient back into the agonies of protracted martyrdom. Upon my return home after a month's absence, in August last, I found Mrs. L. in a most deplorable state of both mind and body. She described the throat as closing, and had abandoned all hope of relief short of the grave, and longed for that relief." This patient, after a course of direct galvanism, was able to drink with almost as much facility as other people. She told me she often voluntarily took a drink of water, a thing that she had never done before for fourteen years. I should mention that, though of a decidedly nervous temperament, the lady is a remarkable sensible and intelligent person, perfectly free from fanciful delusions.

In other cases of this form of dysphagia the cure has been most rapidly, and perhaps most completely, effected; but then the disease was not of such long duration. In some cases the paralysis of the constrictor is followed by dilatation of the tube, and then the character of the symptoms alters. A case of this sort is related by Dr. Watson.(c)

Dysphagia, whether caused by the swallowing of boiling water or corrosive poisons, is seldom due to direct injury of the pharynx. In the former case it is generally caused by inflammatory tumefaction of the epiglottis; in the latter by ulceration of the mucous membrane of the œsophagus.

3. *Diseases of the Larynx and Trachea.*—The diseases of the larynx which give rise to dysphagia may be morbid conditions of the epiglottis of the arytænoid cartilages (or the mucous membrane adjoining them) of the cricoid cartilage or of the interior of the larynx. Indeed, almost all long-continued or severe diseases of the larynx give rise to this symptom. This form of dysphagia may generally be recognised by those not using the laryngoscope by two symptoms:—1st, there are laryngeal symptoms such as hoarseness and cough; 2ndly, there is great pain on attempted deglutition, coughing often takes place during the act, and the food is violently ejected through the nares. Inflammation, œdema, thickening or ulceration of the epiglottis are very common causes of dysphagia. In these cases the patient can generally swallow thick liquids, whilst those of thinner consistence, by getting in beneath the edge of the epiglottis, generally give rise to extreme irritation. In almost all cases of laryngeal dysphagia, the proper treatment consists in feeding the patient with a stomach-tube, whilst the particular local affection giving rise to the symptom is combated by suitable local remedies applied with the aid of the laryngoscope. In a case which I recently saw in consultation with Mr. Kershawe, of Surbiton, the dysphagia was associated with, or dependent on, paralysis of one of the vocal cords. Approximation of the vocal cords being one of the elements in deglutition, paralysis of either one of them seems to disturb the other laryngeal movements which take place in deglutition. Thus, the imperfect closure of the glottis causes the co-ordinate action of the epiglottis to be impaired. At least this is the only way I can account for the passage of food into the larynx in these cases. In the case I referred to just now, there was some slight thickening of the mucous membrane over the cricoid cartilage, but not enough to cause any difficulty in passing a tube into the stomach. The patient was kept alive for several days by the introduction of food in this way.

(c) "Principles and Practice of Physic," third edition, vol. ii., p. 371.

Tracheal dysphagia is a term employed by Dr. Hyde Salter to describe a form of difficulty of swallowing to which he was the first to call attention. The interesting paper which he recently brought before the Medical Society must be fresh in the recollection of all; it is, therefore, unnecessary for me to enter into details with regard to this particular variety of dysphagia. It is sufficient to remark that Dr. Salter considers that the excruciating pain which is present is due to the stretching of the trachea which takes place in deglutition. I have never seen any cases where the pain was of the severe character described by Dr. Salter, but I have seen many where slight dysphagia seemed to be caused by tenderness of the trachea. In cases like that described by Dr. Salter, I should think that the stomach-tube would be useful. Perforating ulcers of the trachea gives rise to a very distressing and invariably fatal form of dysphagia, in which, as in cases of laryngeal dysphagia, the food is violently ejected through the nares.

Diseases of the hyoid bone, and of its connexions with the larynx, are amongst the rarer causes of this symptom.

4. *Diseases of the Œsophagus.*—Spasm and paralysis, inflammation, ulceration, and cancer are the principal causes of dysphagia here. All that has been said with regard to the two first conditions as occurring in the pharynx applies equally to the œsophagus, and the observations already made are applicable here. Œsophagitis, except that form caused by the contact of corrosive poisons, is an exceedingly rare disease, and few Physicians have met with, or described accurately, its symptoms. Abernethy and Graves have each recorded one case. Burning pain between the shoulders and great agony in swallowing are the most characteristic features. Abstaining from all kinds of food—that is, giving the œsophagus perfect rest, is the proper treatment. The patient should be sustained by nutritious enemata.

Organic stricture of the œsophagus is of two kinds, traumatic and idiopathic. The traumatic variety is caused by the accidental or suicidal swallowing of corrosive poisons; the idiopathic form is due to two causes—first, simple ulceration, and secondly, to that chronic change of structure by most pathologists supposed to be characteristic of cancer.

In cases where corrosive poisons have been swallowed, if the œsophagus recovers from the primary inflammation and ulceration, gradual closing of the canal almost invariably takes place at a later period. In most cases the fatal termination occurs within three or four months, but sometimes, where the irritant has not been very powerful, the obstruction may be effected very gradually. Dr. Watson records(d) the case of a man who suffered from gradual closing up of the œsophagus five years after having swallowed a tablespoonful of a solution of the impure carbonate of potass; and the same authority quotes a case from Sir Charles Bell, in which starvation took place twenty years after some soap-lees had been swallowed. Annular stricture, a term derived from the examination of the pathological specimens in Hospital museums, where the clinical history has been lost, is always caused by the action of corrosive poisons.

Chronic thickening of the mucous membrane, and consequent closure of the œsophagus from a traumatic cause, is generally confined to a limited portion of the canal. Such cases should be treated with the stomach-tube, with bougies, and with solid caustic or solutions of nitrate of silver applied by means of an instrument to be presently described. The advantage of the use of the former agents is well shown in a case recorded by Dr. Basham, (e) in which a patient was rescued from starvation by these means. As soon as the treatment was discontinued the case relapsed, but under the use of bougies dilatation was soon effected. The patient, a young woman, died rather more than two years after the accident, but the fatal termination was brought about entirely by her neglecting to attend at the Hospital. The use of bougies is entirely palliative, but the application of caustics might perhaps be curative. If, however, experience should prove that this method does not answer, the establishment of a gastric fistula at an early period of the disease would, I believe, be the most rational treatment.

Simple idiopathic ulceration of the œsophagus is an exceedingly rare disease, though the tube is sometimes opened by the ulcerative process extending from the trachea. The treatment should be the same as that indicated in the traumatic form. The importance of establishing a gastric

(d) *Op. Cit.*, vol. ii., p. 370.
(e) Med.-Chir. *Tran.* Vol. xxxiii., p. 99. 1850.

fistula in these cases has been strongly insisted on by Dr. Habershon in his valuable work on "Diseases of the Abdomen," page 36.

As regards the treatment of malignant stricture of the œsophagus, Dr. Watson observes, "When the symptoms of stricture come on in these cases, physic can do almost nothing. Surgeons pass bougies into the gullet, and attempt to dilate the strictured portion, or to prevent any further narrowing. But this expedient is usually of temporary benefit only, and the patient dies at last of inanition. His miserable existence may, perhaps, be protracted a little by injecting nutritive enemata into the rectum. For maladies like these medicine has no cure, opiates may give comfort, and promote the euthanasia, and this is all."

The application of caustics to the seat of stricture was recommended by Sir Everard Home(f), and several interesting cases have been published by Horace Green(g) in which this plan of treatment greatly prolonged life. Nevertheless, this method of treatment has not met with general approval. Many Practitioners think that even the use of simple bougies is very injurious, and that the diseased part should be left entirely to itself. There is no denying, I think, that simple epithelial growths sometimes take on a cancerous nature from repeated applications of irritant substances. But it must be borne in mind that we have not merely to treat a case of cancer here, but to effect the patency of a canal of the first importance to life. It is not alone the nature of a disease, but its situation also, which must influence the mode of treating it. Hence it is perfectly philosophical to treat a case of cancer of the œsophagus by a mode which we should not think of adopting if the lip or tongue were the part affected, —just as an aneurism of the arch of the aorta must be treated in a very different way to popliteal aneurism. For applying caustic to the œsophagus in cases of stricture, I have had an instrument made on the principle of Lallemand's urethral *porte caustic*. Though I have used this instrument in some cases with decided benefit, I cannot say that my experience has been sufficiently extensive or that sufficient time has elapsed to enable me to speak conclusively on the subject. Cases of stricture that come under a Practitioner's care at a very advanced stage, that is, when the œsophageal canal is entirely blocked up, may be treated by the forcible passage of a fine catheter or tube with a rigid wire in its interior. Of course there is some danger in using an instrument like this. It may be pushed into the posterior mediastinum, and food injected there; in the worst case, however, it can only shorten life by a few hours; on the other hand, it may prolong it for many days. Where a tube is thus forcibly introduced, it should not be withdrawn, but should be allowed to remain in the stricture. How far the establishment of a gastric fistula would be desirable in these cases, and at what period it should be made, are questions requiring more detailed investigation than the limits of this paper would allow.

In cases of stricture of the œsophagus complicated with ulcerative opening into the trachea, the importance of the use of the stomach tube cannot be overestimated. Where the stricture will allow the passage of a small tube, the food can be thus carried beyond the opening in the trachea.

The life of a patient recently under my care was prolonged for many weeks in this way. He was unable to swallow a particle of food or even a drop of fluid, as everything passed into the trachea; but with the stomach tube he could be fed with ease. After death, a large mass of cancerous deposit was found in the œosophagus, and an opening between that tube and the trachea.

5. Diseases of the Parts Contiguous to the Food Tract.—Tumours, whether simple or malignant, and aneurism of the arch of the aorta are the most common contiguous causes of dysphagia. The importance of these diseases, as giving rise to this symptom, was well shown in a valuable communication on Mediastinal Tumours which Dr. Symes Thompson recently brought before the Medical Society.(h) In cases of aneurism, no instruments should ever be introduced into the œsophagus. The cause of the dysphagia can alone be treated, and that only by feeble and indirect means. In the case of other tumours pressing on the lower part of the œsophagus, there is nothing to be done. The sudden enlargement of the cervical glands where children are the subjects sometimes gives rise to dysphagia, and I have even heard of cases where complete inanition has taken place. In these cases the stomach tube would be of the first importance.

In this brief and imperfect paper I have endeavoured to give prominence to the stomach tube as a means of prolonging life. The use of this agent does not appear to me to be appreciated as it deserves by the bulk of Practitioners. In the case of acute and chronic enlargement of the tonsils, new methods of treatment have been suggested, as likewise in cases of dysphagia dependent on neurotic causes. For the treatment of malignant diseases of the œsophagus, attention has been called to a plan which, though long ago brought forward, has never come into vogue. The limits of this communication preclude the possibility of discussing at length some rare conditions (such as œsophageal cellulitis and œsophageal pouches, or of investigating the various reflex causes of dysphagia (such as diseases of the heart and lungs) which occasionally give rise to difficulty of swallowing.

CASE OF ABSCESS OF THE BRAIN.

By T. B. MORIARTY, A.B., M.D., etc.

The subject of this case was a young man of strong plethoric constitution, who was attacked by assassins on December 30. He received two wounds—one a lacerated, two inches in length over the occiput, which laid bare the bone and bled profusely. The other an incised wound—the subject of these remarks—was inflicted over that part of the left frontal bone known as the "temple," in length two inches, with a deep depression in the centre which led to a depressed fracture. Compression later on ensued in consequence of the formation of an abscess between the dura mater and the bone. The wound in the back of the head got well rapidly, and as the depression did not interfere with the mental faculties an attempt was made to produce as much union as possible by the first intention. A bone abscess manifested itself, and the matter, which soon became offensive, ceased to discharge almost entirely after a fortnight's time. The early part of the treatment consisted of counter-irritation, purgatives, and calomel, with a diaphoretic mixture. From the outset there existed a slight incoherency in speaking without the occurrence of any epileptic fit.

On January 19 this man felt well enough to write three business letters.

On the 20th he appeared so much improved as to be allowed to use chicken broth.

On the 21st it is said he vomited a quantity of greenish fluid; and on the night of the 24th he was again seen by me, when his condition was the following:—Lying quite insensible; pupils contracted; pulse 51. Neither asking for anything nor making known his wants in any way. There was no excess of urine in the bladder. These symptoms, as well as my previous acquaintance with the case, led me to conclude that there was an abscess lying beneath the frontal wound. On this account I demanded the assistance of another Doctor. Calomel was given in small doses every two hours.

The following day two pieces of bone came away, and on the ensuing day some two pieces more of bone were extracted. It was then proposed to trephine, as the attempts to raise the depressed bone were ineffectual.

On the 27th I enlarged the wounds longitudinally and laterally by a crucial incision. Another effort was then made to raise the bone by means of the elevator; while doing so, the matter, which was very offensive, got exit, and in a few minutes our patient opened his eyes, and said, "Doctor, you are hurting me." He soon began to recognise those around him.

The following day the depressed bone was broken off, so as to leave no source of irritation; a quantity of sanious matter exuded, which was succeeded by a copious discharge of pent-up pus. As soon as the opening was cleaned the pulsations of the brain became quite visible. Mercury, with chalk, had been administered until salivation was effected, so as to guard against any tendency to meningitis.

February 1.—There has been a copious discharge from the wound, which is filling up with fibrous tissue. Patient going on very favourably; pulse 80; there is no relaxation of the sphincters.

24th.—Is now quite recovered.

Limerick.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SPECIAL REPORT ON THE TREATMENT OF FRACTURES IN THE LONDON HOSPITALS.

FRACTURES OF THE UPPER EXTREMITY.

In the following paper we lay before our readers the ordinary methods we have seen adopted in the various Hospitals we have visited. It will be observed that the simplest possible forms are in most general use, the complicated apparatuses described in the special works on this subject we have not seen employed in any instance; and those that we here describe are such as might be applied at any moment and with the most ordinary materials.

Compound fractures we have not entered upon, the general principles in the treatment of these cases we shall reserve for a subsequent paper.

We are compelled to omit a notice of the treatment of fractures of the scapula, as in collecting materials for this report we have not met with any instances of fractures of this bone. We shall be careful, however, to supply this omission whenever opportunities offer.

FRACTURES OF THE CLAVICLE.

The methods of treating fractures of this bone that have come under our observation are, without exception, of the simplest possible form, and their principles almost identical. First, there is the simplest of all, viz., that of placing a pad of tow or cotton wool in the axilla, and a figure of 8 bandage taken round the shoulders and back, a few turns of which bandage are used to bind the elbow to the side, whilst the forearm is slung up.

A second method, similar to the latter, but rather more complicated in its mode of application, is in very general use. A stout wedge-shaped pad, made of horsehair or webbing stuffed, should be secured firmly in the axilla by stitching a piece of bandage to it, and fastening it round the opposite shoulder; next, a turn or two of a bandage should be taken round the middle of the humerus of the affected side, and passed round the back of the patient, and then round the chest, a sufficient number of turns being made to thoroughly keep it to the side, and slightly back; the forearm should then be laid with the palm of the hand flat across the chest and towards the opposite shoulders, and should be enclosed or bound to the chest by a series of turns round the body, the elbow being supported by a few passed under it and over the opposite shoulder. This apparatus is best kept firm and in its place by stitching together the turns of the bandages in places where the amount of pressure is greatest, and where there is most chance of its slipping.

The simple figure of 8, whether applied by a series of bandages or by an apparatus made of leather passing under the axilla and buckled together in the back, we have not seen in use, being generally objected to by Surgeons, on the ground that by it the inner end of the distal fragment being pressed upon, is pushed behind and below the other, and great distortion produced.

A method is sometimes adopted of merely allowing the patient to recline in bed on his back without any bandages or appliances of any sort, the recumbent position being sufficient to keep the fractured extremities of the bones in apposition, with the best results.

In cases of fracture of the clavicle in children, Mr. Wood merely uses a sling.

The above described arrangement of bandages may be strengthened by applying dextrine, starch, or plaster of Paris, as a means of keeping the fragments more thoroughly in apposition.

A good rough and ready way of keeping the fragments in apposition until suitable appliances can be used may be put in practice as follows, viz., to take two pocket handkerchiefs, and, tying them round each axilla, with the ends left long, these ends being subsequently tied together crosswise behind the back, and so forming a sort of figure of 8. A third handkerchief may be used as a sling. This acts very well as a temporary support.

FRACTURES OF THE HUMERUS.

Fractures of the Neck of the Humerus.—The principle of treatment is much the same in all the cases we have seen. Some Surgeons place a pad in the axilla to keep the upper end of the fragment in position, with a long splint on the outside of the arm, and bandage the elbow to the side. Or an apparatus is employed consisting of a rectangular iron splint with a crutch fitting tightly into the axilla, to which it can be more perfectly adapted, and extension procured by a screw. In this instance care should be taken that the splint does not press too tightly into the axilla and produce œdema. Sometimes splints are not used at all, but a gutta-percha cap is moulded to the shoulder and continued for some way down the arm, a pad being placed in the axilla, and the gutta-percha mould bandaged carefully to the thorax, and the arm carried slung up.

Mr. Erichsen recommends a plan of bending a strip of gutta-percha or sole leather—about two feet long by six inches broad—upon itself, and placing it between the inner side of the humerus and the thorax, with the part formed by the bend pushed well up into the axilla and adapted to its shape. When the fracture is above the insertion of the latissimus dorsi, Mr. Wood uses a stout wedge-shaped pad with the base in the axilla, and a long outside-splint reaching from the acromion to the outer condyle; when below the insertion of this muscle, the apex of the wedge is placed in the axilla. The splint is kept in its place and the arm bandaged to the side and slung up by a figure of 8 bandage. The reasons for applying the pad differently in these two cases is sufficiently obvious from the form of displacement.

Fractures of the Shaft.—These are treated by first bringing the fragments into apposition; next the forearm and hand should be carefully bandaged to prevent œdema; then a well-padded, hollow splint, extending from the axilla to the inner condyle, should be adapted to the side of the arm, a similar one being applied to the outer side from the acromion to the outer condyle, whilst the fragments may be kept in still closer apposition by shorter splints before and behind; these are carefully kept in their places by buckled fillets, bandage, or gum and starch bandages.

In all cases of fracture of the shaft of the humerus, Mr. Partridge recommends the splints applied to the upper arm to be continued to the forearm, on the ground that the humerus the most frequently of all bones is the seat of ununited fracture, this being due to the repeated attempt at pronation and supination during the process of union. We have recently seen two cases of ununited fracture of the shaft of the humerus, under the care of Sir William Fergusson at King's College. In each instance the ends of the bone were bevelled with a saw, and wires passed through and brought round the shaft, firmly locking them together. Perfect union was obtained in each case.

FRACTURES OF THE LOWER EXTREMITY.

These are treated most generally by inside rectangular splints, made either of wood or metal, and well padded; they should be jointed at the bend of the elbow, and be capable of being fixed in any position by means of a screw.

Pasteboard or gutta-percha splints are in frequent use. In all instances care should be taken to leave the joint sufficiently exposed for the application of fomentations—leeches, etc., in cases where great inflammatory action may come on. In very severe cases the arm is best laid on a pillow and treated with evaporating lotions, or merely resting on the splint without being bandaged to it.

Passive motion should be commenced in about three weeks or a month.

A method of slinging fractures of the upper extremity, similar to that adopted in fractures of the leg, we have seen in very general use in Mr. Paget's wards at St. Bartholomew's Hospital. It appears to afford the same advantages that are obtained from slinging the lower extremity. This method of treatment, we may say, in passing, is employed in all severe affections of the arm and forearm; as, for instance, phlegmonious erysipelas, extensive suppuration, bad compound fractures, and in cases of excision both of the elbow and wrist joint. The limb is very easily slung, as it lies on the ordinary angular splint, by means of lengths of bandage, or of webbing, which are passed either over a horizontal bar projecting from the wall above the patient or over some portion of the framework of the bed.

FRACTURES OF THE FOREARM.

Fracture of the Olecranon.—Extension by a well-padded

splint applied to the front of the forearm, or by a gutta-percha splint extending from the middle of the arm to the wrist.

Fracture of Both Bones.—The bones are placed midway between pronation and supination, and two light, well-padded splints placed on the back and front of the arm, and either bandaged or kept on by strapping. Some Surgeons continue the splint on to the tips of the fingers, whilst others leave the fingers at liberty by applying the splint only as low as the wrist or web of the fingers. This latter plan of treatment appears to be a point of very considerable practical importance, especially in the case of those engaged in manual pursuits. When the hand is kept in rigid extension for the necessary period of union of the fracture, it becomes so stiffened and weakened that its functions are impaired for many weeks. On the other hand, when the splint is so arranged (that is, coming as far forward only as the web of the hand) the normal movements—flexion and extension—can be resumed as soon as the first feeling of soreness caused by the accident has subsided; and so it happens that persons whose fractures have been thus treated are enabled, upon the removal of the splint, to resume their ordinary occupation very shortly. We have lately seen several instances of fractures treated by the shorter splint, in which, on the removal of the apparatus, the patients were enabled to return to their ordinary occupation without further loss of time; while after the use of the long splint we believe it not to be unusual that several weeks or even months may elapse before perfect strength and movement is recovered. These splints may have a ridge along their middle to adapt itself to the interosseous spaces, and so prevent the bones from being pressed together.

Fracture of Lower End of Radius (Colles's).—The hand is adducted by a bent or pistol splint, which some Surgeons apply to the palmar, whilst others prefer the dorsal surface; or the pistol splint may be applied to the dorsal and a straight splint extending into the middle of the palm on the front surface. We have seen this form of fracture treated very successfully by applying a broad splint to the front of the forearm and extending only to the web of the fingers, which are bound carefully over the end of it, no adduction being used at all. In fracture of the forearm it is very convenient to fix the splints to the limb, independently of one another, so that in the course of treatment that on the dorsal aspect may be removed for the examination of the fracture, while that on the palmar remains as a support. The upper extremity of the palmar splint should not be placed so as to press upon the internal condyle, as, if it does so, this sharp prominence of bone is liable to be rendered tender, and be a source of discomfort to the patient.

SATURDAY, MARCH 17.

A SAD TALE OF MISMANAGEMENT.

We have adverted more than once to the late disastrous sickness and loss of life among our troops at Hong-Kong. Now that we are fresh from a perusal of a Parliamentary return of all the correspondence on that subject, we make no apologies for laying the matter before our readers.

A feeling of indignation becomes so paramount in the mind at first that it requires a little time before one can look calmly and impartially into the question. One word—retrenchment—supplies the key to the whole, and lays bare the primary cause of these lamentable occurrences. The War Office was determined to make a reduction in the China command in order to save the Indian allowances, and it resisted from first to last every attempt on the part of the officials in China to alter that determination. As those officials were interested in maintaining those allowances, it was not to be supposed that their opinions and judgment could be untainted with sordid motives!

We are accustomed to stories about "fever nests" at home, but the selfishness, if not the humanity, of our opulent classes puts a limit upon the spread of causes which may obviously involve their own lives. It is only in the public services that we can expect to see preventible diseases on such a grand scale as the present.

The documentary evidence about these occurrences at China does not lack any element of interest. It unfolds a very mournful tale; it gives a peculiar insight into circumlocution; at every turn which the red tape makes in its slow unwinding from off the official reel at home disease is advancing with a giant stride abroad. It brings before us in a very forcible way the old truth that when men bid defiance to sanitary precautions they will pay very surely and very dearly for their rashness. This return shows us the marvellous rapidity with which disease increases in hot climates; how the very little cloud of to-day becomes the ominous large one of to-morrow, and attains on the third day an awful magnitude.

As in most stories, so in this, there is something of the heroic—a ring of the true metal in it. Amid all the sickness, sorrow, and trial under which the unfortunate soldiers, their wives, and little children were suffering, from May to October, there was no one more deserving of our sympathy and pity than Surgeon Saunders, of the 9th Regiment. When power and responsibility go hand in hand, the trial may prove a severe one; but in this instance a man was overwhelmed with his responsibilities, and *powerless!* He must be a good man, in more senses than one, who is found tenaciously adhering to his post and working with indomitable energy under such circumstances. Surgeon Saunders' letters are terse, manly productions, abounding in good sense and sagacity. When he found that a month would elapse before the transport he demanded for the invalids was secured, he lost no time in characterising "the delay as a solemn responsibility; many of these men will have perished whose lives might be otherwise saved." He concludes a forcible letter by adding, "You will, I trust, bear with me in making these remarks, as I am solely moved by a deep sense of duty and the cause of humanity." This Hong-Kong affair naturally suggests three questions, and the return enables us to answer two of them. 1. Why were the troops sent at all, and who is to blame for this? 2. Why were the arrangements for their accommodation so defective? 3. How comes it that the Medical Staff were absent at Japan during a time of unusual pressure?

To the first we may answer—*On the War Office unquestionably rests the whole blame;* and here is the proof. Major-General Guy repeatedly and earnestly called attention to the absence of all accommodation for a second European regiment in China. The proceedings of a Medical Board, held at Hong Kong on November 26, 1864, were forwarded to the home authorities, in which the Medical Officers strongly deprecated the further occupation of a place called Kowloon, and supported their opinion by a reference to the late experience of the 99th and 20th Regiments. A corroborative Medical certificate from a civilian Physician was attached to the proceedings of that Board. A letter, dated January 27, 1865, was forwarded to the Director-General of the Army Medical Department by Dr. Dick, calling his particular attention to the very urgent

reasons which existed against sending another European regiment to China at all, pointing out the utter want of proper accommodation, the baneful effect of the climate on the healthiest British soldiers, even when that accommodation was ample and with the aid of every practicable sanitary precaution, and begging the Director-General "to exercise his influence with the military authorities to delay, if possible, the despatch of a second English regiment to Hong Kong." This letter was forwarded by Sir James Gibson, who expressed his concurrence with the views contained in it. Again, on March 29, 1865, Dr. Dick forwarded the results of a laborious investigation into the comparative efficiency of white and black troops in China; and his sanitary statistics proved incontestably the marked superiority in point of health and efficiency of the latter troops.

"The facts indicated by the above figures," he says, "at the present time, when China is about to be garrisoned wholly by white troops, afford matter for very serious reflection, both in a financial and sanitary point of view. It is not within my province to discuss the first. But as regards the other point, there can be no question that little more than ten years would be required to expend (if I may use the word) a force of white troops, and that twenty-five years would be required to expend a similar force of black troops by deaths and invaliding. Then as regards the difference between the daily averages of sick, among the white and black troops, it results, supposing the men to have six nights in bed (and no soldier in this colony ought to have less), that there have been twenty-six more men available daily for garrison duty per 1000 men among the black than among the white troops, or, in other words, that a force of 1000 black troops has really represented a force of 1156 white troops for all purposes of garrison duty, independent altogether of the protection they have afforded the white soldier, by rendering his exposure to solar influence during the hot season unnecessary, and the absence of which will no doubt contribute materially to the increase of disease."

It is only due to the major-general commanding to say that he backed up these protests with all the weight of his authority. We have heard, further, that Dr. Dick did not rest here. When he found expostulations useless, he tried to induce the local authorities to exert their power, and delay the second regiment at Singapore.

The War Office was obdurate: unlike the unjust judge, continued complaint did not weary them into acquiescence. The regiment was sent. Major-General Guy was empowered to reduce the number of troops at Kowloon to the lowest possible amount, by removing to Japan such troops as he was unable to provide for at Hong-Kong. "Lord de Grey was not prepared to sanction the substitution of native for European troops, as suggested." "His Lordship relies with confidence on the efficacy of the measures which have been authorised for improving the sanitary condition of the British soldier in China;" "and there should be no relaxation of your efforts, as there will be none on the part of Her Majesty's Government in this direction." The terse writing of the concluding sentence is manifestly the official way of telling the major-general and his Doctors to hold their tongues and obey. As "to the efficacy of the measures for improving the sanitary condition of the British soldier in China," it is a piece of supercilious nonsense. Of what avail could such sanitary measures be in the face of such difficulties as—no barracks, bad water, worse air, and a still worse locality—such as Kowloon? This is making bricks without straw with a vengeance!

Now, the Major-General had two courses open to him. 1st. To forward the incoming regiment, or the major part of it, to Japan. Had he done this, the amount of garrison duties, as he pointed out, was such that the force left at China could not discharge them. In a military point of view, these duties were paramount in his eyes, of course. As the soldiers would simply have been killed outright by fatigue, the General naturally preferred to adopt that course for which the home authorities had made themselves responsible—viz. (2), to retain the regiment, and poison the men by overcrowding. As it proved, Chinese watchmen and police had eventually to be employed to discharge the duties of the British soldier; for these duties at last pressed so heavily on the remnant of healthy soldiers that they were enjoying only two consecutive nights in bed. Of course, it appears to the non-military reader that it would have been far better to have diminished the military duties at once to the utmost extent, and so husbanded the strength of the soldiers; but, even so, we doubt whether the mortality would have been sensibly affected owing to the presence of the other evils.

2ndly. The 11th Regiment arrived at Hong-Kong a month earlier than was anticipated. It embarked at the Cape at the end of the summer, had a very hot passage, arrived in time for another summer in China, and it was stationed during the worst season of the year in the most unhealthy locality, for want of any other mode of accommodation. Still, no unnecessary delay appears to have taken place in making the best practicable arrangements. The official instructions, notifying the decision of the War Office to send the 11th Regiment to Hong-Kong, were received at the end of February. A Board was held within a week. The greatest difficulty was experienced in securing anything like proper buildings; for it must be remembered there were no such buildings to be had at the station for love or money. Some were finally secured in March; but nearly four months were still required to make such alterations as were indispensably necessary for the accommodation of troops. In the meantime the 11th Regiment arrived. Nothing was ready, of course. Dirt, excessive overcrowding, abominable buildings, a bad position in a malarious neighbourhood, at once came into full play; insufficient rest and laborious military duties followed in due course, and in an increasing ratio as the sick became more and more in number. The end we know, as far as the effects of such gross mismanagement can be said to have an end. Out of 2000 human beings 196 died and 290 were invalided in eight months, and a large number of those invalided died either on the passage or at the Cape. The 9th and 11th Regiments both became ineffective; the latter regiment utterly so: and the retrenchment scheme of the War Office miserably failed after all. The Hospital expenses for the quarter amounted to nearly £2000, and the quinine alone cost £385 10s. Of course, there are the expenses of transport, those attending the landing of the sick at the Cape, *the transport for removal of the survivors of the* 11*th Regiment, and its relief by a black corps after all*, and the pensions of all the invalided soldiers,—not to say anything of the enormous cost incurred by the loss of old soldiers, at a time when recruits are so scarce that a Royal Commission has been appointed to devise means to obtain them.

3rd. To the last question the Parliamentary return affords no answer. By the end of the year the War Office officials commenced to feel very considerable alarm. They yet held one court card in their hand, on the adroit playing of which much depended—the reported absence of the Medical staff at Japan! This has been eagerly seized upon as the only chance of shunting the responsibility from the War Office, and this court card was therefore played with desperate vigour. Earl de Grey "desires to be furnished, after a searching inquiry, with a full explanation of the circumstances under which, at a time of such severe sickness, this extraordinary and unfortunate absence of the principal Medical officers of the command took place." It is very much to be lamented indeed, because it is the only blot that we can find in the case. We await the explanation with anxiety, for with that single exception our Profession has thoroughly performed its duty to the nation.

WE hear that a proposal has been made by a Society of Sisters of Mercy to undertake the management of the nursing in St. George's Hospital, which proposal was to be taken into consideration by a meeting of the Governors on Thursday last.

DR. FARR ON THE PROGRESS OF EPIDEMICS.

The history of Medicine furnishes plenty of evidence in proof of the fact that epidemics have swept at different periods over a greater or less area of the inhabited world, in waves or surges of varying extent; now limited, now extensive; whilst the comparative fatality of the same disease has varied with different visitations considerably. The explanation of the fact, however, still remains uncertain, for little has been ascertained in regard to the laws by which these differences of behaviour have been governed. Recently Dr. Farr has called attention to some points in the history of Rinderpest which deserve special attention, and illustrate in a remarkable manner certain constant features in the rise and fall of epidemics in general.

Mr. Lowe expressed the belief, perhaps, of the majority of people when in the House of Commons, a little time since, he remarked that "if we do not get the disease (Rinderpest) under by the middle of April, prepare yourself for a calamity beyond all calculation." This opinion was based upon the supposition "that there is no reason why the terrible law of increase which has prevailed hitherto should not prevail henceforth." Dr. Farr took exception in one of the papers to Mr. Lowe's statements, and observed "that it admits of mathematical demonstration, that the law of increase which has hitherto prevailed," correctly interpreted, leads to an exactly opposite conclusion, and justifies us in assuming that the Rinderpest will actually speedily diminish in severity and extent. Dr. Farr, calculating the number of attacks for several weeks, found that the ratio of increase was proportionately less from week to week, as will be seen from the following figures:—

1865.	Attacks.	New cases in four weeks.
October 7	11,300	——
November 4	20,897	9,597
December 2	39,714	18,819
December 30	73,549	33,835
January 27, 1866	120,740	47,191

Dr. Farr, moreover, drew the inference that "the rate of increase goes on rapidly decreasing until the ratio itself is decreasing," and affirmed that the Rinderpest would attain its height about the beginning of March, and then speedily decline in frequency. So it has turned out.

This course of the epidemic may be represented by lines of different altitudes corresponding to the several numbers representing attacks, and forming together a curve, such as that represented on the opposite page, for which we are indebted to Dr. Farr. It is merely intended to be an approximation to the truth.

The following table shows the exact number, in figures, of probable attacks calculated up to July 28, 1866:—

RINDERPEST.

Week ending	Actual attacks reported in each week.	Calculated series of weekly attacks.
October 28	1,611	1,437
November 4	1,765	1,849
,, 11	2,580	2,338

The total death rate up to March 3 appears to be 81·8, the recoveries 18·2 per cent. This is shown below, and differs from the totals given by the Privy Council.

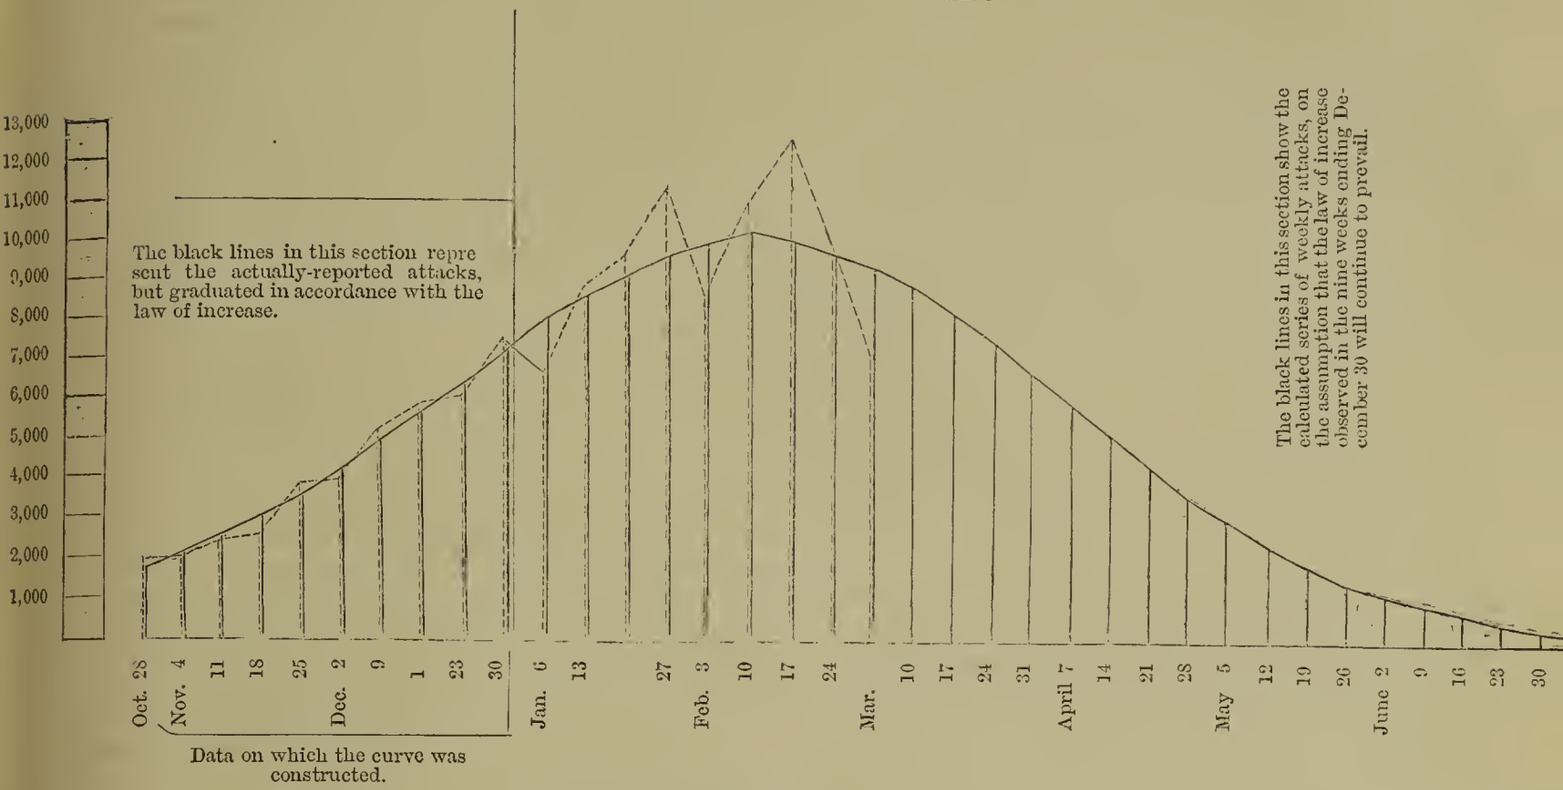
From the commencement of the disease to March 3.		True per-centage.
Died	117,664	81·8 deaths
Recovered	26,106	18·2 recoveries
Total cases terminated naturally	143,770	100·0

The difference between the totals of the "calculated" series of Dr. Farr and those of the Veterinary Department is explained by the peculiar way in which the latter are made up. The returns for the week are often received at a late period, and are then included in those of the subsequent weeks. Dr. Farr purposely took the *reported* cases, as being on the whole more trustworthy, without the admission of the element of "back cases." In some weeks, no doubt, the large number of "back cases" are due to a vigorous use of the official whip. An addition of about *one-fourth* to the reported weekly attacks would quite cover all the back cases. The diagram of the curve shows on January 27 and February 17 a rise above, and, on the other hand, on February 3 and March 3 a fall below the calculated number. This difference is explained by the fact mentioned. It is necessary to add that if certain additional circumstances which have recently arisen, in reference to the spread of cattle plague, such as stamping-out measures, were considered, and a series of calculations deduced from the actual observations, embodying the latest data, that the new corresponding curve would exhibit a much more marked fall than that represented in the diagram.

Now, how are we to explain this mode of progress of Rinderpest, and to what is the subsidence of all epidemics due? Dr. Farr observes "*that diminished activity of the zymotic matter and augmented power of resistance in the survivors are the facts to which the subsidence of epidemics of small-pox, cholera, measles, scarlatina, and typhus, are in themselves referable.*" The diminution in the virulence of poisons is supposed to be specially due to transmission through several animals of the same kind; but, in addition, season must have some influence, possibly depending upon the character of the atmosphere, the amount of ozone or antozone; the degree of temperature, humidity, and the like.

The increased resistant power of those attacked at a later period *in the same region* is due to the varying degree of predisposition to attack, and certain local peculiarities, such as bad hygiene or bad food. It is hardly fair to apply arguments taken from the case of Steppe cattle in this matter to that of cattle in our own country, because of the effect of acclimatisation in the former instance. There are also some unusual agencies that may come into play and modify the progress of an epidemic—viz., the stoppage or increased facilities in the transmission of poison, the greater or less diffusion of the latter by winds, moist clouds, and such like. But making due

CURVE REPRESENTING THE PROGRESS OF RINDERPEST, ACCORDING TO THE LAW RULING IN THE FIRST NINE WEEKS.



The *dotted lines* represent the reported *weekly* attacks of Rinderpest.
The *black lines* are all calculated from the numbers returned in the nine last weeks of 1865, and agree closely with the dotted lines.

All that the curve proves is, that, if the attacks *increase according to the same law* as ruled from Oct. 28 to Dec. 30, the disease will soon attain its maximum. The same kind of law regulates cholera, diphtheria, scarlatina epidemics, where slaughter is out of the question.

Date of first construction—January.

allowance, the fact remains that all poisons of zymotic nature tend to exhaust themselves in the progress of the diseases with which they are associated, and Dr. Farr bases this conclusion upon observation taken with regard to diseases in general.

Now, the same epidemic in different visitations does not preserve the same curve, simply because the concomitants, the quality of the poison, the state of the health of communities, and the obstacles offered to progress of disease, etc., vary very considerably at different times. It is possible, however, to calculate from accurate returns of attacks made during the first few weeks, the probable duration, extent, and even character of any epidemic, and to construct a wave or curve in accordance therewith.

It is only fair to notice some objections which have been made against the law of epidemics by Dr. Farr. Professor Gamgee declares to us that the poison of Rinderpest will, if it can reach them, kill all animals, less ten per cent. recoveries; the reduction in fatality is rapid, because the progressive increase between the distance of infected and healthy beasts offers a difficulty in communication—that is to say, the same number of beasts scattered will not infect so freely as when collected together. Suppose we take Dr. Farr's figures again. On November 7, there were 11,300 beasts diseased; on November 4, 20,897. Now, it may be asserted that the 20,897 were more *scattered* than the 11,300, and could not in the aggregate produce so great an increase of attacks as the 11,300, collected together into the focus in a more circumscribed space. This we scarcely think true. If we examine the map of England, and mark out the spots where the plague exists, we shall be compelled to conclude, calculating as carefully as we may be able, that the sources or centres of poison diffusion, as they now stand, afford a much greater liability to infection than has existed during the earlier progress of the Rinderpest, and the facts of all human zymoses are entirely confirmatory. Professor Gamgee points to the case of Egypt, where the Rinderpest did not step till it had killed every animal in the country; but Egypt is in a very exceptional condition. We must remember that in that country the circumstances favourable to intercommunication and intertransmission are most fully developed. A large number of cattle comes from the lower parts by way of Nubia; the tracts of cultivated land are narrow, and the cattle stations at different points are so many halting spots at which infection is easily accomplished; in fact, speaking from personal observation, and a knowledge of the close contact of men and beasts, we are not surprised at the result. In addition, it is worth mentioning that dead carcases of beasts are never removed away from the habitations of the people, but are allowed to putrify and dry up, giving off pestilential effluvia, which are probably easily conveyed to the adjoining healthy beasts during the humid nights that always prevail. It is an *accidental* circumstance that becomes in Egypt a factor of great power. Professor Gamgee, then, does not think that the virus of Rinderpest (save in Steppe beasts) loses any of its force by transmission through several animals. That it has, however, lost some of its virulence is certain.

If we take Dr. Farr's figures, and calculate the number of those animals in whom one can trace the natural course from the commencement to the termination of the disease, we shall find that the percentage of deaths to attacks is lessening. The Privy Council returns include the five classes—attacked, recovered, died, killed, and unaccounted for; but to arrive at a just result it is necessary to leave out of consideration the killed and unaccounted for. The deaths and recoveries of these two latter classes could probably be estimated, but to include the latter would be like including in the death rate of a Hospital the patients that remain in the wards at the time of calculation; therefore, Dr. Farr has only taken into consideration those cases which can be followed to their termination without any interference. The result is, in the total up to March 3, 18·2 per cent. of recoveries. But more than this; the returns up to January show that only 15 per cent. of recoveries took place, the returns up to the present time 23 per cent.; showing a decided diminution in the fatality of Rinder-

pest. The Privy Council returns do not calculate in the percentage of recovery the proportion of recoveries that would be observed in the killed and unaccounted for; this is manifestly an error. Now this favourable augury is not due to the fact that the Rinderpest has carried off the animals most predisposed, and is now attacking those less liable, to its ravages. This might hold good if the Rinderpest were limited in its spread to the same locality. It attacks, however, new neighbourhoods and beasts that have not been exposed to infection before; in other words, such as are placed under conditions exactly identical with those originally attacked by the disease.

We conclude, then, that the quality of the virus is not so malignant in character as it was; that the epidemic is rapidly losing its hold upon the country; and this fact is an argument against the adoption of the "stamping out" system, especially as we are led to believe that there will be at once a rapid fall in the curve, as represented by the course of Rinderpest. The Continental authorities having adopted the "stamping out" system, are unable to appreciate, from want of facts, the law which obtains in reference to the rise and fall of Rinderpest epidemic.

It may be still allowed that the stamping out system in the early onset of Rinderpest would afford a check to its spread; but it is a question whether if adopted now it would not probably do more destruction than the further progress of the epidemic itself—whether the remedy would not be worse than the disease. In the summary of weekly returns for 1865 these words occur:—"The Rinderpest has created an alarm which could never have arisen in England if people knew the amount of stock and its mortality in ordinary times as well as the laws which govern epizootics precisely as they govern epidemics." A good deal has been said against statistics; they often, no doubt, lead to fallacious results, but rather from the manner of being handled than any other cause. It is necessary to eliminate various valueless factors, and when they are used judiciously and by such an authority as Dr. Farr, we see to what important results they lead. The very important law thus enunciated by Dr. Farr is of the greatest interest to our Profession, and we can only hope that, from the enormous mass of valuable material which is in his possession, Dr. Farr will give us further information and data in reference to the spread of zymotic diseases, individually and collectively.

SMOKE SEWERS.

It appears from official returns that about 5,300,000 tons of coal were brought into London in 1865. It is notorious that a large quantity of this is wasted in the form of *visible* smoke—that is to say, of the common products of combustion, rendered visible by that unburnt carbon which clouds the sky, lessens our daylight and warmth, lessens the actinic power of the sun's rays, both in producing photographic pictures and in tinting the blood of a rich red colour, suffocates our trees and shrubs, dirties our linen and books, befouls and hardens our rainwater, injures our pictures and furniture, and causes our back windows to be shut and our back chimneys to be stopped up, for fear of return smoke and blacks. All this is due to the wasteful and barbarous construction of furnaces and stoves, whereby our coal is slowly roasted or distilled before it is burned, and much of the most valuable part of the fuel, and especially that which forms the bright and cheerful flame, is allowed to escape unburned in the form of smoke. What the amount of waste is we cannot say; but we believe there is no exaggeration in describing one-tenth as a fair estimate.

The first and most obvious remedy is an improved form of stove, so as to secure the entire combustion of the smoke, so that the coals may be put on at the bottom, and so the smoke pass through the fire and be burned, and that nothing may go up the chimney but the heated air charged with carbonic acid, sulphate of ammonia, and other entirely oxidised products, along with just so much light ash as is necessarily carried up by the draught.

But even then the air, though very slightly clouded, would be contaminated with sulphuric acid and ammonia compounds, so that though brighter, or quite bright, it would be more or less in the condition of used-up air. The carbon of one ton of coal requires for its combustion as much oxygen as do the lungs of 2240 human beings for one day.

Obviously the right thing to do is to have no smoke;—not to allow air so vitiated to enter the breathing air of a town, any more than we allow sewage to enter the drinking water from a river. Years ago the notion of abolishing cesspools, and of conveying all the liquid refuse of houses away, even from the river down to near the sea, would have appeared as "frightfully visionary" as we dare say even now our proposition may seem, to stop up air chimneys and convey the smoke in tunnels underground. And what shall be done with it then? Why, let it be washed, and let all the sulphate of ammonium go to enrich the Essex sewage, whilst nothing but cool air escapes from tall shafts at certain distances.

There is nothing new and nothing impossible in this scheme. Years ago the eminent architect, Mr. B. Ferrey, and the late Mr. Cubitt prepared a scheme for erecting houses in blocks, which should all have descending flues, leading by underground pipes to a common shaft. Besides, the thing has been carried out by a country gentleman at Osmaston Hall, near Derby. All the smoke is conveyed by a downward shaft from every room to a distant chimney shaft. The draught is quite good, and there is no dust.

There is no sanitary improvement which would pay better. The wasted coal would be a something in hand, and the comfort and cleanliness would satisfy all but washerwomen, charwomen, and grumblers. We might have roses at every window—unless, indeed, we preferred small salad. Certainly the atmosphere of London in hot days in summer is unbearable when there is a reflux and deficient buoyancy of smoke, owing to a temporary chop of the wind to the east. One Sunday morning last June we could scarcely see across Welbeck-street. This state of things materially abridges the residence of delicate persons in London; and there is no one whose tenants would be more benefited by the proposed reform than the Marquis of Westminster, whose operations for rebuilding a princely suburb in Belgravia afford the most desirable opportunity for an experiment.

At last Parliament seems likely to do something towards abating this nuisance. Thirteen years ago we pointed out how easily and effectually it might be completely suppressed; and over and over again have we and other scientific journals tried to impress our views upon architects and builders and their *employés*, and not all in vain. We may soon recur to the subject; in the meantime, we direct attention to an article referring to our own articles in 1833, that appeared two years ago in the *Social Science Review*. This article will be read with interest at the present moment. It will be found at page 296.

BURIAL ALIVE.

There must be some truth in the stories told of persons apparently dead who have been rescued from the grave. Now what has happened will surely happen again; therefore, it is worth while to direct the attention of the Profession to the matter at the present time, when we are on the look out for a cholera epidemic, for it is just in the haste and terror of such a visitation that poor wretches, cold and pulseless, are likely to be dealt with as if dead. Luckily the time which passes between death and burial in this climate, under ordinary circumstances, is enough to insure either resuscitation or absolute death. But little as the risk may be with us of burial alive, it is not pleasant to think that lives may be lost from time to time through treating the vital spark as hopelessly

extinct, whereas with a little care it might have blown into a vigorous flame.

In discussing this question, we may ask first whether it is consistent with common experience that persons can be, as it were, dead—speechless, motionless, and looking dead to undertakers and others accustomed to deal with the dead, and yet be in the possession both of entire consciousness, and sight and hearing? There can be no doubt of it. Officers who have recovered from cholera in India have told the writer that for a time they lay apparently dead, but quite conscious, and in full possession of the perceptive functions, so that they could hear their attendants talking of their death. After that came a period in which sight and hearing were cut off, and the patient lay perfectly conscious of his own existence and state, but of nothing else. To this succeeded a period of perfect unconsciousness, which seemed a blank when the patients were recalled to life. Some years ago the writer went to see a patient in the country who was dying of phthisis. "Oh, sir," was the greeting of the servant, "we all thought master was gone this morning." The poor sufferer told us of his sensations during a prolonged faint, in which those about him thought him dead. He, too, thought that he had really died; he had no sense of anything but his own consciousness, and was expecting every instant to be ushered into the presence of his Judge, and great was his disappointment when on recovering the sense of any existence save that of his own *ego*, his weary eyes encountered the too familiar furniture of his sick room.

Cases such as these prove the main fact, viz., the existence of consciousness, for a certain time, in persons supposed to be dead, and of supposed death followed by recovery. Of course, careful Medical examination would detect the flickering spark of life; but careful examination is not always Medical, and Medical not always careful. With these remarks we commend the following narrative to our readers:—

"High authorities have said that it is physiologically impossible for a human being to remain more than a few hours in such a state of asphyxia as not to betray signs by which a Medical observer can at once recognise the existence of vitality. But what *are* these signs? Respiration, we have on the best authority, has been quite suspended for a considerable time, and when we consider that under such circumstances there can be little or no waste of tissue, that we see similar things occur in some of the lower animals, and above all, that we have the evidence of truth-telling persons that they have witnessed the resuscitation, or return to life, of those apparently dead; it seems unreasonable to make such an assertion as the one we have quoted. It would be almost as just to say that because it frequently happens that after tying a main artery the limb lies numb and cold, without sensation, and then putrefies, that other limbs never lie numb and cold, and without sensation, and yet get warm and active and useful again—an event we believe because we have seen it, but as difficult for us to explain—and, a hundred years ago, as hard for many 'Medical observers' to believe—as any of the strange tales in Bruhier's treatise.(a) Then is the contraction and dilatation of the pupil a sign of life? I trust not; for in cold weather I have repeatedly seen the pupils of subjects being prepared for dissection contract on raising the lid, and dilate when you shaded the light from them. In temperate climates, such as England, except when the people are terror-stricken by some epidemic or contagious disease, funerals are generally managed quietly and without undue haste; but still if the temperature had much influence *per se* in causing premature interments, we should expect to find that the cases on record which have occurred in France and Italy would have been in the summer, which is not the case; on the contrary, it is specially noted in several that the weather was very cold. Howard, who was no exaggerator, says he saw persons restored to life, when supposed to be dead of gaol fever, by douching them with cold water. The daughter of Henry Lawrens, first President of the American Congress, seemed to die from small-pox; was laid out, and the windows opened to ventilate her room; she recovered, and her father left orders that if he appeared to die, they should burn him before interment. Cases of sudden syncope may be mistaken for sudden death, and the body placed in circumstances unfavourable for recovery. It is well known that some fall into lethargies, as the lawyer of Vesoul (Bruhier), and the maid-servant, who was thrice on her way to the grave, and whom, when she was really dead, they kept a preposterous length of time. Mr. Tritton, the deservedly popular Medical Librarian to King's College, tells me that when coming from India, the wife of one of the passengers, an officer in the Army, died apparently. They were about to bury her in the usual manner afloat; but her husband was very anxious to carry her body to England. Making a coffin suitable for the long voyage home took several days. In the meanwhile she lay in her berth, her body swathed ready for interment. When the coffin was ready, her husband went to take his last farewell, and remove her wedding ring, which was very tight. When he was endeavouring to do so, she recovered, and arrived in England well. She said she had heard everything that had passed. Persons who get into this lethargic condition seem to *sleep the fit out*, and to retain vitality in unfavourable circumstances longer than those who have felt the agonies of suffocation and impending death; whereas the person who falls into trance, or whose animation is suspended, seems to require some powerful physical or mental *stimulus*. The physical stimulus used to be practised commonly enough, generally by the application of a hot iron to the heel; and the woman who was accidentally burnt, the woman whose finger was cut, and many others mentioned by Bruhier and others, show that it is frequently effective, and may be worth trying in doubtful cases. But the sudden stimulus of associated ideas so forcibly alluded to by the Cardinal Archbishop of Bordeaux seems even more powerful. Of this class is the case of the man who was aroused in his coffin by the wailings of his wife, and the following, which was told me by Dr. Campbell, of Jamaica, of the late Dr. Barry, whom he attended Professionally when the latter resided in Jamaica. He took the story from Dr. Barry's own lips. After a severe attack of yellow fever, Dr. B. was lying one morning quite conscious, but unable even to wink an eyelid. He heard his Assistant-Surgeon come in, and the brown nurse ask him if Dr. B. wasn't dead yet. 'Of course he is,' was the answer, 'and the sooner the old fool is underground the better.' He heard a coffin brought, into which he was lifted, and the lid nailed down. The rudely-adapted sun-warped planks of the hastily-made tropical coffin let in a tolerable supply of air, while through the chinks he could see the glitter of his accoutrements laid upon the lid. He felt the coffin lifted up and borne along; he could recognise the voices of his brother officers and the various turnings of the road, and appreciate the gradual shortening of the distance to its dreadful end. At last the procession stopped, and he felt himself lowered into his living grave. Still he could not move; but at last the chaplain came to the words 'earth to earth, ashes to ashes,' and as the hot sand clattered on his coffin it gave him the required stimulus, and he struggled so as to attract the attention of those looking down into the grave, and they lifted the coffin out. As is well known, this singular person died in London only a few months ago. Dr. Campbell also informed me that during the last epidemic of cholera in Jamaica there was considerable difficulty in conducting the funerals with anything like regularity, as most of the poor had a great horror of the malady, and he instanced the following as what he feared was not, except in one respect, such an exceptional case as it should have been:—A labouring man in Kingston died, and notice was sent to the undertaker who conducted that class of funeral. He sent a man with a coffin and cart to take the body away to the place of interment, where clergymen attended to read the service. The man put the corpse into the coffin, nailed it down, and there being some time to spare, sat upon the coffin and taking out some yam and salt fish, proceeded to take his breakfast, he spoke and sung to himself, as negroes always do; in a little while he felt a movement in the coffin, which was repeated; he removed the lid, and out stepped the recently deceased nigger untrammelled by a shroud, his dignity much hurt, but sufficiently recovered to sit down on his own coffin and share the breakfast of his preserver. During the same epidemic a Physician in constant attendance upon all classes was seized with the cholera; his wife, who nursed him, was also attacked, and apparently died. Her husband was too ill to be told, but her brother, an experienced Medical man,

(a) "L'incertitude des Signs de la Mort," par Bruhier. Paris. 1745. *Passim.*

gave the necessary directions; her coffin was brought, and she was prepared for the grave in the usual manner. There were very many funerals taking place, and there was some delay, during which those changes which usually commence immediately after death in the tropics did not appear. The funeral was, however, to take place as soon as possible, but she recovered, and is now well. With regard to the toleranee of a person in stupor of absence of air compared to others, I will mention one instance which came under my own notice. Captain ——, a stout, sanguineous man, called upon me one very hot Sunday afternoon to ask whether sea-bathing would cure a giddiness he was troubled with. I endeavoured to dissuade him, especially as he proposed bathing where I knew the water was too shallow for complete immersion. Next day he was seen by a passer-by wading out. Shortly after this man missed him; but it was an unusual hour for bathers, and he concluded that the bather had entered one of the machines on the sands. Some time after this a boy plashing about in the shallow tumbled over a dead body, in water just enough to cover it. It was taken to the deadhouse, and the persons there, well used to such things, thought it idle to attempt resuscitation, and left, locking the door behind them. A gentleman who happened to be passing asked to be allowed to see the drowned man. He recognised his brother officer, and sent for a Doctor, who resuscitated Captain ——, and I attended him for the next fortnight for congestion of the brain. In the days when they hung for larceny, and before the humane adoption of the patent drop, before Professor Haughton had elaborated a mathematical formula for the exactest method of hanging, recoveries after apparent deaths by strangulation were not uncommon. The Edinburgh apple woman to be seen in the High-street not many years ago, Half-hangit Maggie, was a notable example. Inspector-General ——, now living, told me that his father was apprenticed to a Medical man in the City of London, eminent in his time as a teacher. On the night of his arrival, tired with the long journey from Scotland, Mr. — went soon to bed. He was roused in the night by terrific shrieks, and, opening his door, saw members of the family, of both sexes, running past his room to the end of the passage. He followed them, half asleep, and found himself in a room bare of furniture, except a table and a sink, there was a naked man kneeling on the floor roaring for mercy. The Surgeon pacified the poor man, and put him into a bed. He had been hung that morning, and for *value* received by *him* his body had been handed over to Mr. ——'s new master. After a prudent delay he was sent away, and about a year afterwards the Surgeon received another note from him, saying he was to be hung again the next day, and offering himself for sale, but this former purchaser would not bid.

'Le gibet ne perd jamais ses droits.'"

A. M. E.

THE WEEK.

THE CHOLERA.

Cholera has already re-appeared on the shores of the Mediterranean and in several parts of Europe. A telegram from Malta, dated March 12, states that official information has been received that the disease has broken out at Alexandria. Prompt measures have been taken by the Government, and all arrivals from Alexandria have been placed in thirty days' quarantine. The Berlin correspondent of the *Times* writes that cholera has broken out with great virulence in some swampy villages of the Grand Duchy of Luxembourg and the adjacent district of Rhineland. The coast of Brittany also appears to be suffering severely. At L'Orient, for some days, ten or twelve persons were dying daily (*Gaz. Hebd.*, February 23). At Brest, up to February 12, there had been received into the Civil Hospital, under M. le Dr. Th. Caradec, 109 women, of whom 37 died, and 97 men, of whom 45 died. In the Marine Hospital, out of about 100 male patients, one-half had died (*L'Union Méd.*, February 27 and March 6). We hear of it also at Quimper, and at Bringolo, about ten miles from Guingamp, at Plouaret, and at Coetmieux, a little commune three miles west of Lamballe (Côtes du Nord). In all these little Breton villages the history is the same. Some person comes from an infected place, and is seized with the disease, which then spreads or not, according to the eare taken to stamp it out, or the reverse. M. Pellarin, writing from Guingamp on the 25th February, says,— "The cholera was brought to Bringolo, 12 kilometres hence, by a workman who came from Brest. He was the first to fall a victim, then his wife and two children; afterwards 23 others, out of a population of 800. The disease has not spread in the neighbourhood; and although a relative of the first victim, who went to his funeral at Bringolo, brought it to Plouaret, it has not spread there. The sick at Bringolo were treated with the utmost care by Dr. Benoist, and he, having formerly been an anti-contagionist through reason, is now become contagionist through experience. He must, he says, yield to facts. At Coetmieux a sailor came home to his father's house, was taken ill in an hour, and died next day. His mother and another inmate soon followed."—*L'Union Méd.*

The Channel Islands and the ports of Southampton and Weymouth had better look out. The enemy is only about twelve hours' distance by steam. If it should come, we hope that no pains will be spared to stamp it out promptly.

LOCAL ANÆSTHESIA IN OVARIOTOMY.

This week Dr. Richardson's great improvement has proved very successful in ovariotomy. Mr. Spencer Wells operated on Wednesday in the Samaritan Hospital upon a woman who had an ovarian tumour so large that the heart and liver were pushed up to a level with the nipples, and the uterus (with the inverted vagina and part of bladder and rectum) down between her thighs. Thinking that chloroform might be dangerous in this state of heart and lungs, Mr. Wells rendered the integument insensible by the ether spray before making his first incision. Not the slightest pain was felt. A very large cyst was tapped and emptied. Some extensive adhesions then required to be separated, and a little chloroform was given, the operation being completed under its influence. If there had been no adhesions, the local anæsthesia would have been quite sufficient to render this great operation painless. No more severe test of the value of Dr. Richardson's plan could be imagined, for the immense cyst removed held sixty-four pounds of fluid and itself weighed nearly five pounds.

WORKHOUSE NURSES.

It will be observed from our notice of the subject last week that in his effective speech in support of the scheme proposed by the Association for the Improvement of the Infirmaries of Metropolitan Workhouses the Archbishop of York stated to the effect that there were no paid nurses for the sick in those establishments. Bearing in mind the large amounts which the poor rates annually abstract from the pockets of London rate-payers, it seemed not improbable that the right reverend Prelate had not assured himself of the complete accuracy of his sources of information. From careful inquiries upon the subject we learn that in the parishes and unions of the Metropolis there is expended a sum exceeding £2500 per annum for the salaries of nurses for the sick and imbecile. This amount represents rather less than half the total cost of these officers, as to their salaries, must be added the cost of their maintenance, making a total sum of at least £5000 laid out in nursing for the sick and imbecile in those workhouses in which the system of nursing is said to be "merely nominal."

FROM ABROAD.—DISTRIBUTION OF PRIZES AT THE ACADEMIE DES SCIENCES.

The Aeadémie des Sciences has just announeed its decisions respecting its prizes for 1866. 1. The Montyon Statistical Prize has been decreed without hesitation to M. Chenu for his remarkable work on the Crimean War of 700 pages in 4to., entitled "Rapport au Conseil de Santé des Armées sur les Résultats du Service Medico-Chirurgical dans les Ambulances de Crimée, etc., pendant la Campagne d'Orient." This is justly entitled

a monument of laborious industry and sagacious deduction. The terrible mortality in the French and Russian armies are there set forth, and the superior sanitary arrangements made for the English troops, and the satisfactory results which ensued are duly acknowledged. This work is published, and well worthy of the notice of those of our readers who are engaged in this class of inquiries. Honourable mentions are also decreed to M. Poulet for a Statistical Account of the prevalence of Goître at Plancher-les-Mines; and to M. Sistach for his Statistics of Varices and Varicocele, as grounds of exemption from serving in the French Army. 2. M. Montyon's Prize for Experimental Physiology has been given to M. Bert for his elaborate researches on animal transplantation, or, as he terms it, "Greffe Animale"—the tail of the rat, transplanted into the subcutaneous cellular tissue and the cavity of the peritoneum, having been the subject of a series of elaborate experiments, directed so as to exhibit the effects of various modifying influences. The Academy also notices with approval a work by the late M. Revcil on the "Action of Poisons on Plants." 3. For the Montyon Prize for Medicine and Surgery, three prizes and three honourable mentions are decreed. A prize of 2500 fr. is adjudged to Professor Vanzetti, of Padua, formerly of Charkov, in Russia, for his researches on Digital Compression in Aneurism. A prize of the same amount is also given to MM. Chauveau, Viennois, and Meynet. These gentlemen, at the instigation of the Lyons Medical Society, undertook an elaborate experimental investigation into the Relations existing between Vaccinia and Variola. "By establishing," M. Longet, the Reporter of the Committee of the Academy, observes, "that vaccinia and variola, notwithstanding the points of resemblance between them both in man and animals, are none the less totally independent of each other; that their virus form two distinct individualities; that the two affections thus constitute two different, unalterable species, incapable of transformation into each other; and that consequently endeavouring to produce vaccinia by means of variola would be to pursue a dangerous chimera, capable of reviving all the perils of the old inoculations—in establishing, we repeat, facts of so great an importance, the experiments conducted by M. Chauveau have rendered indubitable advantages to Medical science and practice." The third prize, also of 2500 francs, is given to M. Luys for the pathological portion of his work "Researches on the Structural Functions and Diseases of the Cerebro-spinal Nervous System," the anatomical and physiological portions of this work having been the subject of a former prize. After complimenting M. Luys upon the originality of many of his researches and the importance of the deductions he derives from them, the Reporter goes on to observe "that he has happily availed himself of his anatomical and physiological facts as arguments, and often powerful ones, for invalidating or confirming the opinions of pathologists on the semiological value of the various disturbances of nervous action. Moreover, a large number of cases, disseminated, and, as it were, lost among authors, are brought together and analysed in this work with a degree of vigour which it is very desirable should be oftener found in works on pathology in general, and especially in those treating of diseases of the nervous system—diseases which will yet long offer to the investigations of Physicians a field of vast extent, whose effectual exploration constitutes one of the most difficult tasks. For it must be ever borne in mind that cerebral pathology is so rich in facts that it lends itself to any system. All that is wished to be there seen may be there found; all that is asked of it is given; and, according to the manner in which it is interrogated, it leads to truth or error." An "honourable mention," with 1500 frs., are given to M. Sucquet for his work, published in 1861, "On a Derivative Circulation in the Limbs and Head in Man." In this essay M. Sucquet seeks to demonstrate that, besides the ordinary capillary circulation, there are direct anastomoses between the arteries and veins sufficient to constitute a derivative circulation, brought only occasionally into operation, as contrasted with the ordinary, regular, and nutritive circulation. A similar recompense is adjudged to M. Legrand du Saulle for his essay "Insanity in a Court of Justice," in which the various problems raised by legal Medicine in relation to lunatics are considered. M. Desormeaux receives the same mark of distinction for his invention of the endoscope and the useful applications he has made of this instrument in the diagnosis and treatment of the affections of the urethra and bladder. It may be also employed for the exploration of the nasal fossæ, the cavity of the uterus, the upper portion of the rectum, etc. Others have only succeeded in obtaining "favourable citations"—which seems to be a new mark of approval of a lower rank than the "honourable mention"—viz., MM. Stœben and Tourdes for their "Topography and Medical History of Strasbourg;" and M. Moura for a new instrument for tying polypi of the larynx. 4. The Breant Prize of 100,000 francs for the discovery of the cause and cure of cholera is, of course, still without a claimant. The Reporter of the Committee, M. Serres, observes that "the authors who have sent in their memoirs for several years past have not sufficiently studied the action of cholera on the human economy; and yet if this terrible disease is mysterious in its essence, it is not so in its immediate effects on the organism nor in its symptoms." Among the latter he especially calls attention to the dejections, and the various investigations which have been made into the composition of these, and to the frequency with which cholera may be produced by emanations from them. The investigations concerning the poison so generated made by M. Thiersch, of Munich, are especially referred to, but a definite opinion concerning them is postponed until the ensuing year. In the meantime, the testator having especially indicated in his programme the importance of investigating how far animalcules may be one of the causes of cholera, the Academy has, believing it, we suppose, to be, at all events, a step in that direction, decreed a prize of 2500 francs to M. Davaine for his investigations proving that carbuncular disease in animals and malignant pustule in man may be the result of inoculation with a species of vibrionia, which he terms *bactérides*, which, if not the actual agent of transmission of the disease, are an indispensable accompaniment. To M. Grimaud de Caux, moreover, has been awarded an "indemnity of 4000 francs for the act of spontaneous devotion which he accomplished by proceeding to Marseilles for the purpose of studying the cholera at the height of the epidemic. In according to him this encouragement, the Academy signalises and recompenses, as far as in it lies, the reflecting courage and scientific spirit under the influence of which he has accomplished his labours." 5. The Godard Prize of 1000 francs is adjudged to Professor Hélie, of Nantes, for his laborious work on the Muscular Fibres of the Uterus. M. Brouardel also receives an honourable mention for his work on the Tubercular Affections of the Female Genital Organs. 6. The Barbier Prize of 2000 francs has been divided between MM. Baillet and Filhol for their essay on Intoxicating Darnel (ivraie); and MM. Vée and Leven for their essay on the Alcaloid Extract of the Calabar Bean.

PARLIAMENTARY.—THE CATTLE PLAGUE BILL—ARMY ESTIMATES—PROTECTION OF THE WORKING CLASSES FROM THE RAILWAY COMPANIES—THE SMOKE NUISANCE—FLOGGING AND BRANDING IN THE ARMY—RINDERPEST AMONG SHEEP—CONTAGIOUS DISEASES BILL—THE DWELLINGS OF THE LABOURING CLASSES—IRISH COUNTY INFIRMARIES—WITHDRAWAL OF MR. HUNT'S CATTLE PLAGUE BILL.

On Thursday, March 8, in the House of Lords,

The House went into committee upon the Cattle Plague Bill.

Considerable discussion took place upon various clauses, and several amendments were introduced, but the principal debate arose upon a clause giving to the Privy Council a discretionary power to discontinue the compulsory slaughter of cattle after the passing of the Act.

The bill was finally read a third time and passed.

The House of Commons went into committee of Supply on the Army Estimates; £246,500 were voted for the Hospital establishment.

On Friday, March 9,

Mr. Hughes moved a string of additions to the Standing Orders applicable to Railway Bills, for the protection of the working classes against the incursion of the railway companies on their dwellings, which were opposed by Colonel Wilson-Patten, who recommended the appointment of a Select Committee to inquire into the whole subject, by Mr. Milner Gibson, and by Lord Stanley; and after a short discussion they were withdrawn.

Sir R. Peel called attention to the nuisances arising from the smoke of furnaces in towns and country districts. After referring to the increased consumption and export of coal, and the importance of economising our supplies, he drew an alarming picture of the deleterious effect of the poisoned atmosphere of large manufacturing towns on the health and comfort of the labouring classes. He showed that great saving might be effected by manufacturers by the use of efficient smoke-consuming apparatus, and that legislation by private Bills for particular towns had for the most part failed, and he asked Sir G. Grey whether he intended to bring in a general Bill on the subject this session.

Mr. Henderson made some remarks on the injurious effects of coke-burning and iron furnaces.

Mr. Hanbury mentioned that his firm saved 2000*l.* a year by the use of an efficient smoke-consuming apparatus.

After some observations from Mr. A. Egerton and Sir M. Peto,

Sir G. Grey expressed his readiness to concur in any general measure for putting down this nuisance, but pointed out that the Local Government Act, which had been adopted in hundreds of towns, contained powers quite adequate for the purpose, and that the real difficulty was to get the local authorities to put the law into execution. He mentioned that the success of Lord Palmerston's Act for the metropolis was owing to active supervision of the police under the directions of the Home Secretary, and suggested that if the local authorities would give the same instructions to the police the existing law would be found equally effective.

In Committee on the Mutiny Bill, Mr. Taylor renewed his attempt to strike out the clauses relating to flogging and branding, but was again defeated by divisions of 56 to 17 and 53 to 15.

On Monday, March 12,

Sir A. Agnew asked the Vice-President of the Committee of Privy Council on Education whether he could give any information as to whether the disease said to have broken out among sheep in some parts of Scotland had in any instance been reported by competent authority to be identical with Rinderpest.

Mr. Bruce said that no official information had been received as to the existence of Rinderpest among sheep in Scotland, but he was sorry to say that other information had reached the Government which left little doubt of the existence of the disease in Forfarshire and the county of Fife. As to England, he regretted to say there could be no doubt. An inspection of sheep said to have died by Rinderpest had been made by Professors Simonds and Brown on behalf of the Veterinary Department. The result was to establish in their minds beyond all doubt that the Rinderpest had existed in ten different cases among sheep in England, and that it was accompanied with serious loss. He was informed by Professor Simonds that in every case where he had traced the loss of sheep to its source, the animals had been in contact with cattle suffering from the disease.

Lord C. Paget gave notice that he would on Thursday move for leave to bring in a Bill for the better prevention of contagious diseases in certain military and naval stations.

The Labouring Classes' Dwellings Bill was read a second time, and the Artisans and Labourers' Dwellings Bill passed through the same stage *pro formâ*, on the understanding that the subject would be referred to a Select Committee.

On Tuesday, March 13,

In answer to a question by Mr. Long in reference to the alleged transmission of Rinderpest to sheep, Mr. Bruce said that during the last six months the attention of the Veterinary Department of the Privy Council had been directed to this subject, and during that time twenty-six different phases of the outbreak of what was supposed to be the Rinderpest had been reported in eleven counties, as many as seven occurring in the county of Norfolk. The conclusion at which the Veterinary Surgeons of the Privy Council had arrived was that the disease was identical with the Rinderpest among cattle. The soundness of this conclusion was greatly doubted in various parts of the country, but especially in Scotland. He would, therefore briefly state the grounds upon which the Veterinary Surgeons had arrived at their conclusion. The first experiment made was upon a sheep confined in a pen in which a cow had died of the Rinderpest, and the sheep was attacked by the disease and died. The next experiment was more conclusive. At the Veterinary College some sheep were inoculated with a quantity of Rinderpest *virus*, when they were invariably attacked, and all, excepting two, died, of what appeared to be the Rinderpest. The two surviving sheep were then inoculated with smallpox *virus*, but that disease immediately seized them, and from this fact it was clear that the malady which attacked them in the first instance was not smallpox. The local inspectors consequently had been directed to deal with diseased sheep in the same way as with cattle attacked by the Rinderpest. He might add that the disease did not appear to spread from sheep to sheep as readily as it did among cattle. In Scotland some attempts had been made to convey the Rinderpest to sheep by exposure under circumstances calculated to induce it, but unsuccessfully, and hence arose the peculiar disbelief in that country that the disease now afflicting the sheep was the Rinderpest.

In reply to Mr. Dent,

Mr. Bruce said the experiments had been made by Professor Simonds and Professor Brown.

In the House of Commons on March 14

Mr. Pollard Urquhart, in moving the second reading of the County Infirmaries (Ireland) Bill, said that as the law stood at present an annual subscription of three guineas was required to constitute a governor, and one of twenty guineas to constitute a life governor of a county infirmary. The obvious effect of this provision was to limit the number of subscribers, and the Bill therefore proposed that a subscription of a guinea a year should constitute a governor, and one of ten guineas a life governor. He had, however, inserted a clause securing to those who gave the higher subscriptions a proportionate degree of influence in the elections of Medical officers, etc.

After a conversation, in which the Attorney-General for Ireland, Mr. Bagwell, Sir H. Bruce, and Mr. Synan took part, the second reading was negatived without a division.

On the consideration of the Lords' Amendments to the Cattle Plague Bill, after a long conversation,

Mr. T. G. Baring announced that if Mr. Hunt would withdraw the Bill, the Government would undertake to strengthen the Privy Council Office, and would issue orders for the isolation of infected districts, the protection of disinfected districts, the regulation of fairs and markets, the cleansing of railway trucks, and other matters, on principles which he explained.

Mr. Hunt acceded to this proposal, and, on the motion of Sir G. Grey, the Lords' amendments were ordered to be taken into consideration that day six months.

International Ophthalmic Congress. — The next meeting of the Congress will take place at Vienna on August 25. Professors F. Jäger, Arlt, and Gulz constitute the committee.

Heavy Railway Damages.— Russell *v.* the Great Western Railway Company.—This was an action tried on the Oxford Circuit to recover compensation for damages received in a collision on the defendants' line of railway between the train in which the plaintiff was travelling and a goods train at Norton Junction, between Birmingham and Tewkesbury, in November, 1864. The plaintiff was a farmer and miller, and occupied 182 acres, at an estimated profit £1 per acre, and the profits of his mill averaged £261, his threshing machine £85, and pigs £32 per annum. Before the accident he was a strong healthy man, with good prospects. He now had pains in his head, his eyesight and hearing were affected, and one eye twisted; and he suffered from coldness in the right hand and leg. The Medical gentlemen called said that he had received an injury to the brain and spine from which he would probably never recover. His appearance and examination were such as to call for an expression of opinion from the jury that the case was a genuine one. The jury, after considerable deliberation, found a verdict for the plaintiff—Damages, £5775.

REVIEWS.

A Practical Treatise on Urinary and Renal Diseases, including Urinary Deposits. Illustrated by numerous Cases and Engravings. By William Roberts, M.D., F.R.C.P.L., Physician to the Manchester Royal Infirmary, etc. London: Walton and Maberly. 1865. Pp. 517.

We have read this book with much satisfaction. It will take its place beside the best treatises in our language upon urinary pathology and therapeutics. Not the least of its merits is that the author, unlike some other book makers, is contented to withhold much that he is well qualified to discuss, in order to impart to his volume such a strictly practical character as cannot fail to render it popular among British readers.

The work is divided into three parts, in the first of which Dr. Roberts necessarily enters upon a consideration of the properties of the urine in health and disease, so far as such information is essential to the correct appreciation of their semeiological indications, and to the avoidance of inconvenient digressions in the progress of the book. Dr. Roberts has examined anew the relation between the reaction of the urine and the digestion of food, first pointed out by Dr. Bence Jones, but upon which doubt had been thrown by Vogel, Beneke, and others. The result has been to confirm to the fullest extent the original observations of our countryman. Dr. Roberts finds that the alkalinity of the urine passed after food is due to fixed alkali, not to ammonia, a remote effect of a meal being to maintain and even increase the acidity, and he finds that the remote effect is greater with animal than with vegetable food. Dr. Bence Jones, it will be recollected, explained the alkalinity as dependent upon the withdrawal of acid from the blood into the stomach for the purposes of digestion; Dr. Roberts, however, refers it to a different cause, namely, the entrance of newly-digested food into the blood, basing his opinion partly upon the fact that, while acid is poured into the stomach immediately after a meal, the acidity of the urine does not suffer depression for an hour or two later. Dr. Roberts is indisposed to follow Prout and Bird in placing an important significance upon the appearance of oxalate of lime deposits in the urine. In this, we think, he is quite borne out by general experience. The train of symptoms referred to oxaluria by the writers mentioned may be present in all its completeness without the appearance of oxalate of lime deposits, and on the other hand may be wanting throughout where oxaluria is present in such intensity as to lead to the formation of mulberry calculus. Another moot question among urinary pathologists is the existence of a peculiar morbid state pointed out many years ago by Dr. Prout, to which Dr. Willis gave the name of Azoturia, and which has been said to be characterised by an absolute and relative increase in the excretion of urea unaccompanied by pyrexia. Our author, while stating that there is a deficiency of precise facts in support of Prout's view, nevertheless, does not regard the description given of the disease by Dr. Prout as altogether fanciful. After quoting a case from Dr. Parkes, where a feeble, but a pyretic patient passed a daily quantity of 1130 grs. of urea, the urine reaching 96 oz. in daily quantity, he describes an observation of his own, the patient being a man about 50 years of age. In this case, however, the daily excretion of urea did not exceed 565 grs., being 4·6 grs. on an average for each pound of the man's weight. In Dr. Parkes's case the mean was 10·36 grs. per pound of body weight, the ordinary daily rate of excretion for a healthy man being estimated at about 3½ grs. In both these cases a small quantity of sugar was temporarily present in the urine. Dr. Roberts disposes very briefly of the kiestine, about which so much has been written, as characteristic of the urine of pregnant women. He believes it to be nothing more nor less than the mould fungus which is apt to grow luxuriantly in urines containing organic matters. The urine of pregnant women, from the large amount of epithelial *débris* that it is apt to contain, is a fitting nidus for this fungus. Rough-and-ready methods of testing urine for albumen and sugar find no favour with our author. Nor do they deserve it, inasmuch as a chemical qualitative analysis should always be performed with due regard to the teachings of chemical philosophy, and with that amount of care which the diagnostic importance of the facts which it is sought to elicit must ever demand imperatively from the clinical observer. "In practice, the best method of proceeding is as follows:—When the urine is cloudy from urates, use heat alone; when the urine is clear (or in any case if alkaline), add nitric acid in the way above described; if no turbidity appears above the layer of acid the urine may be with certainty pronounced free from albumen; if a turbid zone is produced, apply heat thereto; if it be not dissipated, albumen is certainly present."—P. 119. The mode of applying nitric acid referred to is filling a test-tube to about the depth of an inch, and then, after inclining the tube, pouring in strong nitric acid in such a manner that it may trickle down the side to the bottom, and form a layer of about a quarter of an inch thick below the urine. The method of testing for sugar which our author prefers is Fehling's modification of Trommer's reduction test. It may not, perhaps, be out of place to copy the formu'a for the test solution, which should be prepared beforehand. It consists of sulphate of copper, 90½ grs.; neutral tartrate of potash, 364 grs.; solution of caustic soda, sp. gr. 1·12, four fluid ounces, the whole being made up to six ounces with water. "Having prepared the test fluid, it is employed in the following manner:—Fill a test tube to the depth of three-quarters of an inch or so with the copper solution, heat until it begins to boil, and then add *a drop or two* of the suspected urine. If it be ordinary diabetic urine the mixture after an interval of a few seconds will turn *suddenly* of an intense opaque yellow colour, and in a short time an abundant yellow or red sediment falls to the bottom. If, however, the quantity of sugar present be small, the suspected urine is added more freely, *but not beyond a volume equal to that of the test employed.* In the latter case it is necessary to raise the mixture once more to the boiling point. It is then allowed to cool slowly. If no suboxide has been thrown down when it has become cold, then the urine may with certainty be pronounced sugar free."—P. 132. For the quantitative estimation of the sugar the differential density test (fermenting one of two samples of the urine) is that which Dr. Roberts prefers, as combining more perfectly than any other method ease with accuracy.

The second part is devoted to the consideration of urinary diseases—diseases of which the chief characteristic is an alteration of the urine. The diseases described are diabetes insipidus and mellitus, gravel and calculus, and chylous urine. The chapter upon Diabetes Insipidus has been prepared with remarkable care—not that this is an unusual feature in the volume, but we mention it because of the manifest effort which the author has made to put into something like scientific order the mass of facts and opinions which confuse the minds of Practitioners who are disposed to study this condition. Dr. Roberts has collected sixty-nine cases of insipid diabetes, and adding three cases observed by himself, has drawn up his account from an analysis of the seventy-two. One remarkable etiological feature is the dependence of the disease in sixteen out of thirty cases, where any exciting cause at all could be assigned, to serious disturbance of the nervous system. In six cases it was referred to blows on the head, falls, etc.; in five to cerebral disease; and in five to intemperance. We quote at length the views held by Dr. Roberts as to the nature and pathology of the disease, as we think the quotation is fully warranted by the interest which attaches to a malady so little comprehended." It may be regarded as probable that the *immediate* anatomical cause of polyuria is a dilatation of the renal capillaries whereby their walls are thinned and rendered favourable to increased transudation of watery fluid from the blood. But how is this brought about? It is now generally believed that the minute blood-vessels possess in their circular and longitudinal muscular coats a provision for an active expansion, as well as an active constriction of their calibre. This provision is under the control of the sympathetic branches of nerves (nervi vasi-motores) and serves to maintain the aqueousness of the blood within certain limits of health. When the tissues and blood are overcharged with water, the renal vessels expand and permit a copious transudation of an aqueous urine; when, on the other hand, the system is undercharged with water, they contract, and thereby restrict the urinary transudation. In diabetes insipidus this endowment seems greatly impaired; the renal capillaries appear to resemble the iris in glaucoma, which remains in a motionless, semidilated state, and neither contracts with light nor dilates with belladonna. In polyuric subjects, the contractile power of the renal vessels is apparently paralysed, and the power of regulating the urinary flow consequently lost. If a healthy person imbibe an excessive amount of water, he rapidly gets rid of the overplus by a sudden and copious diuresis, and then the secretion falls quickly to its ordinary rate; but a polyuric subject under similar conditions shows very little *immediate* increase of urine, but a steady, persistent, though less intense augmentation, lasting many

hours, and which is not succeeded by a fall to the ordinary standard. On the other hand, if a healthy person imbibes a lessened quantity of water, the discharge of urine falls in proportion; whereas the polyuric, under the same circumstances, shows no such adaptation; he still continues to discharge an undue amount of urine, which necessitates constant imbibition of new supplies of water to prevent dehydration of the tissues. On this view, the primary cause of diabetis insipidus must be looked for in some other parts than the kidneys—namely, in some part of the chain of sympathetic nerves which controls the action of the contractile tissues of the renal vessels. This chain extends from the kidneys to the abdominal ganglia, thence to the spinal cord and the floor of the fourth ventricle, where the sympathetic system seems to have its centre. From above, this centre receives impressions from the encephalon. This theory seems conformable both to experiments and to chemical facts."—P. 158. And the author refers to Bernard's well-known experiment of puncturing the floor of the fourth ventricle, and the origin of a large proportion of the cases in injuries of the nervous centres, disease of the brain, injury to the sympathetic, as where cold fluids have been drunk when heated, from alcoholic excesses, etc.

We cannot give much space to the chapter upon Diabetes Mellitus. Suffice it to say, that Dr. Roberts shrinks from the attempt to frame a comprehensive theory of this disease. All he is disposed to say, after giving an excellent summary of the modern physiological researches of Schiff, Pavy, McConnell, etc., is that "it would seem highly probable that diabetes consists proximately in some disturbance of the destiny and function of the amyloid substance of the liver. But this disturbance may be due originally to disease far away from the liver itself, in some part of the sympathetic chain which controls this function. Occasionally, as in traumatic cases, it is possible to place the finger on the primary lesion; but in the immense majority of cases we are left in a sea of conjecture." —P. 185.

Dr. Roberts has bestowed a good deal of labour in clearing up some disputed questions in regard to the solvent efficacy of alkalies upon renal and vesical calculi. He has found by his experiments that while carbonate of potash possesses solvent powers superior to those of carbonate of soda, that its solvent powers over uric calculi were greatest when in the proportion of 40 to 60 grs. to the imperial pint; above this strength the solution was impeded by the formation of a white crust of alkaline bi-urate upon the surface of the calculus. The most convenient way of alkalising the urine he finds to consist in giving frequent repeated doses of the acetate or citrate of potash, using 40 or 50 grs. dissolved in 3 or 4 oz. of water, every three hours. When in any case an ammoniacal state is developed, the solvent power of the alkalised urine is nullified by the deposition of the mixed phosphates on the surface of the calculus. The following are briefly the limitations within which the author holds the solvent material applicable:—1. It is inapplicable to all cases in which the urine is alkaline. 2. When the urine is acid the case may be regarded *primâ faeie* as suitable; but then even, with an acid urine, all those cases are excluded in which it is known or strongly suspected that the stone is composed of oxalate of lime. When the stone is known to be a large one the solvent treatment should not be attempted; the cases especially suitable are those in which it is known or strongly suspected that the concretion consists of uric acid, and has not yet attained any great size. In carrying out the solvent treatment it is of primary importance that the urine should not only be kept continuously alkaline, but kept alkaline to a certain degree. The treatment must be suspended at any time when the urine becomes ammoniacal.

We must be much more brief in our account of the third part of Dr. Roberts's book, in which he treats of the organic disease of the kidneys. Bright's disease of course occupies a large number of pages. We have marked a good many of these pages, but must confine ourselves to noticing the section which relates to uræmia. A very good and succinct account is given of the views held by various renal writers upon this condition. The author then sums them all up. "None of these theories, considered exclusively, explain satisfactorily the protean phenomena of uræmic intoxication. The subjects of Bright's disease suffer under a deep abnormality in the composition of the blood and tissues. The blood is unnaturally watery and poor in albumen; the blood and tissues are unnaturally charged with the primary hystolytic products (creatine, extractives, etc.), and with excrementitious urinary compounds (urea and uric acid), perhaps also with the products of the decomposition of some of these. This state appears to induce in the nervous centres a proneness to sudden disorder and loss of equilibrium. A crisis may at any moment be brought about by an exaltation of one or several of the disturbing elements, as by a supervention of some new and different cause of irritation (hysteria, menstruation). A similar hyper-sensitive state of the nervous system prevails naturally in early life; and an irritation which would be of no moment in an adult (teething, worms, embarrassed digestion, cutaneous irritation, etc.), suffices, in an infant, to awaken convulsive and comatose phenomena, closely resembling those of uræmia."—P. 361. With regard to the treatment of uræmic coma by venesection, which has recently found a new advocate on theoretical grounds in Dr. Richardson, our author very properly observes that a distinction should be drawn as the case is acute or chronic, and according to the strength and general condition of the patient. He considers that a free and repeated venesection is decidedly and urgently demanded in the uræmic coma of acute Bright's disease and in certain classes of puerperal eclampsia, the blood not being as yet materially impoverished, but that the matter stands differently when the renal mischief is chronic and incurable, since in these cases the attacks are not so imminently dangerous, and the loss of blood, already thin and poor, is more likely to shorten than to lengthen life. Throughout the work there is to be observed the same cautious acceptance of theoretical views as in the several special instances we have referred to. Throughout the author gives full credit to all his predecessors in labour in the same field as himself, placing at the head of each chapter the names of the authors and works which he has consulted, and from whom additional information may be derived upon points that he himself may not have regarded as of sufficient or immediate practical bearing to be discussed in this book. The book is enriched also with the detail of a large number of cases, many of them original, and with some very creditable woodcuts.

Peking and the Pekingese During the First Year of the British Embassy at Peking. By D. F. Rennie, M.D., Staff-Surgeon on special service under the Government of India. Author of the "British Arms in North China and Japan." 2 vols., p. 332. Murray, 1865.

This is a most pleasant book; it is quite impossible to convey any idea of the mass of varied information contained in it by quoting occasional passages. In vol. II. p. 38, there is a mention of a young Chinese Doctor who was well known a few years ago in Edinburgh. Dr. Wang-fung, who "was a pupil of one of the Protestant missionary schools at Hong-Kong, and in consequence of the ability he displayed, he was sent to Edinburgh, and maintained there through the kindness and liberality of some of the English merchants at Hong-Kong. He became one of the most distinguished students of his period, took several prizes and received his diploma and degree in a manner reflecting the highest credit on himself. After this he was sent out by the London Missionary Society as Medical missionary at Canton, which appointment he held until nominated Dr. Ainslie's successor at Hong-Kong. Dr. Wang-fung has acquired a thorough knowledge of the English language, and writes it with fluency and accuracy."

We may take this opportunity of commending likewise to our readers, Dr. Rennie's last volume, entitled "Story of the Bhotean War." Like his former volumes, it is the work of a man who is always alive, and always has his eyes open, and who has the knack of bringing what he describes vividly before his readers' minds. The work is full of facts, political and ethnological, and if we mention one, viz., the speedily fatal effect of chloroform on snakes, we feel that we may give some comfort to persons who are obliged to travel in snake-infested countries.

Bones of the Dodo.—Mr. Stevens, of King-street, sold by auction, on Tuesday last, nine lots of various bones of the above extraordinary and extinct bird. The principal purchasers were the College of Surgeons and the Universities of Oxford and Dublin; the first lot fetched 15*l.*, and the last 3*l.* 10s. The nine lots realised only 83*l.* Professor Owen read a paper at the Zoological Society on the 9th of January last, giving a full account of the discovery, and describing in detail these bones then submitted to him.

PROVINCIAL CORRESPONDENCE.

NEWCASTLE-UPON-TYNE AND SUNDERLAND.

(From our own Correspondent.)

March 10.

The Northumberland and Durham Medical Society held its last meeting for the Session 1865-66 on Thursday evening last at the Newcastle Infirmary. There was a large attendance of members, and the papers read were of considerable interest, especially those of Dr. Brown on "Degeneration of the Mucous Membranes in Idiots," and of Mr. Dodd on a series of cases occurring at Donkin's Houses. Dr. William Murray, the active and energetic Secretary of the Society, was warmly congratulated on his recovery from an attack of typhus fever, which has made such ravages in Newcastle, two members of the Profession, Messrs. Watson and Hawthorn, having fallen victims to the disease. The subject of fever naturally gave rise to discussion, and from the remarks made by Dr. Humble, Physician to the Fever Hospital, it would seem that the epidemic is almost as virulent as ever, notwithstanding the active measures taken by the Corporation and Board of Guardians to improve the sanitary condition of the lanes and alleys where the fever abounds. Dr. Humble stated that for the ten years previous to 1866 the average number of patients admitted into the Hospital in the month of February of those years was nine, whereas during the same month in this year sixty cases had been admitted. This epidemic of typhus is attacking most of the large towns in the North of England with more or less virulence, and Sunderland in particular is suffering from it, so much so that there is no accommodation for the cases either at the Infirmary or Workhouse Hospital; consequently the Guardians are at present engaged in erecting a temporary Hospital for fever cases. It is to be regretted that this step was not taken sooner, so that the cases occurring in the closely-packed parts of the town might have been removed at once, and not left at their own homes to propagate the disease. The question as to the causes of fever is engaging the attention of the local authorities, and the Sanitary Committee of the Corporation have appointed Mr. Dixon, J.P., Mr. Paull, and Dr. Yeld to investigate the subject, and make such suggestions as they think will tend to abate the virulence of the epidemic; and no doubt the suggestions made by these gentlemen will be carried out with promptitude and energy. In speaking of Sunderland, I may mention that the Medico-Chirurgical Society, established about two years ago, is in a flourishing condition. Its meetings are held monthly, and several interesting papers have been read during the present session. The new Infirmary, also, which has been talked about for so long a time, has at last been commenced, the worthy Rector of Bishopwearmouth having cut the first sod a week or two ago; and before many months have elapsed it is expected that Sunderland will be able to boast of having one of the best provincial Hospitals in the kingdom. It is to be constructed to hold 100 beds, and, therefore, will be a great improvement upon the present Infirmary, which does not contain above thirty-six beds, and in every other respect is sadly deficient. The new Hospital is to be erected at the outskirts of the town, and it is proposed to separate the Dispensary, which has hitherto been attached to the Infirmary, and place it in the centre of the borough, with a new staff of Physicians and Surgeons. This is a move in the right direction, and will give to the junior members of the Profession an opportunity of obtaining appointments, the occupancy of which always carries a certain amount of weight with the public. At a future day I hope to be able to give you full particulars of the new Hospital and Dispensary, with a few remarks on the other charitable institutions of the North.

GENERAL CORRESPONDENCE.

DR. ALDERSON ON THE SPREAD OF RINDERPEST.

Letter from Dr. C. R. Bree.

[To the Editor of the Medical Times and Gazette.]

Sir,—I read in your report of the annual meeting of the Medico-Chirurgical Society that Dr. Alderson, its President, made the following remarks about the Rinderpest:—"All these fallacious views seem to blind the Legislature as well as the public to facts which are clearly established. These facts are, that the cattle disease, like cholera, follows a certain course, which is undeviating in its direction, though the visitation skips over some localities; that the disease also, like cholera or any other epidemic, abides only for a certain period in each locality, and that it is most virulent and unmanageable at the beginning of each outbreak, and becomes amenable to simple treatment, or any treatment not positively injurious, towards the end of its presence in each place, whilst the ultimate cause of the disease and the law of its progress are unknown to us. All these facts display the fallacy of pretending to stop or exterminate—that is, in the presumptuous phraseology of the day, 'to stamp out' the disease by means of preventing contact; and the same facts testify to the sad want of judgment in sacrificing stock and adding inconvenience to the farmers' loss, in order to obtain an end which, according to the knowledge which we possess, is obviously impossible. None will, of course, deny that there is a certain amount of power to communicate the disease by what is termed contagion or infection, and that moderate precautions to avoid needless contact are wise and good; but it is plain that when the best is done in this direction the laws of transmission and duration will defy all Orders in Council and all Parliamentary enactments either to obtain immunity or to effect 'stamping out.'"

These opinions are directly opposed to those advocated by Dr. Watson, the President of the College of Physicians, and by the Medical men, Dr. B. Jones, Dr. Parkes, and Dr. Quain, who are members of the Royal Commission. They are opposed, I believe, to the opinions of men most experienced in epizootic diseases, such as Mr. Gangee, and I believe they are opposed to every observed *fact* in the history of this fatal disease. If so, let me ask, are they not calculated to do a great deal more harm than good? Ought not such strong opinions, opposed to the imperial regulations for exterminating this disease, to have been supported by arguments and facts? And are not statements of this kind, clashing as they do with other Medical utterances from high quarters, rather calculated to make those in authority regard Medical opinions with distrust, and bring into contempt the value of our evidence upon anything?

I will relate one or two facts which will, I think, conclusively prove the contagious, as opposed to Dr. Alderson's epidemic theory. Mr. A., a farmer, living two miles south of Colchester, bought some sheep infected with rinderpest. This was three or four months ago. The disease spread to his cattle, and he lost the best part of his herd. B., living only two fields off that wherein the infected sheep were grazing, had a splendid dairy of 14 cows or thereabouts. They were attacked with genuine Rinderpest, and he lost thirteen. The veterinary Surgeon accounts for the conveyance of infection by the hares running over the excreta of the sheep, and carrying it on to the turnips from which the cows fed. Now, mark, since that time none of the cattle of the neighbouring farmers have become affected. Again, C., living north of Colchester, had stock on two farms. He introduced the disease by a purchased animal into one herd, which was decimated, while by great precautions the other remained free. One more. D., living six miles eastward of Colchester, had Rinderpest among his cattle, which were decimated, and a flock of sheep grazing in the contiguous field were also attacked, and many died of the disease. This flock was visited by Professor Symonds and Mr. Ceely. In no instance has the disease occurred in this neighbourhood, that I am aware of, in which direct contagion could not be traced. We are, and have been, comparatively free from it round the immediate neighbourhood of Colchester, and have never, in fact, had it as an epidemic at all.

It is, I think, unphilosophical to argue that a disease which can be distinctly traced in its introduction and diffusion in this country to contagion alone cannot be "stamped

out" by rigorous and determined action. At the same time the task is ten times more difficult now than it would have been when first recommended by the Royal Commission.

Dr. Alderson must remember that Dr. Budd, of Bristol, than whom, I believe, no living English observer knows more of epizootic infectious diseases, has distinctly proved that the *materies morbi* of small-pox usually conveyed by the touch may be carried by the wind from one flock of sheep to another at the distance of a mile. It will not be denied, however, that if these sheep were killed and buried that such infection would be prevented. I have the greatest respect for Dr. Alderson, and have made the above remarks in a scientific spirit only. I am, &c.,

C. R. Bree, M.D.,
J.P. County of Essex and Suffolk.

Colchester, March 12, 1866.

P.S.—I hope in this important matter you will admit this letter next week. As a county magistrate, I am actively engaged in "stamping out" this disease; as a "beef-eater," I should be glad to find that any means but slaughter could be arrived at.

THE TREATMENT OF CHOLERA IN INDIA.

Letter from Dr. George Johnson.

[To the Editor of the Medical Times and Gazette.]

Sir,—I find to my great surprise that in a letter published in your paper of to-day I am accused by Dr. Montgomery of having made an "attack upon the Professional abilities of the Indian Medical Service as regards the treatment of cholera." The passage from my paper in the *British Medical Journal*, on which this startling accusation is founded, is reprinted entire in Dr. Montgomery's letter, and I am content to leave to the judgment of yourself, Sir, and your readers the question whether I have there said anything to call for or to justify the personal attack which Dr. Montgomery has made upon me.

The statistics which I quoted are not my own; I am not responsible for their accuracy, neither have I any reason to doubt it. The inference which I drew from those statistics, assuming them to be accurate, I am prepared to defend upon all suitable occasions. I think that I have sufficiently shown my respect for the Indian Medical Service by the very frequent reference which I have made to their writings. If, however, in discussing such a subject as the nature and treatment of cholera we cannot express dissent from the opinions and practice of our Professional brethren without subjecting ourselves to the accusation of imputing to those from whom we differ "incompetence, ignorance, and obstinacy," there must soon be an end of all discussion, and, for my part, I should say the sooner the better.

Dr. Montgomery tells you that I am the author of "a very remarkable," and, in his opinion, "a very erroneous theory," as to the pathology of cholera. If the theory in question be erroneous, it is likely to work much mischief; for it has already made many converts, some of them being men in very high and influential positions in the Profession. I venture, therefore, to suggest to Dr. Montgomery that by pointing out wherein consists the error of that theory he may be doing more to promote the cause of truth and the interests of humanity, and he will certainly afford a more convincing proof that the gentlemen whose representative he assumes to be are my "superiors in good taste," than by making a personal attack upon the author of the theory in question.

I am, &c.

11, Savile-row, March 10. George Johnson.

Prize Question.—The Madrid Academy of Medicine and Surgery offer a honorary diploma and a prize of 250 francs for the best memoir on the following question:—"The Advantages and Inconveniences of Iridectomy as an Auxiliary Means in the Extraction of Uncomplicated Cataract." Essays, written in French, Spanish, or Portuguese, to be sent to the President, 13, Capellanes, Madrid, before October 31, 1866.

Curious Case of Vaccinia after Variola.—A *sergent d'armes*, 41 years of age, unvaccinated in childhood, but who suffered from an attack of confluent variola iu 1834, was vaccinated at Toulon in 1865. Six pustules resulted, producing such excellent lymph that several successful vaccinations have been performed with it.—*Archives de Méd. Navale*, February.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, February 27, 1866.

Dr. Alderson, F.R.S., President.

Dr. Meryon read a paper

ON GRANULAR DEGENERATION OF THE VOLUNTARY MUSCLES.

Since 1851, when Dr. Meryon communicated to the above-named Society an account of this disease, the details of which were published in its *Transactions* in 1852, four more cases have fallen under his observation. In one, which terminated fatally in 1859, the post-mortem examination was carefully conducted by Mr. Savory, who, during a searching microscopical investigation, failed to detect a vestige of disease in any part of the nervous system. The disease appears to consist in a gradual but progressive breaking up of the amorphous membrane which envelopes the primitive muscular fibres, and of a dispersion of the contained granular matter. After these preliminary observations, Dr. Meryon proceeded to describe the case of a gentleman, aged 22, who was present at the meeting, so that the Fellows had an opportunity of examining his present condition. At the age of five years he began to show symptoms of weakness in the loins by a waddling gait; and in the course of two or three years he had difficulty in bending the thighs on the body, as in the act of getting upstairs; next he gradually lost the power of bending the legs on the thighs; and eventually the voluntary motions of the feet and toes were lost also. The morbid action then began to manifest itself in the upper extremities, and the patient has now no longer the power of raising his arms to his head; but he can bend the forearms on the arms, and he still retains a firm grasp with the hands. The tendency of the disease, however, is to extend itself from the proximal to the distal portions of the extremities, and then to attack the muscles of respiration; but in no case are the involuntary muscles or muscles of organic life affected. The history of one case is the history of all; and on the uniformity of the symptoms and the order of their appearance, &c., Dr. Meryon has attempted to distinguish this form of paralysis from all others which are dependent on lesions of the peripheral nerves or nervous centres—1st, by the centrifugal course of the disease, irrespective of the course and distribution of nerves; 2nd, by the entire absence of any symptoms of nervous disturbance during life; and 3rd, by the absence of any trace of lesion in any part of the nervous system after death—at least so far as the most careful investigations have extended up to the present time. There is another difference observed in the muscles thus affected, as compared with paralysed muscles dependent on nervous lesion: it is in the disruption of the sarcolemma and the segregation of the granules which constitute the sarcous matter in the former case; whereas in the latter, the primitive fibres gradually waste, the transverse striæ gradually disappear, and oil-globules by degrees fill the interspaces of the fibres, and occupy the space which the healthy muscular tissue formerly occupied. Dr. Meryon's patient affirms that both he and his sister, who is also a subject of the disease, have retained the condition in which they were when they began to take arsenic. The gentleman has been under the influence of that medicine a little more than a year. In conclusion, Dr. Meryon adverted to the question of priority of description of this peculiar form of disease. He quoted passages from several of the French Medical periodicals in relation to this matter. It is unnecessary to report these, though the following fact may be mentioned—that at the Academy of Medicine M. Cruveilhier referred to Dr. Meryon's plates in illustration of his (M. Cruveilhier's) own diseased muscles, and called the attention of the Academy to a form of paralysis "non encore décrite." Dr. Meryon's paper had been published in *The Lancet* more than a year before, and shortly afterwards appeared also in the Society's *Transactions*.

Mr. Skey said that during a period of some fifteen months, in which he had the charge of the young gentleman of fifteen years of age alluded to by the author, he was informed of an example of a similar disease in one family only, residing in a remote part of Dorsetshire; and with regard to treatment, nothing satisfactory had yet been accomplished. The case related in the paper was interesting from the circumstance that

the manifestation of a morbid condition of the muscular system was not developed till a late period of childhood, or rather perhaps an early period of boyhood—namely, eight years of age. In all the cases with which he was acquainted the change from health to disease commenced in infancy; for while these children were still in their nurses' arms they showed a want of activity and elasticity of movement peculiar to the disease. Again, he observed another peculiarity in the fact that in the cases quoted by the author the change of structure was not confined to one sex; whereas in the two families under his cognizance the females were entirely exempt, and it was the more remarkable because in the family of —— the daughters were noticeable for their healthy and handsome appearance. Nor was it possible to trace the disease from either parent to their male offspring. In the case reported on by the author the morbid changes were confined to the family of the father by his second marriage, thus exempting him from suspicion of personal taint. Supposing the disease to be hereditary, it seemed reasonable to infer that it was obtained through the maternal channel. The treatment adopted consisted in the resort to tonic agents of various kinds—iron, bark, wine, mineral acids, and animal food; but most especially were all the muscles maintained in active exercise at least twice daily, and persisted in up to the point of fatigue: all, however, as the post-mortem appearances showed, without the least benefit. There was one striking feature in this case which he was inclined to consider common to them all—namely, that the morbid changes in the sarcous elements were confined to the muscles of animal life. In the muscular tissue of organic life (the unstriped fibre) no change had occurred; and this he was prepared to expect from the perfectly healthy condition of all the internal functions during life. It could not, then, be asserted that all the muscular tissues are involved, but only those of animal and external life. This fact throws some doubt on the supposed source of the diseased changes in the muscular tissue itself; because if one system be primarily involved, why not both? The sarcous elements are the same, though differently arranged. Why should the myogenic property be arrested in one case and not in the other? If dependent on a morbid state of the nervous centres, we must look to the spinal cord, and exclude the ganglionic system, which for the most part supplies the muscular fibre of organic life.

Mr. Solly said that though he did not deny the probability of muscular atrophy without disease of the nervous system, he was sure that this view of the pathology of the cases described by Dr. Meryon could not be admitted unless there were more complete proof of the spinal cord being perfectly healthy. He felt confident that, in order to detect disease in the spinal cord, it was necessary to examine thin slices of it under the microscope, prepared according to the process enunciated by Mr. Lockhart Clarke; and that until that had been done, we remained in ignorance of the pathology of the disease.

Mr. G. L. Cooper said it had fallen to his lot to see two such cases, and in both instances the symptoms were slow, insidious, free from pain, and ending in a complete degeneration and atrophy of the muscles. He believed that we may assign this disease to a softening of the brain, accompanied by an accumulation of fluid in the coverings of the spinal cord pressing on the nervous centre. The first case was that of a gentleman, about forty-five years of age, who complained of a weakness in his right shoulder, which was soon accompanied by an inability to raise the joint, with an apparent wasting of the deltoid. The muscles of the arm and forearm after a time became flabby and soft, and soon showed a degeneration and atrophied condition of their structure. The left arm has subsequently wasted, and he (Mr. Cooper) suspected would follow the course of the right. The second case was that of a coachman, aged forty-one. He had drunk freely in his early days, and had been exposed very much to the severity of the weather day and night. He suffered from a bad cough with profuse expectoration for many years, but was able to continue his employment until about three years ago, when he noticed a weakness in the thumb of the right hand, which disabled him from holding the whip. The hand soon wasted, and was followed by the forearm and arm in the same condition, with a total loss of power over their action. The left hand and arm were attacked in a similar manner about a year ago, and continued the same course as the right, ending in complete degeneration and paralysis of the extremity, but with more rapidity in its destructiveness. About six months ago his feet, legs, and thighs were similarly diseased, and followed precisely in the same course, ending in complete atrophy or degeneration, with total paralysis. This wasting was not observable in the muscles of the trunk, and the internal organs exercised their functions with a due regularity.

Mr. Lockhart Clarke said that the interesting case which Dr. Meryon had exhibited was considered by him to be one in which there was no lesion of the nervous centres. This opinion was grounded on the absence of pain in the wasting muscles. Now the absence of pain in wasting muscles was no more a proof that their atrophy is independent of lesions of the nervous centres, than absence of pain was a proof of the same independence in cases of motor paralysis. And as we had muscular paralysis without pain, but dependent on lesions of the nervous system, so he believed we might have muscular atrophy without pain, but dependent on the same cause. But whatever *à priori* opinions might be formed on the subject, the question could be decided only by the evidence of post-mortem examination. A few months back a very decisive case came under his notice; or, rather, he received from Mr. Paget the pons Varolii, medulla oblongata, and part of the spinal cord of a child who had died with muscular atrophy of the upper extremities and of other parts, but who had never, he (Mr. L. Clarke) believed, experienced any pain whatever. In the cervical enlargement a small area was discovered, in which the nerve-tissue of the central grey substance had undergone evident disintegration. The pons was healthy, as was every part of the medulla oblongata, except one, where some granular exudation was found extending through the spinal accessory nucleus from behind, and reaching forward into the nucleus of the hypoglossal nerve. At the same level, the lateral parts of the medulla oblongata had undergone a certain amount of disintegration. As Mr. L. Clarke had not received any detailed history of the case, he wrote to ascertain whether the tongue was not in some way affected, and received an answer informing him that the tongue was the part in which the atrophy had commenced. Here, then, was satisfactory evidence of lesions of nerve-centres in a case of muscular atrophy in which there was no pain. This was the more important because pain was not experienced in more than about one-third of the cases of this malady. But when it did occur it was often very significant. Sometimes it took the course of particular nerves, either before or during the wasting of the muscles. Again, the nervous character of muscular atrophy was occasionally indicated by its beginning with an attack of temporary paralysis. Romberg had related a case which began with hemiplegia of the left side. The leg completely recovered, but the arm remained weak, and its weakness corresponded with the wasting of its muscles. No pain was experienced.

Mr. Holmes Coote, in remarking on the interesting nature of the cases now before the Society, said that they were not so uncommon as some of the members supposed, but were "grouped together" in certain Hospitals or under the care of special Practitioners. He had seen, both in the adult and the infant, many cases of such progressive muscular paralysis—a disease which, in course of time, rendered even the bones light and easily broken. In the infant the functions of the sensorium were sometimes disturbed; sometimes not. So also in the adult. And no one had done better service in this department of pathology than Mr. Lockhart Clarke, who had succeeded in demonstrating morbid changes in the grey matter of the nervous centres. His investigations had paved the way to a better classification of these cases, by assigning to them in their varieties one common primary seat—namely, the grey matter of the nervous centres, from whatever cause such disease might arise.

Dr. Fuller said that it had fallen to his lot within the last few years to meet with seven well-marked examples of the disease, which in their progress and in the mode of evolution of their symptoms, resembled precisely the cases related by Dr. Meryon. The cerebral functions remained unimpaired to the last, and the paralysis, which commenced very gradually, did not follow the course of particular nerves, but fixed upon particular bunches of muscles, first in one part of the body, and then in another, quite irrespectively of their nervous connexions. In some of the cases, pain in the limbs and fibrillary twitching of the affected muscles were prominent symptoms; in others, pain was absent, but fibrillary twitching was well marked; and, in two of them, there was no pain, and only the faintest twitching. In one respect Dr. Fuller's cases differed from those detailed by the author of the paper—they all occurred in adults, and in most of them the symptoms appeared to have originated in nervous exhaustion. In one instance, and in one only, the muscles of organic life appeared

to be affected. In that case, which Dr. Fuller saw in consultation with Dr. C. J. B. Williams, the heart, about two months before the patient's death, became extremely feeble in its action, and the pulse fell to 26 in the minute. Dr. Fuller agreed entirely with Dr. Meryon in regarding this disease as quite distinct from ordinary paralysis; and he regarded it also as distinct from the creeping paralysis of the insane, which he believed to constitute the bulk of the cases referred to by Mr. Holmes Coote. As some confusion exists on the subject, Dr. Fuller thought it very desirable that a special title should be assigned to the disease, for at present the nomenclature is quite unsettled.

Dr. Barclay said that previous speakers seemed to him to have lost sight of the distinction which Dr. Meryon had sought to make between muscular degeneration as a cause of paralysis and those other forms which depended on disease of the nervous system. He (Dr. Barclay) believed that several different forms of paralysis had been referred to, and that when the correctness of some of the author's observations was impugned it was because other forms of paralysis presented symptoms different from those traceable in muscular palsy. The presence or absence of the symptoms referred to was the test by which the true character of the affection became known. This was particularly true of the so-called centrifugal direction in which the disease proceeded, in opposition to the ordinary course of gradually extending paralysis dependent on progressive disease of the nervous system.

Mr. Lockhart Clarke, in reply to Dr. Barclay, said that he had been asked whether the morbid changes in the nervous centres might not be the consequences of the muscular wasting. He was sure that the changes he had observed were not so; for they were not simple atrophy of the nerve-tissues, but disintegrations, arising either from softening or from morbid exudations. Moreover, he had lately examined the spinal cord (given him by Dr. Dickinson, of St. George's Hospital) of an old pensioner who had lost one of his legs a great many years ago; but he was scarcely able to perceive any difference between the two sides, and there was certainly nothing at all resembling the disintegrations that he had found in cases of muscular atrophy. For an account of these cases, which he had published, he would refer to recent volumes of the *British and Foreign Medico-Chirurgical Review*, and of Beale's *Archives of Medicine*, particularly to No. 13, vol. iv., which contains one of the most important and interesting cases of any disease on record. He did not, however, wish to be understood to mean that there was no such thing as muscular atrophy without lesion of the nervous system. Such a disease might exist, but the question could be determined only by a sufficient number of post-mortem examinations.

Mr. Skey fully endorsed the truth of the observations of Dr. Barclay. They were discussing various forms of paralysis. He spoke only on that form described by the author of the paper, which is special, if not specific, and which consists microscopically of a deposit of oil or fat globules in the place of muscular tissue. He still believed the disease a very rare one.

Mr. Solly said he thought that Mr. Cooper's case was analogous to the scrivener's palsy, where a nervous centre was exhausted by overwork, and that it might be entitled the driver's palsy, adding another to the list, such as the musician's palsy (of which he had lately had a case under his care), the milker's, the shoemaker's, the nailer's, &c.; but there was no analogy between these cases and those of Dr. Meryon.

Dr. Barker referred to a case of muscular atrophy which had been under his care in St. Thomas's Hospital. The patient was a gardener, not over forty years of age. The first symptoms of the disease were a tripping in his walk, and an inability to prune trees. These were followed by general loss of power. When he first came into Hospital he was plump in appearance, but the muscles of the arms, legs, and thighs were wasted. With the exception of complete loss of muscular power, the man was in every respect well.

Mr. Holmes Coote assured the last speakers that he had had very many opportunities of seeing such cases, not only in Bethlehem Hospital, but also at the Orthopædic and St. Bartholomew's; and that he was not at all likely to fall into the error assigned to him.

Dr. Webster said, in reference to the author's statement regarding a recent speaker at the Paris Academy of Medicine, who had claimed the merit of being the first to notice the malady now under discussion, it should be remembered that French Medical men rarely read English periodicals and seldom speak the language; hence no one ought to feel surprised if Professional questions occupying attention in England do not always become immediately known beyond the Channel. In proof of this, he would mention that at the library of the learned body just named no English Medical journal is accessible for perusal. At least, this was the case not long ago, when he visited the library of the Imperial Academy, where the only English periodical publication shown him by the courteous official of whom he made inquiry was the Registrar-General's Report of Marriages, Births, and Deaths, sent by the British Government. In fact, the tables of that institution are scantily supplied with foreign Medical literature, and very unlike not only this Society, which receives numerous journals of various countries, but likewise dissimilar to several Continental capitals, such as Stockholm, Lisbon, and others, which he might specify from his own personal observation. Therefore Dr. Meryon need not deem it strange whenever any French observer thinks himself an original discoverer, seeing the circumstances above related may perhaps furnish a satisfactory explanation of the assumption narrated.

A SMOKE-RATE, OR THE SMOKE NUISANCE?

(From The Social Science Review.)

This is the age of combination or co-operation. All great things are done by associations. Even in things of the "little-great" order, the same principle of united enterprise is the mainspring of any new undertaking. Our candles come from a joint-stock company of world-wide fame, earning large profits for the general body of shareholders with limited liability for each individual. The company of to-day has entirely put out the tallow-chandler of our early recollections. So with our hotels. Monster edifices are springing up on every side, and the fusty parlour and dingy bedrooms of the old inn are replaced at one-half the cost by the palatial morning room, and the neat, home-like, airy, private apartments of this age of joint-stock. But there is a sad want of originality in the projectors of all these baits thrown out by secretaries and solicitors, and directors, to catch shareholders. One hotel succeeds, and a dozen servile copies instantly appear in the advertising columns of the daily papers. So with banks, water companies, gas companies, omnibus companies, mining, and telegraph companies. One is either a miserable hash, or a highly-seasoned *rechauffé* of some other. There is nothing new in the mind of Young Joint-Stock. He is used up. He has not awakened to the dawn of social science. He does not know how far behind the science of the day is the art of the day. He cannot bring the truths taught by sanitary reformers to the homes of the people. He knows nothing of ventilation, yet the indoor life of the English is a martyrdom. In dining and drawing room—in kitchen and bedroom—at church or in the theatre—in the lecture room or the railway carriage,—carbonic acid reigns supreme, and oxygen is ignominously routed. Our architects and builders are a disgrace to their age and country; they are fifty years behind the knowledge which men of science have been teaching. In the International Exhibition they could show nothing which promised to supply enough air to any living room without exposing the occupants to showers or deluges of cold air. They could show no means of warming our buildings without baking us or setting us all on fire; and they never once thought of freeing our rooms and our streets from the smoke which shuts off our sunlight and etiolates our children—which blackens all our public buildings, hanging like a pall above us, and fouls our skin, our linen, our eyes, and our lungs by an all-pervading nuisance. Our dying plants and withered leaves of neutral-tinted trees, and the pale sallow faces of our smoke-breathing citizens tell more than whole regiments of "blacks" how omnipotent is the evil which science has long denounced, but which art has failed to remove. Years ago it was proved that smoke is unnecessary, and that its consumption is economical; while, thanks to the energy of Lord Palmerston and his contempt of "vested interests," distilleries, breweries, potteries, and steamboats have been compelled to consume their own smoke within certain limits in the metropolis. But the great cloud of London smoke—the dull, heavy, leaden mass which hangs over us, the contribution of the innumerable chimneys of private houses—is as thick as ever. Science has shown that one-half our coal is wasted by the bad construction of our fireplaces, while the production of smoke is doubled. But Art has done nothing to improve upon the teachings of

her sister. Nor has anything been done to free our atmosphere from the smoke which must still escape even when fireplaces are well made, and no coal is wasted. Yet here again our science is ten years ahead of our art; and here sanitary science especially has been in advance, and the comfort of daily life and the public health are sacrificed, because the hands which execute are not equal to the minds which devise; in other words, because our Doctors are a generation in advance of our architects and engineers. In this very matter of the smoke nuisance, a well-known London Surgeon, Mr. Spencer Wells, published an article in the *Medical Times and Gazette*, August 20, 1853, containing the following remarkable passage:—"Let us hope that by an improved construction of fireplaces in private houses, the present wasteful consumption of fuel and unnecessary consumption of smoke may be diminished, as competent engineers have proved that it might be, by at least the half. We do not despair of seeing London freed even from the remaining half, its inhabitants breathing as pure and clear an air as those of Paris, Berlin, or Vienna, and its buildings, cleansed from their present funereal coating, standing forth in all the unsullied beauty of their architecture. In this case, a new feature would be added to the architecture, and we should then see a number of beautiful structures, not unlike miniature representations of the gigantic aqueducts of the ancient Romans, replacing our present unsightly chimneys, and carrying all the smoke through closed conduits to central furnaces, where it would be in a great measure consumed, and its remaining portions discharged at a height too great to be injurious or unsightly. A small smoke-rate, giving us pure air, would surely be as cheerfully borne as a sewer-rate, which only purifies our houses by polluting our river."

Now, let us see whether, after ten years' delay, any of our engineers or architects can put this idea of Mr. Wells, freely offered to them, to some useful and profitable practical purpose. Let some one replace our ugly chimneys by pretty arcades, convert our dirty roofs into clean conservatories, give our citizens and their children some bright sunlight, while the smoke is turned to some useful purpose—cooking for the poor, heating public baths, or ventilating rooms—and the statue of this public benefactor shall stand as high as that of Nelson in the "good time coming." Here, too, is an opening for some joint-stock company who can find a secretary with a fair share of brains, or for some M.P. who wishes to earn a solid claim to a nation's gratitude. As a speculation, it would make the fortune of shareholders. As a social blessing, a smoke-rate, or any other rate, would be hailed with acclamation if it only held out a fair prospect of lessening or removing the smoke nuisance.

OBITUARY.

THE LATE MR. McWHINNIE.

Andrew Melville McWhinnie was born in the South of England in the year 1808. After having been at school in Yorkshire, he was sent, under the care of Lieutenant Martin Miller, to the Continent, where, remaining three or four years, he acquired an intimate knowledge of the French language. Returning to England and entering the Medical profession, he became a pupil of Mr. Stanley, then Assistant-Surgeon to and Lecturer on Anatomy at St. Bartholomew's Hospital. In 1834 he joined Mr. Wormald, the present President of the Royal College of Surgeons, as Demonstrator of Anatomy in the School, and, in conjunction with this gentleman, published in 1838 and 1843 "A Series of Anatomical Sketches and Diagrams, with Descriptions and References." The drawing of these sketches and diagrams was executed mainly by Mr. McWhinnie from recent dissections made by Mr. Wormald and himself. Previously to the time of which we speak, although elaborate and consequently expensive anatomical plates were contained in the different school libraries, scarcely any attempt had been made to provide the ordinary student with sketches which might be kept always at hand, and serve to illustrate the more complicated dissections of the various regions of the body. The object which the authors of this publication had in view was to meet a want which, as teachers of anatomy and as skilful draughtsmen, they felt to be a real one. The effort has since borne abundant fruit, for the work may be fairly called the progenitor of such admirable ones as Holden's "Osteology," and Ellis's Anatomical Plates, which, if they have not opened for the student a royal road to the acquisition of anatomical knowledge, are yet recognised as affording him indispensable assistance. In 1839 Mr. McWhinnie was elected Lecturer on Comparative Anatomy at St. Bartholomew's in the room of Dr. A. Farre, who had just resigned that office. Soon after the Hospital for Diseases of the Skin was founded, in 1841, he was made Assistant-Surgeon to the Institution, and this appointment he retained till shortly before his death. He became Assistant-Surgeon to St. Bartholomew's in 1854, but sent in his resignation of this office and also of the Lectureship on Comparative Anatomy in 1860. Mr. McWhinnie translated Cloquet's valuable work on Hernia, and published, in concert with Dr. Roupell, "Illustrations of the Effects of Poisons." Besides, he wrote essays on "Irregularities in the Muscular System of the Human Body," "Malformations of the Urinary Bladder," "Tracheotomy," "Transposition of the Thoracic Viscera," "Bronchocele," etc., and within the past few years contributed various papers on practical Surgery to the periodicals of the day. Mr. McWhinnie was possessed of considerable natural ability, and he enjoyed many of those accomplishments which are always important accessories in the pursuits of the Profession of Medicine; he was a very skilful manipulator, both in dissecting and operating, and many valuable anatomical preparations made by him are now in the Museum of St. Bartholomew's. He was an admirable draughtsman, and his being so was of great assistance to him in the dissecting rooms. Kind-hearted, amiable, and always anxious to give assistance or information, he was very popular with his pupils. For the past few years he had been compelled by failing health to relinquish to a great extent his private practice, which had never been very extensive. He died at his house in New Bridge-street after a long and painful illness produced by malignant disease of the large intestine on February 27.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 8, 1866:—

Frederick John Wadd, Priory-road, Kilburn, N.W.; Richard Pugh, Llandovery, South Wales; Frederick Martyn Rickard, Stoke Devonport, Devon; Robert Rugg, Dispensary, Stepney; Richard Hake Bush, York-terrace, Regent's-park.

The following gentleman also on the same day passed his First Examination:—

Benjamin Duke, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Althaus, Julius, M.D., has been appointed Physician to the London Infirmary for Epilepsy and Paralysis, Charles-street, Portman-square.

Butt, William F., M.R.C.S. Eng., has been promoted to Senior Resident Surgeon to the St. Pancras Workhouse and Infirmary.

Dudley, John G., M.D. Cantab., has been appointed an additional Physician to the North London Consumption Hospital.

Grier, W. J., L.R.C.P. Edin., has been elected Medical Officer to the Workhouse and Fever Hospital of the Granard Union, Co. Longford.

Jamieson, W. A., M.B., has been appointed Junior House-Surgeon to the Dispensary, Preston.

Mahony, E., M.R.C.S. Eng., has been elected Resident Junior Surgeon to the St. Pancras Workhouse and Infirmary.

Maurice, Oliver C., M.R.C.S. Eng., has been appointed Assistant-Surgeon to the Royal Berkshire Hospital, Reading.

Meadows, Alfred, M.D. Lond., has been appointed an additional Physician to the Hospital for Women, Soho-square.

Milburn, Frederick L., M.R.C.S. Eng., has been elected Assistant House-Surgeon to the General Hospital, Nottingham.

Nesham, Thomas C., M.D. Edin., has been elected Surgeon to the Newcastle-upon-Tyne Lying-in Hospital.

Smith, William A., M.D. St. And., has been appointed an additional Physician to the North London Consumption Hospital.

Sturges, Octavius, M.D., has been appointed an additional Physician to the North London Consumption Hospital.

White, William L., M.B., has been appointed Assistant Medical Superintendent to the Dundee Royal Infirmary.

Yates, Mr. G. I., has been appointed Assistant Dispensor to the Burlington-street Dispensary, Liverpool.

Yorke, Christopher F., L.R.C.S.I., has been appointed Surgeon to the Constabulary, Granard, Co. Longford.

BIRTHS.

ARSCOTT.—On March 8, at Southernhay, Exeter, the wife of Robert Arscott, M.R.C.S. Eng., of a son.

BOUSTEAD.—On January 28, at Kurrachee, Scinde, East India, the wife of Dr. Robinson Boustead, H.M. Bombay Army, of a daughter.

CARTER.—On February 27, at Budleigh Salterton, Devon, the wife of H. I. Carter, Surgeon-Major (retired) H.M. Bombay Army, of a daughter.

CHAMPNEYS.—On March 8, at Battle, Sussex, the wife of Montagu Champneys, F.R.C.S., of a daughter.

MACKINNON.—At Campbellpore, East India, the wife of Assistant-Surgeon Charles Mackinnon, 20th Hussars, of a daughter.

PRALL.—On March 11, at West Malling, Kent, the wife of Samuel Prall, M.D., of a daughter.

RANDELL.—On February 7, at St. Thomas's Mount, Madras, the wife of Assistant-Surgeon Henry L. Randell, R.A., of a daughter.

WIGMORE.—On March 18, at 21, Inverness-road, W., the wife of William Wigmore, Surgeon, of a daughter.

MARRIAGES.

COVEY—HEMSTED.—On March 8, at Whitchurch, Hants, Charles E. Covey, Surgeon, to Harriet, second daughter of T. R. Hemsted, Esq.

PEACOCKE—WILKINSON.—On March 7, at All Souls' Church, Langham-place, George Peacocke, M.D, to Rose E. Wilkinson, only daughter of George Smith, Esq.

DEATHS.

GODDARD, SAMUEL P., M.D. Aberd., at Park Hall, near Longton, Staffs., on March 1.

HALL, STEPHEN, M.D., late of Exeter, on March 5, aged 63.

PEARSON, HENRY W., M.R.C.S. Eng., at Hastings, on March 6, aged 29.

QUARRELL, WILLIAM, M.R.C.S. Eng., at Victoria House, Torquay, on February 10, aged 25.

PAUL, JAMES J., M.D. St. And., at Putney, on March 11, formerly Surgeon R.N.

TABRUM, WILLIAM, M.D. Edin., at Upminster, Essex, on March 12, aged 81.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Alcester Union.—Mr. J. P. Dunn has resigned the Feckenham District; area, 6500; population, 3217; salary, £50 per annum.

Easingwold Union.—Mr. Henry Skaife has resigned the Coxwold District; area, 13,499; population, 1824; salary, £26 per annum.

Keynsham Union.—Mr. J. H. Simpson has resigned the Marksbury District; area, 8895; population, 2050; salary, £40 per annum.

Newcastle-upon-Tyne Union.—The First District is vacant; area, 1400; population, 16,350; salary, £50 per annum.

Sleaford Union.—Mr. Franks has resigned the Heckington District; area, 31,861; population, 5720; salary, £52 per annum.

Thirsk Union.—Mr. Skaife has resigned the Kilburn District; area, 2662; population, 434; salary, £8 per annum.

APPOINTMENTS.

Ross Union.—William H. Plaister, M.R.C.S.E., to the St. Weonards District.

Wilton Union.—Frederic J. Flower, M.R.C.S.E, L.S.A., to the Bishopstone District.

HONORARY PHYSICIAN TO THE QUEEN.—Tuesday's *Gazette* contains the following announcement under the head of "Army Medical Department:"—Inspector-Gen. of Hospitals George Stewart Beatson, M.D., to be Hon. Physician to Her Majesty, vice Sir John McGregor, K.C.B., M.D., deceased.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At the meeting of this Society, held on Tuesday, March 13, in the Hall of the Faculty of Physicians and Surgeons, the following gentlemen were elected office bearers for the present year: *President:* Dr. Allen Thompson. *Vice-Presidents:* Dr. Robert Paterson; Dr. John Coats. *Council:* Dr. Naismith, Hamilton; Dr. W. T. Gairdner; Dr. Yeaman; Mr. Robertson, Renfrew; Dr. Dewar; Dr. Tindal. *Secretaries:* Dr. James Adams; Dr. Robert Perry. *Treasurer:* Dr. Howatt.

WE learn that the operation of ovariotomy has for the first time been undertaken in Portugal by the well-known Surgeon Senhor Antonio Maria Barbosa, of Lisbon. The patient died of peritonitis on the seventh day, under circumstances by no means discouraging to further attempts in the same direction.

WEBBER V. WILLICOMBE AND OTHERS.—Mr. Webber, of Tunbridge Wells, has obtained a verdict of £50 damages against two of the ringleaders of the mob who, it will be recollected, broke his windows and burnt him in effigy. It was stated at the trial that the plaintiff had excited ill will by stating his opinion on the state of the sewerage of the town.

THE NATIONAL PORTRAIT GALLERY, WESTMINSTER.—The *Athenæum* says:—"A good old portrait of Sir William Butts, Physician to King Henry the Eighth, which has suffered in some degree by effacing, but escaped restoration, is a valuable historical accession. The head agrees perfectly perfectly with that of Dr. Butts in the great picture of 'The Barber Surgeons receiving their charter.'"

THE MEDICAL COUNCIL.—The parliament of Medicine is summoned to meet in London on May 15, and will probably sit through Whitsun week. The Medical Council is a highly-paid, deliberative body, representing the Colleges of England, Scotland, and Ireland. Each member receives ten guineas a-day during the session. Its deliberations have generally lasted a week, and cost over £1500 in fees. Fortunately for the fund which has to provide the fees (they are drawn from the pockets of the Medical Profession), most of the members are in lucrative practice, and lose by the arrangement; otherwise speeches costing some £25 an hour might be unduly prolonged, and would be open to even more severe criticism than they now receive. There is one service which the Medical Council might render which would be welcome to the public generally as to the Doctors. They would confer a great benefit if they could persuade the Government to introduce such an amendment of the 40th clause of the Medical Act as should really prevent unlawful practice by Medical pretenders, and enable all men readily to distinguish between legal and illegal Practitioners. This the Medical Act now professes, but fails, to do.—*Pall-Mall Gazette.*

UNIVERSITY OF CAMBRIDGE.—Mr. Edmund Carver, of St. John's College, M.A., F.R.C.S., has been appointed by Professor Humphry to the recently created office of Demonstrator of Anatomy. Mr. Carver has shown himself well qualified for it by his diligent and efficient superintendence of the students in the dissecting-room during the present winter.

ODONTOLOGICAL SOCIETY.—At the ordinary monthly meeting, held at its rooms, 32, Soho-square, on the 5th inst., Mr. Mummery read a paper "On Certain Forms of Irregularity of the Teeth," exhibiting models of cases where great success had followed his efforts to reduce the deformity.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of candidates who passed the Examination on March 14, as Pharmaceutical Chemists:—Alfred Barrowclough, Mirfield; William Beckett, Heywood; Robert Keevill, Clifton; James John Owles, Great Yarmouth; William Phillipps, New Cross-road; Joseph Spencer Robinson, Alfreton; Philip Stoneham, London; Samuel John Weston, London.

ALLEGED POISONING BY MILK FROM A COW RECOVERING FROM RINDERPEST.—The *Pall-mall Gazette* states that the wife of Mr. Thomas Woolfe, of Standon Hall, in Staffordshire, was seized with the symptoms of irritant poison after tasting milk obtained from an animal recovering from cattle plague.

MEDICAL COUNCIL PUNISHMENTS.—The following are the names of the delinquents who have been struck off the Medical Register, a list of whom has been delivered to all Medical Examining Boards, in order to prevent a re-examination and obtaining other qualifications, viz:—

Abercrombie, Robert, well-known in connection with the notorious Strand Museum.

Barrett, John Carter, having been convicted of felony.

Burton, John, his name erased, "having been fraudulently or incorrectly made."

Broatch, John, for having obtained the entry of his name by a false declaration.

Brown, Hugh, his diploma having been obtained by a false statement of his age.

Cumming, William John, having been convicted of felony.

Dougal, Daniel, his diploma having been obtained by a false statement of his age.

Gourley, Daniel de la Cherris, having been convicted of a misdemeanour.

Jordan, Robert Jacob, of the notorious museum in George-street, Hanover-square.

Jones, David Griffiths, having been convicted of a misdemeanour.

Kearney, John, "for infamous conduct in a Professional respect."

La Mert, Samuel, "for infamous conduct in a Professional respect."

Organ, Richard, for "infamous conduct in a Professional respect."

Protheroe, John Edward, the entry of his name "having been fraudulently obtained."

Thomas, Evan, having been convicted of perjury.

Whalley, Thompson, having been convicted of a misdemeanour.

Wrixan, Robert, having been convicted of perjury.

It is stated that other names will be submitted at the next meeting of the General Medical Council for removal from the Register.

NEW HOUSES IN PARIS.—The Préfet of the Seine, in his report for 1864-65, states that a very erroneous belief has arisen that, owing to his demolitions, the number of houses and lodgings had diminished in Paris. So far from this being the case, he says that the contrary is the fact. Thus during 1864-65, there have been constructed 3351 houses, while only 1942 have been demolished—465 through the intervention of juries and 1477 voluntarily—with the view of new and superior constructions. So, too, while 19,924 lodgings or residences have been constructed, only 11,976 have been demolished. Another statement that the tendency has been to create more large apartments at high rents than small and cheap ones, is also erroneous; for according to a recent census it appears that 12,443 houses, containing 71,566 residences, erected between 1860 and 1863 inclusively, may be thus classed:—Rents above 1000 frs., 11,095; between 500 and 1000 frs., 21,369; between 500 and 300 frs., 19,134; below 300 frs., 19,968; total, 71,566. Thus the mean rent of these residences created during these four years is not above 500 frs. for one-half, the rents exceeding 1000 frs. not constituting even one-sixth of the whole number At the present time there exist in Paris 637,369 residences, 17,040 being vacant.

RINDERPEST IN SHEEP.—The murrain caused in Scotland by the alleged outbreak of Rinderpest in sheep has been to some extent mitigated by the investigations into the circumstances of the cases. In the Fifeshire cases undoubtedly the testimony of the professional inspectors as to the disease being Rinderpest is distinct and decided, but great reluctance is shown on the part of practical men to accept their opinion without further inquiry. Into the Forfarshire cases a very careful investigation is being made by the Chamber of Agriculture, and an interim report has been issued stating the symptoms and circumstances. In these cases the local inspector was unable to pronounce that the disease was Rinderpest, and, on being questioned by the committee of the Chamber, he acknowledged that he had seen similar symptoms in other diseases. Professor Strangeway, of Edinburgh, has been appointed meantime to go and examine the flock said to be affected, while the head and intestines of a sickly sheep, slaughtered for the purpose of the inquiry, have been already examined by him, and said by him to show much less distinct appearances of Rinderpest than the Fifeshire cases, although the symptoms were such as might indicate an early stage of that disease. Meantime, the Chamber suspend the expression of their own opinion; but, looking to the mortality usual at the lambing season, the severe snow-storms prevailing in Scotland for the last fortnight, the mildew in the turnips, and the change in the diet of the affected flock lately brought from Berwickshire, it seems to be the opinion of those who have examined the circumstances that the disease in the flock may be otherwise accounted for than by ascribing it to Rinderpest.

KEROSOLENE.—In our two last numbers this substance has been referred to. It consists of one or more of the lighter hydro-carburets procured in the distillation of American Petroleum. Being procurable in large quantities, it is comparatively a very cheap article. It begins to boil about 82° Fahrenheit. In our last number Dr. Richardson states that kerosolene is "no anæsthetic *per se*." But several years ago Professor Bigelow, of Boston, and other Physicians in that city, found that it was a powerful anæsthetic, and used it for a time as such. Like the other more powerful general anæsthetics—chloroform and sulphuric ether—it has a partial *local* benumbing effect when its vapour is applied locally; and besides its evaporation, produces speedily, as is the case with sulphuric ether and other bodies boiling at a low temperature, a state of insensibility by coldness and freezing of the part to which it is applied. When purified by re-distillation, the form in which it is employed by Dr. Bigelow and others, kerosolene is to the generality of people not more unpleasant than sulpuric ether, if indeed it be so much so. Dr. Richardson's apparatus for producing freezing by the evaporation of sulphuric ether has, we believe, greater advantages over the means and instruments used some ten years ago by Guérard Velpeau and others for producing the same effect in Surgery upon the same principle and with the same medicinal agent; but in the present renewed investigation of this important practical subject, it is evidently right that the relative values of the different medicinal agents capable of producing the desired effect should be duly examined and tested. We believe that sulphuric ether is, on the whole, the best agent for local anæsthesia that has hitherto been proposed, and Dr. Richardson's method is undoubtedly the best method of using it. We must recollect that it is not the man who first proposes the germ of a discovery, but he that gets it into actual use who is honoured as the real inventor. Local anæsthesia was in a state of torpor before Dr. Richardson set it going again. If it should aequire vogue and celebrity, the credit of it will mainly belong to him.

WE learn that a new Institution called the London Infirmary for Epilepsy and Paralysis, has been set up at No. 19, Charles-street, Portman-square, W. The president is Lord Wharncliffe. The vice-presidents and committee include some well-known philanthropic names, and the services of Alexander Ure, F.R.C.S., have been secured as Consulting-Surgeon, and of Dr. Julius Althaus, as Physician,—"Confirmed cases of epilepsy and paralysis," says the prospectus, "are excluded on principle from the general Hospitals, as causing a great deal of trouble, and expending in vain the funds of those charities. There is indeed at present only one Institution in the whole of Great Britain specially intended for the relief of such patients; but this is totally unable, single-handed, to cope with the vast mass of misery found to exist. Very many of the helpless and disabled are therefore left to pine away at their homes, under the care of incompetent persons, or without any attendance whatever; while not a few of the epileptic are sent to the workhouses, where they are classed with the insane, and where their condition is truly pitable. In order to afford the help needed for such patients, the London Infirmary for Epilepsy and Paralysis has been established by a number of ladies and gentlemen desirous of extending the benefit of Medical aid to sufferers from these the direst afflictions to which the human system is liable. The operations of this charity are at present limited to the relief of out-patients, but as soon as the funds will allow, it is intended to open wards for in-patients."

DECLINE OF THE RINDERPEST.—There really seems to be reason to believe that a solid and tangible decline has occurred in the Rinderpest. During the sixteen weeks ending March 3 the whole number of attacks reported to the Veterinary Department of the Privy Council has been as follows:—

Week ending	Current cases.	Back cases.	Total.
November 18, 1865	2669	676	3345
,, 25 ,,	3610	2941	6551
December 2 ,,	3828	1903	5731
,, 9 ,,	5356	2129	7485
,, 16 ,,	6054	2133	8187
,, 23 ,,	6256	1951	8207
,, 30 ,,	7693	2263	9956
January 6, 1866	7106	1402	8508
,, 13 ,,	9243	2956	12299
,, 20 ,,	10041	2801	12842
,, 27 ,,	11745	1893	13638
February 3 ,,	9153	2290	11443
,, 10 ,,	11590	4305	15895
,, 17 ,,	13001	5355	18356
,, 24 ,,	10167	1143	11310
March 3 ,,	7310	2060	9370

The public has, perhaps, been led to form erroneous conclusions on the subject, as the abstracts published weekly have taken no account of the "back cases"—that is, the cases not reported in sufficient time to be included in the weekly returns, and carried forward in consequence to the next week. At the same time, the totals referring to these back cases are too considerable to be overlooked. It will be seen that the aggregate number of attacks in the week ending March 3 was less than in any previous seven days since January 6, while comparing the number of attacks in the week ending March 3 with the total for the week ending February 17, we see a decline of nearly 50 per cent. The next two or three weekly returns will be of great importance, as they will show whether the measures recently attempted by the Government have really been attended with the good results which they appear to have produced. Another point of great importance in connexion with this question is that the general proportion of recoveries to attacks at the close of the week ending March 3 was 13·949 per cent., while at the close of the first week of November it was only 5·235 per cent. These figures refer to the general proportion of recoveries to attacks from the commencement of the disease to the dates indicated; but the proportion of recoveries to attacks reported in the seven days ending March 3 had risen to no less than 24·949 per cent. We are thus now saving one out of every four beasts attacked, while the attacks appear to be reduced by one-half.—*Times*, March 14.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending March 3.	Week ending February 24.	Week ending February 17.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.
1. Metropolitan Police District	12	12	16	7612	3211	3485	333	583
2. South Eastern Co.	23	16	26	4989	1558	2779	442	210
3. South Midland Co.	573	711	619	14512	2795	9697	1422	598
4. Eastern Counties	241	262	182	9258	3356	4656	694	552

11. Monmouthshire & Wales	113	268	395	7188	126	5707	999	356
12. Scotland	834	1843	2225	43752	4685	25879	9363	3825
	7310	10167	13001	187059	26135	117664	26106	17154

Note a.—The operation of "The Cattle Diseases Prevention Act," 1866, is indicated by the return this week, showing 5197 cattle as "killed," compared with 1711 last week, and 980 the previous week.

Note b.—246 inspectors have not reported this week in time for this return. Of these 22 reported cases last week—viz. :—For the county of Chester 1; Derby, 1; Lancaster, 3; Lincoln, 1; Norfolk, 1; Stafford, 1; East Riding of York, 1; West Riding of York, 2; the Metropolitan Police District, 1; Flint, 2; and for Scotland 8. These inspectors returned 1281 cases last week.

UNFOUNDED CHARGE AGAINST A PARISH SURGEON.—The Brighton papers contain an account of a charge of neglect preferred by one Henry Davis, of Essex Cottage, College-place, against Mr. George Geere, Medical officer for the eastern district of the parish of Brighton. The proceedings were ordered by the Poor Law Board, and were conducted by the Poor Law Inspector for the district. The subject of the inquiry was the death of a woman named Fanny Hutson, who died on Tuesday, Nov. 21 last, at 11, Paradise-street, the property of Mr. Davis, who alleged that she had died in her confinement through the negligence of Mr. Geere. He called witnesses with the view of showing that Mr. Geere had not promptly attended to the case; but their evidence was of a hearsay character only, founded upon statements which were said to have been made by the husband of the deceased, who had died about a fortnight after the wife of typhus fever. Mr. Pocock, one of the District Surgeons of the Dispensary, who attended the deceased woman up to the period of her confinement, informed the Court that she was suffering from typhus fever, and there seemed to be no doubt that the fever produced a premature birth and death. The persons who were with the family before and after the woman died said they heard no complaint made by the husband against Mr. Geere. All that could be construed into negligence was an unsupported statement that he had been sent for three times on the day of her death, and that he did not attend till after she was dead. It appeared that deceased had been attended from Nov. 17 to 20 by Mr. Pocock for fever, but when he was told she was pregnant he, it being against the rules of the Dispensary to attend to cases of parturition, advised her removal to the Workhouse Infirmary, or the obtainment of a parish Surgeon. On Tuesday, November 21, the husband made application to the parish and obtained a Medical order from the assistant-overseer for Mr. Geere to attend to the case. This order was issued at a quarter past twelve o'clock, and, when left at Mr. Geere's surgery, he was not at home. The woman was confined very shortly after the husband got back, assisted by a midwife who had been sent for; and at two o'clock a little girl was sent with a note to Mr. Geere to tell him Mrs. Hutson was put to bed. He was still out, and the girl brought the note back about four o'clock, having gone to a cousin's in the meantime, and at six o'clock Hutson was going again to Mr. Geere when he met him on the road. By the time he arrived the woman was dead. The assistant-overseer explained that, when the order was issued, the man made no reference to the case being urgent; that he never even said his wife was pregnant, or the order would have been endorsed "urgent;" but he merely applied for his wife to be removed to the Infirmary as suffering from fever. Mr. Geere, in reply to the inspector, said, had the order been marked "urgent," his deputy would have attended to the case. It was proved that others of the family had suffered from fever, and the description of the house was horrible. There were only three rooms in it—a bedroom, kitchen, and washhouse; no back yard or back windows, and there was a stench so offensive that Mr. Pocock said he was compelled on one occasion to stand outside the house to talk to the husband. Mr. Barber, one of the parochial visitors, said he asked the eldest daughter from whence this stench arose, and she pointed to a copper in the corner of the washhouse, and said, "That is where the 'matter' runs from the copper across the kitchen." There was a mark where something had been running from the copper, and had dried up; but in the area, close to the door, there was a privy, which was full and very offensive, and the bricks and mortar had fallen down. The daughter told him they could not use the privy, but were obliged to make use of utensils in the house, and she believed that what oozed from the copper came from the back yard of No. 10, next door. In this "house" there lived eight people! Its condition was reported to the Sanitary Committee of the Town Council, and Mr. Davis, who accused Mr. Geere of reporting it, admitted that he made no complaint against Mr. Geere till after the house was reported, and he gave as a reason why the complaint was so long deferred—six weeks after the death—that he could not obtain reliable information. At the conclusion of the inquiry the inspector said he had to make a report to the Poor Law Board, and had no doubt the guardians would receive it shortly, with, which he had no doubt they would like, an expression of opinion upon the case.

WE understand that the prospects of the Grand International Horticultural Exhibition and Botanical Congress, to be held in London in May next, are most encouraging. The ground to be occupied by the show, which is a portion of the site at South Kensington of the Exhibition of 1862, is already under preparation for the erection of the monster tent; and, according to the plans which have been adopted, the interior arrangements will be made most effective. The complimentary banquet to the learned foreigners who are invited to take part in the proceedings, and to attend as delegates from foreign governments, and which, thanks to the City Corporation, is to be held in the Guildhall, is drawing in as subscribers to the fund many who are anxious to do homage to the distinguished personages who will be present; while the Botanical Congress, which is to be under the presidency of M. de Candolle, is assuming from day to day a more practical shape; several eminent botanists, both at home and abroad, have already joined in working it out to a successful issue. The meetings of the Congress are to be held in the Raphael Cartoon Room at South Kensington, by permission of the Committee of Council on Education. This great horticultural movement, it should be remembered, is wholly of an independent character; and it must be a source of great gratification to the friends of scientific horticulture in this country that it has attracted so large an amount of voluntary pecuniary support, without which, indeed, it would not have been attempted. The expenses, however, will be heavy in proportion to the magnitude of the undertaking, and we learn officially that further aid is necessary to secure that the combined Exhibition and Congress be carried out in a spirited manner, which is highly desirable, having reference to their international character.

HOUSE ACCOMMODATION IN SCOTLAND.—

Rooms without windows	7,964
Houses of one room	226,723
,, two rooms	246,601
,, three rooms	75,933
,, four rooms	37,186
,, five rooms	19,910
,, six rooms	15,278
,, seven and more rooms	37,191
Total houses in Scotland	666,786

From this it would appear that, exclusive of the houses or dens without windows, there are 226,733 houses of only one apartment, or about one-third of the whole houses of Scotland. Any man of the least intelligence may judge what the social state of the people so accommodated must necessarily be. The sick and the whole, the living and the dead, must thus be huddled together without the possibility of separation; and the feelings and moral perceptions of the young must be blunted from their very earliest years. But this—bad as it is—does not represent the full amount of the evil, for 40,703 or

these one-roomed houses have each from six to sixteen persons residing in them, as will be seen by the following table:

18,983	One-roomed	houses have	6	persons in each room

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Will B. B. be good enough to address a note to Dr. Hughlings Jackson respecting the report of his case at the Pathological Society?

Amicus.—Perceival on Medical Ethics.

Leicester.—Mr. Marriott's communication is in the printer's hands, and shall appear shortly.

Pereira's Materia Medica.—Doses of Medicines.—Dr. Farre's letter has reached us too late for publication this week. It shall appear in our next impression.

Oldham, Lancashire.—The proceeding can only be carried out in good faith by the pupil serving our correspondent as his apprentice for a reasonable time.

Beneficence.—Mr. W. C. Grove, of Mere, Wiltshire, lately deceased, has bequeathed £200 to the Salisbury Infirmary, £100 to the Brompton Consumption Hospital, and liberal sums to other institutions not Medical.

Anti-Quackery.—The names of the delinquents have already been removed from the Register, and at a meeting of the Council of the College of Surgeons on Thursday, those of Whalley and Protheroe were removed from the list of members.

W. B., M.D.—It was J. C. Bruner, a Swiss Anatomist, who was born in 1653, who proved that the fluid secreted by the pancreas was not necessary to digestion, and that an animal may live after that viscus is taken out of the body.

H. S., Kennington.—It was not Leo's, but Pope Adrian's Physician, who, the night after the decease of his Holiness, had his door decorated with garlands, with the inscription "To the deliverer of his country."

W. D. S., M.D., Worksop.—You will find an editorial article on the "Re-appearance of Scurvy in Britain and Ireland," in the *Medical Times and Gazette* of November 11, 1848, which will give you the desired information. We shall be glad to hear from you.

Cattle Plague Legislation.—As we have said, it is very likely the amendments of the Lords, amounting, as they do, virtually to a new Bill, will not meet with much favour in the House of Commons. When we consider the extent to which the disease prevails, it seems absurd to call upon the Privy Council to declare a particular district infected, and to subject it to exceptionally severe treatment. It would be better, we think, to invert the process, and allow the Privy Council to declare districts such as Wales and the northern counties of Scotland free from infection. We hope, however, that if the Commons see fit to disagree to the Lords' amendments, they will, at any rate, spare the clause which prohibits movement on canals or rivers so long as there is prohibition of movement on railways, and the clause which forbids the holding of fairs and markets for the next three months. The first is a simple act of justice to railway companies, who would be most unfairly used if forbidden to convey cattle when other means of transit were left open, and the second is aimed at the readiest means of spreading infection, and ought to have been inserted in the original Bill. We suppose this bungling and inadequate legislation is all we are likely to get, and that if not contented we must be at least resigned; but it seems hard that so much of the heavy sacrifices the country is called upon to endure in order to avert this disease should be neutralized by the discordant provisions of two Acts of Parliament and some twenty Orders of the Privy Council. Nobody, we suppose, is to blame, but the result seems only too likely to be that we shall endure many evils in order to get rid of the cattle plague, and fail to get rid of it after all.—*Times, Monday, March* 12.

*** It will be seen from our Parliamentary report, that Mr. Hunt's Bill, after weathering the storm in both Houses, is now withdrawn, and that it is left to the Privy Council to deal with the matter. The progress of the Bill and the warm discussion to which it has given rise, put one in mind of a modern review, where, after all the marching and countermarching, the firing, smoke, noise, and dust, the matter is terminated with the order, "As you were."

Millett v. *Edmonds.*—We have received a statement from Dr. Frederic Edmonds, the defendant in this case, complaining of the comments made in various quarters on his conduct in the matter of an investigation into the cause of death of his brother. No good purpose would be answered by publishing Dr. Edmonds' letter; but we may say on his behalf that he is quite satisfied that all imputations made against the plaintiff were unfounded; and, secondly, that he himself was made to appear to take the part of prosecutor, when he never intended to do so. Suspicions had been aroused, and rumours were afloat, and Dr. F. Edmonds thinks that he was made a kind of scapegoat or catspaw in being put forward as the promoter of those rumours, and as having been made to appear to set on foot an investigation before the magistrates which was, and ought to have been, made by coroner and magistrates and not by himself He concludes by saying—

"Having resided nearly all my adult life out of England, I was, when this unfortunate case occurred, utterly ignorant of the forms and proceedings of English criminal law procedure. I did not know what constituted a 'prosecution,' nor what constituted constructively or technically a 'prosecutor.' I gave no instructions to prosecute Dr. Millett, and I do not know, and cannot learn, to this day by what particular act of mine, or of my solicitor, the so-called prosecution was commenced and instituted. The legal and Medico-legal proceedings in this matter will enable the Profession to understand the extreme difficulty and risk of utter ruin which may result to one by making any inquiry about the causes of sudden or other deaths occurring in the houses or families of Medical men. This case shows that it is equally as dangerous for Medical men, in whose homes such deaths have taken place, to institute any inquiry as it is for other Medical men to do so."

The Rinderpest.

The following is an extract from a letter on the treatment of cattle plague, by Mr. W. Nisbet, of Egremont, which appeared in the *Liverpool Mercury* of March 5:—

"The chief object, however, of this letter is to draw more special attention to treatment. In cases of low typhus and other malignant diseases in man, quinine is largely used, and in visiting malarious countries, as Africa, all Europeans prime themselves with it. Then why not Cinchonise cattle? Surely a valuable beast is worth an ounce or two of quinine. If I possessed stock, and Rinderpest near, I would begin with ten grains of quinine (or half an ounce of Jesuits' bark) two, three, or four times a day and increase the dose on seizure to one or two scruples; otherwise, with proper attention to cleanliness, warmth, ventilation, strict isolation of the afflicted, and the moderate use of chloride of lime around, I would be careful to give the accustomed diet, paying great attention to its being sound and sweet, and, instead of cramming with patent potions or powders, a pint or quart of good ale or porter, repeated several times a day, might be desirable. Altogether, assimilating the treatment to that of man in low types of epidemic disease is natural, and well worth a trial; for if the animal can only be supported by stimulants, or by any means, over a few days, recovery is almost certain.

"I have only further to remark, if Dr. Beale's entozoic theory proved correct, I would be disposed to prescribe the powder of bitter quassia, especially where no milk would be tainted, that its Medicinal virtues might circulate in the system, as I have proved it to be as effectual in destroying grubs and caterpillars in plants as the white hellebore. The same idea presents arsenic in suitable doses as well worthy a trial.

"A similar treatment applies to the diphtheric hypothesis; but here I would suggest a more systematic trial of weak nitric acid or tincture of steel, as I have found them most useful in man, when given in frequent small doses—say one third of a drachm of either in a pint of water every four hours, to which a wineglassful of spirits might be added. Powdered charcoal, with or without borax, given in a quart of meal or rice gruel frequently, for a time, also offer a sound analogous practice. In fine, in all cases of cattle plague, good nursing, good air, and good diet, with the administration of tonics, if Medicine is given at all, and the avoiding of undue meddling and all depressing means, especially harsh drenches, should be the rule, and *nil desperandum* the motto cherished by every grazier and farmer in his present time of hard trial.—Yours, &c.,

"Surgeon."

Naval Surgical Instrument Cases.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—With reference to your very just remarks respecting the instruments which Naval Surgeons are required to provide, let me inform you that these officers have to carry about with them a very cumbrous case containing what is called a "resuscitating apparatus"—that is, a fair-sized pair of bellows, divers tubes, both nasal and laryngeal, and—*horribile dictu!*—an instrument for introducing tobacco smoke into the rectum. It costs three guineas, and takes up much room. Of course no one ever thinks even of opening it; nevertheless, there is no shaking it off; it must be carried about from ship to ship, and certified for periodically. It is good for the Surgical instrument makers; that is all. Why then retain it?

I am, &c., Delta.

The Report of the Army and Navy Medical Services Commission.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The report of the Commission of the Medical Department of the Army and Navy affords another illustration of "the mountain in labour," and is generally regarded as a lame and impotent conclusion. The pay of the executive ranks is slightly increased, but the retiring allowance after twenty-five years' service remains unimproved. Loud and general would have been the rejoicing had the Commission recommended the abrogation of the practice of promoting Surgeons by selection; but on this subject they have given no deliverance, although it is one which, in the ranks of the Department, is eagerly discussed and vehemently denounced.

I am, &c., R. A.

Swelling of the Tongue.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Having seen in "Notes, Queries, and Replies," some statements relating to swelling of the tongue, etc., will you allow the following "notes" to be inserted in your valuable journal?

Two ladies of my acquaintance could not eat celery without enormous swelling of the tongue. With regard to other substances I may mention eggs. A friend of mine (a gentleman) cannot eat a duck's egg without

experiencing disagreeable effects. Two other cases I may mention—both in females—in which the face turned yellow after eating an egg. Cayenne pepper causes itching of the scalp in a gentleman of my acquaintance, and vinegar causes a sensation of dampness under the lower eyelid in some persons. Apologising for taking up your valuable space,

33, Mornington-road, N.W., March 10. I am, &c.,
H. L. Maysmor, M.D., F.R.C.S.E

COMMUNICATIONS have been received from—

Mr. Frederic Clowes; Dr. J. Y. Vinen; Apothecaries' Hall; The Secretary of the International Horticultural Exhibition; Dr. Yeld; Mr. C. H. Marriott; Dr. H. L. Maysmor; Mr. Gaskoin; Zeta; R. A.; Obstetrical Society of London; Dr. George Johnson; Mr. Lawson Tait; Medical Society of London; Mr. Armstrong Todd; Mr. Frederic Edmonds; Dr. John Whitmore; Odontological Society; Delta; Obstetrical Society of London; Dr. Fotherby; Dr. J. C. L. Carson; Dr. C. R. Bree; Amicus; Dr. Bence Jones; Mr. Spencer Wells; Mr. E. Bellamy; Dr. Hughlings Jackson; Dr. Rundle; Dr. B. W. Richardson; Mr. Marsh; Mr. J. COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN FEBRUARY, 1866.

The following are the Returns of the Metropolitan Association of Medical Officers of Health:—

	Total Solid Matter per Gallon.	Loss by Ignition.(a)	Oxydisable Organic Matter.(b)	Hardness.	
				Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction . .	20·99	0·94	0·56	13·9	4·1
West Middlesex . .	20·56	1·09	0·60	13·6	3·8
Southwark and Vauxhall.	22·81	1·34	0·72	13·9	4·5
Chelsea	20·51	1·28	0·64	13·9	4·0
Lambeth	21·15	1·00	0·66	14·0	4·5
Other Companies.					
Kent	20·38	1·45	0·10	18·0	8·5
New River . . .	21·20	1·28	0·39	15·0	4·8
East London . . .	22·20	1·00	0·49	15·5	5·0

(a) The loss by ignition represents a variety of volatile matters as well as organic matter, as ammoniacal salts, moisture, and the volatile constituents of nitrates and nitrites.

(b) The oxydisable organic matter is determined by a standard solution of permanganate of potash, the available oxygen of which is to the organic matter as 1 is to 8; and the results are controlled by the examination of the colour of the water when seen through a glass tube two feet in length and two inches in diameter.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, March 10, 1866, in the following large Towns:—

Boroughs, etc.	Estimated Population in middle of the Year 1866.	Persons to an Acre. (1866.)	Births Registered during the week ending Mar. 10.	Deaths. Corrected Average Weekly Number.*	Deaths. At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·538 in. The barometric pressure fell to 29·02 in. on Wednesday, and rose to 30·23 in. on Saturday.

The general direction of the wind was N.N.E.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 36·8°.

APPOINTMENTS FOR THE WEEK.

March 17. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p m.

Royal Institution, 3 p.m. Rev. G. Henslow, "On Structural and Systematic Botany."

19. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

Medical Society of London, 8 p.m. Clinical Discussion. Cases by the President and others. Mr. De Méric, "On the Use of Mercury in Syphilis."

20. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Pathological Society, 8 p.m. Meeting.

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

21. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Hunterian Society, 8 p.m. Mr. Bader, "On the Impairment of Vision in Albuminuria."

22. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

23. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. H. Bence Jones, M.D., F.R.S., "On the Existence in the Textures of Animals of a Fluorescent Substance closely Resembling Quinine."

EXPECTED OPERATIONS.

St. Peter's Hospital for Stone and Urinary Diseases—The following Operations will be performed on Tuesday at three o'clock:—

Lithotrity (two cases, men); lithotomy (a child).

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

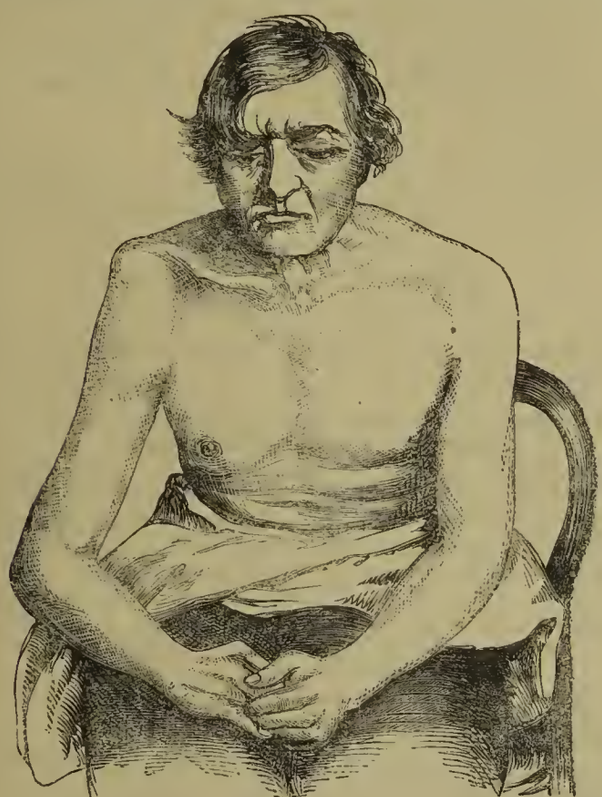
BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

(Continued from page 248.)

Fractures of the Neck of the Humerus.—I have already adverted to the difficulty of distinguishing between a fracture high up and dislocation. You will easily understand that the higher the fracture the more closely do the symptoms approach to those shown by a dislocation. Again let me urge the paramount importance of a correct diagnosis in the first instance. If it is a fracture, crepitus ought to be detected, and if detected, it is conclusive. In most cases other symptoms will be sufficiently definite—the altered axis of the arm, the elbow carried away from the chest, the lengthening of the arm, the limited motion and the very marked sub-acromial hollow, denote the case as one of dislocation. An unusual amount of swelling and ecchymosis, ability to put the elbow close to the side, inability on the part of the patient to make any use whatever of the arm, but tolerably free motion when manipulated by the Surgeon—these all indicate fracture. I speak now, however, not of the common run of cases, in which the diagnosis between fracture and dislocation ought never to be difficult, but of the rare ones, in which either the symptoms are unusual, or, from the patient's extreme obesity, they are difficult of estimation. I show you a stereoscopic portrait of a man with a common dislocation into the axilla, the bone being lodged under the glenoid fossa. It is one in which a mere glance is sufficient for diagnosis.



Subglenoid Dislocation of the Humerus.—The woodcut has been carefully copied from a photograph, and shows well the altered axis and lengthening of the arm, the prominence of the acromion, the lifting the shoulder, etc. I have thought it worth while to introduce this illustration because in the one usually given in books (copied from Sir A. Cooper) the bust and arm are so well covered by drapery that the real points are quite concealed. In this instance the dislocation had existed for ten days before the photograph was taken. It was easily reduced.

Diagnosis of Dislocation in Difficult Cases.—In contrast with it I may mention one which I well recollect, in which a lady of immense obesity was the supposed subject of a dislocation. She was a little mountain of fat, and as for discovering the prominence of a bone on any part of her person, it was a mere impossibility. Her elbows were habitually propped away from her sides quite as much as in the most marked dislocations, and it was hopeless to attempt to detect hollow under the acromion or prominence in the axilla. We administered chloroform, and I then satisfied myself by the freedom of motion which was permitted, that no dislocation existed. Cases more or less similar are not very unfrequently met with, and when they are, indeed whenever from any cause the diagnosis is obscure, I urge strongly the advantage obtained from the use of chloroform. Do not desist from your first examination until your opinion is quite decided, for you will never afterwards have so good an opportunity. I have but one caution to give as to excess in this direction, and that is as regards elderly and feeble patients. Old people not unfrequently suffer from fracture high up through the tuberosities, just as they are liable to fracture of the neck of the thigh bone and of the cancellous structure at the base of the trochanter. In such cases, if the symptoms of dislocation are simulated, you may, perhaps, be led to make an examination which will be injurious to the patient. A good deal of irritation and constitutional disturbance often follows these accidents in old people. Sometimes it amounts to senile traumatic delirium, and now and then it ends fatally. In such patients prolonged examination is dangerous, and likely to much increase the constitutional irritation. In most of the cases in which I have seen traumatic delirium follow fractures of the neck of the humerus or neck of the femur, uncertainty had been felt in the diagnosis, and prolonged examination had been made. In such, therefore, you must be careful, and having once elicited a decided crepitus, at once desist from further movements of the limb.

I have just remarked that sometimes in dislocation into the axilla the symptoms are ill characterised; more especially is the symptom of projection of the elbow away from the chest liable to mislead. It is not by any means always the case that a patient with a recent dislocation cannot touch his ribs with his elbow. Three months ago I demonstrated this to you in a case of old dislocation (six months) in which with the greatest ease the man's elbow could be put to his side. The next week Mr. Dawson (then one of our House Surgeons) told me that in a case which he had reduced the night before my assertion as to the possibility of this was fully borne out. In a third instance, which occurred last Sunday, a man with a subcoracoid dislocation of the most marked kind, and of a few hours' duration, could bring his elbow close to his side with tolerable ease and without any pain. We find, therefore, that we must take symptoms in group, and not rely too firmly on any single one.

Subclavicular and Dorsal Dislocations.—Of the rare forms of dislocation of the humerus we have not recently had any examples with the exception of one of displacement downwards, and to some extent backwards. The head of the bone had not, however, passed fairly on to the infraspinous fossa. It rested just a little behind its edge. I have never seen an instance of dislocation forwards beneath the clavicle and to the inner side of the coracoid process, and agree with those who think that unless the latter process be broken off such a dislocation can scarcely occur. No doubt the majority of what are called dislocations forwards are really subcoracoid displacements. In some of these it is easy to see by the prominence of the head of the bone beneath the pectoral muscle, and by the inclination of the elbow backwards as wells as outwards, that the dislocation is not directly downwards, but in a majority the symptoms are not easily distinguished from those of subglenoid dislocation. From the cases which I have examined, I quite agree with those who think subcoracoid a more frequent form of dislocation than subglenoid. The two together make up what are known as dislocations downwards or into the axilla. Even in the best-marked examples of subcoracoid dislocation the humerus does not invariably slant backwards; often it is merely outwards, and now and then even a little forwards.

Reduction in Recent Cases.—As regards the reduction of recent dislocations at the shoulder, several different plans are of almost equal efficiency. Sometimes one plan and sometimes another is in favour in our receiving-room. Recently I heard of invariable success with the knee in the axilla, and still more recently of the triumphs by the method of elevating the arm. All admit that the old-fashioned plan by the heel in the axilla is very efficient. From the fact that out of the large number which present themselves at this Hospital we scarcely ever have one in which chloroform is needed, we may gather that by one or other method success is generally

obtained easily. Each Surgeon has his favourite plan. The one which I prefer, and which I have "never known to fail," is that of combining extension outwards with the knee in the axilla and the use of the humerus as a lever. The extension force of two assistants is always sufficient, and I have never known pulleys necessary. Let the arm be extended straight away from the chest, then at a certain sign let the elbow be depressed so as to make the humerus act as a lever on the Surgeon's knee. If difficulty is encountered, try the same method again, and make slight rotation of the limb whilst depressing it. I have never heard of a case at this Hospital in which reduction was found impracticable(a). Of course I am speaking of recent injuries only.

Reduction of Old Dislocations.—We get a fair share of old cases of unreduced dislocations, but these are mostly instances of neglected diagnosis, not of failure in the attempt at reduction. A good number of reductions at various periods under three weeks or a month have occurred during the last few years, but I do not recollect any instance of success after unusually long periods. I am not myself an advocate for attempts to reduce very old dislocations. It seems to me that in making such we run much more risk than the prospect of advantage warrants. After all, an arm with an unreduced dislocation at the shoulder is a very useful one, and after the lapse of years the patient experiences scarcely any inconvenience. The longer the duration, the greater the range of motion; it goes on improving with every year the patient lives. Set against this, first, that attempts at reduction will very likely fail after having caused the patient much pain, and perhaps greatly increased the thickening of the tissues about the joint; second, that they are really dangerous, and that many patients have died after them either from inflammation of the part, or from rupture of an artery or vein. In a case, not long ago, of a six weeks' dislocation we were compelled to desist because the skin had torn across the axilla. This curious accident occurred whilst we were trying the heel in axilla method, and without the application of any unusual force, nor was the operator's boot on. Suddenly the skin gave way from side to side and a great transverse rent presented itself. The patient was a woman of 50, of lax, flabby tissues. We were compelled to desist. The wound healed quickly, and the patient is at the present date very well content with her condition, and assures me that she can use the limb nearly as well as the other.

The longer the dislocation has existed, the greater the danger of attempting its reduction, and the less also will be the gain of the patient. If the patient be young, there is certainly in that fact a motive for a careful trial; but if, on the contrary, he be old, and with degenerate tissues, then let me beg of you not to allow any impulse of selfish vanity or the desire to vaunt an unusual success mislead your judgment into attempting that which is not really for your patient's advantage. Let him go elsewhere if he likes, and let another possibly obtain the credit of success; you will still be able to reply, with the celebrated General, that, despite the fact of victory, you still hold to your former judgment that the battle ought not to have been fought. I will relate to you a warning case, which occurred to us about a year ago. Although we made the attempt under a mistaken impression as to the duration of the lesion, yet that does not make the case the less instructive as an instance of what may occasionally follow these attempts.

Death from an Attempt to Reduce an Old Standing Dislocation of the Humerus.—An elderly Irishwoman was one night carried in so tipsy that she could give no account of herself. She had a dislocation of the right humerus into the axilla. The House-Surgeons and dressers tried their utmost to reduce it, and failed. In the morning, when sober, or nearly so, she informed us that her shoulder had been dislocated for several years. I discredited her statement, believing that, as is not unfrequently the case, she wished to deceive us, in order to prevent us putting her to pain. We accordingly gave her chloroform, and again tried to reduce. The method tried was by extension directly outwards, using the knee in the axilla as a fulcrum. We did not employ pulleys, nor resort to any unusual degree of violence. The extension was manual only. We did not occupy more than ten minutes in this second attempt; finding that the bone did not move, I concluded that the woman's story was correct, and desisted. Great inflammation followed this attempt. The shoulder-joint suppurated. The abscesses were freely opened, but the woman, who had been a very intemperate person, in spite of liberal support, sank into a very low condition, and at length died. At the autopsy we found a new cup of bone, formed below and in front of the glenoid cavity, for the reception of the head of the humerus. The soft tissues of the joint were wholly destroyed by suppuration, and every trace of cartilage removed. The dislocation had been subcoracoid, and the head of the bone still rested immediately beneath that process. The chief interest of this case seems to me to be, not in the circumstance that we discredited the statement of a drunken old woman, when unfortunately it was perfectly true, but in the illustration it affords of the dangers which sometimes attend attempts at the reduction of old dislocations. No injury had clearly been done by the first attempt, it was the second one which caused the mischief. Yet this attempt was by no means a prolonged or violent one. I have often tried much longer and used much more force. As regards the degree of usefulness retained by a permanently dislocated shoulder, we may just note that this woman assured us that she had experienced no appreciable detriment. She "could do anything with the arm; it was just as good as the other." In another case, which was under my care a few months ago, an old woman, who had a dislocation into the axilla of three months' standing, said that her arm was quite useful to her, and that, "excepting lacing her stays with it, she could do anything." She could not get the arm behind her. She was most unwilling that anything should be attempted. These facts, showing on one hand that this form of dislocation does not entail much inconvenience if left unreduced, and on the other that attempts at reduction in old-standing cases are not devoid of danger, seem to me to point very clearly to our wisest line of practice.

As regards the Surgical neck, upper third, and middle third of the humerus, I have nothing of especial interest to state. These injuries are easy to treat in almost all instances, for the bone is well buried amongst muscles, so that any irregularity which may be permanent is concealed; and secondarily, so long as we get it straight in direction, a little shortening is of no consequence. A man finds it out if his thigh is shortened after a fracture, but he feels no inconvenience from a little inequality in the length of his upper extremities.

(a) Dr. Hamilton has with great candour recorded a case of recent dislocation into the axilla in which he and his colleagues after four attempts, and after using chloroform and pulleys, were unable to effect reduction.

ORIGINAL COMMUNICATIONS.

ADDRESS TO THE UNIVERSITY MEDICAL SOCIETY, GLASGOW.

February 3, 1866.

By Professor BUCHANAN, M.D.

THE QUANTITY OF BLOOD IN THE BODY—EXPERIMENTS ON CONDEMNED CRIMINALS—THE CARDIOGRAPH AND SPHYGMOGRAPH.

The lecturer explained how he had come to associate together two subjects having so little apparent connection as those discussed below. He had always great pleasure in meeting with the Society, and had therefore been unwilling to decline their invitation, although at this busy season he could not pretend to offer them anything like an elaborate dissertation. He had merely taken up and amplified two subjects which were present to his mind at the time their invitation reached him from his being then engaged in lecturing on the quantity of the blood, and afterwards on its circulation through the body.

1. On the respect enforced by law in this country towards condemned criminals both before and after their death.

The consideration of this subject arose naturally out of the lecture on the quantity of the blood. You are all acquainted with the ingenious process of Valentin for determining the quantity of the blood. It is mathematically accurate as applied to a liquid contained in shut vessels; but as the capillary system of blood vessels resembles much more a sieve than a shut vessel, no reliance can be placed upon Valentin's method for determining the quantity of the blood. The water injected into the vein would be dissipated, and never equably mixed with the whole mass of blood; hence the second measure of blood taken would be too rich, and so the estimate of the quantity of the blood would be too high. Valentin estimates the quantity of blood as one-fifth of the weight of the body.

On the whole, the most straightforward and trustworthy mode of finding the quantity of blood in the body of any

animal is to weigh it, bleed it to death as rapidly as possible, and weigh it again. The difference of the two weights is the quantity of blood which has flowed from the body, and the quantity still remaining in it must be estimated by injecting water into the arteries till it returns free from colour by the veins, evaporating the water, and finding the quantity of blood which the residuum represents by comparing it with the residuum left from known quantities of blood mixed with water.

In this way it has been found that in the sheep the weight of the blood is to the weight of the whole body as 1 to 25 ; in the lamb as 1 to 20⅓ ; in the dog as 1 to 10 or 9·6. Now, it was impossible amid these discrepant results to determine the proportion in man, although it was reasonable to conjecture that it would be nearer the proportion in the dog than that in herbivorous animals. The only method, therefore, of solving the problem was to have the experiment performed upon a man. Now, Weber and Lehmann were enabled, by the intelligence of the Saxon Government, to perform this experiment. They weighed the bodies of two criminals before and after decapitation, thus determining the quantity of blood that flowed directly out of the trunk and head, and then the quantity of blood still remaining in the blood-vessels was determined as above. The result was as follows :—

	Gram.
One of the men weighed before decapitation .	60,140
,, ,, after ,,	54,600
Blood flowing from vessels	5,540
Blood washed out	1,980
Total blood . . .	7,520

This quantity is almost exactly one-eighth of the weight of the body—a proportion confirmed by the result of the experiment made on the other criminal. We may infer, therefore, that in a man of ten stone the quantity of blood is 17½ lbs.

Alongside of these experiments I would place one of Kuchenmeister, who, to show the bad effects of diseased pork upon the human body, introduced cystocerci into the food of a condemned criminal, and found them after death to be developed into tapeworms in the man's bowels.

All of these experiments were made without the slightest suffering to the unfortunate men on whom they were performed, and made to answer ends important to science, and therefore to humanity and to civil society.

Now, I hold it to be the part of a wise Government, anxious to promote the welfare of those subject to it, to adopt every legitimate means to accomplish that object, and that of such means there is none more legitimate than that of converting the bodies of criminals who have forfeited their lives to the violated laws of their country into a source of benefit to the community, always provided that no injury be done to the prisoners themselves. This principle has been recognised from time immemorial in the penal code of our own country, and till of late habitually acted upon. Among the first persons inoculated in London for small-pox were felons, who purchased their lives by submitting to the operation—an excellent bargain certainly for them, and a still better one for the community—profitable, therefore, on both sides, which is all that a commercial people can desire in their mercantile transactions. Such was the public confidence inspired by these trials, that not long after some of the members of the Royal Family were subjected to inoculation. Still further, till within the last thirty years, or thereabouts, the bodies of murderers and other great malefactors were not only permitted, but commanded by law, to be dissected.

But, however sound might be the principle on which this injunction was founded, it is now fully recognised that there was an error in making it a part of the penal sentence that death was to be followed by dissection. It made people suppose that to be dissected after death was ignomnious, because it formed part of the punishment of felons, and thus raised a deep-seated and almost universal prejudice against the practice of dissection, to counteract which the philosopher Bentham, as other great men had done before him, left his body to be publicly dissected for the good of mankind. This faulty legislation did more harm still, by degrading the members of the Medical Profession, by placing them on the rank of the public executioner, seeing they were ordained to complete after death the ignominious sentence of which the hangman had executed the first part.

It was, therefore, a great improvement upon our penal code which was made at the time mentioned above, when the obnoxious law, enjoining the dissection of malefactors as a part of their punishment, was abolished.

But never was the spirit of any law more thoroughly misunderstood than that of the new or amended law here in question. It was enacted on behalf of the members of the Medical Profession, and to do away with an irrational prejudice in the public mind against dissection. But it was never intended to be the palladium of condemned criminals, to render their persons during life and after death sacred and inviolable. But such is the actual interpretation that has been put upon this law, and the practice that has resulted from it. The good old principle of our law, that the dead body of a criminal is public property, and ought to be turned to public account, is held to be a relic of barbarism; and we hold ourselves to have attained to a great height of wisdom and of civilisation, because the dead bodies of felons are in this country held sacred, and interred untouched, immediately after death, within the precincts of the gaol. There is no form of human folly so unbearable as that which disguises itself under the garb of wisdom.

To such a ridiculous length has this form of "red tapeism" been carried, that in the case of a wretched criminal executed in Glasgow the members of the Phrenological Society despaired of being able to obtain a cast of his head; and only obtained it, at length, through the intercession of an intelligent clergyman, whose high character and humane care of the criminal after condemnation gave weight to his intercession. As to the examination of the brain, which would have been so deeply interesting, it was deemed utterly vain to make any application respecting it. The same spirit was shown in a less objectionable form towards the many foolish people who coveted a lock of hair from the head of the great criminal or a tuft from his beard. To all such applications the subordinate functionaries replied with dignity that the criminal was under the protection of the law, and not a hair of his head should be violated.

Now, I regard this as an absurd and misplaced sentimentality, founded on an utter misconception of the spirit of the law by which it is supposed to be sanctioned. I hope the day may soon arrive when a policy on this subject will be adopted in this country which shall be more enlightened without being less humane. The bodies of condemned criminals are public property, and no public property should be uselessly wasted when it might be turned to profitable account. The heads of all persons undergoing capital punishment should be carefully examined; the brain should be taken out, weighed, and examined, the cerebrum and cerebellum separately, and all the so-called phrenological organs, as those of destructiveness and acquisitiveness, leading to murder, violence, and theft; and the whole results should be carefully preserved in a public register. Nor should the scrutiny be confined to the head alone. All the other organs of the body should be carefully examined; and if we fail in finding the treasure we are in quest of, we may trust to the old fable, that we shall receive in another form an ample return for our labour. Besides this, every facility and encouragement should be given to intelligent members of the Medical Profession suggesting experiments and modes of treatment that may redound to the public good without compromising the health or feelings of the prisoners. Lastly, Government ought to sanction a commutation of punishment, extending to criminals of every class, a liberal remission of the awarded penalty being made in consideration of benefit rendered to the public by the criminal submitting to certain forms of diet and regimen, to the operation of certain medicinal agents, and to other physiological conditions, considered by competent Medical authorities as equivalent to the punishment to be remitted.

2. On the cardiograph and sphygmograph of M. Marey.

Under this second heading of his address, the lecturer directed the attention of the Society to the work of M. Marey, of Paris, entitled "Medical Physiology of the Circulation of the Blood," characterising it as among the most important contributions that has been made of late years to physiology and physiological medicine. He described the ingenious instruments devised by Dr. Marey, by which each of the organs of the sanguiferous system is made to tell its own tale, and authenticate it by a permanent autograph, which can be read and studied at leisure. The autographic delineations of the auricles and ventricles of the heart, of the heart pulse, and of the arterial pulse, were then exhibited, as taken from M. Marey's work; and, lastly, the sphygmograph was exhibited in operation.

GUNSHOT WOUND OF THE ABDOMEN.

LODGMENT OF THE BULLET, AND ITS ESCAPE AFTER A PERIOD OF SEVEN YEARS AND A-HALF INTO THE ALIMENTARY CANAL, CAUSING INTERNAL STRANGULATION AND DEATH.

By WILLIAM JOHN RUNDLE, M.D., Ext. L.R.C.P. Lond.

(One of the Medical Officers of the Royal Portsmouth Hospital.)

A. B., aged 40, an officer in the Royal Artillery, received a severe gunshot wound of the abdomen during the Indian mutiny, seven years and a-half before his death. On April 2, 1858, when commanding a company of Artillery at an attack upon some forts of the Island of Beyt, in the Gulf of Cutch, he was struck by a bullet just above the sword belt, which passed down between the cloth and lining of the tunic for a short distance, and then obliquely entered the abdomen two inches above and one inch to the right of the umbilicus. He was immediately carried off the field, placed on board ship, and then taken to Bombay. The Medical officers who attended him had at first very little hope of his recovery, and he was mentioned in the dispatch of the commanding officer as being "very dangerously wounded in the abdomen." The history of this part of the case is very deficient, and little is known respecting the progress of the wound beyond the fact that it healed in the course of four or five weeks, and that he rapidly regained his health and strength. On his return to England, a few months after his recovery, he consulted several Surgeons, who were unanimous in the opinion that the bullet was lodged in the abdomen, and urged him to refrain from all unnecessary exertion for fear of disturbing it from its position.

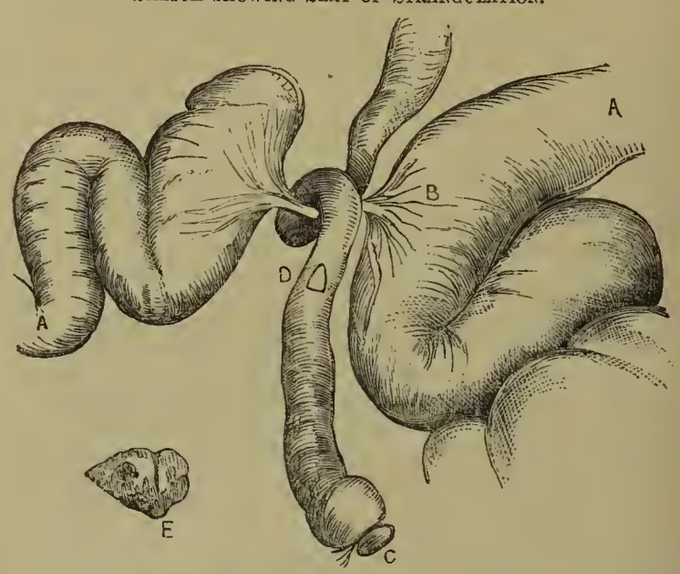
The patient has been well known to me for the last four or five years, and during that time he has suffered from occasional attacks of constipation, which were relieved by gentle aperients and enemata. He continued in his usual health up to Monday, October 16, 1865, when, about midday, he began to complain of sickness and abdominal pain. During the evening I visited him, and prescribed a draught and full enema. In a few hours, however, he rapidly changed, and at five the next morning I found him in a state of collapse, vomiting frequently a fetid and dark-coloured fluid, with a cold skin and almost imperceptible pulse. He gradually sank, and died at 7 a.m.

Post-mortem Examination Forty-eight Hours after Death.—The body presented externally a cicatrix, about the size of a sixpence; it was situated two inches above the umbilicus and one to the right of the median line, and was continuous with a fibro-cellular cord which extended obliquely downwards and inwards through the abdominal walls for two inches, and then became lost in the surrounding structures. On opening the abdomen, the parietal peritoneum was free from adhesions, and everywhere healthy; and no scar or puckering could be seen on its surface marking the spot at which the bullet penetrated the cavity. The superficial intestines were pale and much distended with flatus; but on turning them aside, a few coils, deeply congested, were found lying in the right iliac region. In this situation the alimentary canal was bound together by several old and firm adhesions, and around one of them—a short and narrow band attached to two adjacent pieces of intestine—another portion of the gut had become completely twisted. At the seat of the twist the intestine was stretched into the semblance of a cord, and perfectly occluded, and about three inches below it the bullet was discovered lying loose in the canal. The peritoneal cavity was quite free from any kind of effusion, and there were no flakes of lymph or other traces of recent inflammation. The mesentery was likewise healthy, and contained a moderate amount of fat; and neither in this organ nor in the coats of the intestines could any thickening or cavity be found to indicate the part where the missile had remained encysted for so many years. All the other organs were healthy. The bullet is about the size of a small nut, flattened at one extremity and irregularly conical at the other. It weighs 372 grains, and appears to have been rudely manufactured from a rod of lead, according to the custom of the Asiatics.

Remarks.—From the position of the cicatrix, and the direction of the tract through the abdominal walls, together with the distinct traces of bygone inflammation, it is evident that the missile penetrated the body obliquely, passed into the abdominal cavity, and there found a lodgment between the intestines in the right iliac region. It is also certain that the bullet must have remained encysted for many years, either in some portion of the mesentery or between the coats of the intestines, and recently, under the influence of gravity or muscular action, or else the changes produced by the absorption of the surrounding tissue, it escaped into the alimentary canal. Although the intestines and mesentery were carefully examined, it was found impossible to determine with certainty the part in which the ball had been originally impacted; but this is not surprising when we consider the small size of the cyst, and the rapidity with which such a cavity would contract amid such soft and yielding strictures. Moreover, as a general rule, foreign substances travel very slowly when lodged within the body; therefore in this case it is quite possible that some contraction of the adjacent tissue may have followed the first movements of the ball before it wholly escaped from its position; and even when these gradual changes were accomplished, and it was lying free in the intestinal tube, some days may have elapsed before the fatal accident. The passage of any solid matter along the alimentary canal is always attended with a certain amount of risk; but it was unusually hazardous in this case from the presence of adhesive bands, which bound together the intestinal coils in the right iliac region. These bands, by limiting the muscular contractions of a portion of the small intestine, must have often delayed the passage of its contents; and thus we can explain the occasional attacks of constipation from which the patient suffered. The close proximity of the bullet after death to the seat of strangulation clearly proves that it was the exciting cause of this fatal complication. During some irregular peristaltic movements occasioned by its presence in the canal, that portion of intestine in which it was contained caught on a fibrous band, and then twisting upon itself resulted in the sudden and irremediable obstruction. At the moment of strangulation it is very probable that the bullet was grasped within the twist, and that after death it was dislodged from this position, partly by its own weight and partly by the relaxation of the surrounding structures. It is a singular fact that the products of the peritoneal inflammation which immediately followed the entrance of the ball into the abdominal cavity, formed the snare in which it became entangled, just as it was about to be expelled through the natural passages after remaining imprisoned for so many years.

I am indebted to my friend, Dr. Cousens, of Portsea, for the accompanying sketch of the post-mortem appearances:—

Sketch showing Seat of Strangulation.



A, A, coils of intestine, united by the fibrous band, B, around which th gut, C, was entangled. D, bullet lying loose in the canal. E, size a shape of bullet.

Audrey House, Gosport.

The Reported Outbreak of Cholera at Alexandria.—It has been emphatically denied by the French Consul-General that the epidemic has reappeared at Alexandria. One case is said to have occurred on the 7th inst. The Quarantine at Malta has been removed.

Mr. Baker Brown has just been elected a Member of the Medical Society of Christiania, in recognition of his services in Operative Surgery.

REMOVAL OF A FOREIGN BODY FROM THE URETHRA.

By THOS. B. CHRISTIE, M.D.

The following case I have thought might be interesting, as showing what peculiarities are developed in the insane under the various phases of delusion they are the subject of, and also to what extent the male urethra may be quickly dilated:—

On Saturday, March 10, about 1 a.m., I was called to see an inmate of the Asylum—D. M., aged 55 years—who complained to the attendant of the ward that he was unable to void urine. I found he had lost a quantity of blood, the result of the violence he had used; the bladder was largely distended, and, as a consequence, he was suffering acute pain, straining severely and begging for relief. He stated that he had passed a piece of wax taper into the urethra to relieve a supposed stricture. Externally, by manipulation, I could detect a hard substance within, in the membranous portion. The means I adopted were to dilate as much as possible the urethra by the largest size elastic catheter, and then by passing a thin pair of fine bone forceps, I was enabled, after about half an hour, to secure the foreign substance; this consisting of a piece of wax taper three-eighths of an inch in diameter, and measuring fourteen inches and three-quarters in length. The end was just four inches from the meatus. No untoward symptoms were exhibited afterwards. The forceps, when open, expanded the meatus to just half an inch.

Pembroke House, Hackney, N.E.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 145.)

Case 76.—Multilocular Ovarian Cyst—One Tapping—Ascites—Ovariotomy—Death on the Twelfth Day—Cancer of Tumour and of Peritoneum.

A married woman, 39 years of age, applied to Mr. Wells in August, 1865, with an ovarian tumour, which reached to four inches above the umbilicus. She had been married eighteen years, and had seven children, the youngest being 4½ years old. During that and the former pregnancies she had been very large, and had been increasing in size ever since the birth of the youngest child, but more rapidly since the spring of 1865. The catamenia were regular; the uterus normal; the ovarian tumour moved freely quite independently of the uterus. In general appearance the patient was robust, but fat, and the complexion very florid, particularly the upper part of the face, where many capillary vessels were distinct. The pulse was very feeble, and the heart's impulse almost imperceptible. She was directed to avoid fats and sweets, eat lean meat, and was put upon iron and quinine. She gradually increased in size, and was admitted to Hospital November 24, 1865. The girth at the umbilicus was fifty inches, and she was suffering much from distension. She was tapped two days after admission, and twenty-five pints of brown fluid highly charged with cholesterine were removed. She was much relieved for a time, but the cyst re-filled, and she was re-admitted in January, 1866. The tumour was then freely moveable in surrounding ascitic fluid, and, so far as the local conditions went, the case appeared to be a favourable one for ovariotomy; but she was very fat, the face still highly florid, and the pulse extremely feeble, so that the constitutional condition was far from satisfactory. Mr. Wells was so apprehensive as to the state of the heart that he procured Mr. Clover's attendance to administer chloroform, when ovariotomy was performed on January 31, 1866. Sir Wm. Fergusson, Dr. Makeyeff, of Moscow, and Dr. Skoldberg, of Stockholm, were present. After opening the peritoneal cavity, and evacuating twenty-six pints of clear fluid, a semi-solid ovarian tumour was exposed covered by a piece of adhering omentum. The omentum was separated, and the tumour pressed out entire through an opening eight inches long. A pedicle not thicker than a finger was secured in a small clamp three inches from the right side of the uterus, and the tumour was cut away. There was scarcely any bleeding. The left ovary was healthy. On closing the incision by sutures, Mr. Wells felt that the peritoneum was studded all over with small hard nodules, which at once led to the suspicion of cancer, and this was confirmed by an examination of the tumour at the College of Surgeons with Drs. Bowen and Pettigrew. It weighed 9 lb. 6 oz., and furnished unmistakeable naked-eye and microscopic evidence of soft cancer. A beautifully injected section of the tumour may be seen in the College Museum.

The patient went on remarkably well for the first few days after operation—only required one opiate—and was not sick after the first night; but the pulse was always feeble and occasionally intermitting, and the urine scanty and concentrated. The stitches were removed on the third and fourth days, except the lowest, which was left till the fifth day. On the fourth and fifth days there was a very offensive leucorrhœal discharge. On the sixth day the pulse was 88, but there were occasional feelings of faintness with long sighing inspirations. On the eighth day there were signs of a small quantity of fluid in the peritoneal cavity, and some discharge beside the pedicle. The clamp came off on the ninth day. The bowels were cleared by an enema on the tenth day. After this she complained of much pain in the track of the transverse colon, and had frequent sensations of faintness at night. On the eleventh day she was sick several times, and the urine, which had been clear and more copious for some days, again became scanty and charged with pink lithates. A free sero-purulent discharge went on from the lower angle of the wound, and continued during the twelfth day till she died.

On examination, eighteen hours after death, the body was found to be still warm. In all parts the quantity of yellowish fat was very large. Between two and three pints of brown serous fluid were found in the peritoneal cavity. A few recent adhesions connected the omentum with the abdominal wall beneath the united wound. The right Fallopian tube, and a part of the right broad ligament, adhered to the inner surface of the abdominal wall at the lower angle of the cicatrix. A clot of blood, as large as a walnut, lay below the Fallopian tube between the layers of the right broad ligament. The peritoneum covering the posterior surface of the uterus and the front of the rectum, and generally all over the abdominal wall, and in some few spots on the surface of the small intestines, was studded with innumerable small hard nodules of cancer. The heart was very soft and flabby, and both lungs were soft, œdematous, and friable.

In this case cancer was not suspected before the operation; but Mr. Wells had said that although the operation would probably prove to be an easy one, yet the existence of ascites in a very fat woman, whose heart was very feeble and face very florid, augured unfavourably for her; and the result is confirmatory of a rule which he has laid down, to the effect that a large adherent tumour may be removed from a patient of good constitution with far greater prospect of success than a small unattached tumour from a patient whose heart, lungs, liver, or kidneys are unsound, or who is the subject of some form of cachexia.

(To be continued.)

HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

CASE OF HEART DISEASE IN WHICH THERE WAS A LEFT AURICULAR SYSTOLIC MURMUR—CLINICAL REMARKS.

A few weeks ago we had occasion to bring forward two very instructive cases of heart disease, in which during life an auricular systolic murmur was heard. A contracted state of the mitral orifice was diagnosed. The post-mortem examination confirmed this diagnosis. It is still, however, a question with many Physicians whether it is possible, with any degree of certainty, to say that the mitral orifice is contracted and not dilated. We have therefore this week brought forward additional evidence, in hopes that it may assist us in arriving at a more satisfactory conclusion.

A Case of Heart Disease in which there was a Pre-systolic Murmur.

(Under the care of Dr. H. G. SUTTON.)

Elizabeth G., aged 13 years, was admitted November, 1865. She complained of pain in the region of the left breast, and of

a troublesome cough. She said she had never had rheumatic or scarlet fever; nor had she ever been laid up with any serious illness. She had suffered from her then present symptoms during the previous four or five months.

On examining the chest, the impulse of the heart was felt between the fourth and fifth ribs, and three-quarters of an inch to the left of the left nipple. The area of cardiac dulness was diminished rather than increased. On listening with the stethoscope, placed at the point of the apex beat, a loud, harsh, prolonged sound was heard preceding the beat of the pulse. This murmur was most distinctly heard immediately under and a little to the left of the left nipple; but on listening just above the nipple, it was still heard, but in this position the quality of the murmur did not appear to be either so harsh or to be so much prolonged. In order to ascertain the exact rhythm of this murmur, the stethoscope was placed an inch to the right of and just above the left nipple—in fact, over the fourth rib or the third interspace. There the harsh murmur was very readily detected. The second sound of the heart over the left base that is heard over the pulmonary artery was markedly intensified. After the second sound there was an interval of silence, although a very short one. Next the harsh sound was heard running up to and apparently involving the first sound of the heart.

On placing the hand over the apex beat of the heart a very distinct thrill was felt. On listening over the heart the thrill was found to be synchronous with the harsh, prolonged sound. This thrill was felt over a very limited area, and did not extend beyond the third interspace. This pre-systolic sound was so loud that it was heard all over the cardiac region; also heard over the angle of the left scapula: in the last situation, however, the murmur lost, to a great extent, the character of a pre-systolic murmur, and more resembled a systolic bruit. The pulse was small and rather jerking. Breath was very short on exertion. Urine acid, sp. gr. 1015; no albumen; urine plentiful.

A Case of Heart Disease in which a Left Pre-systolic and a Tricuspid Regurgitant Murmur was heard.

(Under the care of Dr. H. G. SUTTON.)

Isaac S., aged 49, a pale, anxious-looking man, came as an out-patient to the Victoria-park Hospital. He complained of shortness of breath, which had got much worse of late. He had suffered with difficulty of breathing on exertion for about two years. Stated that he had never had rheumatic fever. There was no increased area of cardiac dulness. The apex beat was felt immediately under the left nipple. In a small circle immediately around the nipple a well-marked running-up-to pre-systolic murmur was heard. Over the lower end of the sternum a distinctly-marked systolic bruit was heard—a murmur, much softer in quality, and a good contrast with the left auricular systolic bruit.

Dr. Sutton remarked in both these cases it was easy to make out that the murmur heard over the left apex of the heart was pre-systolic and not systolic. In the case of the female patient, on placing the stethoscope immediately above the left nipple, the murmur could be heard, and, in addition to this murmur, the sharp, loud, intensified second sound produced by the closure of the pulmonary valves. It may have been noticed that after the second sound there was a very short period of silence, yet it was an appreciable period of silence, and after it began the harsh prolonged murmur, which ran into, and appeared to take the place of, the first sound. Again, the click of the second sound was heard. The interval of silence between the second sound and the murmur clearly showed it was not a diastolic murmur; and as it occurred just before the first sound, it was considered to be pre-systolic in rhythm. In some of the cases it was not so easy to prove that the murmur was pre-systolic, and not systolic. One of the difficulties in such cases was that the second sound could not always be heard over the left apex. To obviate this difficulty, Dr. Gairdner has used Dr. Scott Alison's binaural stethescope. With a little care, however, Dr. Sutton has usually succeeded in finding a spot where, as in the first-named case, the second sound and the murmur could be distinctly heard.

There was, said Dr. Sutton, also another way in which the murmur might be shown to be pre-systolic in rhythm. On listening to the murmur, and at the same time feeling the pulse at the wrist, especially in cases in which the motion of the heart was slow, it would be noticed that the murmur preceded the beat of the pulse. Again, in some cases the impulse of the heart's apex against the walls of the chest marked the time of the first sound. Thus the prolonged murmur was heard, next, the impulse of the heart against the chest; thirdly, the second sound.

All cases, however, were not so easy, Dr. Sutton continued, as the two preceding. When the pre-systolic murmur was associated with a systolic murmur it was often more difficult to diagnose it. When the pre-systolic sound was short, feeble, and soft in quality, while the systolic murmur was prolonged, loud, and well-marked, the pre-systolic murmur might be easily over-looked, and it often required the greatest care and attention to distinguish the pre-systolic portion of the bruit.

Dr. Sutton then said, "I may here be permitted to allude to a case I saw in Guy's Hospital—a female patient, Sarah B., in Lydia Ward, under the care of Dr. Wilks, who has kindly allowed me to make use of the case. I examined this patient several times while in the Hospital. On January 11, 1866, I made the following note:—There is a double bruit heard over the cardiac region, but heard with the greatest intensity over the left apex of the heart, and most distinctly audible in the axilla, one inch and a-half to the left of the left nipple. The second portion of this double murmur was heard most distinctly. I represented it at the time by a diagram, such as is used by Dr. Gairdner (see "Clinical Medicine," p. 577). The figure 1 is understood to represent the position of the first sound of the heart and the impulse of the heart. The dark shading preceding the figure 1 represented the first half of the murmur running up to the first sound; the shading behind the figure 1 represented the second portion of the double murmur running off the first sound. The second portion of the bruit appeared to be double the length of the first portion. I further noted down there is no murmur carried along the aorta; the apex beat is between the fourth and fifth ribs, under and to the left of the left nipple. The area of cardiac dulness is bounded by the third rib above and mid-sternal line to the right, and by a vertical line an inch to the left of the left nipple. The second sound heard over the third left costal cartilage is loudly and very distinctly heard, evidently intensified, but no second sound can be heard over the left apex of the heart. There is also a soft systolic murmur heard over the lower end of the sternum; the rhythm of the heart is regular; the pulse is small and feeble. This patient had had rheumatic fever more than once, and had been in Guy's Hospital with that disease; there is great ascites and some œdema of the feet and legs, but the ascites is proportionately much greater than the œdema of the legs. She died February 8, 1866, and the autopsy, conducted by Dr. Moxon, showed, with respect to the heart, the pericardium somewhat thickened on the visceral surface, apparently of old date, and the thickening looked like irregular milk patches on the whole surface; all the cavities of the heart were dilated; the mitral orifice contracted, and its walls thickened; it allowed the tips of two fingers only to pass; it allowed regurgitation freely, as shown by throwing water into the aortic opening, when the water returned in a full stream up through the mitral orifice; the aorta-valves were healthy; the right ventricle was dilated and hypertrophied. Now, bearing in mind what the post-mortem examination showed, it would appear that the first portion of the double murmur had been most probably produced by the blood passing from the left auricle through the contracted mitral orifice, and the second portion of the murmur produced by the blood regurgitating through the orifice. There was no recent pericarditis to account for the murmur, and the thickening of the pericardium was evidently of old date, and the aortic valves were healthy. I would here mention, although it was not possible during life to say positively that the double murmur was not exocardial, yet the fact that it was heard with the greatest intensity to the left of the left nipple, that it remained equally audible for three weeks, led to the conclusion that it was not pericardial, but endocardial.

Such cases as the one just alluded to are, however, not the most common kind. It would appear that one of the most frequent forms of heart disease due to rheumatic endocarditis is where the lining membrane of the left auricle is thickened, milky-looking, and opaque; the fibrous tissue around the orifice thickened, and the orifice diminished in size, but not extremely so; the mitral valve thickened, and the chordæ tendinæ also thickened and contracted,—the result of this being a certain amount of obstruction through the orifice, and imperfect closure of the orifice by the mitral valves, thus allowing of regurgitation. In cases of this kind we would expect to hear a systolic murmur over the left apex and over the angle of the left scapula. There is evidence during life of

regurgitation through the mitral orifice, and in some cases it has appeared to me that there was also evidence of mitral obstruction as well as of regurgitation. Dr. Barlow has kindly allowed me to mention the case of a young girl, who was a patient of his in Lydia Ward a few weeks ago. On listening over the apex of the heart a loud systolic bruit was heard, also in the axilla, and over the angle of the left scapula. A faint systolic murmur was heard over the left and right base of the heart, and carried along the aorta, but no diastolic murmur. So far it appeared to be a case of mitral regurgitation, with some amount of aortic obstruction; but on placing the stethoscope immediately under the left nipple the systolic murmur was noticed to be preceded by a very short, soft sound. This sound was very different to the prolonged, harsh, pre-systolic murmur already spoken of. If care was not used, it appeared to be part of the systolic murmur; by careful listening, however, the loudly-marked click of the pulmonary artery was heard; then the brief period of silence, and then a short murmur going before and running up to the systolic murmur. The presence of this sound again led to the question as to whether it might not be produced outside the heart. I had several times in other cases heard this sound, and suspected it was due to some amount of obstruction through the mitral orifice, but had never had an opportunity of proving it by post-mortem examination. This patient died, and the post-mortem examination by Dr. Moxon showed the pericardium healthy; the mitral orifice contracted, but not extremely so; the mitral valve much thickened and indurated; the chordæ tendinæ were greatly thickened, rigid, and apparently shortened. The aortic valve also showed signs of recent disease. The latter form of murmur is common, and since my attention has been drawn to it I have been led to consider that a great many of the so-called regurgitant mitral murmurs are of this kind—that is to say, there is a short pre-systolic and also a long well-marked systolic murmur. In the first two named cases no murmur followed the pre-systolic sounds, and the latter are typical instances of the auricular-systolic or pre-systolic murmurs, and such as I have found, by subsequent post-mortem examination, to denote a great degree of mitral contraction—the so-called "button-hole mitral." I can call to mind five such cases in which I have heard this pre-systolic murmur, and in every case the examination after death showed the mitral orifice to be exceedingly contracted. Every one of these five cases occurred in Guy's Hospital, and attracted a good deal of attention at the time, so that there cannot be any doubt that such murmurs were heard. One of the patients was under the care of Dr. G. O. Rees, two were patients of Dr. Gull's, and two of Dr. Wilks. Three out of the five have been recorded in the *Medical Times and Gazette*.

In diagnosing contraction of the mitral orifice, the rhythm alone of the murmur can be relied on, for although the quality of the murmur and the position in which the murmur is heard will in many cases lead us strongly to suspect that the orifice is contracted and not dilated, yet it is only by ascertaining the rhythm of the murmur that any degree of certainty can be arrived at. Of the five cases confirmed by post-mortem examination, the pre-systolic murmur was in three out of the five harsh, prolonged, and sounded as if the heart's apex was labouring to get over a rough spot on the pericardium, such as is well represented by Dr. Gairdner by the following aspirated letters—r r r r r f. It is this peculiar quality which renders this sound, once heard, afterwards easily recognised. If at the same time, as not unfrequently happens, the heart's action is slow and regular, so that the rhythm is readily made out, then no murmur is more easily distinguished than this left pre-systolic. In the remaining two cases of the five the auricular-systolic murmur was soft and prolonged, and not harsh. As regards the position in which this murmur may be heard, no rule can be laid down. It is usual to say immediately under or near to the left nipple. This, however, depends on the position of the apex of the heart. In one of the five cases—the patient under the care of Dr. G. O. Rees—the murmur was heard about two inches to the left, and about the same distance below the left nipple, which was owing to the apex of the heart being lowered in consequence of the dilatation and hypertrophy of the left ventricle, associated with granular disease of the kidneys. Again, in some cases the area over which the pre-systolic murmur is heard is exceedingly limited. The size of the cavities of the heart also assists somewhat in the diagnosis. It is well known that the muscle of the left ventricle wastes, and the size of the left ventricle diminishes, in some cases where the mitral orifice is exceedingly contracted; and this owing to the great impediment to the flow of blood into, and in consequence the diminution, in the quantity of blood entering the left ventricle. The result is the apex beat is raised often into the fourth interspace. The apex beat is often seen to the left of the left nipple. This is usually due to the great distension of the right side of the heart. That the left ventricle is distended is shown by the percussion dulness, and in some cases by the still more reliable evidence,—the presence of a tricuspid regurgitant murmur over the right apex. Hence, we are led to argue, the apex beat being raised, the area of cardiac dulness not increased upwards, and no evidence of displacement of the heart, that the left ventricle is diminished in size; which still further assists in forming a correct diagnosis." Dr. Sutton then remarked: "I am led to conclude that it is possible, and in many cases by no means difficult, to diagnose, by aid of this left pre-systolic murmur, that the mitral orifice is contracted. Again, that it is possible not only to diagnose that the mitral orifice is contracted, but further, that the mitral valves are incapable of closing the mitral orifice. Lastly, while in some cases the indications of mitral regurgitation predominate considerably, if great care is used it be possible to diagnose not only that the valves are incompetent, but further, that the orifice is somewhat contracted."

ABERDEEN ROYAL INFIRMARY.

POLYDIPSIA—TREATMENT BY LARGE DOSES OF VALERIAN—IMPROVEMENT—CLINICAL REMARKS.

(Under the care of Dr. REITH.)

Jane T., aged 24, married, was admitted into Ruth's Ward on November 25, 1864. She was sent to the Infirmary as a case of typhus, but no symptom of that disease was discovered. She had always enjoyed good health, and to outward appearance was a stout healthy woman, with florid complexion. Her case was regarded at first as one of febrile catarrh, but on December 5 the nurse called attention to an insatiable thirst of which the patient complained, and also to the enormous quantity of urine she passed daily. On being questioned, the patient said she had suffered from these symptoms for the previous nine months, since her child was weaned. Her father and a brother had both been affected with glycosuria. The brother died of it, but the father died of "consumption," prior to which the sugar disappeared from his urine. Shortly after weaning her child she had an attack of hæmoptysis, and has had one or two slight returns of it since; menstruation is regular. Under the right clavicle the percussion tone is diminished, and dry crackling heard on auscultation; other organs healthy. Urine very pale and clear, not to be distinguished in appearance from water; sp. gr. 1000; urea and chloride present in normal quantity; no albumen or sugar. She was ordered ʒj. of tincture of valerian three times a day. The following is the state of her urine for the next four days:

	Quantity passed in 24 hours.	Sp. gr.	Quantity of tincture valerian per day.
Dec. 7.	17 pints	1000	3 drachms
,, 8.	17½ ,,	1000	6 ,,
,, 9.	16½ ,,	1000	6 ,,
,, 10.	18½ ,,	1000	9 ,,

Doubtful of the accuracy of the urinometer, I prepared some distilled water, and found that in it the urinometer stood one degree lower than 1000; consequently the real specific gravity of the urine should be marked 1001. The powder of valerian was now given instead of the tincture. The result is as follows:—

	Quantity passed in 24 hours.	Sp. gr.	Quantity of valeria per diem.
Dec. 11.	16½ pints	1002	60 grains
,, 12.	19½ ,,	1001	60 ,,
,, 13.	20 ,,	1001	90 ,,
,, 14.	17 ,,	1003	90 ,,
,, 15.	16½ ,,	1002	90 ,,
,, 16.	14 ,,	1004	90 ,,
,, 17.	17 ,,	1004	120 ,,
,, 18.	12 ,,	1004	120 ,,
,, 19.	14½ ,,	1004	120 ,,
,, 20.	12½ ,,	1004	120 ,,
,, 21.	13 ,,	1006	140 ,,

I now lost sight of the patient, owing to an attack of illness, but I was told that before she left the Hospital the specific gravity of the urine had risen to 1008. I afterwards had a sample of the urine sent me on March 3, 1865; the specific gravity was 1006. I have not seen the patient since.

Clinical Remarks by Dr. Reith.—Polydipsia, once established, is generally incurable. Although at first a mere inconvenience, and not interfering materially with the general health (the subjects of it, like our patient, being often stout and ruddy) it, sooner or later—it may be after the lapse of years—tells on the system, and at last it ends in tubercular phthisis. The present case will thus terminate, for there were symptoms of tubercular deposit in the right lung during her stay in Hospital. This case is an example of the undoubted connexion existing between glycosuria and polydipsia. Two of the patient's near relatives were affected with the sugar disease, and although the father was said to be cured, it is evident that the phthisis of which he died must have been induced by the glycosuria of which it is so often the termination. The polydipsia, therefore, in this patient, as in most, if not all, cases of the same kind, had come by hereditary descent, so to speak, from glycosuria. In fact, it is now generally admitted that glycosuria, polydipsia, and even albuminuria are interchangeable; that is, if an individual be affected with one of those diseases, his descendants are liable to either of the others. The well-known experiments of Bernard show that these diseases may be produced by injuring certain parts of the nervous system in close proximity to each other. Hitherto, polydipsia, or, as it is more commonly called, diabetes insipidus, has been regarded as not only incurable, but also irremediable. M. Rayer was, I believe, the first to point out that valerian administered in large and rapidly increasing doses was a most serviceable remedy. Trousseau relates some cases which were perfectly cured, at least for the time, by this treatment. The result of its employment in the present instance was satisfactory, and there is reason to believe that had opportunity been given to persevere in its use, and had the patient been more tractable than she was, she would have been still further benefited.

SATURDAY, MARCH 24.

RINDERPEST IN THE LAST CENTURY.

During the last century the Rinderpest made several visits to this country, raging on one occasion during a period of twelve years—from 1745 to 1757—without any very apparent intermission. It is generally supposed that the epidemic ran a pretty uniform course, and was finally only checked by the adoption of stringent "stamping out" measures. Most of the points connected with the history of the particular visitation to which we refer have been involved in considerable obscurity; we are, however, enabled to give our readers some rather important data, contained in an official "Memorandum" recently issued. This is a trustworthy account of the distemper which existed amongst the horned cattle during the last century, "compiled especially for the purpose of completing, and in some respects correcting, a notice of the distemper of 1745-57, which is contained in the first Report of the Cattle Plague Commissioners." The "Memorandum" has been noticed by the *Times*; but some of the most important particulars which bear directly upon the position taken by Dr. Farr, noticed by us last week, have entirely escaped attention. We have no bias one way or the other, and are only anxious to put before our readers every point of interest in connection with the subject.

It appears that during the first two years of the epidemic the transit of all lean cattle was prohibited, and, says the report, "there is no reason to believe that this prohibition produced any sensible effect upon the progress of the distemper." However, as there was an occasional relaxation of the Orders of Council, perhaps it may not be fair to argue from occurrences under these circumstances, but subsequently severe prohibitory measures were adopted, and "the rules which were in force during the last nine years of the distemper are contained in the Order of March, 1747-8, strengthened by subsequent Acts of Parliament, and they may be assumed to give the results of the experience of these days, for they were renewed upon the occasion of several short outbreaks of the distemper which took place between 1769 and 1800." The most important of these rules were the compulsory and immediate slaughter of infected beasts, the proclamation of infected places and the disallowance of removal of cattle from them, the stoppage of the movement of all cattle without a health certificate, the closing of fairs and markets, and the prevention of the transit of hides and the like from localities where the Rinderpest existed. Notwithstanding these measures, the general conclusions in reference to the "twelve-year" epidemic 1745-57, are thus stated, viz.:—"That it was capricious in its progress and malignity, like similar diseases among men; that it yielded to no remedies; that general regulations for the purpose of checking it were of little or no avail, and were soon abandoned in favour of local action; and lastly, that although it caused severe losses from time to time in different parts of the country, it produced no sensible effect upon the price of meat."

Now, the Appendix A to the "Memorandum" contains "the declared accounts of John Sharpe and Thomas Francis, copies of which have been furnished from the Public Record Office," and shows the amount of compensation paid by Parliament during the twelve years that the cattle plague raged—viz., from 1745 to 1757. Unfortunately there are no details as to the sums paid to each separate county during the first five years (1746-1750), but only during the last seven years (1750-1757). However, there are valuable inferences to be drawn from the figures as they stand in the Appendix. During the first five years £150,670 2s. was paid for compensation, during the last seven years only £44,326 12s. 9d., and of this sum £36,055 5s. in the way of compensation for the losses in Middlesex, Cheshire, and Shropshire,—that is to say, there was an enormous diminution in the virulence of the disease during the last seven years, which would seem, in fact, to have been *sporadic* rather than *epidemic*, and confined mainly to the three counties mentioned. But though we cannot ascertain any details as to the peculiar places ravaged by the distemper during the first five years, we are enabled to see that the largest amount of compensation was paid during the second and third years (viz., 1747-48), as shown by the following figures contained in the report:—

	£	s.	d.
1746	12,949	18	0
1747	70,000	0	0
1748	62,000	0	0
1749	7,400	0	0
1750	13,370	17	6
1751	23,904	3	0
1752	6,600	0	0
1753	5,700	0	0
1754	5,200	0	0
1755	4,300	0	0
1756	500	0	0
1757	500	0	0

The figures also indicate a rapid subsidence of the disease in 1749, a rise again in 1750 and 1751, with a rapid declension during the subsequent years until the disease became "sporadic" or scattered; and this notwithstanding the *uniform* influence of the "stamping out" measures.

Although, then, the Rinderpest remained as a visitant for twelve years, yet it did not preserve a steady onward progress, but it varied considerably in course; and its former behaviour lends very considerable weight to the truth of Dr. Farr's statements. The variation in the virulence of the poison, accounted for by transmission through many animals, was very marked, and is well illustrated by an extract, contained in the "Memorandum," from the *Gentleman's Magazine* for January, 1747:—

"When the disease first appeared in the neighbourhood of London, it seemed too violent to admit of relief. The case is now altered, the symptoms become more moderate, and numbers recover, some with more, some with very little assistance, exclusive of attendance and house warming."

Within the whole of the twelve years during which the cattle plague raged there was no evidence at all that the Rinderpest was or could be transmitted to sheep—a point of some anxiety at the present moment. We would just note this fact, moreover, that during the time that the most stringent measures were in their fullest operation the Rinderpest at first steadily declined in severity; but afterwards a rise was actually noticeable; for example, during 1750-51. We take the amount of compensation as our guide, and this is quite legitimate, inasmuch as it represents a definite number of beasts, according to a fixed rate of value.

We do not from these facts draw the conclusion that "stamping out" measures are useless, but that, as Dr. Farr has pointed out, the Rinderpest has a period of increase and subsidence, due to diminished activity of its virus, independently of any extraneous influences that may be brought to bear upon the whole disease—a statement that does not negative the existence of decided usefulness on the part of "stamping out" measures.

We draw another conclusion, that the Rinderpest, in spite of all we may do, may very likely remain amongst us in a sporadic form for some time to come, and we must not be surprised if occasional intensifications of the distemper appear here and there in the country, just as happened during the last century.

A confirmation of Dr. Farr's position is deducible from the latest returns of Rinderpest. For the week ending March 10 the total of attacks is stated to be 6518, a decrease compared with the numbers of the previous week. The total returns for the 20 weeks ending March 10, exclusive of back returns, amount in attacks to 137,200. Dr. Farr's calculation estimates them at 137,980.

The "Memorandum" contains a notice of the distemper of 1714, which lasted only about six months, and in its severity only half that period. Again, at different times from 1769-81, little evanescent outbreaks were noticed in many parts of England; but the account of none of these furnishes any arguments against Dr. Farr's views. Mr. Dossie, in an essay published in 1771, observes "that the effects of the contagion in all these places were confined to a few beasts, and suppressed in a short time." It may be as well to correct the erroneous impression that Lancisi's suggestion to stamp out the cattle plague from Italy during the last century was ever carried into effect. This is not a fact. The Rinderpest epidemic followed the law regulating kindred diseases, and subsided gradually without any such interference.

It is also an interesting point to remember that Dr. Mortimer, in his third account of the cow distemper, says—"Mr. Theobalds, a diligent inquirer, observed that the first infection was brought over from Holland in 1745, by means of two white calves which a farmer at Poplar, near London, sent for in order to mix the breed. The infection got to Maidenhead, in Berkshire, by two cows brought out of Essex and sold at the fair there." Others imagined it was produced by the arrival of distempered hides from abroad.

Lastly, the effect upon the price of meat appears to have been very trifling. Tooke, in his "History of Prices," speaks of the years from 1715 to 1765 as "long periods of great abundance, and consequent cheapness of the prices of provisions." A scarcity did arise, it would appear, subsequently in 1764, but the Committee of the House of Commons which sat upon the question of scarcity of food did not make any reference to the cattle distemper, "nor to any exceptional period of high prices during the years of the distemper which were then so recent." Smithfield market was less supplied than usual with beasts, but probably ordinary demand was met by the establishment of local markets. The recommendations of the Cattle Plague Commissioners are most valuable as aids to what may be termed "individual security." The poison of Rinderpest may be carried from animal to animal by many agencies, and it is against transporting influences that the "*stamping out*" is especially available.

THE THERMOMETER IN DISEASE.

We propose to continue this week an account of the help the thermometer gives us to distinguish between tubercular and non-tubercular diseases, when the symptoms are so similar that without the aid of this instrument the diagnosis cannot be made.

We again impress on our readers the fact that the temperature is always preternaturally raised when tubercle is being deposited in any of the organs of the body. This elevation often continues for many months. The temperature reached in tuberculosis varies from any point above that of health to 105° or 106° Fah. The usual maximum temperature of the day varies between 102° and 103° Fah.

Not unfrequently when tubercle is deposited in the meninges, or in the substance of the brain, the symptoms that result are almost identical with those that occur from other diseases of that organ. In such cases by an appeal to the thermometer we often gain information by which we can learn the nature of the disease. The correctness of this statement is shown by the following case:—

The patient was a boy of 4 years of age; previous to his admission into Hospital he had suffered from severe pains in the head, frequent sickness, and obstinate constipation of the bowels. There had been no delirium. He was ill rather more than five weeks, and gradually became comatose, from which he could only be partially roused. His head was thrown back, and was fixed in this position by the muscles of the back of the neck. The muscles at this part were rigid and contracted. There was ptosis with intermitting and fluctuating strabismus. The pupils were widely and irregularly dilated, and they acted but little under the influence of light; the skin flushed up to a very unusual degree on irritation. The respiration and the pulse were very slow and irregular for a great part of the time. There was, however, no paralysis, nor rigidity, nor convulsive movements of the limbs. The coma deepened so that he could not be roused, and continued so till the time of his death. The lungs tested by physical signs were healthy. Such symptoms, occurring in a child 4 years of age, were sufficient to lead to the idea that the disease was tubercular meningitis. If the symptoms, however, be more carefully examined they will be found to be insufficient to establish such a diagnosis.

The head of the child was thrown back, and it remained in this position. To what was this position of the head due? In *Children* the three conditions that may cause this are: 1. Angular curvature of the spine. 2. Rickets. 3. Effusion into the ventricles of the brain. With rickets there is great muscular weakness, and the child has much difficulty in retaining the head in the erect position. The head being most weighted

behind, therefore falls backwards; also on account of muscular weakness the back is curved and the shoulders raised; this is the common position of ricketty children. They are said to "sit all in a lump." If the position of the head mentioned above be due to this disease, this can be at once detected by the absence of the symptoms that accompany the other diseases producing it, and by the absence of any rigidity of the muscles of the back of the neck. If, moreover, the position of the child be altered, the head will roll forward, or to either side, and will assume the most dependent position. If it be due to angular curvature of the spine, this cause can be at once detected by inspection and by running the fingers down the spinal column.

If these two diseases can be excluded, and if the head be fixed back by the muscles of the back of the neck so that it cannot be pushed forward except with difficulty, and often not at all, and if the muscles of the back of the neck be rigid and firm, we are justified in diagnosing in a child effusion into the ventricles of the brain. This conclusion is based on many cases on which post-mortem examinations were made. In no case have we known the sign to prove incorrect.

In this case the head was firmly fixed backwards, and the muscles of the back of the neck were contracted and hard. There was no angular curvature of the spine. Hence we were justified in concluding that the child suffered from effusion into the ventricles of the brain.

Effusion into the ventricles is, moreover, sufficient to explain most of the remaining symptoms of the case. From this there results loss of consciousness, loss of sight, drooping of the upper eyelids, strabismus with irregularity of the pupils, flushing of the skin or irritation, slow and irregular pulse, the irregular breathing, and curving of the head backwards.

This case, and that which will shortly follow, prove that these symptoms are not significant of tubercle deposited in the meninges or in the brain. That they may result simply from effusion into the ventricles we conclude from a case in which these symptoms were present. At the post-mortem examination there was found considerable effusion into the ventricles produced by inflammation of the straight and one of the lateral sinuses, and the occlusion of these vessels by a firm, old, and adherent clot. This is the simplest form of the disease that can be met with, as it can hardly be maintained that the symptoms were caused by the inflammation of the sinuses, apart from their producing effusion into the ventricles. The brain itself, with the exception of the effusion into the ventricles, was healthy.

Nor can the remaining symptoms present in the case just given—namely, pain in the head, vomiting, constipation of the bowels—be accepted as proof of the tubercular or inflammatory nature of the affection of the brain; for such symptoms occur in other diseases, as this case proves. The utmost, therefore, that could be arrived at from the symptoms present was the certainty that the child suffered from effusion into the ventricle of the brain.

What diseases may produce such an effusion into the ventricles of a child of this age? 1. Inflammation, simple or tubercular; 2. Tumours of the brain; 3. Coagulation of blood from inflammation of the straight or lateral sinuses, with occlusion, complete or partial, of these vessels. If other diseases cause the effusion, they are very rare. Of those mentioned, the former two are by far the most common. How are we to learn to which of these causes the effusion is due? The thermometer often gives us the information we require. We have seen that the deposition of tubercle causes an elevation of the temperature of the body. If, therefore, the temperature be normal, the disease producing the symptom is not tubercular. It may be objected that tubercle may be deposited in the brain, and the further deposition may cease, and that in such cases the temperature will be normal, while the effusion remains, the symptoms resulting from this will also continue. It is true that such cases occur, but they are infinitely rare, as the deposition of tubercle very generally continues till the patient dies. This is rare of tubercle in the brain substance; it is still rarer of tubercle in the meninges of the brain. How can we learn if the effusion is caused by non-tubercular inflammation of the meninges of the brain? If the temperature be normal at the commencement of the attack, this disease is excluded from the diagnosis. But children much more commonly survive the simple acute than the tubercular inflammation of the meninges of the brain. The non-tubercular inflammation of the meninges either destroys life in five or ten days, or the inflammation subsides and the temperature becomes normal; but in such case the effusion into the ventricle continues and may increase in quantity. How are we to learn that in such a case the effusion is due to a previous inflammation? The two chief points to be relied on are, the age of the patient and the method of invasion of the attack. The former of these is of the most value. Simple inflammation of the meninges in children almost always occurs during the first few months of life. (Tubercle in any of the organs is uncommon under two years and very rare under one year of age) (a). Non-tubercular inflammation of the meninges most commonly begins with an attack of convulsions—tubercular inflammation rarely so. The other cause also of ventricular effusion, namely, tumours, is very rare in children under two years of age. Thus the most common cause of such effusion in very young children is simple inflammation of the meninges.

But while the temperature of the body is raised both by tubercular and non-tubercular inflammation of the meninges in some part of their course, *the temperature of the body is normal in cases of non-tubercular tumours of the brain.*

In the case just given the temperature of the child was *normal*, and thus the tubercular nature of the disease was proved, and as the child came under observation early in the disease, we also excluded simple inflammation of the meninges, and moreover the child was not of the age when this most frequently occurs, nor did it begin in the manner usual with this disease.

The diagnosis, therefore, was that the child suffered from effusion into the ventricles, and that this was most probably produced by a non-tubercular humour (inflammation of the straight sinus and its occlusion by a clot is so extremely rare that this could with probability be excluded from the diagnosis). This conclusion proved correct, for on the post-mortem examination there was found a non-tubercular tumour of the size of a Maltese orange, situated in the anterior and inferior part of the cerebellum. This had pressed on the right half of the medulla oblongata, and had caused much atrophy of this part.

We venture to add another case to exemplify the use of the thermometer in similar cases to the one just given. A boy, aged 11, had suffered from severe pain in the head, with vomiting and obstinate constipation of the bowels. When first seen these symptoms still continued. His head was slightly thrown back, and the muscles at the back of the neck were rigid. His face was flushed, and he was partially unconscious. The pupils were dilated, and failed to act under the influence of light. There was slight strabismus, but no paralysis nor rigidity of any of the limbs. These symptoms are those most commonly met with in tubercular meningitis. *His temperature, however, was always normal.* Thus the disease could not be of a tubercular or inflammatory nature. It was considered probable that he suffered from a non-tubercular tumour of the brain. The symptoms described above disappeared in a few days. He was frequently seized with similar attacks, from each of which he recovered. He died suddenly from some unexplained cause. There was found a

(a) We have met with tubercle in two children both under six months old.

large fibro-plastic tumour, situated in the cerebellum. The ventricles were dilated, and contained about 3 oz. of fluid.

These cases serve to illustrate the assistance we may derive from the thermometer in cases similar to those described.

If in such cases, if the temperature be normal, the disease is not tubercular; if, on the other hand, the temperature be elevated in a child over two years of age, it is in the highest degree probable that tubercle is being deposited in the meninges or in the brain of the patient. For if the elevation of the temperature should be caused by some intercurrent disease, such disease can mostly be detected.

Before concluding this article we add a few words concerning effusion into the ventricles of the brain, and the symptoms that result from this.

If the effusion occur quickly, the consciousness is greatly lessened; if it occurs more slowly, the consciousness is but little impaired. The loss of consciousness is caused by the pressure of the grey matter resulting from the effusion. The brain, however, accommodates itself to slow pressure, and thus the consciousness is but little altered when the effusion occurs gradually. Again, when the effusion has occurred quickly, and the consciousness has been quite lost, if no further effusion take place, or if its further increase be slow, the intelligence of the child to a great extent returns, and after some time has elapsed, it may be chiefly restored. In most of the cases similar to those described, it is the rapid effusion by producing loss of consciousness that quickly destroys life. When the effusion is slowly produced, the children may survive for years, and in some cases they live the number of years usually allotted to man.

The rigidity of the muscles at the back of the neck, and the degree to which the head is drawn back, is proportionate to the amount and rapidity of the effusion. If this displacement of the head is but slight, and but a short time has elapsed, the amount of effusion is small; if, on the other hand, the effusion has occurred slowly, and the head has had time to enlarge, then this rigidity of the muscles, and this position of the head, is but slightly marked. This symptom also disappears after the effusion has lasted some time, if no further increase occurs. It disappears much earlier in young people, in whom the bones of the head are ununited, than in those children whose skull is firmly closed. In the latter it lasts often for a considerable time; it continues long after the intelligence of the child has greatly returned.

The ptosis, strabismus, and inequality of the pupils are but slightly marked when the effusion is slowly produced, and this soon disappears when the further effusion of fluid into the ventricle ceases. Loss of sight, however, is mostly present whether the effusion occurs quickly or slowly, and is one of the last and rarest symptoms to disappear.

The shape of the head, when the fontanelles are open, is so peculiar and characteristic that we need not dwell on it here. The shape, however, somewhat differs when the bones are firmly closed. In such a case, when the effusion occurs slowly, and consequently the patient lives some months, the enlargement is most marked at that part of the skull occupied by the parietal bones. The frontal bone is comparatively little affected. Thus there is formed a very prominent and acutely formed ridge, corresponding to the junction between the parietal and frontal bones. The sudden elevation in some cases amounts to half an inch in extent. It occurs earliest, and is most marked, in the temporal regions.

Death of the Eldest Son of Sir Dominic Corrigan, Bart.—We are sorry to state that the death of Captain J. J. Corrigan, 3rd Dragoon Guards, is reported from Melbourne, whither he had gone on sick furlough from India. It is a remarkable and sad coincidence that the same bereavement should have happened to both the distinguished Physicians selected for the honour of a baronetcy, as representatives of the Profession in Scotland and Ireland.

THE WEEK.

THE MEDICAL COUNCIL.

We inserted last week a paragraph from our lively contemporary, the *Pall-Mall Gazette*, conveying to the public the idea that each member of the Medical Council receives ten guineas a-day for attendance at meetings. This sum, however, is not correct; the fee is only five guineas. It is well known that the presence of the members of the Council at the deliberations generally involves very considerable loss, especially in the case of the Scotch and Irish representatives, and that the sum named is not in the least compensatory. We can only regret that the powers of the Council are very limited, and that they should have been so curtailed by the original framers of the constitution of the Council. A great deal of good, however, has resulted, especially, we think, in the effect produced by the appointment of delegates to supervise examinations; and there can be no doubt that eventually, by steady work, the Council will acquire a degree of moral influence which will lead to results of the highest and most satisfactory character.

THE NEW PHARMACOPŒIA.

We have every reason to believe that the new Pharmacopœia is now in course of active preparation at the hands of Messrs. Redwood and Warrington, who have been appointed by a subcommittee of the Medical Council to undertake the matter. No doubt the errors contained in the former editions will be rectified, and several valuable preparations which are used very largely by the majority of Medical men, but have unfortunately been omitted, will be replaced. We may indicate, for example, *the acetum cantharidis*, *the liquor hydrargyri bichloridi*, *the infusum aurantii compositum*, and *the infusum gentianæ compositum*; in addition, it is probable that some remedies which have been getting into favour of late, such as carbolic acid, may be likewise added. An attempt will also be made to secure a greater uniformity, not only in the arrangement of the contents, but the use of terms. The former edition contained some few contradictions which it would be well to avoid. This was, no doubt, due to the fact that the compilation was effected by several gentlemen who held different views upon similar subjects. The terms "sesquioxide" and "peroxide," for example, will be employed each in a uniform sense. The first and second parts of the Pharmacopœia, including the Materia Medica and preparations respectively, will be incorporated, and the contents arranged in alphabetical order. At present the descriptions of some drugs are separated in twain; some details of the mode of preparation, for instance, are given under one, and the properties under another head. In the forthcoming edition all that is to be said about any one preparation will be said in one place once for all. The Medical Council has expressed a desire at various meetings that, at least a month before the publication of the new edition, the proof sheets of the latter may be placed in the hands of its members, in order that the contents may undergo careful criticism, and that corrections may be suggested if necessary. We believe that the greater part, if not the whole, will be ready for this purpose.

MEDICAL CANDIDATES FOR THE ARMY MEDICAL SERVICE.

We have heard that the promise of better things in our public services has not been without its effect on the London Schools. It is well known that the students at our Metropolitan Hospitals have hitherto held aloof from those services, but there seems to be a general conviction that the recommendations of the late committee will be acted upon, and that a perfect equality in the two services must also follow in time. Many English students, we believe, have presented themselves for the competitive examination at Chelsea. It only remains for the Government to give effect to the hopes of our Profession, and

there will be no lack of good men from all schools. We are glad to perceive that Colonel North will repeat his question to the Secretary for War as to the adoption of the Committee's report after the Easter recess.

THE NAVAL MEDICAL SERVICE.

Dr. Frederick James Brown, of Rochester, has published some "Comments on the Recommendations of the Committee to Inquire into the Position of the Medical Officers of the Army and Navy." As this gentleman has laboured very hard indeed for the cause of the Naval Medical officers, and is thoroughly acquainted with their wishes and interests, our readers will naturally ask what he thinks of those recommendations. In the first place, he expresses his sense of the fairness with which the Committee acted in the selection and examination of witnesses, and he bestows a good deal of praise upon their labours; and no more than they deserve. The recommendations, he says, taken collectively, are liberal. There is only one point upon which he strongly animadverts—viz., the pecuniary punishment (as he terms it) attendant upon optional retirement. Five-tenths of the pay, on which sum such retirement is recommended after twenty years' service, being a commuted allowance in lieu of the half-pay earned by active service, will not be considered a boon. It must be remembered that this was a requisition of the Medical officers of the Army as well as of the Navy. Dr. Brown cordially agrees with the Army Director-General in his protest—indeed, the plan proposed by Sir Jas. Gibson appears to be the more popular one with the Naval Surgeons. Dr. Brown considers that the two Services should be equalised in every particular, and the question of pay ought not to be one that should constitute inequality. In this we must say we agree with him. Compensation for loss of time by half-pay in the Navy is met by a four-yearly instead of the five-yearly increase of pay. By the way, there is an unfortunate mistake—for we hope it was a mistake—into which the Committee have fallen. The present excellent rule of Naval Staff-Surgeons having the option of retiring after twenty-five years' active service *regardless of age*, has been done away with. The recommendation of the Committee restricts that right, rendering age or illness necessary as well as service. On comparing the recommendations of the Committee with the proposals contained in Dr. Brown's pamphlet, we are bound to state that a very large number of his requisitions have been conceded. We may, therefore, join with him in saying to the authorities, "The Medical Profession will repose trust in your good faith. Carry out the regulations of Orders in Council and Warrants in their strict integrity, and you will never want Physicians and Surgeons for your fleets."

SANATORIA.

An important public meeting was held in the Town Hall of Birmingham on Thursday last "for the purpose of considering what measures should be taken to further the success of the scheme for the formation of a Sanatorium in the neighbourhood of Birmingham, initiated by the Committee of the 'Cotton Districts Relief Fund.'" The Cotton Relief Fund promises to contribute £7000 towards this most desirable object, and considerable support has also been already obtained from the public, including a large sum subscribed by the working men of Birmingham. We need hardly say that the scheme has the hearty support of the Medical men of the locality, Dr. Fleming and Mr. O. Pemberton having made able speeches in its favour. We are glad to learn also that the "Prudhoe Convalescent Home" for the benefit of the sick poor of Newcastle may be looked upon as almost a *fait accompli*. Sir W. G. Armstrong, already a munificent supporter of the charity, has offered "to double his present subscription of £1000, provided a sufficient number of existing contributors join in raising a further sum of £1000 by doubling the amounts they have already given." Such an act of generous benevolence needs no word of praise. The establishment of institutions of this kind is one of the most admirable and valuable "movements" of the day.

GINGHAM OR LIFE?

The Hong-Kong correspondent of the *Daily Telegraph*, at the end of a long letter on the tragedy lately enacted in the well-appointed and salubrious military establishment there, makes a statement which, if true, is a new and most striking instance of the minute and considerate care and attention with which the War Office watches over the discipline, health, and expenditure of the British soldier, wherever he may be placed. The extreme heat rendering out-of-door movement in the day time dangerous, unless the head is protected by an umbrella as well as by helmet and *puggery*, and it being impossible to manage without sending orderlies about during the day, the general in command had, with what may appear to ordinary mortals only simple common sense, directed a certain number of umbrellas to be issued to each company. The idea of a soldier on duty carrying an umbrella is, however, too much for the martinets of the War Office, and, moreover, umbrellas probably cost something even in China, so "orders have been received from the War Office that no more umbrellas are to be issued to the troops." *Vive le* pipe-clay and petty economy, and *á bas* the British soldier if his life or health clash with them! His duty is boldly to face all his enemies, sun and sunstroke included. In England no one ever saw the British soldier march with an umbrella; and why, then, should he need it at Hong-Kong? Discipline must be kept up, and the estimates kept down. *Fiat* the will of the Horse Guards, *ruat* the soldier!

DR. RICHARDSON'S METHOD OF LOCAL ANÆSTHESIA.

Dr. Richardson is still engaged in perfecting his method of producing local anæsthesia, and we shall be able in an early number, we hope, to present from himself an account of the improvements he has been able to introduce. Meanwhile, we may report that he has now constructed a very effective multiple instrument composed of three distinct jets, which can be moved to various angles, which can be worked with a single pair of small bellows, and which produces good anæsthesia over a surface of the body three inches long and nearly two wide. He is also, as stated in our last impression, closely investigating the action of various liquids of low boiling point, with a view of ascertaining whether a more efficient agent than ether can be obtained. Up to this time, we understand, ether retains its position, and a singular and unexpected fact has been elicited that, at all events, some fluids which have a lower boiling point than absolute ether (92° Fah.) do not act so efficiently as ether itself. A very pure hydro-carbon obtained from paraffin (photogene oil), analogous to kerosolene, produces an action next best to ether; but in London it is not easily procurable, and the boiling point of different specimens varies so much that it cannot be relied upon.

Lastly, Dr. Richardson has been using various applications to the skin preliminary to the distribution of the spray, in order to prevent the smarting which is sometimes complained of, especially when the action is prolonged. For this purpose he has used different liniments—oils, glycerine, narcotic solutions, and tincture of iodine; the tincture of iodine being apparently the best. On the whole, however, nothing succeeds so well as rapid action of the spray; when complete narcotism is produced in six or seven seconds the process is quite painless.

The reception of the process by the Profession is almost without parallel, and its success may be considered as established. Owing to the circumstance that the demand for absolute ether is as yet greater than the supply, some partial failures have occurred, and we would, therefore, specially

direct the attention of the Profession to the rules on the subject of the ether to be employed, which have already appeared in this journal.

In concluding this short notice, we may observe that Medicine, not less than Surgery, receives a new addition to its resources in "narcotic spray;" the application has proved to be signally serviceable in the local treatment of neuralgia, lumbago, subacute rheumatism, nervous headache, and spinal irritation.

The question is constantly being put to us,—In what operations may the anæsthetic process be used with success? This question can only be answered by experience, but we may state that to our knowledge it has been successfully used in the following operations:—Opening of abscesses and sinuses, removal of tumours, removal of fingers, tooth extraction, removal of the eyeball, dividing tendons, laying open the knee joint, operation for whitlow, dividing carbuncles, removing piles, phimosis, application of nitric acid to ulcerated surfaces, operations for fistula, circular incision round the coccyx, removal of toe-nail, and tying a nævus. The process, as we noticed last week, has also been employed by Mr. Spencer Wells with an unexpected degree of success in the great operation of ovariotomy.

THE MICRO-SPECTROSCOPE IN THE DETECTION OF BLOOD STAINS.

At the trial of Coe for the Mountain Ash murder, corroborative evidence of the presence of blood on the hatchet was furnished by the micro-spectroscope. Dr. W. B. Herapath conducted the scientific inquiry, and we believe has the merit of first using the micro-spectroscope in Medico-legal inquiry. Of course, the evidence furnished by it cannot prove the presence of human blood, but it may prove a valuable corroborator of other testimony. The following is Dr. Herapath's evidence:—

Dr. Bird Herapath sworn: "I am a Fellow of the Royal Societies of London and Edinburgh. I practise as analytical chemist and also Physician. The hatchet produced was given me by Mr. Wrenn, and I carefully examined it. On the metallic portion I did not find any marks upon which I could rely. I removed the handle and experimented on thin slices of wood which I took from underneath the metallic ring. I examined those sections with a microscope, and found the majority of the stains were due to oxide of iron; some of them showed clotted blood—in some cases the woody portions had been infiltrated with the colouring matter of blood changed by the action of water. On some of the sections of the handle I found globules of blood, and by the micrometer I measured the size of those globules. I placed a section of the handle in a glass cell in which there was a fluid medium, and the blood globules floated off into the cell, and by the measurement of these I could determine the size of the globules therein contained. These globules were exactly the same size as some globules from dried human blood which I purposely procured, and tested with the same apparatus in the same way. Finding this evidence of blood to be small, I obtained more numerous sections of the coloured surface of the handle of the hatchet—immersed them in distilled water, and obtained thereby a slightly coloured solution, which after filtering was ready for chemical tests, and for optical examination by the micro-spectroscope. I subjected this fluid to the action of light, and it had undoubtedly the properties peculiar to a solution of blood. When a solution of blood was examined in this instrument (instrument here produced) the fluid absorbed some of the rays of light, and thus altered the spectrum or rainbow. Within the green and on the border of the yellow rays two dark absorption bands were produced by the blood fluid. Only one other substance would produce two dark bands—that is, cochineal dissolved in ammonia, but the position of the two bands was different. The spectroscope alone would not enable me to *readily* distinguish between the two, but combined with chemical examination it would satisfactorily do so. From this optical test I was satisfied that the sections of the hatchet had been stained with blood—and by chemical analysis I also demonstrated it was blood. The combination of the three tests showed that the substance on the hatchet must have been blood.

"Cross-examined: I should not like to say that the stains were those of human blood, but my opinion is that they were."

FROM ABROAD.—PRIZE QUESTIONS OF THE ACADÉMIE DES SCIENCES—DISCUSSION ON TREATMENT OF CARBUNCLE.

The following are the subjects proposed for the next prizes by the Paris Académie des Sciences:—1. The Montyon Prize in Statistics, a gold medal, 453 francs in value, will be awarded for either a M.S. or printed work relating to the Statistics of France. 2. The Grand Prize in the Physical Sciences, 3000 francs in value, for the best essay forwarded before December 31, 1866, on the question "The Production of Hybrid Animals by means of Artificial Fecundation." This prize-question, originally proposed in 1861 for 1863 was remitted to 1866. 3. The Montyon Prize of 764 francs will be adjudged for the work (whether M.S. or published) which shall appear to the Academy to have most contributed to the progress of Experimental Physiology. The works to be sent in by June 1 of each year. 4. M. Montyon's Prizes in Medicine and Surgery and Occupations Inimical to Health. The objects of this prize are discoveries and inventions which shall be deemed of most utility in the Art of Healing, or calculated to render the pursuit of any occupation less injurious to health. No award will be made to any work which does not contain a well-defined discovery. No specific sums can be named, as the number of the prizes to be awarded is indeterminate; but the liberality of the founder of the prize has furnished the Academy with the means of raising them to a considerable value—so that the authors will be compensated for any expensive experiments or researches they may have undertaken, and receive rewards proportionate to the services they have rendered, whether by preventing or diminishing the insalubrity of certain occupations, or in perfecting Medical science. Works or essays to be sent in by the 1st of June of each year. 5. The Academy Prize in Medicine and Surgery of 5000 francs, subject "The Application of Electricity to Therapeutics," not having been awarded for 1865, is offered again for 1866 (1st June). 6. The same observation also applies to the Grand Prize in Surgery of 20,000 francs, offered conjointly by the Academy and the Emperor, for the best essay on "The Preservation of the Limbs by the Preservation of the Periosteum" (1st June, 1866). 7. The Cuvier Prize, consisting of a gold medal 1500 francs in value, will be adjudged to the author of the most remarkable work which has appeared between January 1, 1863, and December 31, 1865, either upon the Animal Kingdom or Geology. 8. The Bordin Prize, a gold medal 7000 francs in value, postponed from 1864, will be adjudged in 1866 (June 1) for the following subject:—"Determine by anatomical investigation whether there exists in the structure of the stems of plants, characters proper to the great natural families, and in accordance with those derived from the organs of reproduction." The same prize will be adjudged, after June 1, 1867, for the best essay on "The anatomical investigation of the pistil and the fruit in their principal modifications." 9. The Breant Prize of 100,000 francs will be adjudged in 1866 to the discoverer of a cure for the cholera, and in the case that *non est inventus*, the interest of the sum will be presented to those who may have most advanced our knowledge concerning cholera and other epidemic diseases. Printed books or essays competing for this acknowledgment must be sent in by the 1st of June of each year. 10. The Gecker Prize will be presented in 1866 to whomsoever the Academy deems the progress of Organic Chemistry is most due. 11. The Barbier Prize of 2000 francs is annually awarded for the most valuable discovery in Medical, Surgical, or Pharmaceutical science. 12. The Godard Prize will be given for the best essay on the anatomy, physiology, and pathology of the Genito-Urinary Organs. 13. The Savigny Prize, the interest on 20,000 francs, will be given to young travelling zoologists who are not in

the receipt of aid from Government, and who especially are engaged in the investigation of the Invertebrata of Egypt and Syria. 14. The Desmazières Prize of 1600 francs will be adjudged to the author of the best work or essay on the Cryptogama which may have appeared during 1865. 15. The Thore Prize of 200 francs will be given in 1866 for the best work or MS. which may come under the notice of the Academy before June 1 on the "Habits or Anatomy of any Species of European Insects."

In resuming the discussion on the treatment of carbuncle at the Académie de Médecine, which we noticed in our number for March 10, M. Gosselin observed that although Surgeons had long entertained the opinion that the erysipelas and purulent infection which sometimes complicate carbuncle arise under conditions which can neither be foreseen or prevented, yet several of them have of late occupied themselves in the investigation whether certain conditions, acting as occasional causes, may not favour this development of erysipelas. Among such may be placed large incisions, the pain these give rise to, and the moral emotions which ensue. And since he has adopted the plan of making deep punctures, in a greater or less number, in the centre of the mortified parts, and evacuating these by compression, M. Gosselin has met with neither erysipelas nor purulent infection. M. A. Guérin's mode of subcutaneous incision is a move in the same direction, and by avoiding large open incisions is calculated to prevent erysipelas. Carbuncle is not in itself a fatal disease, and the only reason that can be argued in favour of large incisions is that they may abridge the course of the disease, and more speedily put an end to the suffering it causes; but they have their own danger, and it is for this reason that some Surgeons substitute other modes of incision, and others resort to caustics. M. Velpeau observed that the real question was whether erysipelas does really arise oftener in consequence of large incisions, and he urged caution in coming to any such conclusion. Between 1835 and 1866, out of 184 cases of anthrax which have occurred in his Hospital practice, he has only met with three cases of erysipelas. Two of the 184 have died from erysipelas, and two from purulent infection; but surely in 184 cases of erosion of the nose or ear as many as three cases of erysipelas would be met with, and what security is there that erysipelas may not follow even small incisions or cauterisation? The pain produced by multiple large incisions, though considerable, has been exaggerated, especially if these are made rapidly one after the other; and it may be obviated by chloroform. As to purulent infection, this does not appear until some days afterwards, and is more probably due to the mortification of the tissues than to the incisions. It is not always necessary to make incisions, and when the progress of the carbuncle, though this may be a large one, seems to be arrested and well defined, they may be abstained from. "I conclude, therefore, from all these considerations that open incisions are preferable to any other mode of treatment, and that from an experience of forty years. There is a tendency at the present time to encourage moderate Surgery, a young ladies' Surgery, in which the bistoury is employed as superficially and as lightly as possible. Subterraneous Surgery is not safe, for you know not what you do. I prefer Surgery open to the day." M. Ricord observed that his experience quite confirmed that of M. Velpeau, that erysipelas complicates anthrax left to itself just as often as when incisions have been resorted to. He certainly does not practise incision so frequently as at the commencement of his practice, but in fitting cases he has a high opinion of this mode of treatment. He does not now follow Dupuytren's practice of making the incisions at a very early stage, in order to induce abortion of the anthrax, which, indeed, can rarely be done, but waits until suppuration is just about to take place. At this period the incisions diminish the pain, and the subcutaneous mode of performing them proposed by M. A. Guérin seems to be an eligible one. But when the suppurative process has once commenced, there is no advantage in cutting beneath the skin, while there is risk of only effecting an imperfect *degorgement* of the parts, facilitating the formation of purulent sinuses, and encouraging the advent of erysipelas and purulent infection. When, therefore, there is suppuration, or gangrene of tissue, free and open incisions should be resorted to. Not only are not incisions responsible for erysipelas which may complicate anthrax treated by them, but in some instances they have arrested an erysipelas already set up. M. Velpeau, in reply to an objection that his cases were all Hospital cases, which as respects anthrax are not as severe as those met with in private practice, observed that he had preferred Hospital cases as being capable of more exact verification; and that, in fact, cases of anthrax are not more serious in private practice, but that Consulting Surgeons are only called in to them at an advanced period, the patients often having resisted efficient treatment until too late. Incisions, too, to be efficacious, must not only be made in good time, but effectual; and cases are every day brought to the Hospital in which they have been imperfectly made, and the patient consequently remaining uncured. But here the Practitioner himself, not the incisions, are to be blamed. To be of use they must be multiple, radiating, deep, prolonged, and practised in good time.

PARLIAMENTARY.—THE CATTLE PLAGUE—ORDERS IN COUNCIL—SUNDAY LECTURES ON SCIENTIFIC SUBJECTS—THE CONTAGIOUS DISEASES BILL—THE COMMITTEE ON ARTISANS' DWELLINGS—TRADE IN CATTLE—THE MEDICAL OFFICERS OF THE ARMY AND NAVY—MANURE AND OFFAL IN THE METROPOLIS—THE MORTALITY AT HONG-KONG.

On Thursday, March 15, in the House of Lords,

Lord Granville, in reply to a question from Lord Ellenborough, stated that any magistrate who should improperly grant a certificate for the removal of cattle without a compliance with the conditions prescribed in the Orders in Council, would be liable to prosecution and dismissal from the magistracy.

Mr. Gregory asked the Attorney-General whether his attention had been directed to the Act 21 George III., c. 49, and whether, in his opinion, that Act applied to Sunday lectures on scientific and religious subjects by persons learned and competent to explain the same; and, if so, whether the Act might not be amended with advantage.

The Attorney-General stated that the point of law involved in this question would be brought before the Court of Queen's Bench in the next term; and, therefore, the House would see that, under these circumstances, he could not undergo any cross-examination upon the matter.

Mr. Childers (for Lord C. Paget) obtained leave to bring in a Bill for the better prevention of contagious diseases at certain naval and military stations.

This Bill was afterwards brought in and read a first time.

On the motion of Mr. M'Cullagh Torrens, the following Committee was nominated on the Artisans' and Labourers' Dwellings Bill:—Mr. M'Cullagh Torrens, Mr. Goschen, Mr. Kinnaird, Mr. Locke, Mr. Knatchbull-Hugessen, Sir C. O'Loghlen, Mr. M'Laren, Mr. Akroyd, Mr. John Abel Smith, Mr. Henley, Lord R. Montagu, Mr. Adderley, Sir M. Farquhar, Mr. Graves, and Mr. Greene; power to send for persons, papers, and records; five to be the quorum.

On the motion of Mr. Monsell, a Select Committee was appointed to inquire into the manner in which the home and foreign trade in animals by sea and railroad is conducted, and to report what regulations, if any, should be enforced with a view of improving the treatment of animals in transit, and to prevent any introduction and spreading of infectious or contagious diseases among them.

On Monday, March 19,

Colonel North asked the Secretary of State for War whether it was the intention of Government to carry out the recommendations as regards increased pay, etc., of the Committee which was appointed to inquire into and report upon the grievances of Medical officers of the army and navy.

The Marquis of Hartington said that as the report of the Committee had been received only a very short time ago, he was not aware what view the noble duke at the head of the

Admiralty took of the subject. He was, therefore, unable to state at present how far the recommendations of the Committee would be adopted.

On Tuesday, in the House of Lords,

The Duke of Montrose inquired the intentions of the Government as to prolonging the prohibition of the removal of cattle by railway after the 25th inst., remarking that the restrictions upon movement at present in force had not interfered with the supply of meat, nor increased its price, while the returns of cattle attacked with disease showed a diminution of numbers that bore testimony to the usefulness of those restrictions.

The Duke of Marlborough complained that foreign cows were imported into London, and were distributed throughout the metropolis without any check.

Lord Granville could not admit that inconvenience had not arisen from the prohibition of cattle transport by railway, but it was intended to continue the present restriction after the 25th inst., until a permissive Order in Council could be issued. The Government intended to-morrow (Wednesday) to introduce in the other House a Bill with the object of extending the powers of the Privy Council.

In the House of Commons,

In answer to a question by Mr. Chambers in reference to the difficulty of getting rid of manure and offal in London,

Mr. T. G. Baring said there was no doubt that great complaints had been made in different parts of the metropolis by the contractors for the removal of refuse that they were unable to remove it in consequence of the orders, or rather the notices, published by various local authorities. The Secretary of State yesterday received a letter from the Board of Works, Holborn district, containing the report of the Medical officer of that district, in which he stated that in consequence of the interpretation put by the contractors and others upon those orders they were unable to remove any of the dirt and refuse of the stables in the metropolis, and that even, which was hardly credible, they declined to remove the street sweepings of the metropolis, because there might be some horse dung mixed up with them. The difficulty appeared to have arisen principally from a misconception of the orders issued by the local authorities. He had obtained the orders of those authorities of which complaint was made, and found that their terms by no means prohibited the introduction into their district of any such articles as were not likely to propagate infection. It seemed to be quite untenable that any local authority should regard the removal of all refuse in the metropolis as likely to propagate the cattle plague, when the week before last there were only fourteen cases of the cattle plague in the whole district of the Metropolitan Board of Works, and last week there were only twelve. The Secretary of State had suggested to Sir J. Thwaites, the Chairman of the Metropolitan Board of Works, that the latter should communicate with the local authorities of those counties whose orders were supposed to prevent the removal of those materials from the metropolis.

Colonel North moved for the appointment of a Select Committee to inquire into the mortality in the troops in China, the causes which led to it, and into the conduct of those departments of the Government whose duty it had been to administer to the wants of those troops, prefacing his motion by a brief statement, and spoke in terms of warm praise of the conduct of the Medical Department, and especially of Dr. Saunders, Surgeon to the 9th Regiment.

Sir H. Verney seconded the motion.

The Marquis of Hartington, in acceding to the motion, said it was the anxious desire of the War Office that the causes of this deplorable calamity should be strictly inquired into.

The motion was then agreed to.

On Wednesday,

Mr. Adam obtained leave to bring in a Bill to amend the Acts relating to Lunacy in Scotland, and to make further provision for the care and treatment of lunatics.

Sir G. Grey obtained leave to bring in a Bill to amend the Act of 11 and 12 Victoria, cap. 107, to prevent the spreading of contagious or infectious disorders among sheep, cattle, and other animals.

BLACK OR BLACKENED SKIN?

(*From a Correspondent.*)

About the latter end of 1857 two female children, one apparently about twelve and the other eight years of age, were found on Fraser's Island, at the mouth of the Brisbane, on the eastern coast of Australia. When found they were both *black*, but when washed they became white, except in parts which remained as irregular black patches, scattered about the skin. The black appeared to have been rubbed in, the white skin seemed natural, and the theory was that they had been shipwrecked on the island, and so marked by natives. The younger turned out clever and industrious, the elder proved a complete idiot, and was sent to the Parramatta Lunatic Asylum. Mr. Rowling, now a distinguished student of King's College, was then Assistant Medical Officer of the Institution, and it occurred to him that the question whether the girl was of black or white origin might be determined by the odour which is peculiar to black races, whether African or Australian. He therefore encouraged this girl to dance until she was in a copious perspiration, when the characteristic perfume, which in Mr. Rimmel's catalogue would be styled "the bouquet d'Afrique," was very easily recognised by every one present. Some time after this the poor girl died, and Mr. Rowling preserved some of the skin. After coming to England he asked Professor Beale his opinion, who told him that the skin alone would decide whether the pigment was natural or rubbed in. The skin has recently arrived from Australia, and Professor Beale has determined by microscopical examination that the pigment is natural; showing Mr. Rowling to have been correct in his judgment founded on the African odour. This disappearance of pigment will not so much surprise any one who has seen much of the West Indian negroes, especially the turtle fishers.

MR. FARNALL AND THE LONDON GUARDIANS.

(*From a Correspondent.*)

The active part taken by Mr. Farnall—the Poor-law Inspector of the Metropolitan district—in connection with various schemes for the abolition of the existing bodies of Poor-law Guardians in the Metropolis, the erection of district Infirmaries under the auspices of the "Association for the Improvement of the Infirmaries of Workhouses," and other matters which have lately received much attention in the columns of the daily newspapers, has not been without fruit. We understand that at least one Metropolitan Board of Guardians has addressed the Poor-law Board with the object of ascertaining whether the proceedings of the Inspector are in accordance with the views of the Board.

The Cold Blast.—The present very inclement and most changeable weather is telling seriously on the aged of both sexes, more particularly females, if we may judge from the obituary column of the *Times*, where, on Monday, Tuesday, and Wednesday last, the deaths of 19 ladies and 8 gentlemen were recorded, all of whom had reached 80 years and upwards. The united ages of the 19 ladies amounted to 1614 years, giving an average of 84 years and rather more than 11 months to each. The oldest was 95, and the youngest 80 years of age. The united ages of the 8 gentlemen amounted to 659 years, giving an average of 82 years and upwards of 4 months to each. The oldest was 85, and the youngest 80 years of age. Our country friends will perhaps be surprised to hear that our parks and squares were covered with snow on Wednesday morning, which continued to fall up to 1 o'clock.

House of Industry Hospital, Dublin.—Sir Dominic Corrigan, Bart., having been compelled by the pressure of other Professional engagements to resign his post as Physician to the above Hospital, the election of a Physician in his stead has been fixed for Thursday, the 22nd inst. By Sir Dominic's resignation, Dr. Banks, King's Professor of the Practice of Physic, becomes the Senior Physician to the Hospital, and Drs. M'Dowel and Gordon, of course, obtain a step. It is generally believed that Dr. Lyons will be the successful candidate for the vacancy so created.

Cattle Plague on the Continent.—Rinderpest is said to be raging at Merxem, near Antwerp. It has also broken out in Russian Poland, but a few hours' distance from the Prussian frontier.

REVIEWS.

Report on the Sanitary Condition of the City of Edinburgh, with Relative Appendices, etc. By Henry D. Littlejohn, M.D., F.R.C.S.E., Medical Officer of Health for the City. Edinburgh: Colston and Son. 1865. Pp. 195.

Dr. Littlejohn's report manifests the pen of a master of sanitary science With unsparing but skilful hand he removes the bandages that have hidden from view the festering sores which have been undermining the social and moral health of the northern metropolis,—the classic seat of many a historical tradition, and the favourite abode of philosophy and learning. Nothing can well be more complete in its way than this extensive and elaborate statement. No subject of importance to a discussion of sanitary relations is omitted from consideration, and the whole of the author's remarks are savoured with an amount of good, sound common-sense, and exhibit a freedom from prejudice, which are rarely met with among writers upon subjects connected with public hygiene. Most of these—and we do not exclude here even our own Metropolitan Health Officers—have some particular hobby or other which, although they may endeavour to cover it up, so evidently influences the advice they tender as to dispose public bodies with whom they should consult for the public benefit, to trust less implicitly in their direction than they would probably be disposed to do were the opinions they express more logically deduced, and the anticipated successful issue of sanitary improvements more modestly put forward. When, for instance, a public body is told by their Medical adviser that the carrying out of certain works for improved drainage, closet accommodation, and such like, will inevitably result in a reduced death-rate, and, from a variety of circumstances, such as the outbreak of an epidemic sickness, or an influx of a more pauperised population, or overcrowding consequent on the demolition of dwelling-houses, or from an increase in the price of provisions, such a prophecy fails in its fulfilment, the failure is certain to bring into disrepute indisputable sanitary improvements in the minds of men who have not been taught to make the necessary allowances for all these possible contingencies. To health officers who thus commit themselves we heartily recommend the study of Dr. Littlejohn's report. One important lesson is taught in it, and this is the inapplicability of any one system to the abatement of any one sanitary fault when observed in different circumstances. Let us illustrate this—somewhat out of its order, indeed—by what our author tells us about the absence of "conveniences" in the houses of certain parts of Edinburgh. He maintains that the present arrangement by which they are excluded from the many-storied houses in the old town of Edinburgh is the best that can be adopted, and that to force the erection of "conveniences" upon the owners would result in the most deplorable consequences. "In England, where the poorest houses are self-contained and necessarily small, with a court behind in which the convenience is placed, the system works admirably; . . . but the houses in the densely-peopled districts of our Scottish towns are not supplied with such courts, and were conveniences placed outside the houses, from the large population which would use them, they would closely resemble those which are scattered throughout the city for the use of the public. . . . What is intended as a public benefit is very apt to become a nuisance to the surrounding neighbourhood. If, however, as has been proposed, they were placed on each flat of our tall 'lands,' all the evils already referred to would exist in a confined atmosphere and close to the sleeping-rooms of our crowded poor." Dr. Littlejohn is prepared to support as the best system of cleansing, not only for Edinburgh, but for other large towns, that which consists in the deposit of all refuse and filth not passed into water-closets, upon the surface of the streets, from which it is removed by the scavenger. What would some of our sanitarians say to this? and yet no one of them, perhaps, is in a position to maintain that, so far as the old town of Edinburgh is concerned, Dr. Littlejohn is not right.

Edinburgh for sanitary purposes naturally divides itself into three parts—the old town, the new town, and the southern suburbs, the first being the grand focus of pauperism and wretchedness, the second of respectability and comfort, while the last is more mixed in the character of its population. One of the most interesting tables in the book is that which exhibits the mortality per 1000 in each of these respectively. In the new town in 1863 it was only 18·3 per 1000, in the old town 30·73, and in the southern suburbs 20·36.

There are some interesting tables at pp. 43—45, together with some plans showing the influence of elevation upon the death-rate generally, and that from the fever epidemic of 1847-48 and the cholera epidemic of 1848 particularly. Arranging the entire city in terraces, each of 50 feet elevation from the sea level to an elevation of 450 feet, an apparent result is, that while the death-rate in the three lower terraces stands at from 19·56 to 25·85, and that from fever at from 3·87 to 8·28, and that from cholera at from 1·12 to 1·86; the death-rate on the terraces from 150 to 300 feet elevation has for a total from 26·12 to 29·73, for fever from 30·64 to 69·11, and for cholera from 3·61 to 5·88. This would in the last-mentioned disease would appear to invalidate Dr. Farr's well-known law. But the explanation is no difficulty to any one that is acquainted with the ins and outs of the city of Edinburgh. It is at elevations of from 200 to 300 feet that the poor population principally resides, and so far the advantage of site is over-ridden by the pauperism of such districts as the Grassmarket, Cowgate, etc. Taking one poor district, however, tolerably uniform in the character of its population, the law of elevation death-rate is distinctly seen in operation. Dr. Littlejohn selects the district of St. Giles, where the following table, an abstract of that given at page 45, tells its own story:—

Height above the sea, in feet.	Total Death-rate per 1000 in 1863.	Fever, 1847-8.	Cholera, 1848.
400—450	17·54	0	0
300—350	21·31	17·38	6·73
250—300	26·31	89·75	10·36
200—250	35·	184·55	19·92
150—200	46·08	4·6	4·6

The population living beneath 150 feet elevation is very small—only 217 persons—so that the percentages for this portion of the district can scarcely be considered in the general result.

Edinburgh is not a manufacturing town, so that the principal sources of trade nuisances lie in the evolution of smoke from brewing, printing, and furniture works, and of this the author complains bitterly, on the ground of its compelling the residents in the neighbourhood of such works to deprive themselves of a proper ventilation of their houses by the closure of the windows of their dwellings. Free ventilation of houses in Edinburgh is the more necessary on account of the system of drainage adopted, which is calculated at all times to promote offensive and dangerous emanations into the houses. Every house-drain, where house-drains are present at all, is constructed of rough masonry, such as, under the best of circumstances, is calculated to impede the flow of sewage matters, and soon becoming leaky, permits the saturation of the soil about and in the basement of the house. Moreover, every house-drain has a cesspool attached, and intervening between it and the sewer, the more solid matters collecting in the former, while the sewer only receives the liquid overflow. A dip-stone is provided in the cesspool to prevent, so far as it will, the incursions of rats and the access of gases from the sewer to the house. From circumstances which are explained, these cesspools are very apt to be choked up with excrementitious matters, and their cleansing to be neglected for years together.

Dr. Littlejohn gives a sad account of the condition of the cowsheds, which appears to be worse now than the condition of the London cowsheds was prior to the time when they commenced to be licensed, and thus became amenable to the sanitary requirements of Medical Officers of Health. From cowsheds to diseased meat the step is a short one, and as this is a subject which interests us in London very much at the present time, we feel justified in quoting pretty largely from Dr. Littlejohn's remarks upon it. "It is generally urged by the advocates for the traffic (in diseased meat from cowsheds) that the flesh in question is not unwholesome, and that to deprive the poor of this as an article of diet would seriously diminish their means of substance. The question, however, of the wholesomeness and unwholesomeness of the meat of diseased animals can only be settled in two ways—first, by the common sense of the public; and second, by a large induction carried on for a series of years, during which a general careful market inspection is maintained over the country. . . . . No doubt we cannot appeal to cases of sudden disease caused by the eating of such flesh—cases of so-called poisoning. But we must remember that the stomach, when

in a healthy state, can resist the actions of animal poisons, and that it is the continued use, day after day, of meat from diseased animals that we should expect to be attended with marked results. . . . . But I hold myself warranted in attributing to its use many of those instances of indigestion which come on so unexpectedly, characterised by dulness, lassitude, and inability for mental exertion, and which resist the usual remedial treatment."—P. 59. We think, although agreeing with Dr. Littlejohn as to the probability on *à priori* grounds of this connexion, that we ought to know on what grounds of observation he bases a statement of opinion so decided as this. He is usually very cautious, and what we have been long asking for is proof of this asserted fact. Dr. Littlejohn would be conferring a real benefit on sanitarians if he would put into print the facts which warrant him in attributing such cases of indigestion to the use of diseased meat. We quite agree with Dr. Littlejohn that in obscure sanitary, as in therapeutical indications, a reasonable probability should suffice for our guidance, and that we need not and ought not to wait until absolute proof of any preliminary question is obtained; but still the establishment of such preliminary question should be sought after with equal earnestness. Dr. Littlejohn then advocates a strict supervision of the traffic in meat, and believes the best results will follow if our chief towns are in earnest in insisting upon a sounder quality of beef. "The rearer of stock will be more careful in selection and in up-bringing as regards pasturage and exposure. The cattle dealer will protect his drove with increased caution against the admission of infected animals, and will exercise the sharpest scrutiny in approaching a crowded market, feeling assured that the contact of a single diseased animal may imperil his gains for many a season. . . . . Lastly, our dairymen will be still more careful in their choice of cows; while, as we have seen, there will be year by year fewer chances of mistake in their purchases. They will feel the necessity of improving the condition of their dairies as to cleanliness and ventilation, as well as providing suitable accommodation for any infected animal, thus securing the remainder of their stock from disease."—P. 61.

The following extract from Dr. Littlejohn's final observations will conclude our review, and we quote them as manifesting a philanthropic spirit which cannot too sedulously be infused into all our sanitary work. To the honour of our Profession it may with truth be said that it is in such a spirit that this work has been pursued, we believe, without exception, by modern sanitarians, from Dr. Combe to the present labourers in the field which he so successfully opened for cultivation. "It is cheering to reflect that all measures which have for their object the improvement of the sanitary state of communities have a corresponding influence in raising their moral and social condition. On all sides, in the most degraded localities, physically and morally, we find ourselves surrounded by religious agencies, busying themselves in attending to the higher interests of the masses in the most devoted manner and at great outlay. Bitter complaints have been made as to the poverty of the results obtained by such multifarious and strenuous endeavours. This need be no wonder, when we reflect on the overwhelming disadvantages under which the missionary and the philanthropist have to contend. Our poor are so lodged that to inhale the atmosphere in their houses is enough to produce a lethargic depression, to escape from which is but to be exposed to the temptation of the High-street and Cowgate. With no comfort at home, the poor labourer is forced to go elsewhere for enjoyment. To his sleeping-place he returns to find himself in a crowded apartment, where there is no attempt to maintain the ordinary decencies of life. With so many and varied proclivities to vice in all its forms, it is a heartless task to talk to such a one of righteousness, temperance, and judgment to come. The agencies employed ought, in my opinion, to be more varied; and woman might be enlisted in the cause with great advantage. I have found the missionaries of all denominations nobly discharging duties to the poor of Edinburgh which would be more fitly rendered by the other sex. By means of female assistance, the houses of the poor would be rendered more comfortable and the food of the working classes would be more economically and better prepared. There would be less temptation to seek the pleasures of the alehouse, and lessons of thrift would be imparted in the management of the household that would pave the way for the higher ministrations of the ministers of religion. In attempting to raise the poor in our towns from their degraded position, we must attack that which lies on the surface. Until the dwellings of the poor are rendered more habitable, and the poor themselves are taught the wholesome lesson of outward cleanliness, it is not to be expected that their deeper nature can be effectually stirred."—P. 120.

The Modern Practice of Photography. By B. W. Thomas, F.C.S. London: Harrison. 1866.

The value of the art of photography to Medical and scientific men as a means of recording the experience of the eye, for the after use of themselves and others, is now so fully appreciated, that we are glad to be able to speak favourably of a small treatise on its practice by Mr. Thomas, and to recommend it to those of our readers desirous of taking up the art. As far as can be, the author seems to have ensured successful results to the amateur who carefully follows his directions. The particulars of each step in the ordinary process are given in the form of a series of short essays. The theory of the subject is purposely omitted.

GENERAL CORRESPONDENCE.

PEREIRA'S MATERIA MEDICA—THE DOSES OF MEDICINES.

Letter from Dr. Farre.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have not, except on one occasion, replied to the reviews of "Pereira's Manual of Materia Medica;" because reviews, if fair, are frequently beneficial by their suggestions both to the author or editor and to the reader; but I think I ought not to pass over in silence such an attack as Dr. Bree's, because it assumes the principle of the Editor's responsibility for the contents of the work. As Dr. Bree finds fault with the posology of the Manual, and with the editors whom he considers to be answerable for the posology, I beg to state that whatever is faulty in that part of the work must be laid to the charge either of Dr. Pereira or of myself. I have, indeed, in much of the work had the advantage of the very able assistance of Professor Bentley and Mr. Warington, the former of whom has been prematurely elevated by Dr. Bree, F.L.S., to the Presidency of the Linnean Society, but neither of these gentlemen took any part in the posological table, to which alone Dr. Bree refers. Dr. Bree has alluded to the disappointment felt at the absence of a posological table from the British Pharmacopœia. He thinks that a table given in the Manual by one of the editors of the Pharmacopœia should have been unexceptionable; and as it is in his opinion very faulty, he evidently thinks that if the Pharmacopœia had contained a posological table, it might have been little more satisfactory. I think so too, not only on account of the different opinions that exist with respect to doses, but principally for the following reason:—

The Pharmacopœia does not teach therapeutics, but only defines and describes certain articles which have been selected as especially deserving of use in Medicine, and certain preparations and compounds of these which are considered to be the best forms for their administration. Doses belong to therapeutics; they are the quantities of these drugs, or of their preparations, which are administered in certain diseases to produce certain effects. The doses will vary not only with the nature and stage of the disease, and with the effects intended to be produced, but also with the age, sex, strength, and constitution of the patient, and with the temperature and climate and other externals to which he is exposed, so that the dose which is proper in one case may be highly improper in another. In posological tables the dose is generally supposed to be such as is suitable for an adult; and when a Medicine is used for two or more different purposes, the dose is usually given in each case. More than this is seldom attempted, except a limited range of doses between what are roughly called the maximum and minimum doses; probably, however, few Medical Practitioners restrict themselves to these extremes. The range can only be considered the average range of doses. Far smaller doses than what are commonly called minimum doses are often useful, especially if given in combination with other ingredients, while larger than maximum doses are occasionally required; but if these were included in the average range they would make it useless as a guide. These objections apply to all posological tables, but especially to an authorised one. A posological table is probably most useful when it has

no authority beyond the reputation of its author, and when it does not interfere, except as a guide, with the liberty of the Practitioner; but an authorised table could hardly fail to be felt as some restriction, and would have a tendency to limit original investigation.

A treatise on Materia Medica and therapeutics, by entering at length into the circumstances in which Medicines are employed, does away with most of the difficulties I have mentioned; but a table must always be an insecure guide when consulted alone.

I have been led into making these remarks by Dr. Bree's allusion to what I believe to be the judicious omission of a posological table in the British Pharmacopœia. I will now reply *seriatim* to his charges.

He has selected eighteen or rather twenty-four articles, of which he considers the doses in the posological table to be too large. I reply to this that the work in question only bears my name as the chief editor; but that it is still "Pereira's Manual of Materia Medica," and in order that it should continue to be so I have stated in the preface that I have avoided, as far as I could do so, interfering with the opinions of the author. Now the doses of Medicines are certainly examples of the author's opinions, and as such I have generally left them untouched, except when the strength of a preparation has been altered, or for some other special reason. Hence my doses are for the most part merely repetitions of Pereira's; and to such Dr. Bree's objections are rather late. The doses have been long before the world, and Dr. Bree's objections would have been better made while the author was living.

Of the articles selected by Dr. Bree, the minimum doses of twelve—namely, ammoniæ carbonas, argenti oxidum (not oxydum), atropia, capsicum, extractum aconiti, extractum belladonnæ, extractum hyoscyami, liquor morphiæ hydrochloratis (now half the strength of P. L.), lobelia as an emetic, tinctura colchici seminis, vinum colchici, and tinctura opii—are those of Pereira.

Extractum aconiti is now more carefully prepared and is a better preparation than that of the P. L., but the latter was generally inert, at least in one-grain doses.

Lobelia.—Dr. Bree says lobelia ought never to be given as an emetic in spasmodic asthma (Manual, p. 330, 331). I have merely followed my author. The dose of the tinctures, Dr. Bree says, is dangerously large. If he refers to Manual, p. 331, or to Pereira, vol. ii., part 2, p. 13, he will see that the dose of the tinctures, as an emetic and anti-spasmodic, is stated to be from one to two fluid drachms, repeated every two or three hours till vomiting occurs. It is true that a smaller dose is named as an expectorant; but what does Dr. Bree think of Pereira's recommendation, that for children one to two years old the dose is from ten to twenty minims?

Tinctura Colchici Seminis, Vinum Colchici.—Dr. Bree incorrectly quotes the maximum dose of both of these preparations, which he says has been known to cause death, as fl. drs. ij. I have followed Pereira in giving fl. drm. j. as the maximum dose of the wine. The maximum dose of the tincture only I have given as two fluid drachms. I rarely myself give colchicum to produce purging, but Pereira, after mentioning one drachm as the ordinary maximum dose, says, "I have repeatedly given two drachms of the tincture at a dose without any violent effect." See also Dr. Barlow's recommendation of drachm, drachm and a half, and two drachm doses of the tincture night and morning till it purges briskly (Manual, p. 195).

In three other instances my minimum dose, which Dr. Bree considers too large, is either less than Pereira's, or, at all events, not greater.

Liquor Strychniæ.—I have given min. vi. = gr. $\frac{1}{20}$ of strychnia. Pereira says, "the dose of strychnia or its salts is at the commencement $\frac{1}{16}$ or $\frac{1}{20}$ of a grain." I rarely begin with less than $\frac{1}{20}$, but cases undoubtedly occur where much less than this, even $\frac{1}{100}$ of a grain has caused temporary spasm. I have alluded to such cases in Manual, p. 319, but they are exceptional, and need not influence practice.

Aloe Barbadensis, Aloe Socotrina, gr. iij. to gr. v.—Pereira says, "The ordinary dose is gr. v." I have given both kinds largely alone, and find that three grains produce in from twelve to twenty-four hours one, two, or three evacuations. I consider it better to increase the aloes than to add extract of nux vomica, except in cases of great torpor of the bowels such as occur in some forms of paralysis.

In five cases only, if in so many, does my minimum dose exceed that of Pereira.

Acidum Hydrocyanicum Dilutum, min. iij. to min. vij.—Pereira says, "The dose of the acid of the London College may be taken at from two to seven minims;" and again, "I generally give from three to five minims of the dilute acid three or four times a-day." Some persons are unfit to take hydrocyanic acid in any dose; but I have seldom given less than four minims, and certainly never saw "symptoms of poisoning" from three minims, and feel pretty sure that no serious symptoms could arise from such a dose, unless the acid was altogether unsuitable.

Pilula Colocynthidis et Hyoscyami, gr. viij. to gr. xx.—Dr. Bree finds two grains usually sufficient, and four always so, and asserts that Dr. Christison's practice was the same as his own. My experience is somewhat different; and Dr. Christison, in his Dispensatory, gives as the dose, not 2—4, but 5 to 15 grains; and Pereira did the same.

Extractum Opii, gr. $\frac{1}{2}$ to gr. ij.—The minimum dose in Pereira is gr. $\frac{1}{4}$.

Ipecacuanha (as an expectorant), gr. i.—Pereira says, "Not exceeding one grain."

Zinci Sulphas (as a tonic), gr. ij. to gr. x.—Pereira gives one grain as the minimum dose, and says that he has not found it of much value in epilepsy or chorea. I find it very valuable in chorea, but I seldom begin with less than three grains, and should think that the use of one grain would be loss of time. I generally, but not always, find ten or twelve grains sufficient.

I believe, then, that the only cases of any importance in which I can be said to have substituted a larger minimum dose for a smaller one of Pereira are, extractum opii, pilula colocynthidis et hyoscyami, and perhaps ipecacuanha. I admit that a quarter of a grain of the extract would have been better, and I am willing to say the same of ipecacuan if by that means I can appease Dr. Bree.

Dr. Bree will, however, perceive from the foregoing observations, that if he should at any time put his threats into practice he will be virtually plucking the great pharmacologist whose work I have had the pleasure as well as the labour of editing. Apologising for the length of this reply,

I am, &c., Fred. J Farre, M.D. Cantab.

St. George's-road, Pimlico, March 14.

THE NURSING IN THE METROPOLITAN WORKHOUSES.

Letter from Mr. E. Hart.

[To the Editor of the Medical Times and Gazette.]

Sir,—The estimate which you give of five thousand pounds for paid nursing of the pauper sick and inmates in the Metropolitan Workhouse Infirmaries in your last number affords in itself a very striking illustration of the truth of the statements which you seem to consider that it invalidates.

In the London Hospitals it would be considered necessary to supply for the 6000 Infirmary cases in the London Workhouses nurses who would cost, at the same estimate which you admit as a basis, £30,000. Besides these 6000 sick and disabled, there are 1800 idiots, imbeciles, and epileptics, and 10,500 old and infirm, of whom about one-half are in the Doctor's hands, and a small army of nurses are needed for these.

But no mere money estimate of the disparity could give any idea of the shocking barbarities incidental to a system of pauper nursing, or the cruelty of that lack of night nursing which is found in most, if not all of the metropolitan Infirmaries. Pauper nursing is, as the archbishop described it, a system of pure wrong-doing from beginning to end. I am, &c.

69, Wimpole-street, March 27. Ernest Hart.

FEES FOR PUBLIC VACCINATION.

[To the Editor of the Medical Times and Gazette.]

Sir,—Through the medium of your journal we beg to call the attention of the Poor-law Medical officers and public vaccinators to a meeting, held by the Medical officers of the Fulham Union on March 13, to consider the proposed Vaccination Bill. At this meeting it was proposed:—

"That a fee of two shillings and sixpence, and three shillings and sixpence, should be substituted for one shilling and sixpence, and two shillings and sixpence, in consequence of the responsibility involved, and the trouble necessitated by the several certificates required by the proposed Act.

"That in successful re-vaccination the same fee should be

paid, inasmuch as it will involve more trouble than primary vaccination, and in many instances such re-vaccination will be unsuccessful, and therefore cannot be charged.

"That the appointment of a public prosecutor should be made compulsory."

Letters expressing these resolutions were forwarded to Messrs. Bruce and Baring, and a petition was drawn up for presentation to Parliament, to the Lower House if time permitted—if not, to the Upper House. At the same time it was felt that this movement, to carry weight, should be a combined one, and with this view that meetings should be held by the Medical officers of, at least, all the metropolitan districts, where either separate petitions should be forwarded to Parliament embodying the opinion of the Poor-law officers, or that our petition should be forwarded to the next Union for signature, and from thence forwarded in turn to the next adjoining, till the round of the metropolitan district is made.

We meet again on March 28, at 12 a.m., and shall be glad to receive any suggestion from the Medical officers of other Unions. We are, &c.

The Medical Officers of the Fulham Union.

52, King-street East, Hammersmith, W., March 20.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, February 7, 1866.

Dr. Barnes, President.

The following gentlemen were elected Fellows:—Messrs. J. C. Burrows, Brighton; Robert Jones, Manchester; J. J. Phillips, Guy's Hospital; Samuel Tilley, Rotherhithe.

The President announced that several important responses had been received in answer to the invitation to aid the approaching exhibition of instruments. Dr. Radford, of Manchester, had forwarded a very large and valuable collection. Dr. Hugenberger, of St. Petersburg, promised contributions from St. Petersburg and Moscow; Prof. Ninon, from Denmark; Drs. Laggati and Casati, from Italy; and Dr. E. A. Meissner, Secretary of the Obstetrical Society of Leipzig, offered the cordial aid of that Society.

Dr. Meadows related two cases of

AMPUTATION OF THE CERVIX UTERI.

In both the operation was performed for *allongement* of the uterus, with more or less complete procidentia. In one case the patient was 23 years of age, single, and had suffered from procidentia three years. Treatment of various kinds, by pessaries and otherwise, had been tried without any benefit. The uterus measured four inches and three-quarters in length, the length of the cervical cavity being fully two inches and a half. The *allongement* was limited to the infravaginal portion of the cervix. There was no rectocele or cystocele. About an inch and a half was removed by means of the écraseur, the patient making an excellent recovery. In the second case the patient was 28 years of age, married, and had had two children and two abortions. She first suffered from procidentia after the birth of the second child, and for several years the uterus has been outside the vulva. On examination, it was found to measure no less than five inches and a half, the uterus being also much thickened and indurated. There was neither rectocele nor cystocele. About two inches of the cervix was amputated with the écraseur, but so difficult was it to cut through the thick indurated cervix that no less than two wire ropes and three chains were broken before the operation was accomplished. The uterine wall at the seat of amputation measured fully an inch in thickness. The patient has since made an excellent recovery, and in both these cases the uterus has continued so high up that there is every reason to hope that a cure will be effected.

Dr. Barnes related two cases of

SUDDEN DEATH DURING LABOUR.

In one case, that of a primipara, maniacal excitement came on during the dilatation of tha cervix. Chloroform was given to induce moderate anæsthesia, so as to facilitate the application of the forceps. Gentle traction, aided by uterine contraction, effected delivery in half an hour. The placenta was cast. The patient maintained a good pulse; she spoke deliriously at times, but also rationally afterwards. Death occurred almost suddenly ten hours after delivery. No post-mortem examination was held. He (Dr. Barnes) did not think death was owing to the chloroform, but was disposed to attribute it to the nervous shock which was manifested before the chloroform was given. The other case was more clear. The woman was in her seventh labour. Convulsion, stertor, and syncope set in before the expulsion of the child. The child was expelled alive. The mother died in twenty minutes afterwards. A small clot, quite recent, was found in the left thalamus opticus; and another, larger and of a dissecting character, in the left crus cerebri. The abdominal and pectoral organs were healthy. The record of such cases Dr. Barnes considered to be exceedingly important, as supplying illustrations of the fact that death during labour might occur independently of any fault on the part of the Practitioner.

Mr. Benson Baker read a paper on

ABORTION AND MENORRHAGIA DEPENDENT UPON LEAD-POISONING (WITH CASES).

The author observed that this subject had received little attention in this country. In Dr. Graily Hewitt's work on the Diseases of Women there was an allusion to it, and reference to a paper in the *Archiv. Gén. de Méd.* This was all the author had been able to learn from the obstetric literature of this country; consequently he had availed himself of M. Paul's paper, of which he had made an abstract. The author's cases and observations afforded concurrent testimony of the effect of lead-poisoning in the woman. The lead poison killed the fœtus in utero, and then abortion took place. Not that abortion was dependent upon the action of lead on the muscular structure of the uterus. After abortion took place, persistent menorrhagia was often found to exist, and which would not yield to ordinary treatment, but was cured by treating the patient for lead-poisoning. With respect to the mortal effects on the spermatozoa, the woman being free from lead taint, cases had not come under his observation, although M. Paul affirms that the mortality to the fœtus is equally great whether the father or the mother be permeated with lead poison.

Dr. Sansom read a paper

ON THE ANÆSTHETIC PROPERTIES OF THE BICHLORIDE OF CARBON.

The author considered that this new anæsthetic would be of great value to the Practitioners of obstetrics. Very much as to its constitution and properties had yet to be determined, and more could not be attempted at present than the presenting to the Society a few scattered hints and observations. Dr. Sansom claimed to be the first to describe this body as an anæsthetic in his book on Chloroform, published in May, 1865. It was then called tetrachloride of carbon; it has since been determined to be a bichloride, and Sir James Simpson has suggested for it the convenient term chlorocarbon. The fluid possesses many of the characteristics of chloroform; its odour, however, is more pleasant and less pungent; its density is slightly greater, and its volatility less. It takes a longer time to induce anæsthesia. On the 4th of July, 1864, the author, in conjunction with Dr. John Harley, tried the effect of the inhalation of the new anæsthetic upon a frog. The circulation in the web of the foot was observed by the microscope throughout the process. It was seen to cause a considerable amount of irregular muscular action, and a very decided contraction of the capillary arteries. A state of torpor was then induced for three-quarters of an hour, but reflex action was not wholly abolished. Experiments were made upon dogs and guinea-pigs. In these there was considerable muscular agitation at the outset. Deep anæsthesia was slowly produced, but, once induced, continued very profound until death. The post-mortem signs were, complete collapse of the lungs and distension of the right side of the heart, so that the organ assumed a globular form. The sensations produced by the inhalation of the bichloride of carbon are at first very agreeable: there is a pleasant sensation of warmth, and, as the author thought, a freedom from the vertigo such as is produced by chloroform. Dr. Sansom has employed it in cases of midwifery. It was readily inhaled: it mitigated the pains, and in one case almost completely abolished them; it did not interfere with consciousness. In reviewing the relative merits of the two anæsthetics, the author considered (1) that chlorocarbon has the advantage over chloroform in its being inhaled with greater comfort; it is not susceptible of decomposition with the formation of deleterious chlorine compounds; and its cost will probably be considerably less. Being much less volatile than chloroform, it will probably be best administered by pouring it upon a sponge wrung out in hot water. (2) It is,

during its early stage of action, a powerful stimulant to the circulatory system. It will probably be especially valuable in midwifery, for it abolishes pain without affecting consciousness, and its tendency is certainly to increase muscular action. (3) It is not advisable to induce deep narcotism by means of this agent. Its profound effects are very persistent, and it is eliminated from the system slowly.

Dr. Greenhalgh stated that two and a half months ago he requested Dr. Sansom to administer chloroform to a lady during the removal of a large polypus from the uterus. She was extremely anæmic and feeble, from large and frequent losses of blood occurring over a period of two years and a half. She had a damaged heart, and a profuse sanious and offensive discharge from the vagina. Shortly after the administration of the chloroform, and before complete anæsthesia was induced, her pulse began to falter, her breathing became embarrassed, and her countenance livid. Dr. Sansom, without delaying the inhalation, substituted ether with the best results. Dr. Greenhalgh begged to ask that gentleman if he had adopted a similar practice in other cases with good effects; and if so, whether he considered that the vapour of ether could be regarded as an antidote to the evil consequences of chloroform, and whether he could offer any physiological explanation of how such beneficial effects are brought about.

Dr. Sansom replied that it was his constant practice to administer ether if in any case chloroform seemed to produce a depressing effect. Indeed usually, in prolonged operations, he thus maintained the anæsthesia. The substitution, or rather addition, was never attended by any return of sensation. He always found that the plan answered admirably: it certainly restored the force of the circulation. It was perhaps premature to explain the *rationale* of the procedure; but he would remark on the singular circumstance that whereas chloroform tended to empty the blood-corpuscles, ether tended to distend them—chloroform reddened the blood, and ether darkened it. There thus existed, as it were, a natural antagonism amongst agents of the anæsthetic class. Again, they influenced differently the sympathetic system. Ether would cause contraction of the heart and arteries even during the period of the influence of chloroform, and the bichloride of carbon did the same in a marked degree.

Dr. Snow Beck read a paper

ON ENLARGEMENTS OF THE UTERUS WHICH FOLLOW ABORTIONS, PREMATURE OR NATURAL CONFINEMENTS (WITH CASES).

The author remarked that these enlargements had been long recognised by pathological anatomists, and quoted some microscopical observations by himself, and communicated to the Medical Society of London in 1851, which showed that the pathological condition essentially consisted in an enlargement of the muscular tissue of the uterus, without the presence of any inflammatory or heterologous deposits. The causes were considered to depend chiefly upon—(1) a want of complete and persistent contraction of the uterus, which permitted an increased circulation of blood in the gravid organ, and interfered with the changes which took place after parturition; and (2) on the partially developed state of the uterine tissue in abortion, which appeared to be unfavourable to the development of those changes necessary to its complete reduction in size. The enlargement of itself gave rise to few and comparatively slight symptoms, unless it existed to such an extent as to be felt as a tumour in the hypogastrium; but it rendered the patient liable to profuse hæmorrhages, coming on suddenly and without appreciable cause. These enlargements might exist for many months, or even for some years, without any symptoms of importance; but from the recurrence of the catamenia, or other causes, congestion of the enlarged organ was gradually induced; or congestive inflammation, which may be either of the whole or of any portion of the uterus, might take place, the usual symptoms of uterine affection being then present. Amongst the subsequent changes which took place were anteversion and retroversion, with more or less bending of the organ, which lesions interfered with subsequent impregnation. But a more important change was a gradual hardening of the organ, which reduced it to an indolent state, and rendered it very rebellious to treatment. The modification of the symptoms thus produced was shown by the cases recorded, and the physical examination of the organ detailed. The author found that in these cases the uterus was equally enlarged, smooth, pyriform, the cavity enlarged, and the orifice open. The sound readily passed to an extent varying from three to five or six inches. When inflammation was added the organ became tender, the arteries were felt to beat with more or less force, and the interior became very sensitive. Subsequent and various alterations were made; the lips became enlarged, often lobulated, projecting into the vagina, red and raw in appearance, and bounded by a distinct line, which marked the division between the mucous membrane of the vagina and that of the uterus. It was this condition of the organ which had been so frequently described as ulceration, although no such morbid change actually existed. With respect to the treatment, various cases were recorded showing the importance of injecting the cavity of the uterus with astringent lotions, and the safety with which it could be done, provided the actions of the uterus were perfectly quiescent. The cavity of the uterus being enlarged, and the orifice open, impregnation readily took place, and the physiological changes which followed were decidedly the best means of restoring the organ to the healthy state. Congestion or inflammation, when present, would have to be met by the usual means; and when the uterus was in the hardened, modified condition, in addition to the ordinary means of treatment, it would require some local stimulant to rouse the local action, and enable the other remedies to act. For this purpose cauterising the lips with potassa cum calce had been generally employed.

The President observed that he continued the practice of injecting a solution of perchloride of iron into the uterus to arrest hæmorrhage after abortion and labour, and with excellent effect. He no longer dreaded flooding as of old. So far he could illustrate by experience the safety of intra-uterine injections. But he thought a more desirable method of applying fluid styptics or caustics to the inner surface of the uterus would be by swabbing—that is, soaking a bit of sponge or cotton-wool in the liquid, and passing it into the cavity. He had contrived an apparatus for this purpose. An excellent plan of applying solid nitrate of silver was one he had learned from Sir Benjamin Brodie. That eminent Surgeon dipped a silver probe in fused nitrate of silver, thus obtaining a thin stratum, which could be passed freely and safely into a sinus. This was the safest way of cauterising the inner surface of the cervix or body of the uterus.

Dr. Greenhalgh said that Sir J. Y. Simpson had described these enlargements under the terms of subinvolution or incomplete involution of the uterus. He (Dr. Greenhalgh) quite agreed with the author as to their frequency and the obscurity of the local symptoms. He regarded it as a common cause of sterility, but that where impregnation resulted it was always curative, except where abortion ensued. In this disease he had found the uterus enlarged, flabby, and ill-defined, the sound entering an enlarged cavity four inches, and even seven inches and a-half. He considered that hæmorrhage was not a frequent symptom in this disease, and, where it did exist, was mainly attributable to some affection of the lining membrane of the uterus. He advised, where hæmorrhage was frequent or profuse, so as to affect the general powers and resist the ordinary treatment, the injection of the compound tincture of iodine into the uterus; but laid great stress upon the importance of first freely dilating the internal os uteri, which dilatation in itself was more or less curative. He had found resolvent and sedative pessaries of value, as also douches of tepid and cold water with a Kennedy's syringe, and medicated fluids. He likewise advocated the administration of tonics, with the iodide of potassium and liquor of the ergot of rye, and alterative doses of the bichloride of mercury. He relied greatly for success upon improvement of the general health, out of some impairment of which this affection frequently originated and persisted.

Dr. Wynn Williams agreed with much that had been stated, but, remarking on that portion of the paper alluding to ulceration of the os uteri, he considered there were various degrees of ulceration in mucous membranes as well as in the skin, according to the strength and nature of the irritant. Fortunately, the mucous membrane covering the os and cervix uteri is not ordinarily exposed to an irritant powerful enough to produce the amount of ulceration which we so often see in prolapsus uteri. He found that superficial ulceration, or excoriation, happens when perverted or irritating secretions remained in contact with the mucous membrane of the os and cervix uteri. For treatment he relied on constitutional and local remedies, and found nothing answer so well as the injection of weak solutions of iodine. As before stated to the Fellows of the Society, he considered iodine as perhaps the most powerful disinfectant or decomposer of the products of animal decomposition we possess.

Dr. Rasch said he saw a great number of cases of subinvolu-

tion of the uterus, in some of which the sound would pass six or seven inches. Careful bi-manual examination left no doubt that there were no tumours in the uterus, the walls being in some cases quite thin and flaccid, like a bladder. He had often practised intra-uterine injections. He had mostly used acet. pyrolign , recommended by Carl Mayer, though not for this purpose. Diluted with equal parts of water, it had often checked obstinate flooding, and not produced untoward symptoms. The patient should stand or walk after the injection, to allow the fluid to gravitate out of the uterus. He thought before injecting, if any flexion of the uterus existed, it should be known, as this prevented the ready outflow of the fluid. To distinguish between broken and merely reddened mucous membrane on the os uteri, he used, with a brush, a solution of nitrate of silver. The parts denuded of membrane presented an appearance strikingly different from those which were covered.

At the annual meeting, on January 3, the following bye-law was passed:—"That a limited number of Medical students, each bringing a recommendation from his Lecturer in Midwifery, be admitted to the ordinary meetings of the Society, without privilege of participating in the discussions." Applications to be made to the honorary secretaries.

THE PATHOLOGICAL SOCIETY.

Tuesday, February 20.

Dr. Peacock, President.

Dr. Barratt showed (at the previous meeting) a specimen of a

PILIFEROUS CYST OF THE OVARY,

not dissected, but containing more elaborate structures than those that spring from epithelial development—viz., true bone and cartilage.

Dr. Barratt next exhibited a specimen of an

ABORTIVE CRANIAL BONE REMOVED FROM AN OVARIAN CYST.

It was a small, well-ossified bone, resembling in part a miniature sphenoid. The patient was, as in the former case, unmarried. It showed an abortive plastic attempt, but of a more advanced kind than is usually met with in such specimens. There were also observable true foramina, not unlike the foramen ovale, the foramen rotundum, and foramen spinosum. There were what looked like nervous filaments passing through these foramina. During cleaning much glistening ligamentous tissue was removed, and the bone had been developed between two strong membranes.

Dr. Barratt then showed a specimen of a

LARGE MULTILOCULAR CYST.

Accident had thrown more than usual interest around this specimen. The patient was operated on for presumed ovarian cysts, and her Medical history affords nothing worth recording. After the customary incisions, a few adhesions and straight vessels were observed running from the lower border of omentum, and from the upper surface of the cysts, and on looking for the pedicle none could be found. In fact, it was "sessile" on the omentum; the ovaries and uterus were present, and they were healthy. The nature of this cyst, Dr. Barratt remarked, is of more than usual interest, and it was more by a process of exclusion, and by saying what it is not, that he could arrive at the truth of what in great probability it was. Dr. Wilson Fox, Dr. Barratt added, had kindly joined him in the examination, and he contented himself with saying that it was an ordinary group of cysts with contents and structures, such as are uniformly seen developed in ovarian dropsy. In the first place this cystic growth was not indigenous to the omentum; cysts of this membrane are generally simple filmy bags with a thin serosity in them; they are dilatations, as it were, of the peritoneum. It was not a translated cyst from the par ovarium, for they are single, small, and generally have a pedicle, as Dr. West describes them; neither has it for its origin an ovary which by twisting on itself has been severed (as happened in the case recorded by Dr. Turner, of Edinburgh), and had thus attached itself to a neighbouring place. "Thus," Dr. Barratt said, "I have exhausted almost all possibilities, except one—viz., that it may be a detached cystic growth from the parietes of the uterus. The uterus was, however, quite normal. I believe it to be a link that was wanting to prove the truth of the views held by the Ritchies, a few others, and myself—viz., that the ovum is itself oftentimes the point of departure for cystic degeneration. The Graaffian follicles, the corpora lutea, the stromä of the ovary, each and all have been regarded as giving rise, in different modes, to capsules of fluid, which, by pressure and by aggregation, become the large growths we see in the ovary. But one cannot long examine ovaries without asking the question, Does the unimpregnated ovum always die? In connection with such researches it is only right to mention the name of the late Dr. Charles Ritchie. Dr. Ritchie exhibited a diseased cyst, developed in the Fallopian tube, to the Fellows of the Obstetrical Society, December 6, 1865. In the specimen I am alluding to I cannot but conclude that its origin is really ovular, and that it escaped from its receptacle, the Fallopian tube. If so, the share the ovum may take in cystic disease is made apparent, and, as I believe, in looking at the three specimens before us, we are only contemplating different phases of the same structure—pathologically developed in the one and physiologically in the two others, by the diseased cysts. These cases, I may add, were all operated upon successfully by Mr. Baker Brown, and I am indebted to his kindness for having them at my disposal."

Dr. Moxon showed a specimen of

RUPTURE OF THE HEART.

Dr. Moxon said:—This heart I removed from the body of a man who was brought dead into Guy's Hospital on January 17 last. The history was short: he had been seized with faintness whilst sitting in an omnibus; he tried to get to the door of the vehicle, but in doing so he fell dead on its floor. The state, upon inspection, of the other organs of the body I may pass over. The pericardium was full of blood, pretty firmly coagulated. This had issued from the heart by a rent situated in the usual place of spontaneous rupture—that is, the anterior face of the left ventricle, rather more than one inch from the apex; this rent was near the septum, at right angles to it, and about three-quarters of an inch long. So far the case was only a usual one of rupture of the heart; it was only on viewing the injury from within the cavity of the left ventricle that the conditions were seen which I thought would be worthy of the attention of the Society. The left ventricle being opened down its hinder wall, there was seen a tear across the septum near its lower part, transverse in its direction, and irregularly continuous with the fatal tear in the outer wall. Above this for nearly two inches, and below it for half-an-inch, was a patch of inflammatory granulations on the endocardium. On section into the substance of the septum under these granulations a pale cheese-coloured fibrinous mass was found embedded in the septum; this mass exactly resembled firm decolorised blood-clot. The interest concerning this appearance seems to me to turn on the relation it bears to certain specimens of so-called fibrinous deposit which have been at intervals shown to the Society. These deposits are nearly always in the septum—a part where laceration might be expected less frequently to reach the surfaces. The opinion which has occurred to me is that these so-called fibrinous deposits are really none other than clots formed in the substance of the wall of the ventricle by injury to the vessels, in spontaneous ruptures which fail to reach either surface of the wall. Another view is of course possible—it may be supposed that my case is an instance of rupture of the wall of the heart due to weakening of the wall from the presence of "fibrinous deposit," this being supposed to be the cause rather than the effect of the rupture. I, however, think this view not to be the correct one. The state of the left coronary artery, which is seen to be in a very advanced stage of atheromatous and calcareous degeneration, is sufficient cause of the rupture of the ventricle, and it is unnecessary to assume a further cause of rupture. Whichever view is received by the Society, I do not doubt that the fibrinous matter here present in the walls of the heart is of the same nature as those masses in the heart which have been formerly shown to the Society as fibrinous deposit.

(To be continued.)

We regret to announce the death of Dr. John Spurgin, from the effects of severe injuries received during an attack made upon him by thieves in Bishopsgate-street last September. Dr. Spurgin graduated at Cambridge, after having studied in London and Edinburgh. He was a Fellow of the College of Physicians, and Honorary Physician to St. Mark's and the Foundling Hospitals. In 1851 he delivered the Harveian Oration. Dr. Spurgin, it will be remembered, was the author of the essays entitled "Fallacies of the Faculty Fallacious," "The Drainage of Cities," and other works.

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON. The following Candidates passed the late examination for the Degree of

MASTER IN SURGERY.

Pass Examination.

Edwyn Andrew, M.D., University College; Peter Maury Deas, M.B., University of Edinburgh.

Examination for Honours.

Peter Maury Deas, M.B. (Scholarship and Gold Medal), University of Edinburgh; Edwyn Andrew, M.D. (Gold Medal), University College.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 15, 1866:—

John Frederick Pritchard, Southsea; Richard Ley, South Molton; Henry Cecil Smith, Kensington-park-gardens; Frederic Tickoll Prince, Sawston, Cambs.; William Henry Ellis, Swavesey, Cambs.; Patrick James O'Neill, Canning Town, Essex.

The following gentlemen also on the same day passed their First Examination:—

Robert Vaey Ash, St. Mary's Hospital; Thos. Edwd. Stainthorpe, Middlesex Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

COLLIE, A., M.D., has been appointed Assistant Medical Officer to the London Fever Hospital.

DAVIDSON, ALEXANDER, M.A., M.B.Edin., has been appointed Lecturer on Comparative Anatomy and Zoology at the Liverpool Royal Infirmary School of Medicine.

DEWSON, Mr. F. S., has been appointed Resident Dispenser at the Queen's Hospital, Birmingham.

GIBSON, FRANCIS W., M.B., has been appointed Assistant Medical Officer to the Broadmoor Criminal Lunatic Asylum, near Wokingham.

JACKSON, JABER, L.F.P.S.G., L.M., has been appointed Medical Officer and Public Vaccinator to the Fourth District of the parish of Birmingham.

NICOLL, R. CHARLES, Esq., F.R.C.S., has been appointed Medical Officer to the Charterhouse.

WILLIAMS, W. RHYS, M.D., has been appointed Resident Physician and Medical Superintendent of the Royal Hospital, Bethlehem.

BIRTHS.

BARRIE.—On March 10, at Glasgow, the wife of John Barrie, M.D., of a daughter.

BUSWELL.—On March 20, at 5, Loughborough Villas, Brixton, the wife of Richard Buswell, M.R.C.S.E., of a son.

CRISP.—On March 16, at 42, Beaufort-street, Chelsea, the wife of Edward Crisp, M.D., of a daughter.

DATE.—On March 8, at Ilkeston, Derbyshire, the wife of William Date, M.R.C.S. Eng., of a son.

DRYSDALE.—On March 19, at Sheerness, the wife of A. Knox Drysdale, F.R.C.S., Surgeon R.A., of a son.

FARQUHARSON.—On March 7, at St. John's-road, Stockton-on-Tees, the wife of John Farquharson, L.R.C.P. Edin., of a son.

LEGAT.—On March 8, at South Shields, the wife of Andrew Legat, M.D., of a son.

MAWHINNY.—On March 5, at Woodlawn, Mount Nugent, Co. Cavan, the wife of Dr. T. Mawhinny, of a son.

M'CABE.—On March 2, at Waterford, the wife of Dr. M'Cabe, of a daughter.

MOXON.—On March 8, at Northampton, the wife of William Moxon, M.R.C.S.E., of a daughter.

MUNRO.—On March 15, at Boulogne-sur-Mer, the wife of Alexander Munro, M.D., of a daughter.

MARRIAGES.

FLEMING—CHARLES.—On March 1, at Moneymore, Samuel Fleming, L.R.C.S. Edin, to Margaret, daughter of the late Stewart Charles, Esq.

MASSY—YIELDING.—On March 14, at St. Thomas's Church, Dublin, D. G. Massy, Esq., Bengal Medical Staff, to Fanny Augusta, eldest daughter of H. Massy Yielding, Esq.

DEATHS.

BOWDEN, ALFRED, M.R.C.S. Eng., off Port Phillip Heads, on January 15, aged 45.

GRAY, WILLIAM, M.R.C.S. Eng., late of Orford-hill, Norwich, on March 4, aged 35.

JONES, W., M.R.C.S. Eng., at Byrom-street, Manchester, on March 3, aged 51.

LOWE, JOHN, Surgeon, at Coupar Angus, N.B., on March 9, aged 84.

MORISON, Sir ALEXANDER, M.D., at Balerno Hill House, Edinburgh, on March 14, aged 87.

PARCHAPPE.—M. Parchappe, Inspector-General of Asylums, one of the most distinguished of the French psychologists, well known by his writings on the nervous system and as Director of the St. Yon Asylum, Rouen, which was built after his design, died March 12, aged 65.

SPURGIN, JOHN, M.D. Cantab., at 17, Great Cumberland-street, Hyde-park, on March 20, aged 69.

WELLS, FREDERICK J., M.R.C.S.E., at Blyth, Worksop, on March 16.

WINTER, JAMES, M.D. Glasg., at Hampstead, on March 13, aged 34.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Cockermouth Union.—Mr. Henry Bell has resigned the First Cockermouth District; area, 22,061; population, 8046; salary, £30 per annum. Also the workhouse, salary, £20 per annum.

St. Saviour's Union.—Dr. Edward Hibberd has resigned the St. Saviour's District; area, 124; population, 18,887; salary, £75 per annum.

APPOINTMENTS.

Bridge Union.—Henry G. Sadler, M.R.C.S.E., L.S.A., to the Third District.

Crediton Union.—Charles Snape, M.D. Edin., M.R.C.S.E., L.S.A., to the Marehard Bishop District.

Forehoe Incorporation.—Robert J. Tunaley, M.R.C.S.E., to the Fourth District and the Workhouse.

Poplar Union.—Henry S. Gale, M.B. Lond, M.R.C.S.E., L.S.A., to the Western District.

THE LEVÉE.—At the Levée held on Monday, by H.R.H. the Prince of Wales on behalf of Her Majesty, the general circle was attended by Sir Henry Holland, Physician in Ordinary to the Queen. The following presentations to the Prince on behalf of the Queen took place:—Dr. R. H. Bakewell, by Mr. Beresford Hope; Dr. A. Bryson, C.B., on appointment as Companion of the Bath, by the Duke of Somerset; Surgeon T. Duka, Bengal Army, by the Secretary of State for India; Sir William Fergusson, on being created a Baronet, by Earl Granville; Surgeon H. J. Gane, by the Secretary of State for India; Dr. Horatio Goodday, by Major-General E. R. Hill. The Levée was attended by Drs. Frederick G. Reed, Breslin, Sieveking, Forbes Winslow, Acland, Armstrong, R.N., T. King Chambers, Minter, and by Messrs. Toynbee, F.R.S., and Erasmus Wilson, F.R.S.

THE MILITARY MEDICAL SERVICE IN NEW ZEALAND.—In the "General Orders" published by General Chute on the taking of the Putahi pah, Dr. Gibb, Deputy-Inspector of Hospitals, and his staff are thanked for their "zeal, energy, and attention upon the occasion."

SIR ALEXANDER MORISON.—We regret to announce the death of this distinguished Physician. Sir Alexander Morison was known as one of the most successful Practitioners of his time in the treatment of mental disease, and was one of the first, if not the first, Physician who delivered special courses of lectures on insanity. He graduated at Edinburgh in 1799, became a Fellow of the Edinburgh Royal College of Physicians in 1801, and was at one time President of that College. In 1808 he obtained the Licence of the London College and was elected to the Fellowship in 1841. He was the author of several treatises on mental disease, and founder of a Society for Improving the Condition of the Insane. He held the offices of Consulting Physician to the Middlesex County Asylum and to Bethlehem Hospital. The honour of Knighthood was bestowed on him at the time of the coronation of her Majesty. Sir Alexander had reached the venerable age of eighty-six.

THE election of a Medical officer to the Charterhouse has been decided in favour of Chas. R. Nicoll, Esq., Battalion Surgeon, Grenadier Guards. There were originally eighteen candidates, one of whom did not go to the poll. Amongst them were two Army Surgeons, one retired Militia Surgeon, one or two Physicians, and the rest were general Practitioners. The appointment has for many years been considered the great prize for the general Practitioners of the vicinity.

OBSTETRICAL SOCIETY OF LONDON.—We are given to understand that the Fellows of the Obstetrical Society will dine together on Thursday, March 29th (the day following the conversazione and exhibition of obstetrical instruments at the Royal College of Physicians). The distinguished foreigners, several of whom have announced their intention to be present at the conversazione, will be invited to meet the Fellows at the dinner. The occasion will be an interesting one, and we doubt not that the dinner will prove a successful termination to this great obstetrical gathering. The dinner will be given at Willis's Rooms, King-street, St. James's.

THE will of the Countess Dowager of Dundonald has been proved by Sir Charles Locock, the sole executor under the will. Sir Charles received all the property of the late Countess "in compliance with the wishes of my late husband, to discharge, so far as lies in my power, a debt of honour incurred many years since."

ALLEGED DEATH FROM DISEASED MEAT. — The *Guardian* states that at Topcliffe, near Thirsk, a labourer's family were poisoned by eating diseased mutton, and a child named Henry Stringer died.

THE installation of Mr. Carlyle as Rector of Edinburgh University will take place on April 2, when it is hoped that the state of his health will permit him to speak his address.

PETRIFIED NATIVE. — Mr. Stevens, of King-street, Covent-garden, announces that he will sell on Tuesday, the 27th, a petrified aborigine from South Australia. It is the only specimen known in the scientific world; is stated to be very perfect, and, of course, "is believed to be of great antiquity."

RAILWAY DAMAGES.—A dentist named Huet, practising at Wolverhampton, has recovered £850 from the London and North Western Railway Company as compensation for injuries received in a collision which occurred on September 2. The symptoms proved were "headache, giddiness, numbness of limbs, and impaired vision."

TRICHINIASIS.—In consequence of the announcement of several deaths from trichiniasis, the municipal councils of Lille, Marseilles, and other towns in France have resolved that the Veterinary Surgeons appointed to inspect the butchers' meat offered for sale shall be supplied with microscopes for a more minute examination.

THE HONITON CLIST MURDER.—A woman named Mary Ann Ashford has been sentenced to death for the murder of her husband by the administration of arsenic and strychnia. Both poisons were found in her possession, and arsenic was found in some tea she had prepared for her husband. Mr. Herapath, sen., was the expert employed.

A SCRAP FOR THE ANTHROPOLOGISTS.—Miss Edmonia Lewis, half negro and half red Indian, has taken a studio in Rome as a sculptor.—*Guardian.*

A NEW NAME.—M. le Docteur Caron announces in the *Union Médicale* that his public conferences on *Puériculture* are about to commence.

CARBOLIC ACID AND THE CATTLE PLAGUE.—Mr. W. Crookes, F.R.S., in a letter to the *Times*, states that the great demand for carbolic acid as a disinfectant has led to the fraudulent sale of an imitation composed of oil of tar, which is utterly valueless for disinfecting purposes. He gives the following tests of the purity of carbolic acid:—Commercial carbolic acid is soluble in from 25 to 70 parts of water, or in twice its bulk of a solution of caustic soda, while oil of tar is nearly insoluble. To apply these tests—1. Put a teaspoonful of the carbolic acid in a bottle; pour on it half a pint of warm water; shake the bottle at intervals for half an hour; when the amount of oily residue will show the impurity. 2. Dissolve one part of caustic soda in ten parts of warm water, and shake it up with five parts of the carbolic acid. As before, the residue will indicate the amount of impurity.

RINDERPEST IN SHEEP.—The Committee of the Chamber of Agriculture and Scottish Farmers' Club, at a meeting held at Edinburgh, on Wednesday, resolved, on the motion of Mr. Hope, Fentonbarns, "That the evidence of sheep having taken Rinderpest is far from conclusive, and that if sheep become affected with the disease they are certainly not naturally susceptible of it." The Edinburgh Cattle Plague Committee, on the other hand, have adopted a resolution of an opposite tenour—namely, "Having carefully inquired into the alleged cases of Rinderpest in sheep reported to have occurred in the county of Fife, having had the advantage of hearing a full statement on the subject by one of their own number, Professor Strangeways, Veterinary Surgeon, who went down to Fife for the purpose of examining into the matter, and having themselves witnessed the post-mortem examination of several of the sheep in question, they are of opinion that the cases reported from Fife are undoubted cases of Rinderpest, and that it is expedient that measures should be adopted for the prevention of the removal of sheep from infected places to places hitherto uninfected."

AN HYSTERICAL FREAK.—The fascination which the idea of depth exercises over some minds has been often observed, and some persons by no means generally nervous shun great heights, as they are conscious of an almost irresistible desire to leap into space. On Wednesday, a girl under treatment for hysteria in King's College Hospital was coming down the stairs which wind round the lofty walls of the vestibule; when she reached the level of the Surgical wards, she sprang over the banisters, and was seen by Mr. Howells, the House-Surgeon, descending like a parachute, or rather as a parachute should, but seldom does, for she landed on her feet, and, except a slight strain of the ankle, was uninjured by her descent of more than twenty feet. She screamed when falling, but says that she now forgets all about it.

CLINICAL TEACHING OF MENTAL DISEASES AT MILAN. —The directors of the Milan General Hospital, among numerous changes that have been made, have instituted a chair for the clinical teaching of insanity. M. Verga, the chief Physician of the Hospital, has been appointed the first Professor, and it is said to be his intention, before commencing his lectures, to visit the foreign countries where similar *cliniques* have been founded, in order to examine into their operation. In the absence of such institutions, neither England nor France will be honoured with the learned Professor's presence!

ACCUMULATION OF STABLE MANURE IN LONDON.—Dr. Septimus Gibbon, in his fortnightly Report presented to the Board of Works, Holborn District, on March 12, 1866, draws attention to the non-removal of stable manure from the mews, laystalls, and streets of London in consequence of a clause of the Cattle Disease Prevention Act 1866, which forbids the exportation of manure, offal hides, etc., from the Metropolis or any other place in which cattle plague has existed within six months previously. This provision extends from March 1 to April 15. The Board have memorialised the Home Secretary on the subject, and it will be seen from our Parliamentary Report that this matter has come under the notice of the House of Commons and the Government.—We may add that orders for removal are easily obtained through the police, except in cases where there is reasonable fear of infection by Rinderpest.

THE VACCINATION FIASCO.—The feuilletonist of *L'Union Médicale* exclaims that "This *maudit* contagious typhus of cattle brings us nothing but surprises and 'sells.' Doctors Murchison and Ceely have constituted themselves apostles of the doctrine put forward timidly long ago by Bouvier and Auzias Turenne, that the Rinderpest is identical with small-pox, and set all England at work to find proofs of this by the effects of vaccination. The identity of Rinderpest with small-pox has been disproved by the most conclusive experiments, but not before every one hastened to vaccinate the cattle, nor until there was no lymph left, and knaves sold mixtures of collodion and lytta instead."

"LA NOBLESSE MEDICALE."—Under this title the feuilletonist discusses the honours awarded to Medical men. La Baronnie of Sir W. Fergusson he thinks due to his belonging to the metropolis, and he is glad that Sir Dominic Corrigan has got a Barony too, for "*verte* Erin" has had no Doctor raised to this dignity since Sir H. Marsh died in 1860, and she now welcomes the honour paid to "one of her most devoted patriots." As to Sir James Simpson, he considers the choice must have been an easy one, as the only wonder it excited was that the Barony had not been awarded long ago, so completely has he outstripped all his rivals. The writer makes some graceful allusions to the sad events which have occurred almost coincidentally with the honours paid to the great Scotchman. He also has a few words of sympathy for those who might reasonably have expected Earl Russell to remember their claims, and shows that the names of Syme, Christison, Watson, Lawrence, and Burrows are well known and honoured on the south of the Channel.

A DYING CHILD IN ST. PANCRAS WORKHOUSE.—On Tuesday Dr. Lankester, the Coroner for Central Middlesex, opened an inquiry at the Elephant and Castle Tavern, Camden-town, upon the body of an infant which, it had been alleged, was "laid out" while alive, under the extraordinary circumstances detailed in the *Times* of Monday. Charlotte Adams, the first witness called, said she was the grandmother of the infant, which was seven weeks old, and was the illegitimate child of her daughter, Elizabeth Adams. Her daughter was confined in St. Pancras Workhouse, and left there with the child three weeks last Saturday. She had since been taken into custody on the charge of deserting her child—the deceased—and she was now awaiting her trial upon this charge. Dr. Sidney Ringer, the Materia Medica Professor of the University College, and Physician of University College Hospital, who had been instructed by the Coroner to make a post-mortem examination, said he thought the death arose from a

slow wasting away. He was decidedly of opinion that if the child had been "laid out" for some hours such treatment would accelerate its death. Mr. James Inches Hillocks, of 34, Stanhope-street, Regent's-park, who described himself as the evangelist of Tolmer-square Congregational Church, repeated the statement made in his letter referred to in the *Times* of Monday. The Coroner said this was a most important inquiry, and one which should be closely investigated. Mr. Hillocks had given his evidence in a very clear and open manner, and he would, no doubt, attend on a future occasion to answer any questions which might be asked of him. The inquiry was then adjourned for a week.

The Etiology of Heart Disease.—Jackson and Wife *v.* the Lancashire and Yorkshire Railway Company.—This was a case tried before Mr. Justice Mellor at Manchester on March 14. The action was brought to recover compensation for injuries suffered by the plaintiff's wife through the negligence of the defendants; one of their carriages in which the plaintiff's wife was riding to Oldham in May last having run off the line, whereby she received a serious nervous shock, which had resulted in heart disease and dropsy, from which she was expected not to recover. It appeared that after the accident she had had pleurisy and bronchitis, and it was urged for the defence that heart disease might have been occasioned by those complaints. The liability of the defendants was admitted, but it was contended they were not responsible for damages which might have been occasioned by a common cold caught after the accident. The plaintiff, it appeared, had been subjected to expense in nurses and servants consequent on his wife's illness, and also in Medical attendance and wine and expensive diet for her during her illness. His Lordship, in directing the jury, told them that the defendants' railway company were not insurers, and were only liable to make good injuries which had been suffered from some want of due care on their part. In the present case the carriage in which the plaintiff's wife rode, being the third carriage, ran off the line, from some unexplained cause, and the defendants' liability might have been a question; they did not, however, dispute it. The plaintiff's wife, it appeared, was 37 years of age, and not likely to live. Whether the shock she had received had rendered her more susceptible of cold and had caused the pleurisy and bronchitis from which she had suffered was for the jury. They must take all the circumstances into their consideration—the station in life of the plaintiff, and the expenses to which he had been put, and the loss he had endured, and give a reasonable verdict accordingly. The jury found a verdict for the plaintiff—Damages £300.

Alleged Poisoning by Mistake.—Home Circuit, Lewes, March 21.—Richard Noakes, a chemist and druggist at Brighton, was indicted for the manslaughter of one Samuel Boys in August last. The death had been caused by the administration of aconite by mistake, and it excited some interest. The prosecution, it was stated, had not been instituted by the relatives of the deceased, but by the public authorities, who considered that a trial ought to take place. Mr. Boys, the deceased, was an old gentleman of the age of 80, who resided at Lansdown-terrace, Brighton, and suffered from disease of the heart. He had been attended by a Dr. Dill, who had prescribed for him 30 drops of henbane, to be taken occasionally, with a view to his relief. The deceased kept the drugs he used in a medicine chest in his own bottles, and among those he took were henbane and aconite. The prisoner (who is about 60 years old) was stated by the counsel for the prosecution to be a most respectable chemist, and he from time to time supplied Mr. Boys with drugs and medicines, and, among other things, for years with aconite, and on one or two occasions with henbane. The last day he supplied any drugs was on the 16th of August, when two bottles were taken by Mrs. Boys to his shop "to be filled," one of them being labelled "henbane, 30 drops," and the other was labelled with the name of a medical oil which was required as a liniment, "for outward application only," and the bottle had those words also on it, but in small letters. It was admitted that on this occasion the prisoner himself had filled the bottles, which were sent to the house of the deceased, and given to his servant; and there was no doubt that they found their way to the medicine chest of Mr. Boys. On the night of Sunday, the 20th of August, he felt an attack of his disorder, and said he would take a dose of the henbane, which he then accordingly did take, measuring it out himself in a "drop-glass," as it is called, which measures the number of drops. The dose, it will be borne in mind, was thirty drops (which was written on the outside of the bottle), and there was no reason to believe that it had been exceeded. Upon swallowing it, however, he observed that it "felt hot." About a quarter of an hour afterwards he said his limbs had become benumbed. After this he felt sickness. He became alarmed and looked at the bottle, having a suspicion that there was some mistake; but on looking at it and seeing it marked "henbane," he said, "It's all right." He was extremely ill all night, and early in the morning desired that the bottle should be sent to Mr. Noakes to see if it was right, retaining, however, a portion of it in the house. Not long afterwards he became drowsy, and in the course of the hour he died. The attention of the Medical men was directed to the contents of the bottle in question, and they were satisfied from its pungent taste that it was aconite. A post mortem examination, however, disclosed the seat of the cause of death was the heart. The jury returned a verdict of not guilty.

Discussion on Local Anæsthesia.—At the meeting on March 14 of the Imperial Society of Surgery of Paris, M. Giraldès in the chair, the following discussion took place on local anæsthesia, induced by a jet of pulverised æther. The subject was brought forward by M. Le Fort, who described Dr. Richardson's recently-introduced method, and that by dropping the æther and causing rapid evaporation by a current of air. M. Foucher had employed and seen employed a similar apparatus to that exhibited by M. Le Fort for local anæsthesia. He had only been able to induce an incomplete and transient anæsthesia, so he gave it up. M. Demarquay had done many operations, using ether to produce local anæsthesia. Generally he let it fall drop by drop on the part he desired to render insensible, and he kept up rapid evaporation by a current of air. He thus obtained a superficial local anæsthesia sufficient for the almost painless performance of usually painful operations, as removal of nails, opening of abscesses, &c. For all operations of that class M. Demarquay has, thanks to the local application of æther, given up the practice of general anæsthesia. Æther thus employed only acts as a refrigerant. M. Velpeau had been a witness on many occasions of the application of æther as a local anæsthetic agent, and, like M. Foucher, never saw very wonderful results from it. On the contrary, almost always the anæsthesia so induced was superficial, incomplete, and transient. Besides, the abundant dissemination of the æther vapour by the new apparatus cannot be without inconvenience to the assistants. M. Velpeau would not wish that a desire for new things should lead to forgetfulness of the old. There is a very simple and very efficient method described by Arnott, consisting of pounded ice and salt in a muslin bag. M. Velpeau uses it constantly in removal of the nail. Its application for some minutes is sufficient to produce insensibility. When the skin of the toe is white you may extirpate the nail absolutely without pain. This is, therefore, superior to æther, as it, according to the confession of M. Demarquay, does not wholly suppress the pain. M. Desormaux has used, for ten years at least, a little bellows, invented by Charrière, throwing air and æther on a part at once. More recently he has used the vaporiser of the perfumers, and on one occasion exhausted *l'energie pulmonaire* of six of his pupils without results. He has found that patients complained of the pain of Arnott's freezing mixture, and preferred to be operated on without it. M. Laborie, in removal of the toe-nail, used æther and a tight ligature round the root of the toe. M. Perrin has seen pain as acute as that of the knife induced by æther. M. Broca mentioned a case where Robert removed the great toe so congealed that during the operation the assistants could hear the flakes of ice crackling under the bistuary; there was no pain, and not a drop of blood lost. The flap healed by first intention.—*L'Union Médicale*, March 17.

Preparing for Cholera.—On Saturday last at the Clerkenwell Police Court, Edwin King, and the other owners of property in Grosvenor-street, Essex-road, Islington, were summoned by Mr. William Mayes, sanitary inspector, for knowingly suffering to be occupied a front room on the basement floor, contrary to the provisions of the Act for the better local management of the metropolis (the 18th and 19th of Victoria, cap. 120), there not being an area three feet wide in every part from six inches below the floor of the room to the surface of the ground adjoining. There were other summonses against the defendants under the Nuisances Removal Act for England, 1855, for allowing the houses, the inhabitants whereof consist of more than one family, to

be so overcrowded as to be dangerous to the health of the inhabitants. Mr. William Mayes said he is sanitary inspector to the Vestry of Islington. On the 22nd ult. he inspected the houses in Grosvenor-street, and found at No. 2a that the kitchen was used as a separate dwelling by a man, his wife, and two children. A death from fever had taken place in this house about six weeks since, and there was now one person in the house under Medical treatment. The house is filthy. At No. 6, the kitchen was occupied by a man and his wife, and there was a bed and bedstead in it. At No. 7 the kitchen was occupied by a mother and daughter, and there was a sofa-bedstead in the room. The house No. 8 was overcrowded, seven persons sleeping in a room, which only gave 123 cubic feet of air to each person. The house No. 11 was occupied by thirty-two persons—viz., six men, eight women, and eighteen children, seven sleeping in the front and five in the back kitchen. At No. 14a, the house was occupied by thirty-six persons—viz., eight men, eight women, and twenty children, the front kitchen being occupied as a separate dwelling by one man, one woman, and four children. The back kitchen was occupied by one man, one woman, and two children. A child recently died in this room, and one that was then under Medical treatment has since died. The room is very damp, the drains are very defective, depositing the liquid soil in the passage, which saturates the partition and floor boards. Frequently the water flows under the bed. The first-floor front was occupied by one man, one woman, and six children. No. 15 was occupied by 33 persons—viz., five men, eight women, and 20 children. Here the front and back kitchen were occupied by three and four persons separately. No 16a was occupied by 39 persons—viz., eight men, eight women, and 23 children, the front parlour being occupied by one man, one woman, and three sons, aged 9, 12, and 19, and the back parlour by one man, one woman, and four children. The whole of these houses contain eight rooms each, the largest of which is 12 ft. by 14 ft. by 9 ft.; the annual value of each is £30, but as they are at present let they are producing £65 each per annum. The basement of the whole of the houses are very damp; the drainage is defective, the yard being without any, the surface water in one instance flowing into the back doors, the water running down the wall, washing off the paper at the side of the bed. The houses generally are in a very filthy condition. The 32 houses in this street contain 528 men, women, and children. Eight of the above houses belong to Mr. Edwin King, and contain 239 men, women, and children. Dr. Edward Ballard, Medical Officer of Health for the Vestry of Islington, gave evidence generally confirmatory of the previous witness as to the kitchen occupation and overcrowding. The overcrowding is dangerous to health. During 1865 there was a very high death rate on all houses in that street—viz., 13 deaths in 16 houses. Seven of them were children under five years of age. This year, in January and February, four children have already died. Mr. Layton called the attention of the Court to the fact that Mr. Goodwin, the district surveyor, had certified that these underground dwellings were contrary to the provisions of the Act 18 and 19 Victoria, cap. 120. The defendants all said that they would remedy the evils complained of as soon as possible. The magistrate made orders for the abatement of the nuisances, and fined the defendants in sums varying from 10s. to 2s. 6d., besides ordering the defendants to pay the costs. Mr. Layton applied for fourteen other summonses of a similar description, which were at once granted.

THE RINDERPEST.—Dr. Andrew Smart has addressed a letter to the Lord Provost and magistrates of Edinburgh, in which he brings forward additional evidence of the value of the sulphites and hyposulphites in the preventive treatment of the cattle plague. The evidence is chiefly that of agriculturists who, living in infected districts, have administered to their cattle the hyposulphite of soda, and have escaped losses by the disease. His letter terminates with the following paragraph on Rinderpest in sheep:—"Before closing this letter I shall ask your lordship's permission to express, in reply to many urgent requests, once more my opinion upon one of the most vital and important questions of the day, namely—do sheep take Rinderpest? In a report which I had the honour to submit to your lordship and colleagues, dated December 11, and subsequently published, I stated that I had completed a careful experiment, undertaken for the purpose of deciding that very important question, and that I had succeeded in inducing the disease in a perfect form in a sheep which had during a lengthened period been kept in contiguity with affected cattle. Although there were at this time many conflicting opinions and apprehensions as to the ovine susceptibility to the poison of Rinderpest, this report, so far as I am aware, gave the first public announcement of the fact deduced from conclusive experiment that sheep were undoubtedly liable to the disease. And had the distinct note of warning which I then sounded been heeded, and the simple precautions attended to which I had recommended, I venture to think we should not now have had the plague amongst our flocks, and anxious owners of stock would have been spared the perplexity of diverse opinions. I would again repeat the opinion which I formerly expressed. There need be no great apprehension as to the disease passing over the country as an epizootic among the sheep, as it has been with cattle. With the exercise of ordinary precaution such a catastrophe will not occur, although isolated cases and occasional little outbreaks are inevitable during the continuance of the disease in this country. Let it be remembered that ovine susceptibility to the virus of true cattle plague is greatly less than pertains to the oxen tribe, and sheep succumb to the disease only after inoculation, or in consequence of lengthened exposure to the contagion in a more than usually concentrated form."

NEW REMEDIES.—EXTRACT OF COD LIVER.—This substance is an extract from the cod liver, and is prepared in a form suitable for pills and sugar plums. It differs from cod liver *oil* in these respects;—that whereas the oil *is oil* mingled with certain fishy matters, to which it owes whatever superiority it may possess over other oil, this *extract* professes to give us in a bodily form those very fishy matters themselves. Therefore it is argued that the extract may not only be a substitute for the oil, but may be available in many cases in which the oil is either rejected by the stomach or is inadequate to relieve the maladies for which it may be prescribed. The extract is said to contain ichthyoglycine, propylamine, gaduine, etc., in the proportion of nearly 80 per cent.; whereas the oil contains these mysterious bodies in the proportion of only ½ per cent. If, therefore, the virtues of cod liver oil depend upon propylamine, gaduine, etc., aforesaid, it is clear that the extract must, according to Cocker, be 200 times as efficacious, weight for weight. The question may be raised, however, whether the oil is not of value as a peculiarly light and digestible form of fat, independently of these mystical bodies. Be this as it may, any one who is condemned to take cod liver oil, and who would be delighted to have a substitute in the form of pills and sugar plums, had better consult a little pamphlet on the "Medicinal Properties of Cod Liver," by M. Guffroy, published by Mr. Hardwicke, Piccadilly.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked.			2. Result of reported Cases from the Commencement of the disease.				
	Week ending March 10.	Week ending March 3.	Week ending February 24.	Attacked.	Killed.	Died.	Recovered.	Unaccounted for.
1. Metropolitan Police District	14	12	12	7639	3234	3490	333	582

Note.—225 inspectors have not reported this week in time for this return. Of these 15 reported cases last week—viz.:—For the county of Buckingham, 1; Chester, 2; Lancaster, 1; Lincoln, 1; Norfolk, 1; Oxford, 1; Salop, 1; East Riding of York, 2; the Metropolitan Police District, 1; and for Scotland 4. These inspectors returned 1416 cases last week.

STATISTICAL SOCIETY.—The following is the list of Members of Council and Officers for 1866-67:—*President:* The Right Honourable Lord Houghton. *Council:* Major-General Balfour, C.B.; *Lord Belper; A. J. Beresford Beresford-Hope; Sir John Boileau, Bart., F.R.S.; William

John Bovill; Samuel Brown; William Camps, M.D.; Edwin Chadwick, C.B.; *David Chadwick; Leonard Henry Courtney; *William Ewart, M.P.; William Farr, M.D., D.C.L., F.R.S.; Right Hon. Earl Fortescue; William Augustus Guy, M.B.; James Thomas Hammick; Frederick Hendriks; James Heywood, M.A., F.R.S.; William Barwick Hodge; Charles Jellicoe; *William Stanley Jevons, M.A.; Francis Jourdan; Leone Levi, F.S.A.; William Golden Lumley, LL.M.; Matthew Henry Marsh, M.P.; George Moffatt, M.P.; William Newmarch, F.R.S.; Frederick Purdy; *Rev. J. E. T. Rogers, M.A.; Col. W. H. Sykes, M.P., F.R.S.; *John Walter. [Those marked (*) are new members.] *Treasurer:* William Farr, M.D., D.C.L., F.R.S. *Honorary Secretaries:* William Augustus Guy, M.B.; Wm. Golden Lumley, LL.M.; Frederick Purdy.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

A Subscriber.—Yes.

Opium in Continued Fever.—This paper shall be inserted.

Igno.—Consult any respectable Surgeon and pay him his fee.

J. W. H.—John Woodall, Surgeon to St. Bartholomew's Hospital, invented the Trephine in 1626.

A *Student.*—The Registration commenced at the College of Surgeons on the 22nd inst., and will close on the 31st inst.

A. B.—Legal qualification to practise now depends on registration. What qualification may be required by a candidate for a Medical office in a county Infirmary depends entirely on the laws of that Infirmary.

Tyburnia.—The skeleton of Jonathan Wild, which is contained in the Museum of the College of Surgeons, is that of a short man. The body of Sterne was removed by resurrectionists from Marylebone and sent to a professor of anatomy at Cambridge.

Medical Charities.—Mr. William Whitehead, of Dobcross, Saddleworth, Yorkshire, lately deceased, has bequeathed to the Manchester Eye Hospital £100; to the Manchester Blind Asylum £500; to the Huddersfield and Upper Aybridge Infirmary £1000; to the Manchester Deaf and Dumb Asylum £500.

Ozone.—We have received so many inquiries about that mysterious substance, ozone, that we think we cannot do better than lay before our readers a general account of it, what it is, how it is produced, and what are its properties. This we hope to do in our next number. Ozone has been talked of by many as a substance of such exceedingly active powers for good and for evil, in a sanitary point of view, while there are, at the same time, such slender proofs of a direct kind of its existence as a specific form of matter, that we are not at all surprised at the peculiar interest manifested about it by the members of our Profession.

Congleton.—Belladonna has failed over and over again as a preservative against scarlatina. If the homœopathic doctrines were true, no organism under the influence of a medicine *could* be susceptible to the attack of a miasm or other pathogenetic agent. But they are. *Ergo*, the doctrines are false. Any woman can treat patients homœopathically, for the globules all come out of one bottle. Physical diagnosis and morbid anatomy are superfluous; the disease is the symptoms, and the symptoms are the disease, says Hahnemann, and the symptoms being known, the right globule can be found in the Index. It is rather unlucky that some morbid changes have no constant symptoms.

An Old Carthusian.—The body of Thomas Sutton, the founder of the Charter House, was embalmed by Edmund Phillips, who received £40 4s. 8d. The two Serjeant-Surgeons who opened and embalmed George II., received £122 8s. 9d. each, and the apothecary £152 for "a fine double cere cloth, and a due quantity of rich perfumed powders."

H. L., Barnsbury.—The famous epigram on George the Third's Physicians, to which you allude, is an example of the advantages of rhyme, the wit lying in the metrical form, and in the form only, viz.:—

"The King employed three Doctors daily,
Willis, Heberden, and Baillie,
All exceedingly skilful men,
Baillie, Willis, Heberden;
But doubtful which most sure to kill is,
Baillie, Heberden, or Willis."

Trichinosis.—An Hungarian agriculturist writes to a Vienna journal that in his country the pigs have been long known to be affected with trichinæ. That if the disease is not communicated to man, it is owing to the thorough cooking and smoking to which the meat is subjected, and also to the circumstance that they do not consume trichinal meat. They easily recognise it, as meat affected with trichinæ gives to the eater the sensation of sand being between his teeth. He maintains that in Hungary they cure trichinous pigs in about fifteen days by giving them hempseed to eat, and they distinguish the diseased animals by their savage propensities and their mania for gnawing wood.—*L'Union Medicale*, February 15, 1866.

Erratum.—P. 277, col. 1, last line, *for* Dr. Phipps *read* Dr. Helps.

"Scientific Opinion."—Under this title a new scientific journal is to be published on April 4. We understand that it is to be conducted upon the model of *Public Opinion*, and will contain extracts from the more important articles which appear in the English and Continental journals. Reports of the local and foreign Societies, and notices of new books, will also form part of its scheme. In this age of periodical literature it is utterly impossible to get even a satisfactory glance at the several scientific magazines; *Scientific Opinion*, therefore, meets a serious and growing want. By its means those of our Professional brethren who are desirous of being posted up in the doings of the *savants* will be kept quite *au fait* of scientific progress.

Disease among the Finches.—For some time past a disease has caused considerable havoc among the poultry. Fowls which at evening had gone to roost apparently well were found dead the next day. Those which resisted the attacks of the disease presented all the symptoms of pip, soon followed by such a wasting that the wind raised them like feathers, and carried them sometimes to considerable distances, where they lay on their sides unable to rise. After that form of epidemic ceased to ravage the useful family of gallinæ, the family of the passeres had their turn. But there the disease took quite a different character. The sparrows and finches, which have been specially attacked, come and fly around persons as if they were tame. This surprising change is due to an almost complete blindness. The eyes of the unfortunate birds are covered with a white membrane sufficiently tense almost to conceal the pupil. On nearer examination, the lens can be seen to be opaque. It is affected with true cataract. Unable to seek their food, the poor flutterers die by starvation if they do not fall into the clutches of man or some animal. The cause of this disease we must seek in the air. But the air, physically and chemically, is a very complex fluid. One meets sometimes in the open sea floating banks of dead fish as if they had been poisoned *en masse* by some unknown agent. Why should not analogous phenomena be produced in the gaseous ocean which on every side envelopes our earth, and the depths of which we occupy?—*L'Union Médicale*, February 20.

Poor-law Medical Reform.

Mr. Griffin begs us to inform the Poor-law Medical officers that the following subscriptions have been received by him towards the funds of the Association:—G. Taylor, St. Faith's, 19s.; H. D. Ellis, Poole, 5s.; Haynes, New, and Haynes, 21s.; Newman and Atkins, Cosford, 10s.; A. Roberts, Holborn, 10s.

By Mr. Prowse:—T. Odell, Hertford, 10s.; H. Jepson, Kingston, 10s.; A. Kirkland, Amersham, 10s.

Griffin Testimonial Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following subscriptions have been further received on behalf of the above fund:—C. H. Carter, Esq., Pewsey, 10s. 6d.; J. Breach, Esq., Aston-up-Thorne, 10s.; Dr. Ed. Ray, Dulwich, £1 1s.; amount previously announced, £134 5s. 3d.; received at *Lancet* office, £13 11s. 6d.

I am, &c.

Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate Without, March 21.

Local Anæsthesia.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Visitors to King's College Hospital last Saturday afternoon had an opportunity of judging as to the efficiency of sulphuric ether spray as a local anæsthetic. Fortunately, there were two cases very similar to each other—viz., tumours, tolerably superficial and well defined, situated in the left infra-maxillary regions of two women, about the same age. In the first case, after the skin had been exposed to the spray for several minutes, Sir W. Fergusson pinched the skin and drew the back of the knife along the blanched surface, and after waiting a short time longer, desired chloroform to be administered. She became rapidly insensible, the tumour was removed, and she now says she felt nothing except the pinch and the scratch. In the second case, the skin was exposed a considerable time to the spray. Mr. Henry Smith removed the tumour with his usual expertness, but, to judge from the woman's behaviour then and her statement now, hyperæsthesia was the condition which obtained during the operation. Perhaps in cases where greater isolation could be effected, as in pendulous tumours, or the digits, more satisfactory results might follow. Nearly six ounces of ether were used—all that was in the house.

I am, &c.

An Eye-witness.

Scientific Evidence at the Trial of M. A. Ashford.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In the report of the trial of Mary Ann Ashford at the Devon Lent Assizes for the murder of her husband, William Ashford, by administering the poisons arsenic and strychnine to him, you will find that Mr. Herapath, sen., when enumerating the symptoms of poisoning by arsenic, stated that retention of urine was one.

Now in this he was manifestly wrong, for the reverse of retention takes place, as is well known. There is an incessant and most painful desire to micturate, amounting to strangury. In Ashford's case the bladder was empty and contracted to such a degree as I have never before witnessed—probably this was due to the action of strychnia—its lining membrane deeply injected, and this state of irritation was continued to the outer urethral orifice.

I am, &c.

Exeter, March 18. F. H. Warren.

Dr. Smart's Report on the Cattle Plague, and the Edinburgh Cattle Plague Committee.

The following letter has appeared in the *Scotsman*:—

"Sir,—Since the outbreak of the terrible epizootic, which for so many months has ravaged Great Britain, I have read with deep interest all that has been contributed to our knowledge of this very remarkable and formidable disease. Amongst the very first, and, I venture to say, most valuable contributions made in this country to our knowledge of Rinderpest, must assuredly be placed the admirable report on "The Pathological Appearances of the Cattle Plague," by Dr. Andrew Smart, which was

published in your columns on September 13. In that report Dr. Smart, who had only a short time before (September 1), been appointed by the magistrates to investigate the prevalent disease, gave the result of a laborious and painstaking investigation into the pathological anatomy of Rinderpest, and placed on record a mass of facts which, whilst they have served to enlighten those whose duty it is to recognise the disease, served to dispel certain errors which prevailed as to the supposed analogies existing between the, to us, new disease, and certain malarias already well known to affect man. Although a considerable time has elapsed since the report to which I have referred was published, it constitutes one of the very best contributions to our knowledge of the cattle plague, and, as such, most certainly entitles its author to the credit which I trust all who are acquainted with the subject have freely allotted to him.

"Some weeks after the appearance of Dr. Smart's report (September 29), a Medical committee was appointed by the Town Council of this city to investigate the disease which was attracting so much attention, and, in accordance with the request of the magistrates, this committee—of which Dr. Smart was only for a very short time a member, and over which Dr. Andrew Wood presided—commenced its studies: studies which, in so far as the public have as yet been informed, merely led the commissioners to conclusions which have been proved to be erroneous, and to suggestions of whose uselessness experience has long since acquainted us.

"Such being the facts of the case, my astonishment was considerable to find, on reading a pamphlet on the cattle plague by Professor Playfair (which originally appeared in the *North British Review*, but which was afterwards reprinted in a separate form), that Dr. Smart's report is to a certain extent placed to the credit of our very worthy, but, I venture to say, very useless Cattle Plague Committee. 'We refer with approbation,' says Dr. Playfair, 'to the description of the disease given by Dr. Smart in the excellent and practical report of the Edinburgh committee, over which Dr. Andrew Wood presided. The Committee worked with uncommon energy, and produced a report in about a week after they were appointed by the Lord Provost and magistrates—a report which in reality contains one of the best descriptions of the morbid anatomy of disease which have yet been published in this country.'

"When it is remembered that Dr. Smart's pathological report was published on September 12; that the Cattle Plague Committee only came into existence on the 29th of that month; that the first report of the Committee was only published some time after; and that the Committee never published any pathological report, I cannot easily understand how Dr. Playfair could have attributed to the Committee what was undoubtedly the result of Dr. Smart's individual labours. My astonishment at Dr. Playfair's inaccuracy is all the more heightened by the fact that Dr. Playfair is himself a member of this Committee.

"It is a knowledge of the fact that there is nothing more galling to a scientific man than to find the results of a painstaking and successful investigation attributed to those who neither directed it nor shared in the toil, which prompts me to ask you to find a place in your columns (in which Dr. Smart's report first appeared) for a statement which the wide circulation of Dr. Playfair's pamphlet renders eminently called for.—I am, &c., "AN EDINBURGH PHYSICIAN."

COMMUNICATIONS have been received from—

Dr. T. C. SHINKWIN; APOTHECARIES' HALL; Mr. R. GRIFFIN; Dr. HERAPATH; Mr. W. H. PLATT; Mr. R. LAWSON TAIT; Dr. S. GIBBON; Dr. A. FLEMING; Dr. R. FOWLER; Dr. T. M. LEAK; A SUBSCRIBER; IGNO; Dr. A. MEADOWS; ROYAL COLLEGE OF PHYSICIANS; Dr. F. J. FARRE; ETHNOLOGICAL SOCIETY OF LONDON; STUDIOUS READER; Mr. F. H. WARREN; Dr. G. H. PHILIPSON; Mr. GEORGE S. GIBBS; Dr. CAMPS; MEDICAL OFFICERS OF FULHAM UNION; ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Mr. J. JACKSON; Dr. FREDERICK J. BROWN; Mr. T. P. MORASSY; A. B.; Mr. R. HARRISON; Dr. BUCHANAN; Mr. G. GASKOIN; Dr. CHRISTIE; Mr. SPENCER WELLS; Mr. J. HUTCHINSON; Dr. HUGHLINGS JACKSON; Dr. DUNCAN MACINTYRE.

BOOKS RECEIVED—

Owen's Comparative Anatomy. Vol. II.—Dobell, On Winter Cough.—Odling's Animal Chemistry.—Morgan, On the Danger of Deterioration of Race.—Local Museum Notes. No. 1.—De Morgan, On the Use of the Chloride of Zinc.—Memorandum for the Sanitary Committee. By the Medical Officer of Health, Glasgow.

NEWSPAPERS RECEIVED—

Saunders' News Letter.—Macclesfield Courier.—Birmingham Daily Post—The Cambrian.—Sunday Gazette.—The Grocer.—The Scotsman.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·396 in. The barometric pressure was 30·23 in. on Sunday, and fell to 28·97 in. on Saturday.

The general direction of the wind was variable.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Duhlin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 36·8°.

APPOINTMENTS FOR THE WEEK.

March 24. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Rev. G. Henslow, "On Structural and Systematic Botany."

26. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

27. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p m.; St. Peter's Hospital for Stone, 3 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. John Crawfurd, Esq., President, "On the Invention and Use of Writing Materials." Prof. Dadabha Naorji, "Notes on Mr. Crawfurd's Paper on the European and Asiatic Races."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. T. Holmes, "Case of Lumbar Colotomy." Dr. Morchead, "On the Pathology of Pneumonia and Hepatitis."

28. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

29. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

30. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

MAW'S CATALOGUE.

A NEW EDITION OF

S. MAW AND SON'S

PRICED CATALOGUE OF

SURGEONS' INSTRUMENTS AND APPLIANCES,

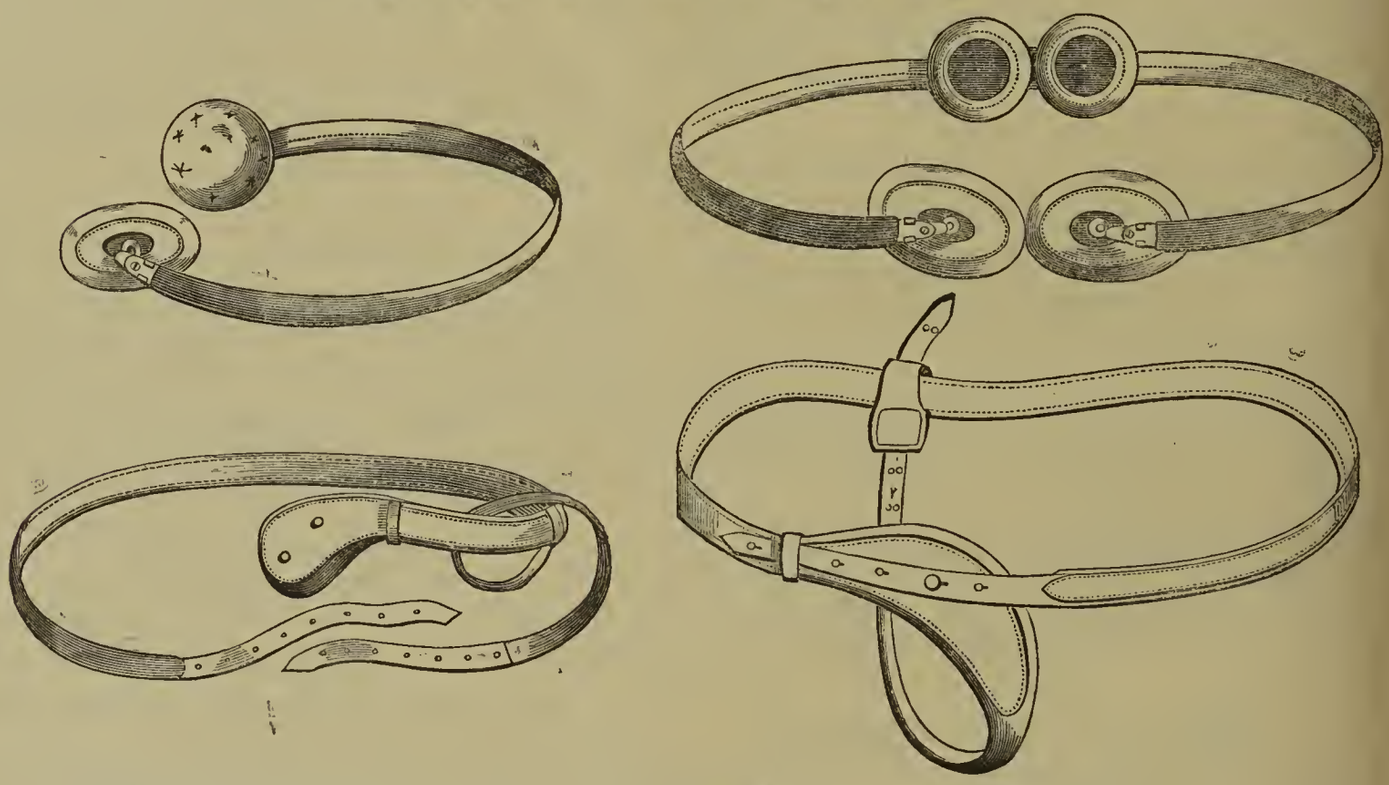
Greatly enlarged, and profusely illustrated, is now ready, and may be had gratis by members of the Medical Profession on application at 11, Aldersgate-street, London, E.C.

Parties at a distance will be supplied on furnishing name and address, either through any respectable Chemist, or free by post on receipt of four stamps.

S. M. and Son, in order to consult the convenience of the Profession, and to obviate the multiplicity of small accounts, have made such arrangements that Instruments of their manufacture may be obtained through most Chemists throughout the United Kingdom at their list prices.

11, Aldersgate-street, London, E.C., Feb. 1st, 1866.

TRUSSES.



COMMON SINGLE TRUSSES, Circular Form, covered with Basil and Chamois Leather, warranted best springs	per dozen.	£1	0	0
Do., do., covered with Red Leather or Stout Calf, and lined with Jean	per dozen.	1	10	0
COMMON DOUBLE TRUSSES, Circular Form, covered with Basil and Chamois Leather, warranted best springs	per dozen.	2	0	0
Do., do., covered with Red Leather or Stout Calf, and lined with Jean	,,	2	14	0
SINGLE PATENT TRUSSES, on Salmon and Ody's expired patent principle	,,	2	0	0
Do. do. do.	,,	3	18	0

These Trusses are capable of being lengthened or shortened, and are furnished with an extra spring to increase the strength if necessary.

Truss for Scrotal Hernia, with elongated pad—Single, 5s. each; Double, 10s. each.

S. M. and S. have made such arrangements that members of the Medical Profession, not having accounts with them, will be able to obtain Trusses of their manufacture at the advertised prices through most respectable Chemists, or they will be forwarded, on receipt of a remittance, direct from

S. MAW & SON, 11, Aldersgate-st., London, E.C.

ORIGINAL LECTURES.

ON

GENERAL AND LOCAL CHEMICAL AND MECHANICAL DISORDERS ARISING FROM ERRORS OF CHEMISTRY IN THE DEVELOPMENT AND REPAIR OF THE BODY.

By H. BENCE JONES, M.D., F.R.S.

Part IV.—Lecture XI.

Instead of giving you one lecture on this subject it might well, from its vastness, furnish me with materials for a complete course, for the chemistry of nutrition is much more complex than the chemistry of oxidation because it includes not only the chemistry of the formation of the tissues or the assimilation of the albuminous principles of the blood to each organ, but also the chemistry of the removal of the used materials. This chemical building up and chemical taking down must have a direct dependence the one on the other, both in the substances taking part in the quality of the actions, and in the rate at which those actions are carried on.

Moreover, oxidation is actively concerned in rendering the old materials volatile, or soluble, or removeable, and this source of fuel is an economy of the machine; and when food is insufficient, or starvation occurs, it enables it to continue its work, using the products of its own structures and its own stores of fat as sources of power.

If the chemistry of repair is complicated and imperfectly understood, far more ignorance exists regarding the chemistry of development. The chemistry of the formation of the first blood globules, the first nerve cell, or muscular substance, or cartilage in the fœtus, will perhaps never be understood; but when once these substances are formed, it seems comparatively easy to comprehend that like produces like, although this universal law is only a statement of the fact that nerve produces nerve, and muscle muscle, and bone bone, and furnishes no explanation whatever of the chemistry of development or of repair.

The clearest idea I can offer you at present is that each particle of the body must be considered as a ductless gland, having a contact action on the materials of repair brought to it, so that it separates the substances that can be changed into its own structure. If the fœtus would grow where the mammary gland exists, so that instead of milk being formed the fœtus would take from the blood just that which is required to form each structure and tissue of the body, you would on a great scale have a demonstration of the different chemical actions which are continually going on in the building up of each particle of our textures. Each portion of muscle, or nerve, or other tissue takes from the blood that which can nourish it, but in order that this nutrition may be effected not less than three different actions must simultaneously be going on.

First, the food must be brought; secondly, the chemical action of assimilation must take place; and thirdly, the old materials must be taken away. If the balance is not rightly kept between these mechanical and chemical actions, malformations and all degrees of wrong growth between hypertrophy and atrophy will occur.

I shall divide the diseases from the wrong action of one or of all these causes into two great classes; one I shall consider arises from pertrophic, and the other from subtrophic, chemical actions. Hypertrophy and atrophy constitute extreme cases of opposite actions in these two classes of disease.

In every machine the wear must be proportioned to the work, and the amount of repair required depends upon the wear. Hence, from the amount of work done, you may draw some judgment as to the amount of repair that is necessary. Helmholtz states that the best Austrian steam engine can raise its own weight 2700 feet in one hour; whilst he calculates from the pressure of the blood that the human heart raises its own weight 20250 feet in one hour, so that the human machine requires an amount of repair very much beyond that of a first-rate steam engine, and errors of repair, pertrophic and subtrophic, must be ready at all times to occur.

In nutrition the first important condition is that nutritive substances should be brought to the spot where the action of assimilation is going on; this is effected primarily by the circulation through the blood vessels, and secondly by diffusion of lymph into the structures. The third equally important condition is that the used substances should be taken away, and this also is effected primarily by the circulation through the blood vessels and, secondly, by the circulation through the lymphatics. As the circulation in the blood vessels is under the regulating power of the nervous system, it follows that two out of the three simultaneous actions of nutrition are under the direct influence of the nerves.

There is as yet no evidence that the second necessary condition, that of assimilation, can be altered directly in quality or quantity by the nervous system. Indirectly, by lessening or increasing the amount of substances that go to or come from any part, the nerves can exert a potent influence on the pertrophic or subtrophic actions; and indirectly by altering the circulation the nerves can exercise an influence on the peroxidation or suboxidation in any tissue, and thus the temperature at which the process of assimilation is carried on may be affected.

In the vegetable world, on account of the much greater variations of temperature that occur, it is easy to see how assimilation is influenced by heat. The tropical plants will grow in our light, provided the heat of the tropics is given to them here. If in the full light of the sun a plant could be kept all the year round at a temperature just above freezing little or no assimilation would take place.

In animals also the chemical actions of assimilation depend on the temperature, and the variation of a very few degrees makes a material difference in the chemical actions which take place in the textures.

In the present state of our knowledge it is not possible for me to classify the different diseases that are produced by different errors of repair arising from errors of action in the different processes of nutrition. At some future time there will be a class of diseases arising from excess or deficiency of materials to be assimilated, another large class arising from wrong chemistry of assimilation itself, and another arising from excess or deficiency in the removal of materials that have assimilated. Ultimately animal chemistry will enable us to make a far more perfect classification of pertrophic and subtrophic diseases than at present is possible; and now, from want of knowledge, more than from want of space, I shall take only one or two of these diseases of nutrition, and omitting any explanation of the wrong chemistry that produced the malformation and sets up the mechanical diseases, I shall again show you how secondary chemical diseases may arise from the mechanical errors which may be vastly more dangerous than the slight chemical errors by which the mechanical diseases were originally produced.

Perhaps two of the most striking examples that I can bring before you will be imperfect closure of the foramen ovale, and imperforate hymen—two opposite errors of development, the one depending on subtrophic and the other on pertrophic action. Each of these opposite chemical wrongs produces an opposite mechanical effect; and these mechanical diseases give rise to chemical disorders, which ultimately may stop the working of the machine. Imperfect closure of the foramen ovale and ductus Botalli produces general suboxidation, and imperforate hymen causes an absorption of poisonous products of decomposition, which affect and ultimately stop all the chemical actions of nutrition.

In the first disease the result of the subtrophic action is that a space between the two hearts is not filled up. The blood in consequence passes from the right to the left side, without going through the lungs. By this slight mechanical error, as it might seem, compared with the perfection of the rest of the machine, the whole chemistry of respiration is reduced to its lowest point. The absorption of oxygen is so diminished that the blood is not arterialised, and the carbonic acid is not liberated. The chemical action that takes place outside the capillaries, on which the heat and the power of the body depend, is reduced below the average. Dr. Forster, in the *Dublin Quarterly Journal*, August, 1863, mentions some experiments in two cases. In one, "the fingers were seldom more than 5° F. to 8°, the toes 1° to 3° higher than the temperature of the room. In the other the fingers were from 6° to 9°, the toes 2° to 4°. In the mouth in one the temperature was 96°, and in the other 97½°. In one it once fell as low as 90°, and in the other to 92° F." Even the chemistry of repair, by which the reformation of the different structures takes place, falls below the healthy amount. The body is weak, and

wastes until premature death liberates the elements and allows the forces they possess to act with greater energy.

Thus, then, the results of this slight deficiency of nutritive action is general suboxidation from insufficient supply of oxygen to the blood and textures; and from this local passive congestions are apt everywhere to occur, and general subtrophic action is the final result.

The first chemical causes of the disease cannot be touched, and the mechanical complaint itself is not within reach; so that the symptoms and complications are alone capable of treatment, and as these proceed from suboxidation and subtrophic action, the mechanical and chemical promotion of oxidation and nutrition are the indications to be continually carried out. The oxidation may be promoted by constant attention to the warmth of the surface and by mechanical friction. Dr. Foster says that peroxide of hydrogen in eight minim doses three times daily improved the colour, made the breathing less laboured, and caused a rise of temperature. The subtrophic action may be palliated by warmth and friction, and also by reducing the work of the machine so far as to avoid all exhaustion. By giving the utmost external warmth the minimum amount of the force set free in the body is required to be expended in keeping up the temperature of the body; and the greatest amount of force remains capable of conversion into motion in those muscles which are necessary for circulation and respiration. If a part of the total force is spent in voluntary actions by strong exertion, the supply of power to the heart and lungs is so lessened that the tendency to passive congestions in the circulation is increased, and then mechanical obstructions, which constitute the most dangerous complications, are produced.

In contrast to this subtrophic disease, I will now shortly bring before you the pertrophic malformation of which I spoke to you, imperforate hymen. Whether a locally increased supply of nutriment leads to the excess of development, perhaps will never be determined, but the mechanical wrong remains for years, producing no bad effects; and if menstruation did not take place, the original complaint might remain unknown throughout life. As soon as menstruation begins, the chemical secondary disease begins also. The excrementitious blood finds no means of escape. It remains within and undergoes chemical changes; products of disintegration, which chemistry has yet to determine, are formed. Those that are soluble are absorbed with the water of the effused blood, and month by month this process is repeated, until the blood and the textures are poisoned, and nutrition and oxidation are modified or stopped, and anæmia, debility, dropsy, and death may result.

With regard to the treatment of the symptoms and complications arising from the chemical disease, nothing need be said, because the mechanical disease can be got at. If it were otherwise, chemistry has no antidote for the poison, and as in uremia or in jaundice, we should be able, perhaps, to do very little for the chemical cause of the complaint, but in imperforate hymen the slightest mechanical operation is all that is required to remove the mechanical obstruction, and then if no inflammation comes on, as no further poisoning takes place, gradually the blood and textures recover their healthy composition—all the poison is oxidised and removed.

Instead of drawing my examples of the origin of chemical disease from malformations, I might show you that the same relationship exists by taking errors of reformation or repair. In nutrition pertrophic or subtrophic errors occur, and from these mechanical and chemical errors arise, which may be far more serious than the original wrong action. In the three simultaneous actions that constitute nutrition, it is not always possible to separate the effects of each action in producing the error of nutrition; but in some cases it is possible to find more of one than of the other two actions, as in the following examples:—

First, let me bring before you chemical diseases of repair, arising chiefly from variations in the supply of nutriment.

Speaking of Hunter's well-known experiment, Mr. Paget says, "When the spur of a cock, for example, is transplanted from the leg to the comb, which abounds in blood, its growth is marvellously augmented, and it increases to a long, strange-looking mass of horny matter, such as is shown in two preparations in the Museum of the College. In one (54) the spur has grown in a spiral fashion till it is six inches long, and in the other (52) it is like a horn curved forwards and downwards, and its end needed to be often cut to enable the bird to bring his beak to the ground in feeding and to prevent injurious pressure on the side of the neck." If this mechanical pressure had not been removed by operation, it would probably have caused the death of the animal by obstruction or starvation. So that here is an instance of a pertrophy producing a serious mechanical complaint.

Instead of an excess of nutriment there may be a deficiency, and the sub-trophy from the want of raw material may be rapidly fatal. I am again indebted to Mr. Paget for my illustrations. "A Medical man wished to be bled in a fit of exceeding drunkenness, and some one bled him—bled him to three pints. He became very ill, and next day both his feet were mortified from the extremities of the toes to the instep."

One of Mr. Swan's donations to the College Museum is the larynx of a man who, while in low health, cut his throat, and suffered so great a loss of blood that the nutrition became impossible in one of those parts to which blood is most difficultly sent, and before he died his nose sloughed.

Secondly, I will mention states of pertrophy and subtrophy arising from the actions of assimilation going on in a part, and I shall then show you the mechanical and chemical diseases produced from these altered states of nutrition.

I shall draw my examples here from enlargement of the uterus during pregnancy, because the first commencement of the increased growth does not depend primarily on the increased flow of blood, but on the changes in the uterus itself which determines that flow. The increased action in the uterus itself must be set up by the intense actions going on in the impregnated ovum, and by the internal mechanical pressure of the foreign substance in the uterus. As soon as the increased nutrition begins, the increased flow of blood follows, and keeps up the rapid formation of the different structures of which the uterus is composed. As soon as the pressure is removed, and more or less loss of blood has occurred, the structures cease to be nourished, and in a few weeks no trace of the increased nutrition can be found.

During the time of the greatest pressure very many different mechanical results may be produced, and thus mechanically very different secondary chemical diseases may arise. In speaking of tubular nephritis I have mentioned the obstruction of the renal vein in pregnancy, and the consequent production of Bright's disease and uræmia. Another most frequent chemical disease from the pressure is jaundice. More rarely gall-stones and all their tertiary mechanical agony occur. Another disease resulting from pressure is hæmorrhoids, and these inflame and cause great additional suffering.

When the pressure in the act of delivery reaches an extreme height, then many more chemical diseases are produced. Of these I may mention a few, as sloughing of the soft parts; inflammation of the perineum from rupture; inflammation of the peritoneum from rupture of the uterus; rupture of the air vesicles of the lungs and general emphysema of the cellular tissue; stoppage of the chemical action of respiration in the fœtus.

It is in the highest degree probable that by chemical agents the force of assimilation in the different textures may be increased or diminished in its action. Animal chemistry at present has hardly touched upon this subject, and I can only give you one or two examples, which, however, may serve to point out the vast and important field which is here open for future research. When I come to the classification of medicines I shall endeavour to show you that one grand class consists of those substances which promote or retard the chemical actions of nutrition—not by causing more or less blood to flow to any part, nor by hastening or retarding the removal of the used substances, but by increasing or diminishing the chemical actions which are concerned in assimilation.

The example which I will here mention of increased nutrition by the action of a chemical substance is for the chemist that invaluable fact that iron, even metallic iron, iron rust, or the finely-reduced metal itself, taken into the body produces an increase of blood globules. Where and how this chemical action takes place chemistry cannot yet make out. The iron, when taken, is probably acted on by acids in the stomach, and is absorbed into the blood and diffused into every structure; but whether the colourless corpuscles in the lymph, the spleen, and the blood itself by the action of iron and oxygen form hæmatocrystallin cannot be determined. We know that lymph reddens when exposed to the air, and that in the spleen transitions from white to red corpuscles may be observed, and coloured cells and nuclei, which appear to be disintegrated blood globules, may there be found mixed with products of oxidation—as uric acid, hypoxanthin, xanthin, leucin, tyrosin, inosit, volatile fatty acids (formic, acetic, bytyric), lactic acid, many colouring matters, an albuminous substance, con-

taining iron, and generally very many iron compounds. This tells us very little as yet; but chemistry will some day say how and where the increase of hæmatocrystallin occurs when iron is taken. A somewhat similar, but less important example exists in the action of phosphate of lime and of carbonate of lime in increasing the growth of the bones in cases of rickets; and a well-known and often-applied theory exists that phosphorus taken, not only in substance, but even as phosphoric acid, can increase the formation of nerve substance; but for this there is at present not the smallest shadow of foundation. It has also been said that zinc is to the nerves what iron is to the blood; but there is absolutely as yet no chemical evidence that zinc, or any salts of zinc, have any power over or take any part in the formation of nerve substance. Far more probable is it that zinc acts like lead, and perhaps silver, in retarding or stopping the chemical actions which are taking place in assimilation, and thus producing what I may be, perhaps, allowed to designate as a chemical disease.

One of the most striking instances of the action of a chemical substance in diminishing nutrition is lead disease. The poison may be seen in the gums, and felt in the bowels, and be got out of the muscles of the arm, and as three grains of sulphate of thallium, when given to a rabbit, could in six and a half hours show thallium distinctly in the aqueous extract of the lens, and as even two grains in six hours also gave there slight traces of thallium, there can be little doubt that the salts of lead pass everywhere—into the blood globules, into the muscles, into the gums, and even into the lens of the eye, and that according to their power and according to the actions going on in the parts, it exercises a greater or less influence upon the chemical changes which are taking place. In the voluntary and involuntary muscles the lead must either combine with the syntonin or be precipitated in it as an insoluble sulphuret, and so stop the chemical changes upon which the action of the muscles depends. It is highly probable that salts of lead act upon other textures; as, for example, on the young blood-globules, stopping the formation of hæmatocrystallin; and on the sympathetic nerve, causing the violent pain of colic; also on the muscular coat of the small arteries, lessening their increased action, as when applied as a lotion in inflamed skin; but on all these points chemistry must give us far more exact information than we at present possess. I might say the same for silver, arsenic, copper, and many other medicines.

The action of salts of silver in making the conjunctiva blue when applied as a lotion, and in making the skin permanently blue when it has been taken as medicine, shows how substances enter and act chemically in the textures. A grain and a quarter of sulphide of silver was given to a guinea-pig in twelve days. The silver was found in the ashes of the liver, kidney, and stomach; less distinctly in the bile and the urine, still less in the lenses of the eye. It was not detectable in the ash of the brain, probably because the quantity taken was too small.

The two diseases of repair which will best bring before you the origin of chemical and mechanical disorders are anæmia and lead paralysis, the one arising from the absence of iron and the other from the presence of lead.

The chemical diseases of subtrophy and suboxidation which are produced by anæmia are as opposite as dropsy and fatty degeneration. General debility, not only muscular and nervous weakness, but feeble growth and feeble production of heat, characterise anæmia. The pressure of the blood in the arteries becomes so feeble that the circulation stagnates in the capillaries and the effused lymph in the cellular tissue tends to accumulate, not only in the lowest part of the body, but even in the lowest part of different organs.

Local congestions are ready to produce obstructions, around which the lowest degrees of peroxidation are set up, and the most feeble inflammations give rise to a fresh resistance, which is often more than the heart can overcome. In every texture the want of healthy change from imperfect supply of oxygen becomes evident, not only in the function of many organs, but even in the fatty formation and deposition which in anæmia rapidly adds to the general weakness and contributes to the subtrophic action which the deficiency of oxygen occasions.

Thirdly, I will show you the relationship of chemical to mechanical disease in the results of errors of excess or deficiency in the process of the removal of the assimilated materials.

That removal of a product does exercise an influence on its growth is evidenced in shaving the hair, or cutting the nails, or taking away the milk teeth; and within the organs it is highly probable that some medicines hasten the formation and removal of disintegrated substances. Thus oxygen, mercury, iodine, and, indirectly if not directly, alkalies increase the changes in the assimilated material, and, as in the example of mercury, may set up so rapid an action that peroxidation, even as evidenced by all the phenomena of inflammation, may be produced.

Moreover, errors of deficiency of removal may give rise to chemical diseases, from which mechanical disorders may follow. Lead palsy, again, well illustrates this, and shows also the relationship that exists between the chemical actions of assimilation and removal, for the poison stops both processes, and thereby produces a loss of mechanical power, which is seen in the inability of the muscles of the forearm to support the weight of the hand.

(To be continued.)

THE PHYSICAL AND CHEMICAL CHANGES IN LIVING BEINGS FROM A PHYSIOLOGICAL POINT OF VIEW.(a)

By Dr. LIONEL BEALE, F.R.S.,

Fellow of the Royal College of Physicians, Professor of Physiology and of General and Morbid Anatomy in King's College, London, and Physician to King's College Hospital.

If we look upon muscle as a mass of chemical material and regard the brain as a pulp, the modern chemical and mechanical theories may appear plausible. Accepting this, we might proceed to discuss the changes which take place in them, just as we might those occurring in a precipitate undergoing chemical changes in a beaker, a retort, or a crucible. And we might say that to facilitate chemical change the mass of brain or muscle is penetrated here and there by tubes which carry solutions of muscle and brain to those parts where new muscle or new brain is to be precipitated, while, at the same time, the circulating fluid carries oxygen to burn the wasted stuff and dissolves and carries away the substances resulting from the combustion.

Those who maintain that the process of nutrition as it occurs in animals and man can be studied from a chemical point of view only seem to forget that the tissues cannot be fairly looked upon as chemical precipitates, because each is composed of certain minute anatomical elements or cells, and each cell is an active agent, performing many parts. Some, however, admit thus much, but assume that each cell is provided with a certain peculiar *machinery* by which it is supposed to alter matter and condition force. Not one of the mechanico-chemical philosophers has, however, attempted to explain what really takes place in the cell, or demonstrate the *cell-conditioning machinery*. The advanced modern chemist summarily dismisses all cell considerations as if they were out of his province.

Moreover, the general conclusions upon the subjects of nutrition and growth, health and disease, life and death, arrived at by those who have considered these matters from the chemical point of view, are not in harmony with what has been ascertained by actual observation. It has been proved that in these minute bodies ("cells"), and through their agency alone, nutrient pabulum undergoes *conversion* into *new substances* characteristic of the particular being or texture of which they form a part. And it is therefore obvious that a thorough investigation of these cells as they live under different circumstances by careful microscopical observation with the aid of the highest powers, combined with a minute chemical examination of the various substances entering into their composition, is essential. The entire tissue or organ is but an aggregation of units. It is a mass composed of a number of these individual parts, and if we could learn the history of the life of one of them, we should be able to give a clear account of the entire tissue or organ; so that the facts of the case do not permit us to look upon tissues and organs as masses of chemical pulp in which mere chemical change is going on. Each constituent cell is a perfect working laboratory, but without apparatus or chemist, and a machine without the imperfections necessary to machinery, for it is self-forming, self-producing, self-regulating. The cell, therefore, is neither a laboratory nor a machine, for a room in which there is neither apparatus nor a chemist is not a *laboratory*, and no *machine* makes itself, but every machine is made by us.

(a) Part of a lecture delivered in connexion with the physiological course at King's College, 1865.

Nor do these observations apply only to questions of structure and development of interest only to the minute anatomist. The same careful study of the individual cell is necessary for working out the nature of the phenomena of disease. We cannot hope to arrive at any general conclusions with reference to some of the most simple morbid changes until the phenomena occurring in the cells have been carefully ascertained and the differences resulting from the action of different external conditions, various kinds of pabulum, etc., demonstrated. Had chemists made a careful comparison between the cells of a tissue in a state of health and those of the same tissue in a state of inflammation, they would have seen differences which would have convinced them at once that the morbid state did not differ from the healthy state merely in the activity of oxidation or other chemical processes, and a very little reflection would have led them to doubt if there was increased oxidation after all. Simply because there is increased heat, the chemist at once jumps to the conclusion that there must be increased oxidation. Is it impossible that a high temperature can result in any other way, or is this only impossible to the chemist? Little real advance seems to have been made of late in purely chemical physiology. Crude and sweeping general observations, perhaps interesting and plausible enough at the time they were first advanced, have been revived and repeated till the mere repetition has made them ridiculous. In these days, even non-Professional persons desire to penetrate a little into the nature of the wonderful phenomena going on in living organisms, and do not accept as a satisfactory explanation the assertion that a certain homogenous plasma becomes *differentiated* into such and such elements of structure; that the lungs are a furnace, and the windpipe its chimney; that in inflammation the fire burns a little too fiercely, from the draught being too great; that fevers are fermentations, and fermentations catalytic actions. People want explanations, not dogmatic assertions and high-sounding but empty phrases and words of many syllables. Scientific men are bound to give simple explanations of those things which they can explain, and confess their inability to account for that which they do not understand. The wonderful phenomena which *sharply* distinguish things living from things inanimate can be explained far more clearly by referring to some simple organism than by reference to the most complex. That marvellous process of nutrition never has been and cannot be rendered intelligible by the many attempts to explain how the entire organism of man is nourished, because "nutrition" comprehends many departments of physiology. The case, however, is somewhat different if we try to explain step by step what goes on in the nutrition of a monad or single cell, and by confining the exposition to so limited an area an opportunity is given to those we are teaching to ask us questions as we proceed, and observers who think or interpret differently from us can express their disapproval of any statement made, every chance is afforded for free discussion, and any general conclusion arrived at may be analysed or minutely dissected by an opponent, and objections urged to every one of the many positions taken up, while the weak points of the arguments cannot escape being exposed and seized upon.

The recent very positive assertions of chemists concerning oxidation and the development of heat in living organisms will be justified only if it should appear that they really know very much more than they have stated. The physiologist is told that fat and starch are oxidised; but when he asks how and where, he gets no satisfactory answer. Perhaps he is told to look at a burning candle, and when he meekly suggests a little difference in the temperature, etc., he is silenced by "differences certainly, but only of degree!" The quantity of muscle consumed in providing the motor force necessary to take a man to the summit of Mont Blanc has been calculated to a nicety; but the chemist has not even inquired whether the removal and reproduction of the large amount of muscle he estimates be possible within the time. It is very well to assert roundly that the heart consumes half its own weight in the performance of every twenty-four hours' work; but before the chemist accepted such a view it would have been well to have inquired how so much could have been taken away and added within so short a time. To the chemist who knows nothing of structure, the *oxidation* of a little old muscle and the *precipitation* of a little new muscle may seem surpassingly easy; but the physiological student is not so easily satisfied. He inquires what goes on during the oxidation and precipitation. He knows that the muscle has a remarkable structure, and takes a much longer time for its formation than the new philosophy allows. Any one who has carefully considered these things, and has seen with his own eyes what can be seen, will have formed a very different estimate of the process. It may be profoundly satisfying to some who yearn for knowledge to be assured that the sun *forms* the heart, and that all our actions are mere attractions and repulsions; but to real students such meaningless dogmatising looks like a melancholy effort to obstruct or prevent inquiry. Any one attempting to force upon us these and other doctrines of the same anti-philosophical character gives us credit for the possession of but a very small amount of common sense. Oxidation and the heat-producing process have been much regarded of late from a physico-chemical stand-point. It may therefore be interesting and advantageous to look at these phenomena from a somewhat different point of view.

In some papers published in the *Medical Times and Gazette* last year I discussed the process of nutrition in the single cell, and I propose now to consider the subject of oxidation from the same point of view. I showed that nutrition might take place without oxidation, and that oxidation was not a necessary accompaniment or result of nutrition. Oxidation in living organisms involves the previous occurrence of nutrition. Life may exist without nutrition; but it cannot *extend* without this process taking place. Life may, however, exist and extend from particle to particle without oxidation. Life is no more a *result* of nutrition and oxidation, or the *consequence* of these processes, than the mind that designs the engine, or the workman who makes it, or the factory in which the manufacture has gone on, are results of the putting of coals into the furnace and their combustion after the machine has been completed.

ORIGINAL COMMUNICATIONS.

ON LOCAL ANÆSTHESIA BY DR. RICHARDSON'S METHOD.

By ARTHUR ERNEST SANSOM, M.B.Lond.

As soon as possible after Dr. Richardson's announcement of the details of his process, I endeavoured to follow in his steps. The narrative of my progress, my failures, and my successes, may not be uninstructive to those who come after.

My preliminary experiments convinced me that the anæsthesia which was produced by the ether spray was due simply to the low temperature caused by the rapid vaporisation. The very facts of the production of cold, the consequent contraction of the blood-vessels, and the paralysis of the nerves, render impossible any absorption of the anæsthetic.

The first case in which I employed the anæsthetic spray-producer was one of local hyperæsthesia. A patient had suffered from obstruction of the gall-duct. It seemed to be not from gall-stones but from gritty bile. The urgent symptoms had passed off, but there was exquisite tenderness over a small portion of the epigastrium. I directed upon this portion of the skin the ether spray for a considerable time. The temperature was reduced to zero. I am constrained to say that only small relief was afforded. I repeated the operation many days successively, but relief was very transient, and finally the hyperæsthesia was removed by large doses of ether internally administered. I think the sequel will show that this case brings no discredit on the local anæsthesia process, but simply indicates that the tenderness and pain were due to causes too deeply seated for the congelation method to influence.

The next case was a sebaceous tumour of the neck, just below the ear. I attempted its extirpation. I directed the spray upon the tumour for nearly two minutes. I then made an incision, which caused very little pain. On endeavouring to seize the cyst-wall, however, pain was experienced, so that I desisted and again applied the ether-spray. Some inconvenience was occasioned by the cold produced, and the wound smarted; and even then, on removing the cyst-wall, pain occurred. Altogether the patient (a Medical man) did not approve of the process.

A third case was a patient of Mr. Baker Brown's, at the London Surgical Home. An operation was intended for removal of an hypertrophied clitoris. I know by experience the exquisite pain occasioned by this operation; it is one which usually requires the most profound influence of chloroform. I therefore suggested to Mr. Brown that the patient

should be narcotised to the end of the first degree of anæsthesia; that the ether-spray should then be directed upon the region whereon the operation was to be performed, and thus the patient should be spared the effects of a very deep narcotism. Mr. Brown, who is always willing to try the effect of any process which may promise to be an improvement upon the established state of things, immediately gave his permission, and the measures contemplated were carried out. The cut of the scissors, however, though the spray was applied for at least two minutes, caused very evident expressions of pain. Indeed, the effect of the local measure was almost *nil*. Soon afterwards I had the good fortune to meet Dr. Richardson, and I laid before him the narrative of my failures. He attributed these to my use of the ordinary ether of commerce, which is manifestly impure. I have, however, since been assured that the ether I employed was chemically pure; but then, on examining my spray producer, I found that by substituting for the fine wire in the centre of the exit tube another which was supplied by the manufacturers, I obtained a much more finely-divided spray. I determined to try again and employ the ether recommended by Dr. Richardson, and supplied by Messrs. Garden and Robbins.

On March 18 I saw a little boy who had a large subcutaneous abscess at the back of the neck. The child was very sensitive; he could not bear the pain of an incision, and the abscess required an immediate relief. I applied the spray gently at first, and the little boy complained slightly of pain. I desisted for a moment, and covered the whole part with olive oil. I then reapplied the spray, and suddenly, at the end of about forty seconds, the skin covering the abscess became as white as a piece of note-paper. I made an incision which was absolutely painless, and gave exit to a couple of ounces of pus. Not the smallest ill-effect was produced; the relief was complete and permanent.

Yesterday I again applied the spray in a case of abscess in the perineum. One knows how extremely sensitive these parts are. Suffice it to say that the white appearance was produced in about a minute. The process was completely successful. So contracted was the skin that the extrusion of matter was almost complete, and to-day I find that healing is taking place with more than ordinary rapidity.

"Honour to whom honour!" I have stated my failures that my successes by Dr. Richardson's process may stand out in more bold relief. The former teach certain lessons which it will be well for all to bear in mind.

1. Be careful that the instrument is so arranged as to produce an equable and very finely-divided spray.
2. Employ perfectly pure ether.
3. Never commence any incision of the skin until a perfectly white appearance has resulted from the application of the spray.
4. In sensitive persons do every step of the process gradually, cover the sensitive parts with a bland application, and nothing is so suitable as olive oil.

This process will be invaluable in operations which principally involve the surface of the skin. In those in which the more deeply-seated parts are concerned, I think that it may be with great advantage combined with general anæsthesia. But in cases of severe or capital operations, I think that the absence of consciousness induced by chloroform is all-important. These are most potent words written to Sir James Simpson by a patient of his own who suffered all the horrors of an operation before the days of anæsthesia:—

"The unconsciousness of the patient secured by anæsthetics is scarcely less important than the painlessness with which he permits injuries to be inflicted on him. To steep his senses in forgetfulness, and throw the intellectual machine out of action, when, if allowed to work, it only moves with a rapidity and irregularity which threatens its integrity and permanently injures it, is to do him a service second only to that of saving him from suffering."

29, Duncan-terrace, N.

The subject of anæsthesia by the ether spray has again been under discussion at the "Société Impériale de Chirurgie." M. Marjolin complained of ill-success with Lüer's apparatus, though used by M. Lüers himself, and of the inconvenience arising from the vapours of the wasted ether. M. Leon Le Fort called attention to the necessity of using *rectified* ether only, and declares that this is sufficient for small operations. For capital operations he has no intention of proposing it.—*L'Union Médicale*, March 27.

NOTES OF

SOME CASES IN WHICH ACUPRESSURE WAS EMPLOYED.

By Mr. LAWSON TAIT.

Acupressure has now had a sufficiently lengthened trial by some of our well-known Hospital Surgeons to show that it is deserving of confidence; and that, while it is as perfectly safe and under the Surgeon's control as is the ligature, it is possessed of many advantages over it, and can be used in cases where the ligature fails. In no case is the last statement borne out more thoroughly than in those troublesome cases of wounds of the wrist. How often do we find that patients who sustain such an injury have to go through the painful and tedious process of dissection and ligature of both bleeding ends of one or more vessels, and this repeated perhaps two or three times; and may after all have to submit to tight compressing, with the resulting profuse inflammation and sloughing of the disturbed tendons; finally, an almost useless hand Recently, I saw a case of this injury where tight compresses had at once been resorted to, and in spite of them, the bleeding was still going on. I at once removed them, and on discovering that there were only two bleeding points, one on each side of the wound, I secured them both with one needle, passing it through the edges of the wound, and bringing them together with a loop of wire, thus making the needle act as a stitch. The needle was removed in twenty-eight hours without the recurrence of hæmorrhage, and the wound was healed in four days. In another case, where a young girl had the dorsal artery of the foot divided, both ends were secured with one needle, with a perfectly satisfactory result.

The above cases, and most of the others which I shall have occasion to mention, occurred while temporarily engaged in country practice; and I may here state my opinion that if the employment of acupressure has proved an advantage in the hands of the Hospital Surgeon, it will prove one of infinitely more consequence to the country Practitioner. The application of the usual form of ligature requires an assistant, save in the hands of the most expert manipulators; while a recently-suggested improvement (?) on the old method of application requires three persons for its performance. It is but seldom the case that a country Practitioner can secure the services of a competent assistant on short notice; and therefore the fact that acupressure never requires more than one pair of hands for its application is of importance.

Wounds of the scalp, from their frequent occurrence in persons of drunken habits, and consequently of unsound constitutions with great tendency to erysipelas, require to have particular attention paid to the absence of all irritation which can possibly be procured. Thus it is that many Surgeons condemn even metallic sutures applied to such wounds as bad Surgery. Here acupressure shows to great advantage by getting rid of the presence of setons, and by the fact that frequently wounds can be closed and flaps kept in their places by the same means which check the bleeding. A man, while in a very drunken condition, fell heavily on the floor of a public-house, his hand, which held an ordinary dram-glass, falling under his head. The glass gouged a large V-shaped flap out of his forehead, and then breaking, cut the neighbouring skin very much. On examination it was found that there were three bleeding points, which were secured by needles, and in such a way that when the operation was over the flap was retained in position and the large wounds closed by the three needles without any stitches. The needles were removed in twenty-four hours, and the wounds healed absolutely by primary adhesion. This man had but shortly before recovered from a severe attack of erysipelas of the head and neck, and the absence of this complication after the accident is remarkable.

Two other cases have occurred to me of scalp wounds, in one of which the temporal and in the other the occipital artery was divided; the bleeding points in both were secured as in the case of wound of the wrist, and the needles were removed in about twenty hours, with most satisfactory results.

Recently I assisted Dr. Kirk, of Bathgate, in removing a fatty tumour from a lady's neck, and this case is of extreme interest, as it enables us to contrast the relative advantages of acupressure and the ligature, when both were placed under precisely similar circumstances. The tumour was of considerable size, and situated under the sterno-mastoid, while the

wound necessary for its removal was nearly four inches long, and in direction nearly parallel with the muscle.

No artery was divided which required to be secured, but two veins, one at either end of the wound, bled profusely. One of these veins was secured by a ligature and the other by a needle used in Knowles' method, and when the latter was removed at the end of thirty hours the wound was found perfectly glued together, and in this condition it remained for six days, when the track of the ligature began to suppurate, and continued to do so until it was forcibly removed on the fifteenth day after the operation. Now, in this case the wound was absolutely closed by primary adhesion until the seton action of the ligature re-opened the part where it lay embedded, and had no ligature been used there never could possibly have been a drop of pus. In this case the different hæmostatics had equal justice done them; the wound was large and deep, and remained, with the exception of its being closed by sutures, perfectly uninterfered with.

It has been urged by the opponents of acupressure that the presence of needles in the wound must give rise to great "pain and laceration," but I think the following case will convince any one that such is actually not the case. Dr. Kirk performed primary amputation at the upper third of the arm of a boy, aged 14, and had to secure five vessels, which he did by means of needles used in Knowles' method. The only kind of wire available at the time of the operation for attaching to the needles was of very bad quality, and on this account when the needles came to be removed two of them remained in the wound because their wires broke in the eye. No further attempt was made to remove them, and they remained in the wound for two weeks, and then making their appearance at the inner edge the patient removed them himself; while the fact of their creating no pain and no disturbance is borne out by the circumstance that the patient was unaware of their presence until he saw their heads sticking out. In this case the patient was a weakly, rather strumous-looking lad, so that union without the appearance of pus was not to be expected, but the amount of pus was marvellously little.

In another case of primary amputation of two fingers three vessels were secured by needles which were likewise made to do duty as stitches.

Since the above was written I have had a case of scalp wound caused by a tooth of a crown wheel which fell on a man's head. The tooth made a deep punctured wound, which bled very profusely from a divided artery. Had I applied a ligature (or more probably it would have been two ligatures) in this case, it would have necessitated a considerable extension, but by simply thrusting an ordinary sewing needle diagonally through the wound the bleeding was at once checked and the necessity for dissection avoided. Also in another case of amputation of a finger, when only one vessel bled, the needle did duty as a stitch, and was removed in twenty-four hours with a good result.

Thus, I think, it will be evident that while in the major operations of Surgery acupressure has advantages over the ligature, yet that it is in minor operative interferences where it is of most use—in such cases as every general Practitioner has under his care daily.

Since noting the above cases I have met with several instances of skin wounds, and in all of them, whether there was a bleeding point or not, I have used needles with the loops of wire instead of stitches, as I find that they are removed with less pain to the patient, and are preferable in many respects to the ordinary form of stitch.

Acupressure is, I am delighted to say, making a progress so rapid as to be in this respect almost unparalleled in Surgery. Dr. Stephen Scott, Surgeon to the Colonial Hospital at Demerara, who was in this country during last summer, and had opportunities of seeing acupressure employed, went home convinced of its practicability and advantages, and writes that he has now performed five amputations in which he employed it with perfect success.

Death of Dr. Thomas Dodgson, M.D.—This well-known Physician in Craven died at the Union Workhouse, at Skipton, and was interred in the cemetery on Wednesday afternoon. The Doctor at one time had a large practice, and was much respected. In his effort to improve the town he erected private baths. These were not appreciated. For some time the Doctor's health has been failing; he had reached his 75th year. The Medical gentlemen of the town attended the funeral.

PECULIAR AFFECTION OF THE INTERNAL CAROTID ARTERY IN CONNEXION WITH DISEASE OF THE BRAIN.

By PATRICK MANSON, M.B.,

Late Assistant Medical Officer in the Durham County Asylum.

Any fact, however obscure its bearing on the subject, in connexion with disease of the nervous system is at present considered valuable. On this account, and also because circumstances prevent me continuing my observations on the subject of this communication, I have ventured to bring it in this imperfect form before the Profession, confident that it will receive the attention which its singularity deserves.

In the course of seventeen consecutive post-mortem examinations of patients dying in the Durham County Asylum, I have, under the direction of Dr. Smith, carefully dissected the large arteries of the neck, and with very few exceptions have found a peculiar dilatation of the internal carotid. This dilatation was usually about three-fourths of an inch in length, and invariably involved the first part of the vessel, the remaining portion of the artery being of normal appearance, at least as far as its entrance into the petrous portion of the temporal bone. In some cases the shape of this small aneurism—for such it was—was fusiform, in some pyramidal, the broader portion springing from the common carotid; in others, again, the bulging occupied only one side of the vessel. In several cases the dilatation had a diameter double of that of the healthy part of the vessel; in the majority it was quite as great as that of the common carotid. This I ascertained by measuring the vessels after injecting them with wax or plaster of Paris. The coats of the vessel where dilated were thickened, in most cases atheromatous, and in one instance a red body, like a granulation, projected into the canal of the vessel. No similar dilatation was detected in any other artery, although the vertebrals, subclavians, etc., were frequently examined; but this condition of the internal carotid always co-existed with more or less atheroma of other parts of the arterial system, and atheroma of the other arteries was almost invariably accompanied by this condition of the internal carotid. Both vessels were always similarly affected.

Of the seventeen cases examined, six were general paralytics, and in these, with one exception, the internal carotid was invariably dilated. In this one exception the absence of dilatation coincided with a peculiarity in the origin and distribution of the vessels, arising from the arch of the aorta. The first vessel met with in tracing the aorta from the heart was a thick trunk; this, after a short course in an upward direction, divided into the right and left common carotids, the course of which, and the distribution of whose branches then became normal; the second vessel arising from the aorta was the left subclavian, which pursued its usual course. Posterior to the left subclavian, and slightly farther removed from the heart, was the origin of the right subclavian; this vessel, passing backwards and inwards between the œsophagus and spine, gained the right side of the body, and thus reached its usual position. This peculiarity in the origin and course of these vessels, taken in conjunction with the absence of dilatation of the internal carotids in one of a class of cases in which this pathological condition was otherwise invariably present, is significant.

Of the seventeen there were four other cases in which dilatation was absent or only slight. The ages of these subjects were respectively 24, 23, 23 (?), and 17; three of these died of tubercular phthisis, the other, the youngest, of congestion of the lungs and exhaustion, after a prolonged series of epileptic fits. The general paralytic, in whom the dilatation was absent, and the distribution of some of whose vessels has just been described, was 24. The average age of those whose internal carotids were dilated was about 45, though one, a female general paralytic, who afforded a very marked example of the affection, was only 25.

I regret that, from not having my notes beside me, I am unable to classify these cases, and give them a more detailed analysis; but as far as my memory serves me, the dilatation was most marked in general paralytics, in the old, or in any case in which there was considerable atrophy of the brain, or in which the patient during life had been subject to great and prolonged excitement. Excepting in general paralytics it was least marked in the young. Both sexes were alike affected, and although it always concurred with atheroma of the arterial system, there existed no fixed ratio between the amount of atheroma and the degree of dilatation of the internal carotid.

I do not regard this lesion as confined to the insane, though doubtless it is most frequent among them, but consider it as likely to be met with in any case in which the two following conditions, which I look upon as its principal causes, concur:—

1st. A weakened state of the vessel as indicated by atheroma of that particular locality, and signs of degeneration in other parts of the arterial system. 2nd. An increase of the eccentric pressure of the blood in the affected vessel. This latter may be the result of any disease in the brain preventing a free onward flow of the blood; atrophy of the organ, from whatever cause, would have this effect; for a diminution in the size of the brain almost implies a diminution in the size and number of its capillaries, if not of its larger vessels, consequently a retarded flow of blood in the carotid and vertebral arteries; the heart continuing to propel the blood with unaltered force, or in cases of mania or of temporary excitement, so common among the demented, with increased force, a greater force is brought to bear on the walls of the carotids, and these being already weakened by atheroma or other degeneration, a dilatation results. Just as in cases of cirrhose atrophy of the liver the obstructed portal circulation relieves itself by an ascitic effusion, or rupture of the intestinal capillaries, so the obstructed circulation through the brain relieves itself, or rather results in a dilatation of the internal carotid; the ascites in the one, and the dilatation in the other, both being the effects of mechanical pressure on the walls of the vessels. In the same way we explain the enlargement of the urethra on the vesical side of a stricture or the bulging of the gut on the gastric side of an obstruction. Again, in cases of mania, or in cases in which there is increased flow of blood through the brain, although the patency of the vessels in the brain may not be affected, yet there is an increased pressure upon the walls of the vessels in, and going to the brain, and if any part, as the origin of the internal carotid, is weakened by disease, it yields to the pressure, and an aneurismal dilatation is produced. The same explanation would hold good in other cases, provided there existed increased pressure of blood on weakened walls. It would be interesting to ascertain if in atrophy increased vascular action, etc., of other organs the supplying artery is similarly affected.

The hypothesis I have just advanced may serve to explain the occurrence of this lesion in those advanced in life, whose arteries are weakened and whose brains are atrophied; in general paralytics, the capillaries of whose brains are so much diseased, and in whom the brain is so frequently atrophied and the whole system degenerated; in the maniacal, in whom the encephalic circulation is so much increased; but it does not explain why this particular part, the origin of the internal carotid, should be invariably selected for dilatation, or why the vertebral artery does not become similarly affected. Possibly the origin of the internal carotid artery may be more liable to degeneration than any other part of the vessel; perhaps the unyielding envelope surrounding the vertebrals may counteract the injurious effects of pressure; possibly the vasa motor nerve supplying this part of the carotid may be prone to some form of disease, though the absence of dilatation in the case of the general paralytic with abnormal origin of vessels would almost disprove this supposition; perhaps the selection of this part of the vessel may be the consequence of mechanical laws, and of these alone. Whatever be the cause, the fact remains, that in certain forms of disease of the brain the origin of the internal carotid is dilated.

Medical Society of London.—The following gentlemen have been elected at the ninety-third anniversary meeting as the officers and Council for 1866—67:—*President.*—Charles J. Hare, M.D. *Vice-Presidents.*—George D. Gibb, M.D.; Henry Smith, Esq.; W. R. Rogers, M.D.; and John Birkett, Esq. *Treasurer.*—Peter Marshall, Esq. *Librarian.*—Edward Head, M.D. *Secretaries in Ordinary.*—W. Abbotts Smith, M.D., and Walter J. Coulson, Esq. *Secretary of Foreign Correspondence.*—Julius Althaus, M.D. *Council.*—F. E. Anstie, M.D.; W. H. Broadbent, M.D.; I. Baker Brown, Esq.; Thomas Bryant, Esq.; C. Cogswell, M.D.; W. J. Coulson, Esq.; Victor De Méric, Esq.; C. F. Du Pasquier, Esq.; W. Tilbury Fox, M.D.; Samuel Day-Goss, M.D.; C. H. Rogers Harrison, Esq.; Ernest Hart, Esq.; James Jones, M.D.; Henry Lee, Esq.; Francis Mason, Esq.; J. W. Ogle, M.D.; James Palfrey, M.D.; J. H. Paul, M.D.; W. F. Teevan, Esq.; E. Symes Thompson, M.D. *Orator.*—F. W. Headland, M.D.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

HOSPITAL FOR DISEASES OF THE THROAT

CONGENITAL CLEFT PALATE—OPERATION OF STAPHYLORAPHY.

(Under the care of Sir WILLIAM FERGUSSON.)

The notes of this and the two following cases were furnished by Mr. Wasdale Watson:—

Jessie R., aged 23, from Glengarry, applied at the Hospital January 4, 1866, very desirous to submit to an operation for the cure of a congenital cleft palate. The articulation was of the ordinary imperfect nasal character, and in swallowing liquids a portion was occasionally violently ejected through the nose. The malformation affected the whole of the soft palate, but not the osseous structures. Sir William Fergusson performed the operation in his usual way on January 11, first dividing the levator-palati, palato-pharyngei, and palato-glossi muscles; secondly, paring the edges of the fissure from above downwards; and, thirdly, bringing the edges together with sutures, passed on each side from before backwards. There was very slight hæmorrhage. The case progressed most favourably.

On the 15th the sutures were removed, and a week later the patient was discharged cured. At the time of her discharge the palate presented no trace of the defect beyond the cicatrices of the sutures.

FALSE EXCRESCENCES IN THE LARYNX—TRACHEOTOMY—RECOVERY.

(Under the care of Dr. FRASER.)

George J., aged 28, a sailor, applied at the Hospital September 5, 1865, complaining of hoarseness and difficulty of breathing. He stated that, with the exception of having had yellow fever six years ago, he had enjoyed good health till 1862, when he caught a violent cold in the throat in the north of China, and was unable for some weeks to get any Medical treatment. Since then his throat had been steadily getting worse. He had lately been a patient at Guy's Hospital. A laryngoscopic examination showed a high degree of congestion of the mucous membrane of the larynx and numerous irregular out-growths presenting the appearance of excrescences. These out-growths of thickened mucous membrane projected from both the vocal cords and from beneath their anterior insertion.

October 30.—In spite of various kinds of treatment (including the local application of solutions of nitrate of silver and perchloride of iron, inhalation of steam, creosote, etc.), the patient had become much worse. The dyspnœa was now constant, and severe paroxysms of suffocation occurred very frequently. He could not lie down at night, but was obliged to sleep in an arm chair. At Dr. Fraser's request, Dr. Morell Mackenzie now examined the case, and with his concurrence removed several portions of the projecting mucous membrane with his "laryngeal forceps."

The next day there was a great improvement in the breathing, but the character of the voice was not altered.

Soon after this the patient felt so much relief in breathing that he without sanction discontinued his attendance.

December 5.—The patient returned to the Hospital in a much worse condition. The breathing was now stridulous and greatly embarrassed. The laryngoscope showed intense hyperæmia and some thickening of the mucous membrane of the larynx. The forced inspiration was accompanied with such strong movements of the epiglottis that it was difficult to make a very accurate examination.

A few days later he became much worse, and Dr. Fraser admitted him into the London Hospital on December 12. Though suffering from extreme dyspnœa, he refused to submit to tracheotomy, and it was not till December 17, when being in a delirious condition, that the trachea was opened by Mr. Dove, the House-Surgeon. "Previous to the operation," says Mr. Dove's report, "he could with difficulty be roused to answer questions, and his replies were quite irrational. Pulse exceedingly weak and rapid. Respiration carried on with great difficulty and attended with much noise." The operation was performed as a *dernier resort*, the patient's condition scarcely leaving a hope of his recovery.

The operation was performed in the usual way, though a rather freer opening than usual was made in the windpipe on account of the rapidly-increasing severity of the symptoms it was obliged to be done quickly; fortunately there was no considerable hæmorrhage at the time. Just as the operation was completed, the pulse and respiration both failed. Artificial respiration was vigorously employed. Brandy enemata were administered, and in an hour the breathing became regular and tranquil. For several days the patient suffered from severe venous hæmorrhage from the wound in the trachea; the bleeding, however, was controlled by the application of a strong solution of perchloride of iron. The pulse continued at 120, and the delirium did not wholly wear off for more than a week. At the end of December, the breathing being perfectly free, the tube was removed, at the urgent desire of the patient, who complained that it caused him a great deal of discomfort. The opening very soon healed up. The patient is again attending at the Hospital for Diseases of the Throat. There is an excrescence occupying about one-fifth of the area of the laryngeal canal, projecting from beneath the anterior insertion of the vocal cords, and there is also some thickening about the right arytænoid cartilage.

Remarks by Dr. Fraser.—This case seems to be one of chronic inflammation of the lining membrane of the larynx, which has resulted in the formation of irregular thickened projections of the mucous membrane. These presented the appearance in the mirror of warty growths, but as they do not possess the pathological character of epithelial tissue, containing merely the imperfectly organised products of inflammation, Dr. Mackenzie very properly called them "false excrescences." Though the same permanent benefit could not result from removing outgrowths that occurs in the case of true warty excrescences, the dangerous symptoms caused by their presence are of course at once alleviated by their removal, as was strikingly shown in this case. At a later period the operation performed by Mr. Dove had undoubtedly snatched the patient from the very jaws of death. He was quite insensible when the operation was performed, and retained no recollection of it afterwards. Some difference of opinion might exist as regards the tracheal opening having been allowed to close up. The mechanical impediment was only partly removed, though the urgent symptoms had quite passed off. The patient's own views were so strong on the subject that they in point of fact decided the question.

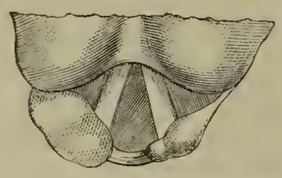
ŒDEMATOUS INFLAMMATION OF THE EPIGLOTTIS—SCARIFICATION—RECOVERY.

(Under the care of Dr. MORELL MACKENZIE.)

John R., aged 30, applied at the Hospital on October 14, 1865, on account of difficulty of swallowing and pain in the throat, which had been gradually coming on for a fortnight. For a week he had not been able to swallow solids, and for the last thirty-six hours liquids could not be taken. Attempted deglutition now invariably resulted either in a violent paroxysm of coughing, or in the forced ejection of the liquid through the nares. A laryngoscopic examination showed the epiglottis to be of a bright red colour and enormously swollen. The normal contour of the epiglottis was completely lost, and the valve presented the appearance of three red, slightly projecting, semi-transparent tumours, the largest one being on the right side. The œdematous epiglottis covered the right half and the greater part of the left side of the larynx. The parts which could be observed were seen to be much congested. The appearance is shown in Fig. 1. The patient was ordered

Fig. 1.

Fig. 2.



to inhale hot steam continuously, and blistering fluid was applied externally beneath the angle of the jaw.

October 15.—Patient much worse. Completely unable to swallow, and so weak that enemata of beef tea and brandy were thought necessary. Dr. Mackenzie scarified the epiglottis freely with his laryngeal lancet, and afterwards the patient bled a good deal. Half an hour after the scarification the patient was able to swallow, though it caused him some pain. In the evening a laryngoscopic examination was made, and the swelling of the epiglottis was seen to have greatly diminished.

16th.—The patient was able to swallow without difficulty. The epiglottis was seen to be no longer swollen, though the marks of the punctures were visible as minute hæmorrhagic spots. The return of the epiglottis, however, to a healthy condition permitted a more general inspection of the larynx, and the right ary-epiglottidean fold was seen to be œdematous. The laryngoscopic appearance is shown in Fig. 2. The œdematous fold of mucous membrane was freely scarified.

17th.—The œdema had completely disappeared, though some congestion remained.

20th.—The patient was discharged "cured."

KING'S COLLEGE HOSPITAL.

MALIGNANT STRICTURE OF THE ŒSOPHAGUS, WITH ULCERATION AND PERFORATION OF ITS ANTERIOR WALL, COMMUNICATING WITH THE TRACHEA.

(Under the care of Mr. PARTRIDGE.)

The following case is one of great pathological interest, and one in which Surgical interference could be of but little use. The operation of tracheotomy was performed, of course merely with a view of prolonging the patient's life for a short time; but it showed how far the disease must have progressed when so much of the nourishment taken found its way through the fistulous opening from the œsophagus into the trachea. From the post-mortem examination this opening must have existed for a considerable length of time. This condition we believe to be of somewhat rare occurrence, although cancerous stricture of the œsophagus is tolerably frequent.

We are indebted for the notes of the following case to Mr. E. Ireland, the dresser:—

R. G., aged 44, married, ostler, admitted February 21, 1866, into Fisk Ward, under the care of Mr. Partridge, with stricture of the œsophagus. Patient states that he first noticed any difficulty in swallowing in May, 1865, and that after every meal he vomited a portion of his food, and had to eat very slowly; he had no pain whatever. This state of things gradually got worse, and in October he was unable to swallow at all, taking no food whatever by the mouth for seven days; about this time he applied at Westminster Hospital as an out-patient, and attended as such till January, 1866, being there treated with bougies, but from which he says he derived no benefit. He was advised to apply at King's College Hospital, and was admitted on February 21.

Upon admission it was found that he could only swallow very small portions of solid matter, and that with great difficulty, although he can swallow fluids in small quantities with comparative ease; he has no pain, but spat up blood about three weeks ago, which he attributes to a cough which he is at present suffering from, attended with a good deal of expectoration. Patient has much emaciated since the occurrence of the stricture, as he is unable to take sufficient nourishment.

February 24.—Condition of patient much the same, with the exception of the cough and expectoration, which have increased. Ordered,—℞. Sp. chloroform, ♏ xv.; ammon. carb., gr. iij.; aquæ, ℥ j. ter die sumend., M. ft. haust, which partially relieved him.

26th.—Much the same. On the evening of this day he complained of difficulty of breathing, feeling as if there was a constriction at the upper part of his throat, which prevented him getting any air. Ordered steam inhalations, which for a time relieved him, but getting worse he had chloroform administered, which gave him temporary relief; but the dyspnœa afterwards becoming so urgent, the House-Surgeon, Mr. Howells, performed tracheotomy about 2 a.m. on the 27th. The operation was performed above the thyroid body, between that and the cricoid cartilage, only one ring of the trachea being divided. There was no hæmorrhage, and the tube, which was a large sized one, was easily introduced. The operation gave immediate relief to the dyspnœa, and the pulse, which before the operation was 140 and weak, fell to 120 and became stronger. Ordered wine, brandy, beef-tea, etc., *ad libitum*.

28th.—Can breathe with ease through the tube, but has occasional fits of coughing, and brings up a large quantity of purulent matter mixed with the expectoration; pulse 120.

March 1.—Can only swallow fluids, the act inducing spasmodic cough, portions of the fluid getting into the trachea and are coughed up through the tube; pulse 120; patient getting weaker.

2nd.—Condition much the same; pulse 120.

3rd.—Patient much weaker and very restless; cannot sleep. He can swallow better to-day, but portions of the food return through the tube. Can only take nourishment in the shape of fluids. To have injections of strong beef-tea every two hours, and continue the wine, brandy, etc. Has occasional flushes of heat, which appear almost to stifle him, and has great congestion of the vessels of the head. Pulse 120. Skin dry. Tongue moist, and slightly coated. Has no delirium. Bowels act regularly; stools small and fluid. Cannot breathe so well to-day, and coughs up a large quantity of muco-purulent fluid, both through the tube and by the mouth. His water is thick and muddy, and he has frequent desire to micturate. Complains of constant thirst and dryness of the mouth. To suck small pieces of ice. Patient gradually sank, and died quietly at 9.40 p.m.

5th.—*Autopsy Forty-two Hours after Death.*—Body pale and emaciated. The tongue, trachea, and œsophagus were removed intact. There was no œdema of the glottis. Upon slitting up the œsophagus it was found to be quite healthy till opposite the bifurcation of the trachea, where was observable on its anterior wall a large rugged ulcer (about the size of a florin and apparently of a scirrhous nature), with hard base and everted edges, perforated about its centre by an opening, through which the first finger could easily be passed into the trachea. The lungs, the right of which weighed 3 lbs. 0½ oz., and the left 2 lbs. 8 oz., were much consolidated at, and throughout, the whole of the lower lobes and lower portions of the middle lobes, and presented an appearance as if food had lodged in the air-cells, although some of the lobules were healthy. There was recent lymph effused on the surfaces of the lower lobes, and between them and the diaphragm. The other lobes were healthy, and there were no adhesions. The bronchial glands were not affected. The liver was healthy, and it and the stomach together weighed 6 lbs. 7½ oz. On the outer surface of the stomach there were several hard, enlarged glands, which, under the microscope, presented all the appearances of scirrhus. Kidneys apparently healthy, together weighing 13 oz. Spleen, 4 oz.; healthy. Heart, 15½ oz.; enlarged, but healthy. All the veins of the head were much congested, being filled with large clots of coagulum.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 307.)

Case 77.—Multilocular Cyst, never tapped—Ovariotomy—Recovery.

An unmarried dressmaker, 32 years of age, was sent to Mr. Wells in January, 1866, by Mr. Roughton, of Kettering, suffering from an ovarian cyst, which was increasing in size rather rapidly. She began to increase in size a year before, but had only altered her dresses during the last five or six months. For about six weeks past she had suffered much pain in both hips, but now only on the left side. The catamenia were rather excessive in quantity, and recurred every three weeks. The tumour contained one large cyst and several groups of smaller cysts. The uterus was normal, and no tumour could be felt by the vagina. As tapping could be of very little service, she was advised to come into Hospital for ovariotomy, and was admitted on January 27. The catamenia appeared on the 31st, and lasted till February 4. Ovariotomy was fixed for the 13th, but the catamenia appeared again on the 12th. At that date the girth was 40½ inches, and the distance from the umbilicus to sternum, 9 inches; to symphisis pubis, 8½; to right ilium, 11½; and to left ilium, 12.

Ovariotomy was performed on February 20. Messrs. Baker and Clay, of Birmingham, and Mr. Roughton were among the visitors. An incision, six inches long, reaching from just below the umbilicus to within two inches of the pubes, exposed a cyst which was adherent anteriorly, but the adhesion yielded very easily to the hand. One large cyst was emptied of sixteen pints of fluid, and the rest of the tumour (weighing four pounds and a half) was withdrawn entire, not a drop of fluid entering the peritoneal cavity. A very broad thin pedicle extended from the right side of the uterus to the cæcum. On measuring this afterwards on the cyst the extent was found to be nine inches; yet it was easily secured in a small clamp, and this was fixed outside the abdomen with some little traction. There was scarcely any blood lost. The left ovary was rather larger than usual, but appeared to be healthy. The wound was closed by silk sutures in the usual manner.

The progress after operation was most satisfactory. The pulse never rose above 88. Only two opiates were required. The stitches were removed on the third and fourth days. Uterine epistaxis came on on the sixth day, and lasted during the seventh and eighth days. The bowels acted on the tenth day, and the clamp came off on the twelfth. The patient continued to gain strength, and left the Hospital on March 14, twenty-one days after operation. She called on Mr. Wells on the 22nd, looking and feeling quite well.

Case 78.—Multilocular Cyst—Embolism—Tapping—Suppuration of Cyst—Pyæmic Fever—Ovariotomy—Death in Twenty-five Hours.

The wife of a domestic servant in Essex called upon Mr. Wells on February 6, 1866, by the advice of Professor Lister, of Glasgow. She was 26 years of age, had been married sixteen months, and had never been pregnant. The abdomen was filled as high as the ensiform cartilage by a multilocular ovarian cyst, which appeared to be free from adhesions. The uterus was rather far back, and its mobility was restricted by a tumour which could be felt between the uterus and bladder. The catamenia were quite regular. Increase in size had been first noticed about four months after marriage; but for nearly a year before marriage she had suffered from pain in the iliac regions, first on the right and afterwards on the left side. Both legs had been swollen and painful at times, the left more than the right, for the past five months. She was admitted to Hospital on February 8, the left foot and leg having become more swollen after her journey. She was flushed and feverish, and the pulse was rapid and feeble. On the 9th Mr. Wells tapped the largest cyst, and removed eighteen pints of fluid like thin arrowroot. Some groups of cysts were then found adhering above the umbilicus, nearly as high as the sternum. The swelling of the left foot increased after the tapping, and remained red, hot, œdematous, and extremely painful till the 13th, after which the pain and swelling gradually diminished. Pulsation in the anterior tibial artery, which had been imperceptible since her admission, returned. But for the next ten days she remained in a state of general fever, which Mr. Wells attributed partly to suppuration in the cyst, and partly to the clot which had obstructed the anterior tibial artery. He stated that he should rather regard the condition as one of *pyæmic fever* than of *pyæmia*. There was one rigor, but none of the recurring rigors with apyrexial intervals so commonly observed in acute pyæmia. There were also some pains in all the principal joints; but these passed off without effusion. The pulse was feeble, and excessively rapid, as in pyæmia (120—140); but the skin and tongue, instead of being moist, were hot and dry. The urine was scanty and concentrated. Abdominal pain came on, with increasing debility and emaciation, and the sac refilled rapidly. On February 24 Mr. Wells tapped again, and removed fourteen pints of fluid. That which flowed first was clear ovarian fluid, but the last three or four pints were nearly pure pus, not at all fetid. The next day she felt better, but had a smart rigor. Five grains of quinine were ordered every four hours. On the 26th Mr. Wells consulted Sir Wm. Fergusson and Dr. Greenhalgh as to the propriety of doing ovariotomy. Delay was advised by both, on the ground that in such a condition of fever the operation would be almost necessarily fatal. On the 27th and 28th she was quite deaf from cinchonism, and the quinine was omitted. She then improved a little. On March 3, rather a free discharge of ascitic fluid commenced from the seat of the tapping. On the strength of Polli's experiments, and of two cases communicated to Mr. Wells by Mr. Lister, in which patients with all the constitutional symptoms of acute pyæmia had recovered under the use of sulphite of potash, this substance was given in ten-grain doses every two hours. It was begun on March 4, and on the 5th and 6th she was in many respects better, although the rapid pulse, hot dry skin, brown tongue, and scanty urine, with hurried shallow breathing continued. Believing all this to be due to the presence of the suppurating cyst, Mr. Wells decided to remove it (after Dr. Jenner had ascertained that there was no solidification of either lung), although the hope of success was very small indeed.

Ovariotomy was performed on March 7. Sir Wm. Fergusson, and Drs. Donnet, Mackay, and Macleod, R.N., were present. On exposing the cyst by an incision five inches long, it was seen to adhere to the anterior part of the abdominal wall. The adhesions were rather vascular, but yielded easily to the hand. The tumour, when freed, was drawn forward, a

large cyst was opened, and about five pints of curdy pus were pressed out of it, and carefully kept from entering the peritoneal cavity. By passing his hand into this empty cyst, breaking up some smaller cysts, and pressing out their contents, Mr. Wells was able to remove the whole tumour without enlarging the incision. A pedicle as broad as three fingers was secured between two and three inches from the left side of the uterus in a small clamp, and fixed outside with but little traction. The right ovary was healthy. Some four or five ounces of blood clot were removed from the peritoneal cavity after the cyst; but there was no separate vessel bleeding, only a general oozing from the surfaces where the adhesions had been separated. After the wound was closed, there was oozing of bloody serum beside the clamp, and firm pressure was made on the abdomen by pads of lint, straps of plaster, and a bandage.

The patient was very faint after being put in bed, and the pulse became very feeble; but after giving brandy by mouth and rectum, she rallied fairly. The pulse remained feeble, however, and very rapid. She was freely stimulated, taking brandy and milk by the mouth, and brandy with beef-tea being injected into the rectum on alternate half hours. There was neither vomiting nor tympanites. No opium was given, as there was no pain. The secretion of urine was very scanty. She was cheerful, and passed a quiet night; but gradually became weaker and died twenty-five hours after operation.

On examination, eighteen hours after death, the omentum and some of the small intestines were seen to be united to the abdominal wall by recent lymph. The peritoneal edges of the wound were well united. One ounce of clot and eleven ounces of dark red serum were removed from the peritoneal cavity. The pedicle was perfectly secured by the clamp. The liver was pale and fatty. The lungs and heart healthy. In all the cavities of the heart there were firm fibrinous clots. Those in the right cavities extended into the third and fourth divisions of the pulmonary artery. No purulent deposits were found anywhere.

Many may be disposed to doubt whether it was right to perform a serious operation upon a patient whose general condition was so bad as this woman's was. But it was felt that without operation death was inevitable, while with it there was a slender chance of recovery, and as the patient and her husband, after the case was fully explained to them, were anxious that an attempt to save life should be made, it was made. Probably, in nineteen out of twenty such cases, it would also be made unsuccessfully; but if it succeeded in one, that one, and the consciousness of duty done, would be a sufficient reward to most Surgeons for the anxiety and disappointment of the nineteen unavailing efforts to save life.

Post-office Orders and Drafts on Army or Navy Agents, should be made in favour of Mr. James Lucas, 11, *New Burlington-street, W.*

Medical Times and Gazette.

SATURDAY, MARCH 31.

EQUALISATION OF THE METROPOLITAN POOR'S-RATES.

The first or baby stage of philanthropy is, as we have often said, that of indiscriminate giving. "There is a poor man; give him something." Such is the cry of every child who sees a beggar; and it is through this propensity of grown-up children that our streets swarm with sturdy beggars, and the nightly wards of Workhouses with "casuals." But when children grow up, a little care of self comes to be added to love of doing good, and there is apt to spring up what may be called the "Robin Hood," or "picturesque" philanthropy,—that kind of feeling which so impressed a man at a charity sermon that he felt ready to pick his neighbour's pocket of a shilling to put into the dish! that which makes people delight in hearing how the bold outlaw plundered rich barons and abbots, and gave to poor widows and beggars.

A scheme which we venture to class with this Robin Hood philanthropy is brought forward from time to time under the name of equalisation of poor's-rates. It is a scheme for making the so-called "rich" parishes pay the rates of the "poorer" ones; and as numbers of our Medical brethren live in these so-called "rich" parishes, and as it is proposed to take from them an additional poor's-rate, varying from fourpence to nearly a shilling in the pound, it is just as well that their eyes should be open, and that they should hear what there is to say on the other side of the question.

In the first place, there is a transparent fallacy in the use of the word "rich." It really seems to be taken for granted that because people live in a rich parish they are rich. The Marquis of Westminster and Lord Portman live in rich parishes and are rich, therefore all others who live in rich parishes—Medical men, artists, tradesmen, and lodging-house keepers—are rich also. Rents are very high, and so because a man at the West-end pays a heavy rent, he ought also to pay poor's-rates for the East-end, where rents are low. Capital logic!

Let us look for a moment at this subject of rent. A house may be rented highly because it may be well placed for business or for pleasure, or because it is a good house in itself, able to accommodate a family, etc. Now, here it is that the highly-rented man at the West is rated and taxed out of all proportion to the lowly-rated denizen of the East. A house which in Marylebone or St. George, Hanover-square, would cost £120 per annum, may be had at Clapham for £50, and at Kennington for £30. Is it fair, then, that the West-end man, who is taxed so heavily in the item of rent, should pay the poor's-rate of a man who gets housed at a low rent, partly because rates are high?

Such a scheme, really to be logical, should aim at a general equalisation of property: that is, confiscation. Out of two Medical men, one who has his expensive house and plant in a "rich" neighbourhood is suddenly called on to pay a shilling in the pound, which his *confrère* in a cheaper neighbourhood pockets.

One argument there is which is sometimes heard—viz., that property at the East End is so bad that it *can't* bear the necessary rate.

If this were true, the poor working man could lodge more cheaply at the East End than at the West End. Is this so? Not a bit of it. We have made personal explorations of the working men's homes in St. George's, Hanover-square, in Soho, in Bethnal-green, and St. George the Martyr, Southwark; and find that the price which is charged for a lodging is the same throughout—half-a-crown, three and sixpence, five shillings. In fact, is it not a stock argument at philanthropic meetings that the face of the poor man is literally ground by the extortionist owners of small house property, and that the worse this property, the better it pays in proportion? Is this statement true? If so, and we appeal for its truth to the whole philanthropic world, ought not the persons who derive large profits from tumble-down property—which property is a perfect warren or preserve of human beings who are sure to come on the rates—to pay the poor's rates which are the necessary complement and consequence of the existence of this property? The existence of such houses is one cause of high rates; and we, forsooth, are to help keep up this system?

Then look at the quality of the houses. In Marylebone and St. George's, Hanover-square, they are, at the least, decent,

weather-tight; there are signs of whitewash and of the visits of the sanitary officers; the ratepayers look after their poor, and such wretched shanties as those in Bull's Head-court and Fox's-buildings don't exist. But at the present rent Bull's Head-court and Fox's-buildings would be a better investment than Belgrave-square; and we are to help to pay the rates for them!

Then it is sometimes said that the inhabitants of the West-end parishes use the labour of the poor, and then send them in sickness and destitution to die in the East. How do they use their labour? Are the labourers not employed in factories and workshops in the East? Because the West-end people consume manufactures, ought they also to bear the burdens of the wealthy manufacturer, and discharge his duties towards the workpeople?

If the East-end parishes could point to a good sanitary state of things, they might well ask for help; as it is, they are asking for the power of spending other people's money without one sound pretext. The shilling that is demanded from the West would soon be doubled.

True, London is the visionary El Dorado of the destitute—the "needy casual's general home;" and there are hundreds of poor people who flock to it, and who are relieved by public and private charity on which they have no real claim. We really cannot see, as we have said before, why the mere fact of a man's hiring a house (*i.e.*, being a *ratepayer*) should make him liable to every sort of burden, reasonable and unreasonable. If there is a mass of floating poverty and sickness to be relieved, let all classes share the burden, and take part of the revenue derived from beer, spirits, and tobacco for the purpose.

THE CONVERSAZIONE OF THE OBSTETRICAL SOCIETY.

As we are compelled to go to press on Wednesday this week, it is impossible for us to give more than a sketch of the arrangements for the *conversazione* of the Obstetrical Society of London, to be held (by permission) at the Royal College of Physicians, that evening, and the rich and magnificent display of obstetric instruments exhibited on the occasion. We must reserve till next week the pleasure of giving our readers a detailed account.

The collection of instruments is undoubtedly the largest of the kind ever brought together, the appeal of the Council of the Obstetrical Society having been responded to by the arrival of liberal contributions from the most distant parts—from Belgium, Sweden, Denmark, France, Austria, Prussia, Russia, and Italy, in addition to a large number of loans from the obstetricians and mechanicians of our own country. Instruments used in every branch of operative midwifery are exhibited, and also such as are used in the operations of ovariotomy, vesico-vaginal fistula, chloroform inhalation, and the like. The instruments are arranged, for the most part, according to the nature of the operations in which they are used. Thus, in one group, all those which are available for the purpose of destroying the child; in a second, those used for delivering the child alive, such as forceps and vectes, are placed. Moreover, they are grouped, as far as possible, in chronological order, so as to represent historically the modifications adopted at different times and in different countries. Necessarily this must have been a difficult matter. The object aimed at by the Society in this plan, however, was to show, as far as practicable, by the advancing improvements in the construction and simplification of the instruments, the progress of any given operation.

The forcipes, representing all kinds, sizes, and varieties, old and modern, numbered considerably above a hundred, and this without taking into account a single duplicate. Amongst the most interesting of the collection were the original forceps of Chamberlen, kindly lent for exhibition by the Medico-Chirurgical Society; the identical pair used by the celebrated Richter, sen., to bring into the world the present Emperor of Russia; a pair of Japanese forceps, of neat construction, brought home by Sir Rutherford Alcock, lent by Dr. Matthews Duncan; and also those of Denman, Smellie, Boers, Davis, Assalini, Torg (of Leipsic), Busch, Naegele, Saxtorph, Tarcitani (of Naples), and the long forceps of Baudelocque.

The cephalotribes, a most formidable set of child destroyers, were well represented, the original cephalotribe of Baudelocque being amongst the number, as well as those of Professor Braun (of Vienna), Nyrop (of Copenhagen), and Assalini, sent by Lollini (of Bologna), etc.

There was a large and valuable collection of instruments from St. Petersburg, sent through the kindness of Professor Hugenberger and Dr. Lazaréwitch, of Kharkoff.

The Council of the Obstetrical Society have determined to afford to those who may be unable to attend the *conversazione* an opportunity of seeing the valuable collection, and have issued a notice that by the kind permission of the President and Council of the Medical Society of London they will keep open the exhibition at the rooms of the Medical Society, 32A, George-street, Hanover-square, till Thursday, April 5. Members of the Medical Profession will be admitted on presenting their card at any time between the hours of 12 a.m. and 6 p.m.

As it would be simply impossible for any one to have made himself acquainted with half the interesting varieties of even one kind of instrument, during the short space of an evening, especially during a *conversazione*, the opportunity for examination at leisure afforded by the Council will be most valuable, and we have no doubt will be thoroughly appreciated.

Amongst the objects of general interest which we observed were the sphygmograph, Dr. Richardson's apparatus for inducing local anæsthesia, specimens of living trichinæ, the new patent binocular microscope of Powell and Lealand, photographs on opaque glass by Messrs. Moira and Haigh, Wheatstone's alphabetical telegraph, the micro-spectroscope exhibited by Messrs. Spence and Browning, and various works of art by the following artists:—Messrs. Raven, Knight, Solomon, Bedford, Holliday, Moore, and J. M. Richardson.

The Obstetrical Society have much reason to congratulate themselves upon the complete success of the arrangements for this unique *conversazione*.

ORGANIC LIFE AND DISEASE.

The subject of the influence of minute life in the production of disease is acquiring to itself every day more decided importance, and there are not wanting indications that a more extended study of this branch of scientific inquiry may yield results of great moment, especially in so far as therapeutical operations are concerned. A careful examination of the literature and clinical history of parasitic diseases in general leads to the conclusion that we possess clearer and more precise knowledge of the part played by animal than by vegetable bodies; but although a less number of observers have been at work in regard to the latter, they seem to be rapidly rising to a very high position in the scale of significance, as producers of disease.

The past season has been characterised by a remarkable prevalence of forms belonging to both the animal and vegetable kingdom; and many men have felt disposed to revive the "animalcule theory of disease,"—a doctrine suggested by the coincidence of the invasion of localities by swarms of flies, and the outbreak of pestilences. It was strenuously upheld by Kircher, Linnæus, Hecker, Sir Henry Holland, and others, and accredits to minute insects of various kinds the power of generating or favouring the production, or at any rate the conveyance, of certain miasmatic and virulent poisons. Several instances have been recorded of late in which death even has followed from the bites of flies. A good illustration, perhaps, is afforded by the case of Egyptian ophthalmia,

*

which would seem to be inoculated from person to person by the same agency. This, however, is not our point.

Vegetable parasitism, which we especially notice now, demands careful examination and for its proper elucidation much special botanical and chemical knowledge, as well as an analysis of the facts and phenomena of diseased conditions of life in general are required. Firstly, there can now be scarcely a doubt of the truly vegetable nature of many parasitie bodies which live upon our surface. The mere action of liquor potassæ may fairly be allowed to set the matter at rest, for there is no known animal structure that will resist its action as fungi do; and Dr. Tilbury Fox's recent experiments have confirmed him in his original statement that the so-called spores and mycelium possess a capacity of independent existence and growth when removed from the influence of the structures of the body itself, and that fungus germs can be traced in the earliest stages of disease travelling from without inwards and not from below upwards towards the exterior. Every day appears to bring to light some new fact in proof of the identity of the various forms of fungi found on or in man. The most recent is that noted by Dr. Purser in the *Dublin Quarterly Journal*. He gives a description and plates of the nail fungus in its different appearances representing achorion, oidium, and even puccinia; but Dr. Fox believes that no true puccinia occurs on the human surface; that the so-called puccinia is only a form of oidial fructification—a terminal clavate thread. De Bary and Tulasne's admirable researches, lately referred to by us, have completely established the wide existence of polymorphism, one fungus actually possessing six different kinds of fructification, the uredo itself exhibiting four, most of these having been looked upon as distinct species.

Fungi would seem to be most active in their early stage of existence—in their spermatiferous form,—and to effect an entrance by various means: by outshoots or germinating processes that penetrate beneath the epidermal cells; through natural openings—*e.g.*, the hair follicles, or through traumatic lesions, as in podelkoma; whilst sometimes the germs are carried up by growing parts, as when sporules find their way to the spongioles or cotyledons of plants or the roots of the hairs. In other cases the cell contents alone become absorbed and appear sufficient to give rise to mischief, but it is not unlikely that the nucleoli are introduced into the internal parts of the beings subsequently diseased. Lastly, the carbonic acid given off by the terminal cells of the fungus may dissolve away the lime salts of a hard outer covering, and so allow progress into the interior by continuous budding. The general law appears to be that all germs are derived from without, and that fungi will not flourish on absolutely healthy surfaces, but that each requires its proper pabulum.

Having once effected a hold upon the system, fungi act not in one but several ways, and error has arisen from particular observers confining their attention to and arguing for one alone of these modes of operation. Fungi act (1) mechanically, giving rise to simple irritation, interference with function, and destructive change. This kind of action can be proved by experment. If a diseased hair containing spores be removed from the body and placed under favourable circumstances the spores will germinate and split up the body and shaft into ultimate fibres; in fact, you can produce the effects of ringworm out of the body. The action of fungi, then, in parasitic disease cannot be accidental; and loss of hair is a direct result of the influence of the growing fungus upon the formative papillæ. (2) By inducing local chemical change. Fungi absorb oxygen and give out carbonic acid, absorb water, and tend to give rise to fatty change. Many writers attribute much to the presence of fat as favourable to parasitic growth, but the latter would certainly seem in many cases to induce fatty change, well seen in artificial germinations out of the body. (3) As conveyors of poison, in the same way that the pus cell of variola or that of syphilis acts. The spore cells are ubiquitous, resist the action of heat and cold, are easily, prodigiously, and rapidly multiplied. That inoculation with fungi would seem to produce general before local symptoms, as in Dr. Salisbury's experiments, is undoubted, and very suggestive of the "conveying" property of fungi. (4) In virtue of their inherent virulent qualities. This action, however, must be slight in most cases. (5) In addition, fungi appear to be developers of various poisons, to induce change of a chemical nature in solids and fluids, the result depending upon the composition of the material acted upon, in each instance; the property of absorbing oxygen and evolving carbonic acid being especially concerned in this phenomenon. Such would seem to be the chief inference deducible directly from the experiments of Pasteur, Lemaire, Letellier, Speneux, Leplat, and others on fermentation and germination. A paper was read by M. Trècul, not long since, before the French Academy, on the phenomena connected with the growth of the torula, the author contending that the changes depended upon the nutritive processes going on in the vegetable structure, and not upon catalysis, whatever that may be; in fact, that the change known as fermentation was due to the act of nutrition. This kind of change may apparently go on inside the body when and where delay of food, moisture, heat, and torula are present, giving rise to irritation, the evolution of gas, etc., as in sarcinal disease, chronic diarrhœa, the green stools of the young, etc. Outside of the body, however, the larger number of illustrations are to be met with. Acute poisons may be produced, giving rise to measles (?), influenza, hay asthma, or phlebitic mischief. Dr. Collin, of Nievre, declares that he has recently observed very serious inflammation of the vessels of the arm follow wounds inflicted with the implements used to cut off vine shoots infested with the oïdium, and apparently caused by some condition of the juices of plants associated with the growth of the latter. Indeed, death has been affirmed to have resulted from this cause.

The effect of ergoted grain, as in pellagra, the late Russian epidemic, and some ulcerative diseases, illustrate the indirect action of vegetable fungi in the production of chronic ailments. Not only man, but animals, have been apparently poisoned by eating oats and fodder of other kind affected with fungi.

Now in all these cases, the influence of the fungus alone is wholly insufficient to account for the results seen; this was the theory maintained by Dr. Daubeny before the Ashmolean Society some years ago. Clearly there is a joint action of fungus and pabulum, the resulting product being the efficient cause of mischief. The exact nature of the poisons is doubtful: some think them alkaloids, but this view has as yet not been sufficiently criticised.

The inter-transmission of diseases of animals, plants, and man is now an undoubted fact, and is especially exemplified in the case of "mange" and ordinary "herpetic" ringworm, where the mechanical action of parasites is seen in contrast to other examples where their agency as "conveyers" is marked. There cannot be a question but that the most definite and certain results are likely to follow from the investigation of the particular subject under notice; in the detection and even isolation of certain poisons, not only of acute but chronic action; and in the recognition of the action of fungi as conveyors of disease. Knowledge of this kind suggests mechanical means to prevent the entrance of germs, and remedies, such as sulphurous acid, of power to destroy septic and other poisons. It would seem also not improbable that by experiment on living beings, in transmission of poisons from one to others of different kind, modified forms of poison may result which may be protective against the original malady. This is the case with vaccinia, and apparently rubeola is antagonised by the catarrh (?) produced from inoculation by the fungus of

wheat straw. Just now an intense amount of interest attaches itself to the matter of syphilisation. Clearly we have a hint from pathology that we may discover a modified form of syphilis which may be curative of the original malady itself.

THE WEEK.

THE AMENDED MEDICAL BILL.

THERE is a report, which we believe to be well founded, that Sir George Grey has at length put the President of the Medical Council in communication with the counsel of the Home Secretary's Office in reference to drafting the Amended Medical Bill. It is generally felt that the Council has done good preliminary service by investigating and discussing facts, and that now the time has come for entrusting them with power, more especially as regards Medical education. The subject of illegal practice is environed with more difficulty; still it is felt that more may be done without violating the "liberty of the subject," especially with regard to the obscene crew who advertise secret remedies.

DR. BENCE JONES'S DISCOVERY OF A QUININE-LIKE SUBSTANCE IN THE ANIMAL BODY.

AT the last Friday evening meeting of the Royal Institution, Dr. Bence Jones gave a singularly lucid and interesting account of one of those discoveries which from time to time open up entirely new fields of research. It seems that Dr. Bence Jones some months ago desired to detect the presence of quinine in the animal body. For this purpose a test was essential, and the test he adopted was that peculiar influence (fluorescence) of this alkaloid on the refraction of light, whereby it makes the dark part of the spectrum beyond the violet ray luminous. Having fixed on this as a test, and prepared standard solutions of quinine so that he might be able to get something like a notion of quantity, by comparing the effects of solutions of various strengths on the spectrum, he set to work on a guinea-pig—gave the creature three grains of quinine, then tested the blood and crystalline lens and other parts, and obtained the most satisfactory evidence of the presence of quinine. Luckily, however, for science (though, as it may be imagined, it was a source of great perplexity at the time), Dr. Bence Jones, in order to complete the experiment, submitted the same parts of a guinea-pig which had taken no quinine to the same test, and out came the same reaction; every part of the *non-quinised* animal—heart, liver, kidney, and lens—when treated, like bark, in such a way as to dissolve out and purify any alkaloid that might be in them, gave the same spectral reactions as similar solutions did from the animal that had taken quinine. Here was a puzzle! Undismayed, however, Dr. Bence Jones set to work to make out the mystery. He soon convinced himself that the tissues of all animals contain a something which, if dissolved out like quinine, gives the same fluorescent reaction with light. One solution of quinine, interposed in the rays of light, cuts off the fluorescence of another; so does a solution of the quinine-like substance; and so does each upon each interchangeably. Common salt and hydrochloric acid also lessen the fluorescence of both. This quinine-like substance, too, can be demonstrated in the tissues (in the lens), fresh, or preserved in glycerine; and can be demonstrated in the living as well as in the dead. Mr. Bowman had shown it in the eyes of his dog; and Dr. Bence Jones sat down before the electric light, which Professor Tyndall adjusted so as to let the audience see the strange fluorescent gleams from the interior of his eye. It has been found impracticable as yet to isolate this substance, so rapidly does it undergo oxidation; but Dr. Bence Jones had carried out an interesting series of investigations which convinced him that this quinine-like substance was part of the natural constituents of the body; and that, judged by the quantitative reactions, the quantity of it was temporarily increased by giving quinine. It was shown by this means that quinine in a very few minutes after its administration passes into every tissue of the body; that its maximum effect is produced in two or three hours, and then decreases till it disappears in about seventy-two hours. The demonstration of its presence in the crystalline lens gave ground for hope that substances might be found hereafter to remedy perverted nutrition of the non-vascular tissues—as cataract, and even the deposits of gout in cartilages. Then, what a glimpse these investigations afford of the possible *modus operandi* of quinine in the cure of ague! We call quinine a "specific"—a term which indicates our notions—or want of notions—of its action, and nothing more. But is it not possible that ague may depend on the absence of a natural quinine-like substance from the tissues? that quinine may supply this want,—(thus, by the bye, showing the futility of all attempts to distinguish between food and physic)—and that arsenic, on the other hand, may act within the body as it does without, by preserving certain matters from decomposition? Such is a rough note of this very interesting address, which was as valuable for what it promised for the future as for what it showed at the present.

LOCAL ANÆSTHESIA AT KING'S COLLEGE HOSPITAL.

DURING the last week there have been several carefully-executed attempts to produce insensibility to pain during the performance of Surgical operations. On Saturday Mr. John Wood operated upon two patients in the theatre whilst they were severally being subjected to the local action of the ether. In the first case the patient was a little boy with an obstinate hydrocele. The agent was first very carefully applied to the whole of the front of the scrotum, and a silver wire was passed through the sac by means of a large needle. The boy did not show the least evidence of having suffered any pain whatever. In the second case the operator removed a small scirrhous tumour from the breast of an old woman. The ether was first most carefully applied, and when the skin was thoroughly whitened the incision was made across the tumour, and whilst the knife was being carried over it the ether was still allowed to follow the course of the knife. The patient gave but little evidence of pain during this part of the operation; but whilst the dissection was being carried on in the deeper parts, she complained a good deal, although the anæsthetic agent was still injected into the cavity.

On the same day, and at the same time, Mr. Henry Smith operated upon a girl who had an encysted tumour on the neck about as big as a marble. Here the ether was carefully used for some minutes before the operation was commenced, and the patient not only gave no indications of pain during the incision through the skin and the dissecting out of the cyst, but afterwards she confessed she felt scarcely anything of the operation.

On Monday last Mr. Henry Smith twice used this agent very carefully on two patients,—one of them was a little girl with a very large abscess behind the ear; the ether was applied for some minutes over the whole surface of the abscess, and an incision fully two inches long was made. The girl made very little complaint of pain, except when the knife was being withdrawn, when she complained pretty loudly; but it was clear to the bystanders that the operation altogether was comparatively painless. The other was a patient, a young woman, suffering from extensive warty growths around the anus. The spray was applied most carefully for fully five minutes. During the period of its application the patient complained greatly of a burning sensation, which gradually subsided. Strong nitric acid was then applied, and the patient complained somewhat, but on questioning her afterwards she explained that her sensations during the time the nitric acid was being applied were those of extreme cold.

THE BRIGHTON MURDER.

Recent trials prove that the plea of insanity has failed to exert the spell over our criminal law courts which a few years ago it seemed likely to establish. That there is a sense in which it is undoubtedly true that every great criminal is mad may be freely allowed; but that such "madness" implies or is connected with the abolition of responsibility is a figment of pseudo-philanthropy which the common sense of juries refuses to accept. We have always regretted the countenance which such an idea has received from a portion of the Medical Profession. We hold it neither to be founded in sober psychological science nor calculated to advance the safety and morality of society. We are glad to see that this plea, which was advanced by the defence in the case of John William Leigh, who has been condemned for the murder of Harriet Harton at Brighton, was unsupported by a single Medical witness. There were some facts, however, which seemed to lend countenance to the theory. The man had been a drunkard, and had been known for his reckless, violent conduct, had suffered from "delirium tremens," and been called by his neighbours "Mad Leigh;" and these were urged by his counsel in support of the plea of moral insanity. The Medical officer of the gaol where the prisoner was confined, however, stubbornly refused to accept such a conclusion. He said that Leigh, when deprived of spirits, was particularly intelligent and clear-headed, and had the entire use of his faculties. The justice of this opinion and of the verdict of "Guilty" returned by the jury received terrible confirmation from the prisoner himself, who, on being sentenced to death by Lord Chief-Justice Erle, said, "I have nothing to say, my Lord. I cannot justify myself. I was responsible for my acts."

THE CASUAL POOR.

The revelations of the "Amateur Casual" in the *Pall Mall Gazette* have produced a certain amount of good. First, they have secured the inspection of the casual wards at the various metropolitan Workhouses by the police; secondly, they have caused the Poor-law Board to regulate, by an official order, the allowances to be given for the keeping together of soul and body. The order which has been issued on the subject directs that

"The destitute wayfarers, wanderers, and foundlings admitted into the vagrant wards shall henceforth be dieted with the food and in the manner described and set forth herein, namely:—Supper: For all persons above 9 years of age, 6 oz. of bread and a pint of gruel; for children under 9 years of age, 4 oz. of bread and half a pint of gruel. Breakfast: For all persons above 9 years of age, 6 oz. of bread and a pint of gruel; for children under 9 years of age, 4 oz. of bread and half a pint of gruel. The pint of gruel for supper for all persons above 9 years of age to be withdrawn from the 25th of March to the 29th of September in each year."

Two or more copies of the dietary, legibly written or printed in large type, are to be hung up in the wards. The order applies to the following Unions:—Fulham, Greenwich, Hackney, Holborn, Lewisham, City of London, East London, West London, St. Olave's, Poplar, St. Saviour's, Stepney, Strand, Wandsworth and Clapham, Whitechapel, and to the Parishes of St. Matthew, Bethnal-Green; St. Luke, Chelsea; St. James, Clerkenwell; St. George, Hanover-square; St. George-in-the-East; St. Giles-in-the-Fields and St. George, Bloomsbury; St. John, Hampstead; St. Mary, Islington; St. James, Westminster; St. Mary Abbots, Kensington; St. Luke, Middlesex; St. Margaret and St. John the Evangelist, Westminster; St. Martin-in-the-Fields; Mile-end Old Town; St. Marylebone; Paddington; St. Pancras; St. Leonard, Shoreditch; St. Mary Magdalen, Bermondsey; St. Giles, Camberwell; St. George-the-Martyr, Southwark; St. Mary, Lambeth; St. Mary, Newington; St. Mary, Rotherhithe. As, since the passing of the Metropolitan Houseless Poor Acts, the various Boards of Guardians alike contribute for the relief of the casual poor, it appears but just that they should be compelled to give a uniform amount of fare.

FROM ABROAD.—THE MEDICAL SERVICE IN THE UNITED STATES ARMY—PROFESSOR SCHÖNBEIN'S RESEARCHES ON OXYGEN.

The Medical officers of our Army may take what consolation the fact affords them that there is scarcely an army in Europe—if, indeed, there be one at all—in which the Medical Department is not calling for redress, or would do so did they not know that all complaints concerning their unsatisfactory position would pass unheeded. In the United States, where a little more equal justice might *à priori* be expected, matters seem to be on pretty much the same footing. In the last number of the *New York Medical Journal*, the editor, speaking of a new bill brought into the Senate for the reorganisation of the Army, in which the Medical Service is but scurvily treated, makes use of language which might with the greatest propriety be transported to our own columns, as descriptive of our own position:—

"We have no hope that the public will ever adequately recognise the value of the services of the Medical Staff of the Army, or that Congress will cease to manifest indifference, and even impatience, when called upon to legislate in its behalf. The Medical officers of our Army have always had to contend against the prejudices and intolerance of the officers of the line and other staff departments. They were 'Doctors,' and nothing more—any pretension to be military officers was to be rebuked and checked. . . . This injustice and narrow-mindedness are born of the notion that 'the Doctor' is a non-combatant (during the late rebellion thirty-six Medical officers were either killed or died from wounds received in action)—a tolerated civilian in the Army organisation, with only nominal rank. This prejudice against the Medical officer is not peculiar to our service; it flourishes to the same degree in the British, French, German, and Russian. It prevails with greater intensity in the Navy, and the Naval Medical officer often receives gross insults from the quarter-deck autocrat. This anomalous and unfortunate position of the Army Surgeon, which exposes him to frequent indignities, is due simply to the absence of substantial rank, which it is not desired should confer any military command outside the Hospital, or beyond the specific sphere of duty, for no Medical officer would contend for an authority he is not qualified for. . . Tradition and fossilism have triumphed, and the Medical officer, after serving forty years, finds himself no farther advanced in rank than he might have been thirty years before. A majority, to which he is entitled after five years' service, is the limit he may reach. He sees all his brother officers who entered the service with him promoted as they advance in years; but he is met with the inexorable stay-law of 'Thus far shalt thou go and no farther.' Deprived of substantial ranks, debarred from promotion after arduous and dangerous service and its welcome and needed attendant, increase of pay, an ever-present sense of imposed inferiority keenly felt, with

'No spur
To prick the sides of their intent,'

is it to be wondered at that Medical youth of conscious ability hesitate before entering the Army, or, at the period when matured experience makes them useful to the country, have to resign, and seek in civil life more solid rewards? A Surgeon after ten years of active service in that grade should have the rank of Lieutenant-Colonel, and after fifteen years the rank of Colonel."

Various scientific journals having recently announced that Dr. Schönbein, of Basle, had succeeded in decomposing oxygen into ozone and antozone, the French Scientific Association addressed a request to him that he would repeat before it the experiments establishing this discovery. In his reply the celebrated chemist observes,—

"You are perhaps aware that for the last 30 years I have been almost exclusively and uninterruptedly engaged in researches relating to oxygen, and in the course of this long series of investigations I have discovered, concerning this elementary body, a considerable number of new facts, from which I believe I am able to draw the following conclusions:

—1. Oxygen may exist in three different allotropic conditions. 2. Two of these states are active and opposed to each other; I designate them by the names ozone and antozone. 3. Equal quantities of ozone and antozone neutralise each other, forming inactive or neutral oxygen. 4. Neutral oxygen may be separated or transposed, one half into ozone and one half into antozone. But it is to be observed that the experimental demonstration of the justice of these conclusions is not as simple as, for example, that of the decomposition of water, and in order to apprehend their logical sequence, it is absolutely essential to become acquainted with a considerable number of facts relating to it. The exhibition of these facts by suitable experiments could not be accomplished at a single demonstration. The journals, moreover, have been in error in announcing that I had succeeded at isolating ozone and antozone in a state of purity. It is true for a long time past I have been engaged in attempts in accomplishing so desirable an end, but have not thus far met with complete success. Ozone and antozone are always mingled with neutral oxygen, which depends upon causes intimately connected with the generation of the two active modifications of oxygen. If the Association, after what I have said, continues to wish that I should visit Paris, and if the state of my health allows of my doing so, I shall have great pleasure in delivering a short course of lectures relating to the entire subject of my researches on oxygen."

We need hardly add how acceptable such a course would be from the distinguished discoverer of ozone.

PARLIAMENTARY.—STREET ACCIDENTS—FRESH IMPORTATION OF THE CATTLE PLAGUE—THE BRITISH MUSEUM—THE RIVER COMMISSION — THE VACCINATION BILL — THE LABOURING CLASSES DWELLINGS BILL—CONTAGIOUS DISEASES BILL—CAPITAL PUNISHMENT — THE CATTLE PLAGUE ORDERS IN COUNCIL.

In the House of Lords on Thursday, March 22,

Lord Westmeath drew attention to the frequency of street accidents, and condemned the conduct of the Home Secretary, who, he said, had taken no steps to prevent the loss of life and bodily injuries which were daily occurring.

Lord Granville admitted the necessity of some steps being taken to lessen the number of accidents which occurred in the crowded streets of the metropolis, but pointed out the difficulties which presented themselves to all the plans that had hitherto been suggested. The Government were most anxious to act efficiently, and there were no grounds for the attack upon the Home Secretary.

The subject was then allowed to drop.

The Earl of Lichfield asked the President of the Council whether it was true that the cattle plague had been reintroduced into several parts of the metropolis by means of a cargo of animals imported from Holland.

Earl Granville: I am sorry to say there is no doubt whatever that within the last day or so a cargo of Dutch cattle have arrived, affected as the noble Earl has stated. I am told that the disease was not sufficiently visible, being only in a state of incubation, and that the Custom House authorities did not detect its existence, but admitted the cattle into the metropolis. I may add that information having been received yesterday by the Secretary of State for Foreign Affairs that proper precautions were not taken in Holland for the prevention of diseased cattle coming to this country, Her Majesty's Ministers have asked Her Majesty to appoint a council to be held this week with a view to the issue of an order prohibiting the importation of cattle from Holland until further notice.

Lord Denman urged the Government to establish a dead meat market. He was sure it would cause no inconvenience to the trade, and would tend much to prevent the spread of disease among cattle.

In the House of Commons, in answer to a question by Lord H. Lennox,

The Chancellor of the Exchequer said there was no correspondence between the Government and the trustees of the British Museum, and no decision had been taken as to filling up the post of principal librarian under the same conditions as it was recently held by Mr. Panizzi. In the view of the Government, the first step to be taken was to submit to that House the vote which they had given notice of their intention to propose for the erection of a building at Kensington; and they could take no other step of a definite character until the House had decided on that.

In answer to a question by Mr. Neate as to the report of the River Commission,

Mr. T. J. Baring said the report was now in the press, and would be presented to Parliament before the recess. That report related to the River Thames, to which the hon. member's question alluded.

On the order of the day for going into Committee on the Vaccination Bill.

Mr. Bruce begged to postpone the Committee until the Wednesday after the Easter recess, but he wished to take that opportunity to remove a misapprehension which had created a great deal of alarm, and that was, that re-vaccination was made compulsory by the Bill. That was not the case. The object of the Bill was to remove a doubt whether the public vaccinator could be paid for re-vaccination, and it would enact that if any person desired to be re-vaccinated the public vaccinator might receive two-thirds of the ordinary fee for his services.

The Committee was then postponed.

The Labouring Classes Dwellings Bill, which enables Government to advance money on interest for the erection of suitable dwellings for the artisan and labouring classes, passed through Committee.

Lord C. Paget, in moving the second reading of the Contagious Diseases Bill, explained that it was intended to renew an Act passed in 1864 for the health of our soldiers and sailors in the various ports, with additional powers recommended by a Committee of Medical men. It was proposed to refer the Bill to a Select Committee.

Mr. Henley and Mr. Ayrton objected to the Bill on moral and religious grounds.

The Chancellor of the Exchequer observed that it was hardly possible this subject could be discussed then with the fulness which would be desirable. His noble friend, in proposing the second reading of the Bill, had merely proposed the continuation of a system which had received the sanction of Parliament. Neither his noble friend nor Her Majesty's Government was desirous of flinching from a full consideration of the numerous difficulties by which this matter was surrounded; and the noble marquis had announced his intention, at the proper time, to propose that the Bill be referred to a Select Committee. It would be desirable that those gentlemen who had charged themselves with the painful duty of looking into this question should serve on that Committee. The object of the Government was to have all the assistance on the subject which the intelligence and impartial judgment of Parliament could afford. They wished the matter to be examined free from prejudice of any kind. He, therefore, hoped there would be no objection to having the Bill read a second time.

The Bill was then read a second time.

On Friday, March 23, in the House of Lords,

The Lord Chancellor, in moving the first reading of a Bill to amend the law relating to capital punishment, said that a few years ago Her Majesty appointed a Commission to inquire into this very difficult subject. The Commissioners had made their report, and he now proposed to lay on the table a Bill for carrying their recommendations, with some modifications, into effect. He intended to move the second reading of the Bill on April 17.

The Bill was read a first time.

Their Lordships adjourned until April 12.

In the House of Commons,

Mr. G. Hardy asked the Secretary for the Home Department what was the purport of the Orders in Council which were about to be issued on the subject of the cattle plague.

Sir G. Grey said that the purport of the new Order was the revocation of all the existing orders, with the view to the modification of the whole of the existing regulations with regard to the plague. Many of the conditions contained in the existing orders would at the same time be re-enacted, as for example those having reference to the appointment of inspectors, who would be required to give notice of the appearance of the disease in any particular district, and to see that the premises in which diseased cattle had been were properly disinfected. It was desirable that a good many regulations of that description now in force should be renewed, and the new order would contain provisions with regard to the proclamation of infected districts and the prohibition at certain times of all markets and fairs, except those held under the licence of the Privy Council. With respect to the removal of cattle, it was intended to extend the provisions of the existing Act until April 16, and to substitute a regulation authorising the

removal of cattle by railway or by highway under certain licences, some of which would be left to be granted by the local authorities, and others would be provided for in the schedule. It was intended that the substance of this Order, or the greater part of it, should not come into operation until April 16, but part of it would come into operation immediately, and it would be in the possession of the Courts of Quarter Sessions in the week after next.

The House adjourned until Monday, April 9.

SCIENTIFIC EXAMINATIONS FOR THE M.B. LOND.

(From a Correspondent.)

We must again say a few words on scientific examinations for the degree of M.B. Lond., and the late manifesto of the Senate. In doing so we cannot help stating our opinion that the University regulations might be modified with benefit.

We are informed that the thirty-nine candidates rejected in botany, "especially failed in their descriptions of the plants set before them;" and if we turn to the paper laid before the students, we find that of the six questions it contains only one refers to vegetable physiology, two to minute anatomy, one to morphology, another to the derivation and meaning of certain terms, and the last to descriptive botany. It is on this last question that the Examiners seem to place most importance, implying, as it does, according to them, more of accurate observation than the other departments of botany, and thus affording a better preparation for the exact study of Medicine. To part of this we give a hearty assent, but surely it is not the whole truth, seeing that be how accurate a man's observation may, if he do not describe what he sees in botanical language, it goes for nothing. Now, we humbly submit that the catalogue of names, which this implies, is both troublesome to acquire and burdensome after acquisition, as well as demanding in the process an amount of time which might be far more profitably spent in the pursuit of knowledge that will prove more lastingly beneficial. We have seen instances of men who, in other respects, knew very little of botany, yet could very readily describe a plant in scientific jargon, for it is really nothing else, this only implying, on his part, a considerable amount of exercise in the open air and the habit of examining the plants picked up in his rambles. Now to the London student this would doubtless be highly beneficial, but it also implies an expenditure of time and money that we do not care to contemplate. Considering that only four years are allowed to the entire study of Medicine, we consider that one year, which is the very least that could be put down, according to the standard of the University of London, to be rather too long a period devoted to such a subordinate subject as botany. Neither do we consider the descriptive department of botanical study to be the most important, so far as Medical students are concerned, nor do we think it the highest apart from all connexion with those engaged in its pursuit. To us it seems that an exact knowledge of the constitution, origin, growth, and organisation of those simple beings which botany offers for our investigation, of far greater value to one whose life is to be devoted to the regulation of that most complex of all machines, the human system, than an acquaintance with any number of technical terms and their exact application. It is true that the London Senate complain of deficiency here also, but we scarcely think that the questions, contained in the paper we refer to, can be taken as a good test of any one's knowledge of the subject.

If we turn to zoology, which follows next in order as a plucking subject, the objections above urged with regard to botany strike us with still greater force. If it is difficult to acquire a sufficient knowledge of botany in the time assigned for its study, this task must become still more grievous when an exact knowledge of zoology is required along with it. We are far from saying that a knowledge of these sciences is useless to a Medical student, yet their utility is so much subordinated to other subjects, that we would be inclined to limit the extent of ground to be gone over in their case to those departments most likely to prove useful in after life. Let exact knowledge in these be rigidly demanded, provided it can be acquired in a reasonable time, but as for other and minor points, let a general knowledge suffice.

P. P.

THE PROMISED REPORT OF THE VETERINARY DEPARTMENT.

(From a Correspondent.)

It was announced at the beginning of the year that the Veterinary Department of the Privy Council would make public within two or three weeks a report which had been in active preparation as to the progress of Rinderpest up to December 31. Such report was intended to be a full account, based upon the weekly returns, of all that was known of the progress of the cattle murrain up to the date above named. It is not our custom to bring forward unnecessary complaints; indeed, we are only too ready to make allowance for difficulties, especially such as are inseparable from the conduct of all newly organised undertakings. We think, however, that it is high time the public should know something in detail of the doings and opinions of the various local inspectors, beyond the matter of the collective weekly issue of some half-dozen columns of figures. We desire information upon the different modes which have been adopted in various districts, both as to the attempted "stamping out" of the disease and the systems of treatment that have been tried. All these things are essential to a right judgment upon points which involve controversy, and it does seem not unreasonable to inquire how much longer we are to be kept on the tenter-hooks of expectation. If it be true, as we have understood, that Dr. Williams's Report will deal only with the facts relating to the period from the first outbreak of the disease up to the 30th of December last, and will take no cognisance of what has happened this year, one would think he might have produced something long before this. If he delays much longer his subject will be matter of history alone, and all interest will have died out with the gradual decline of the disease. The "origin" and "nature" of Rinderpest have been pretty well determined already, and the only interest of Dr. Williams's promised Report would seem to lie in the "treatment" and "preventive measures" adopted. Was it not within the compass of official energy to supply the "comprehensive digest" of the information under these two heads, which was promised by the Cattle Plague Commissioners in their Second Report, before such information became stale—a relic of the past? This delay is the more remarkable, inasmuch as it is rumoured that during the preparation of this Report the customary periods of cessation from work for purposes of rest, and also for the observance of the Sunday, have been virtually abrogated in the Veterinary Department. Probably this rumour, like hundreds of others, has but a grain of truth behind it; yet it might be worth while for some right reverend prelate to inquire in Parliament whether the Government were setting a good example in calling upon their own *employés* thus to violate the fourth commandment. Fasting and humiliation will hardly work in harmony with Sabbath-breaking, and the unfruitfulness of such labour is best proved by its abortive results so far.

The Princess of Wales visited the London Surgical Home at Notting-hill on Wednesday, March 21.

Sir Dominick Corrigan has retired from the position which he held as Physician to the House of Industry Hospitals. It was filled on Thursday, when Dr. Lyons, formerly Pathological Commissioner in the Crimea, Professor in the Catholic University, and Physician to the College of Maynooth, was chosen by a majority of one.

UNIVERSITY OF LONDON—ALTERATIONS IN THE REGULATIONS.

The following is a summary of some important alterations which have reeently been made in the regulations relative to the various Examinations and Degrees in the University of London. We call special attention to the matter in the belief that the ehanges are not sufficiently known to students in general:—

First, in regard to *fees*. Formerly, a candidate who failed to pass, was allowed, without the paymeut of any additional fee, to present himself for examination at any and every subsequent period. Now, however, such admission will be limited to *two* subsequent occasions, in the case of the Matriculation and Bachelor's degrees; and to *one* sueceeding examination for the degrees of Doctor and Master.

Several important changes have been made in the lists of subjects in which the various candidates are examined.

At *Matriculation*, option is no longer allowed between the Latin and Greek grammar papers on the afternoon of the first day. Candidates are now required to pass in both of these. The Greek paper will contain passages to be translated into English, with questions in grammar, history, and geography. The paper in Latin will also contain passages to be translated into English, and questions in history and geography, as heretofore, but the grammar will be set in a separate paper, which will also contain easy sentences of *English to be translated into Latin*—that is to say, there will be one Greek paper, but two Latin papers, one of the latter, which has no counterpart in Greek, being devoted to grammar and the translation of English into Latin. It is well to know that special credit will be given for accurate answers to the grammar questions.

At the *First Bachelor of Science* an addition has been made to the subject of inorganic chemistry. Candidates are required to answer "*Questions on the Unitary System.*" The best information on this matter will be found in a series of articles, headed "Doctrines of Modern Chemistry," contained in the *Medical Times and Gazette* for the last half year—in the numbers 788, 798-9, 800-2-3-5-7. The series is, however, not yet completed.

In Botany, also, an acquaintance is demanded with the distinctive characters of *ten* in lieu of *six* large orders of Dicotyledons, the four additional being *Cruciferæ*, *Caryophylleæ*, *Umbelliferæ*, and *Scrofulariaceæ*. To the list of Monocolytedons, *Cyperaceæ* have been added; and to Acotyledons, *Lichens*. The Demonstration of the Botanical Characters of Plants, upon large and conspicuous specimens, provided by the examiners, is expected as usual.

At the *Second Bachelor of Science* the Scholarship in Biology has been done away with, and two others substituted for it, the one for Zoology and the other for Botany.

Bachelor of Medicine.—Some modifications have been made in reference to this degree.

At the *Preliminary Scientific M.B. Examination* the subjects of Inorganic Chemistry and Botany are the same as in the First B.Sc. just noted, and corresponding changes have been made in regard to the "Unitary System," and the inclusion of four additional orders amongst Dicotyledons, Cyperaceæ amongst Monocotyledons, and Lichens amongst Acotyledons.

At the Second M.B., in regard to the certificate "of having attended the Medical Practice of a recognised Hospital during two years, with clinical instruction and Lectures on Clinical Medicine," a modification has been introduced: attendance during three months in the wards of a lunatic Asylum, with clinieal instruction, may be substituted for a like period of attendance on (may form part of the two years) Medical Practice. The Senate wish to encourage the possession of a knowledge of lunacy on the part of the M.B. candidates.

It has also been necessary for the candidate to produce evidence of having had, subsequently to attendanee on Surgical or Medical Practice, six months' special eharge of patients in some institutions. This certificate may now be given in *Surgery*, as well as in Medicine or Midwifery.

The Degree of *Bachelor of Surgery* shall be in future attainable by those who have taken the M.B. Degree, who have received instructions in operative Surgery, and who have operated on the dead body. It may thus be taken *immediately* after the M.B. No Scholarship in Surgery will in future be given at the second M.B., but at the Honours' Examination for the Degree of Bachelor of Surgery instead: the candidate who stands second in the list of honours will also receive a gold medal. The B.S. is, in fact, the second M.B. Honours Examination.

The Degree of Master of Surgery will in the future be obtainable by those only who possess that of the Bachelor of Surgery, with one exception to be mentioned directly. Instead of the certificate of attendance on Practical Surgery during six months with special charge of patients in a Hospital, Infirmary, Dispensary, or parochial union, the candidate will be required to produce evidence of having attended subsequently to having taken the B.S. (1) to Clinical or Practical Surgery during two years in a recognised Hospital or institution, or (2) to Clinical or Practical Surgery during one year, with three years' Professional practice, or (3) five years' Professional practice before or after taking the degree of B.S. In the case of those who have been placed in the first division at the B.S., one year's Hospital practice or two years' Professional practice will be dispensed with—that is to say, a B.S. first division may take the M.S. the following year if he attend in the meanwhile the Surgical practice of a Hospital.

The exception mentioned applies to those who have taken the degree of M.B. before 1866; these will be admitted to the M.S. examination without having taken the B.S, the commencement of attendance on Surgical practice dating from the passing of the M.B. Degree. A gold medal, value £20, will be awarded to the most distinguished candidate. The M.S. is thus placed exactly on a par with the Degree of M.D.

Memoirs of the Anthropological Society of London. Vol. I. 1865.

The Anthropological Review and Journal of the Anthropological Society of London. Vols. I.–III.

Thirty years ago the students of the science of man in England at least were in the state of casual paupers at a modern charitable institution. They were only too glad of information at any priee, and did not care from whose hand it came, or what was the value of it when acquired. We can only call to our mind two original English anthropologists who taught prior to 1840—one the late distinguished teacher of Surgery at St. Bartholomew's, whose writings were the first to interpret to our English publie the facts which Blumenbach had previously taught in Germany; the other the illustrious Robert Knox, whose influence on the thoughts of his English disciples has led to the production of the works before us. In 1840 an English student of the science of man would have looked in vain for a text-book. Many of the eauses which have retarded the advance of the science are due to a mistaken prejudice on the part of a large section of the general public; some are unquestionably the fault of anthropologists themselves. The public have three great objections to anthropological study. First, anthropology is a science which pledges man to the belief that his remote ancestors were baboons; and every anthropologist, before being elected a member of the society founded in England to advance his science, is solemnly pledged to promote the transmutation hypothesis. This theory is intensely popular, and consequently without a grain of fact to support it. The Anthropological Society is precisely the place where the hardest blows that the transmutation hypothesis has yet received have been dealt, and where those advocates of the ape-origin of man who elsewhere address sympathising audiences have hitherto failed to secure a hearing. Next, an anthropologist considers the lower races of men as "chattels," and much political obloquy has been launched against the London society by reason of the fact that some of its members have contributed papers which militate against sentiments generally popular amongst a large section of amiable philan-

thropists. The aborigines of Queensland have been shot down like dogs; half a tribe amongst them has been destroyed by a present of flour mixed with arsenic; the protecting ægis of "the humane classes" is not thrown over these victims of British colonisation. The Anthropological Society of London is, so far as we know, the only place where these facts have been announced before a British public audience. But the fact is evident that some races have a prescriptive right to be the victims of popular philanthropy; and while, if the Anthropological Society had, as has been charged upon it, introduced political discussion into its scientific field of inquiry, no one would condemn them more strongly than ourselves. We must recognise the fact that the time must come when a knowledge of the physical and mental characters of all the races of men must be imperative on every Medical officer on foreign service. Again, the students of anthropology are charged with being inimical to the Christian religion, and the same suspicion and obloquy which greeted the advance of astronomy and geology have resounded along the path of anthropological inquiries. We believe, however, that these have now almost died out; and it is highly creditable to the intellect, if not to the good feeling, of the educated public that they should now prefer to inquire what it is that the anthropologists are working at than to annoy the advocates of a science which they can neither retard nor destroy. There is no book so intensely anthropological as the Bible, and no work in which a knowledge of the varieties of man's moral and physical nature, according to race, is so important as it is in that of the minister of religion, at home or abroad. In the Old Testament, the inherent depravity of certain races is sternly insisted on; in the New, all races are declared to be subjects of Almighty love; the only bit of ethnology in its offensive sense is the quotation by the great Apostle to the Gentiles of the poet's dictum that the "Cretes are always liars." Such, however, have been the principal reasons why anthropology has been so little pursued in England. But anthropologists themselves have also been much to blame. The inexactitude of the terms they employ might have been excused in days gone by, but is out of place in the period of Welcker and Lucae. Modern anthropologists have not disclosed any truth bearing the aspect of novelty; centuries before the days of Knox, Virey, Desmoulins, or Carus, the problems of the science were discussed. The questions of anthropology have never been examined with the tact or discrimination which the students of "exact sciences" have practised. The terms "species," "race," "variety," are often used as convertible or synonymous, and the terminology of the science of man thereby stands out in unenviable contrast to that of the botanist or of the chemist. Anthropologists often use, perhaps correctly, the word "race" as implying a group of nations linked together by certain constantly observed characters, without expressing any opinion as to their origin, or the fertility of the hybrids who might be derived from them. "Species," on the contrary, implies too often a theory. The term "variety," as used in anthropology, is essentially vague, and the monogenist alone is entitled logically to use it.

Certain known facts demand some solution at our hands. We have such races as the English and the Australian, of which every physical and moral character are as distinctly opposed as can be conceived. As M. Broca has pointed out, the progeny of the white and the Australian rarely arises, and is scarcely ever prolific. Yet in the text-books of the day the white and the Australian, like most other varieties of man, are recognised to be of identical species with each other. Anthropologists have to inquire when or how were such races thus scattered on the earth. Are they the remains of primitive races of man, each originally produced in various localities; or have they all diverged from one common centre, the birthplace of the whole human race? Are the peculiarities which prevail amongst the various races of man such as we may suppose to be capable of being modified under various circumstances, and if such an assumption be granted, what may we suppose to be the range of such modifiability? But this whole question which involves the distinction between the monogenists and the polygenists rests on the metaphysical definition of "species" and "race," which any individual student of the science of man may think fit to adopt. The question of the classification of the races of man is one which has engaged the attention of anthropologists from an early period. The French and American naturalists have been inclined to adopt a more minute sub-division than either the English or Germans. The researches of the best informed anthropologists, and chiefly of Professor Broca, have distinctly demonstrated the fact, that if we take the hybrid progeny of any single two races of men, although their ancestors may have bred together with perfect success, nevertheless in the third or fourth generation of the intermediate mongrel progeny traces were visible of a physical degeneration, which ultimately, swiftly, and inevitably tends to the extinction of the hybrid race. Mulattos are the shortest lived of any class of the human race, and less capable of undergoing fatigue than either the blacks or the whites. Their females are peculiarly delicate, and subject to a variety of chronic diseases, whilst various causes tend to produce the early deaths of their children. But the whole question of hybridity is in its infancy. Even although it were granted that the balance of evidence at the present time may be against the unity of man as a species, we must recollect that we have not to decide the question upon the evidences of hybridity alone. So few philosophical observers have ever stated the true case in favour of monogeny, that we are perfectly content to suspend our judgment until some one may, as some one probably will, arise to answer the arguments or to demolish the evidence which the advocates of more than one origin for the human species have brought forward. The science is as yet quite young enough to permit an inquirer to wait with hope and patience.

The theory of the unity of the races of mankind has been advocated under several aspects; as a theological dogma, as a moral fact, and as a question of physical descent. With regard to the alleged moral unity, Waitz, the most intelligent advocate of the doctrine of unity, because he is the one most entirely emancipated from external prepossessions, suggests that such innate ideas as, *e.g.*, the belief in God or in a future state, are to be observed in all nations upon the earth. This statement, however, has met with positive denial. It is alleged that there are millions of people on the face of this planet to whom the metaphysical ideas of any religion are as foreign as are the conclusions of science or the beauties of art. Sir Charles Nicholson and Dr. Lang have told us that with respect to some of the aborigines of Australia, they "have no idea of a superior divinity, no objects of worship, no idols or temples, no sacrifices, nothing whatever, in the shape of religion to distinguish them from the beasts." The Andaman islanders, with their minimised cranial capacity, are alike destitute of any such generalisations as those which induce the Mohamedan to propagate a religion by force, or the American to endure tortures in the hope of future rest. In the words of one of our most truthful modern writers, the savage too often "dies the death of a coward and a dog, for whom the grave brings darkness and nothing more." The picture is indeed a melancholy one, but the European who may enjoy a belief in the existence of a moral law does not value his privileges the less for the knowledge that there are inferior races to whom the cherished aspirations of his own belief are incomprehensible; while there are races who are destitute (so far as present appearances go) of the conception of any supernal being as the Creator or Regulator of the Universe, others there are in whom the idea of a moral law is equally absent. The Kamschadale is sunk in the grossest depravity; offences against the property and person form the daily task and amusement of his life; his neighbour is loved only as a being whom it is possible to rob; but to scrape off snow from his own shoes, or to pierce coal with a knife, becomes a serious moral offence. Some tribes of savages have no word in their language, or conventional embodiment of an idea, to express the attribute of "honesty," except the negative quality of "not stealing." Again, it is alleged that a fear of the dead, and a honour shown to their memory are present in all uncultured nations. We can scarcely grant this. "Natural affection," as it is wrongly called, is no work of mere nature. Regarding this question as a physical one, we want facts. What is the extreme limit of moral and physical divergence amongst the posterity of one pair?

The subject of acclimatisation has been much discussed of late before the Anthropological Society of Paris. The French anthropologists are strongly inclined to endorse the opinions of Dr. Hunt and Sir Ranald Martin, that there is no such thing as true acclimatisation; that men, neither rapidly nor slowly (time being, it must be observed, no factor in the case), can be displaced from one region and located in another without physical degeneration. If the Government of England were to recognise these and other anthropological facts—if they could be induced to abstain from the unphilosophical and cruel sacrifice of human life which is perpetrated at their

will, by the exportation of thousands of unhealthy English soldiers to India, where their constitutions are unable to maintain the vital power, and where they die out ere being acclimatised—a great economy of human life would result. The rulers of the English armies will hereafter recognise that it is vain to struggle against the plain dynamical facts of science; and we hope that eventually, by the judicious selection of individuals of robust constitution from our regiments, and their classification according to temperament, the fearful waste of the blood of Englishmen which now prevails in India may be diminished.

These and other considerations are now being pressed on the mind not only of anthropologists, but of thinking men in general. In the works whose titles we have placed at the head of our article they are discussed in detail. Anthropology is a science of exceedingly wide-spread ramifications. While it includes to a great extent much that the human anatomist should diligently study, its practical bearings recommend it to every educated man. We consider it, therefore, to be an excellent sign of the healthy progress of the science of man, that we have now flourishing anthropological societies at Paris, London, Madrid, and Moscow, while societies are now in course of formation at New York, St. Petersburg, and even at Rome. The anthropological section which has been formed at the Paris Universal Exhibition will, we doubt not, further accelerate the progress of anthropology; and we trust that the few practical results which the last few years' work has afforded may, in time, lead to the acquisition of new and important facts which may render the science of man especially interesting to the Medical Profession.

GENERAL CORRESPONDENCE.

FRACTURE OF THE RADIUS AT THE STYLOID PROCESS.

Letter from Mr. Lawson Tait.

[To the Editor of the Medical Times and Gazette.]

Sir,—In answer to Mr. Barnett's note, I can now inform him that he can have Gordon's apparatus supplied at the price of five shillings and sixpence by Mr. Gardner, surgical instrument maker, 45, South Bridge, Edinburgh, to whom I have sent a pattern.

Another case of this fracture occurred here a few days ago in Dr. Kirk's practice, to whose kindness I am much indebted for the use of cases, which illustrated to a remarkable degree the diagnostic value of the fact of the patient falling on the palm of the hand. In this case the deformity was very slight, and there was no crepitus to be felt. Indeed, this latter point is a very remarkable feature in the diagnosis of this fracture, as it is almost the rule that crepitus is absent; indeed, in the seven cases that I have seen crepitus was only to be felt in one, and then only to a very faint degree.

Dr. Heron Watson writes me that he applied Gordon's splint to a fracture of the radius at the lower third some days ago, and that as yet the apparatus is giving every satisfaction; and I have no doubt but that it may be applied with advantage in fractures even higher up.

There are many objections to the habit of connecting lesions and anatomical structures with proper names. It often gives rise to great confusion, besides being frequently unjust. For instance, I question very much if many London or Edinburgh students being examined by a Dublin Board would answer the question "What is Colles's fracture?" in a manner to satisfy their examiners; and, again, in M. Trousseau's "Clinique Medicale," exophthalmic goitre and its attendant symptoms are christened "Maladie de Graves," while many think that the name might have been with equal, or even greater, propriety "Maladie de Begbie."

Thus it is that the fracture of the radius produced by the fall on the palm of the hand, and presenting the peculiar sigmoid deformity, is not entitled to have Professor Colles's name attached to it, as the fracture described by him in the *Edinburgh Medical Journal* for April, 1814, is stated as "taking place about an inch and a half above the carpal extremity of the radius," while the fact is that it is almost invariably confined to within half an inch from the extremity of the styloid process.

I am, &c.

Bathgate, March 10. R. Lawson Tait.

REPLY TO DR. G. JOHNSON.

Letter from Dr. Howard B. Montgomery.

[To the Editor of the Medical Times and Gazette.]

Sir,—May I solicit your permission to reply (as briefly as is consistent with the importance of the main question at issue) to the charge of employing undue personality in reference to Dr. G. Johnson's censure of Indian Practitioners in the treatment of cholera?

Dr. G. Johnson, by a question to which an affirmative answer was distinctly implied, endeavoured, in my opinion, to refer increased mortality from cholera to an alteration in practice. The circumstances under which this alteration occurred clearly constituted it malpraxis of a character that could only be accounted for on the supposition that those making it were of themselves either incompetent to treat disease on sound principles, ignorant of opposite views regarding treatment, or obstinately adherent to their own views, even though other and more rational ones were within their cognisance.

It appeared to me that the mere suggestion that increased mortality was due to malpraxis was a breach of Professional ethics; and, further, that the grounds upon which it was made were for many reasons insufficient.

My reply was simply a personal expression of my own opinion that Dr. G. Johnson had violated Medical ethics in a way which I did not think Indian Practitioners would imitate. In attributing to them "superiority in good taste," I was solely referring to the purely Professional view of this point in ethics.

Whether or not Dr. G. Johnson reflected on the abilities of Indian Practitioners I am willing to leave to the Profession and to abide by the result; but while I state that my own opinion on the point was unhesitating, I am also anxious to add that I did not, and do not, desire to make it a justification for any personal attack upon the author of the passage in question. It is, however, noteworthy that, although Dr. Johnson had an admirable opportunity of denying the supposed intention, he has, so far from availing himself of it, actually repeated it in his expressed adherence to his former views.

Had the supposed imputation proceeded from any person not holding a high Professional position, I should have passed it over in silence; but a censure pronounced by a gentleman of Dr. G. Johnson's known ability and high Professional standing would prove a grave cause of regret to all upon whom it fell.

These very attributes of the author of it (and I cordially and most sincerely recognise them) tended to render the more imperative an immediate refutation, if possible, of the grounds upon which it was based; and to disprove the latter was doubly important, for if in India Practitioners had been guilty of malpraxis in the treatment of cholera then, *à fortiori*, it was probable that we would prove unskilful in the management of other diseases not so essentially those of India, and in almost all of which we must of necessity have less experience.

In the facts submitted by me, when questioning the data relied on by Dr. G. Johnson, I endeavoured to prove, firstly, that we had no satisfactory data upon which to fix the *pro rata* mortality from cholera in 1818-19; secondly, that all investigations up to 1852 showed a rate of mortality that fell far short of that stated as now existing in Bengal; thirdly, that subsequent experience in Madras showed that in no single instance has it been reached in Madras (so far as my information at present goes); and, fourthly, that percentage of deaths to admissions is not of necessity a fair test of Professional ability as now existing in comparison with that which may be inferred from statistics compiled at a time when, from deficient arrestive measures, several minor cases were almost certain to occur, which, being rarely fatal, would tend to diminish the proportions of deaths to admissions. To none of these points does Dr. G. Johnson make any reply.

Dr. G. Johnson pleads that he is not responsible for the statistics upon which his query was based. This is, to say the least, a novel defence. I now, for the first time, learn that it is ethically correct to quote facts without being responsible for them; and yet to make them appear as confirmative of a foregone conclusion, and the grounds of laying (or appearing to lay) a serious imputation upon those who, of all people in the world, have the management of the largest number of cases of this the most fatal disease known.

Dr. G. Johnson says he has no reason to doubt the accuracy of the statement of the Bengal Sanitary Commission. But does even it justify a generalisation of any inference from it as applicable to India at large? I think I have shown that in Madras it does not hold good. On this point I shall gladly lay comprehensive facts before your readers on a future occasion, should you feel disposed to afford me an opportunity of doing so.

I also with pleasure accept the challenge to justify my expressed opinion of Dr. G. Johnson's theory, which I shall do at an early date. In any controversy that may arise thereon, and in any remarks I may make, it will be my particular aim to avoid personalities; and I am prepared to credit Dr. G. Johnson with every personal and Professional virtue known to mankind if he will kindly, in deference to the feelings of those concerned, avoid the use of language that (even though in error) may be fairly construed so as to expose us, in addition to the risk of loss of life in India, to the even greater loss of Professional reputation.

I am, &c., Howard B. Montgomery, M.D.,
Surgeon Madras Army.

16, Durham-terrace, Westbourne-park, W., March 20.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, February 20.

Dr. Peacock, President.

(Continued from page 323.)

Dr. Murchison exhibited specimens showing

PERFORATION OF THE BOWEL IN ENTERIC FEVER.

1. A case in which, throughout the fever, there had been constipation, scybala being found in the bowels after death. 2. A case of peritonitis, without actual perforation. 3. A case of three perforations of the large intestine, with extensive peritonitis. This patient lived fourteen days after development of symptoms of peritonitis. 4. A case of perforation of the appendix vermiformis; death from peritonitis. 5. Lastly, a case of much practical interest—viz., death from perforation on the forty-fourth day, the patient having got well enough to go to his work. He died on the fourth day of his second illness.

The President remarked that all the specimens exhibited by Dr. Murchison were interesting, but the last was especially so, showing, as it did, the late period at which perforation might occur in cases of typhoid fever, and the consequent necessity for care after all the symptoms of active fever had subsided. He had himself known perforation occur in a case after recovery was so completely established that the patient had been discharged from the Hospital. In a case which he had recently seen, the patient died with perforation on the thirty-fifth or thirty-seventh day, and yet the fatal event was evidently due to active disease, the perforation having been produced by a small slough, which had involved all the coats of the intestine, and which had separated on one side, so as to form a kind of valvular opening. In this instance there had been a partial recovery and then a recurrence of the fever. In a former volume of the *Transactions* he had described a case in which after complete convalescence a recurrence of febrile action had taken place and the patient died, and after death recent sloughs and old healing ulcers were found in the intestines.

Dr. Morell Mackenzie exhibited some

SMALL PIECES OF AN EPITHELIAL CANCER REMOVED FROM THE LARYNX OF A WOMAN AGED FIFTY,

with the aid of the laryngoscope and an instrument of his own invention. This consisted of a fine curved rod terminating in a loop. The instrument was introduced into the larynx, and the projecting growth, which was attached just below the anterior insertion of the vocal cords, was jerked off and brought into the mouth. Dr. Mackenzie said that in cases successfully treated with the laryngeal écraseur, he believed the particles had simply been broken off, and that the wire of the écraseur had not been drawn through the eyes of the instrument—in short, that the instrument had not acted on the principle of the écraseur. The instrument now brought forward was simple, safe, and could be used by any one. Dr. Andrew Clark had examined the specimen microscopically, and considered it to be the most typical and malignant specimen of epithelial cancer which he had ever seen as a small growth in the larynx.

Dr. Mackenzie also exhibited a specimen of Epithelial Cancer of the Œsophagus.

Dr. Conway Evans exhibited

A RUPTURED SPLEEN,

removed from a patient who died in King's College Hospital, under the care of Mr. Partridge, from hæmorrhage into that organ. The patient, an old man, was accidentally crushed in the street between a cartwheel and the kerbstone, and sustained fracture of many ribs on both sides. On admission, shortly after the accident, he appeared to be suffering considerably from shock, but was much better the next day, and, indeed, presented no symptoms of serious internal injury until the fifth day, when he sank somewhat rapidly. On examination the spleen was found to be extensively lacerated, and surrounded by clotted blood in large quantity. Much of the blood was situate between the substance of the spleen and its capsule, and all the coagula were limited to its immediate neighbourhood. The chief points of interest in the case were the length of time which the patient had survived the accident, and the complete absence of symptoms indicative of internal injury; and the pathological explanation of these circumstances afforded by the autopsy, which tended to the conclusion that, although the substance of the spleen had doubtless undergone laceration at the time of the accident, it was not until late in the case that its capsule gave way, and permitted the outpouring blood to escape into the abdominal cavity.

Mr. Curling exhibited

A LARGE TUMOUR OF THE LEFT TESTICLE

removed by operation from a healthy-looking man from Nottingham, whom he had seen in August last year. Both testicles were diseased and greatly enlarged. The right was removed last year, and the left the day before by Mr. Thompson, of Nottingham. who had forwarded the specimen to Mr. Curling. The tumour presented remarkable appearances, different from the ordinary diseases of the gland. It was referred for examination to Mr. Sibley and Mr. Hulke to report on.

Mr. Carr Jackson brought before the Society a patient who had an

ENLARGED LEG—OBSTRUCTION TO THE LYMPHATIC CIRCULATION.

The patient was sixteen years of age. The left leg was much enlarged, the limb was in parts redder, and there was more hair on it. There was a dotted pustular eruption over the inside and front of the thigh, in the stage of crusting. Mr. Jackson pointed out "bunches" of enlarged lymphatics, on puncturing which a milky fluid exuded having, on microscopical examination, all the characteristics of lymph.

Dr. Brinton showed a specimen of a

LARGE ABDOMINAL TUMOUR.

The specimen had been sent to him by Mr. Ikin, of Leeds. It had been removed from the belly of a child ten years of age, who had received an injury a year before, and who had been under Medical advice seven months. There was a precocious puberty, and the child became very stout. At length the child had pains, next paraplegia, and then coma and convulsions for fourteen days; after which she died. The tumour was cancerous, and contained a large quantity of blood. Dr. Brinton remarked on the frequency with which such tumours followed an injury.

Mr. Nunn exhibited a drawing, and remarked on the

EFFECT OF DIVISION OF NERVES ON TEMPERATURE.

The ulnar and median nerves had been divided, and the temperature fell ten degrees. When sensation returned the temperature became normal.

Mr. Nunn also showed a photograph of

TERTIARY SYPHILITIC AFFECTION OF THE SYNOVIAL TISSUES ON THE TENDONS OF THE DORSUM OF THE FOOT.

He said little had been written on syphilis of the synovial tissues. He felt quite sure that there was one affection of bursæ which was clearly syphilitic. Mr. Nunn then made further remarks on the subject.

Mr. Nunn next showed a specimen of

GUMMY TUMOUR OF THE LOWER LIP.

In this case there was no history of syphilis; but there was evidence of it in syphilitic ulceration of the palate.

Dr. Cayley showed a specimen of

NUTSHELL FROM THE LARYNX.

The child was six months old, and was brought to the Hospital for stridulous breathing, and paroxysm of dyspnœa. Tracheotomy was performed by the House-Surgeon; but the child died.

Dr. Cayley also showed a specimen of

CANCER OF THE RECTUM OPENING INTO THE VAGINA.

The interest of this case was, that on the wall of the vagina opposite the actual perforation was a patch of cancer.

Mr. Barwell showed

PARTS REMOVED IN EXCISION OF THE HIP-JOINT.

The patient was a child, six and a-half years of age. The disease had been very severe, there being abscesses at the back of the trochanter and on the inner side of the knee. Mr. Barwell referred to another case in which, after removing the head of the femur, he had taken away the floor of the acetabulum, and had let out much matter from the pelvis. Both children were now walking about without crutches. Mr. Barwell spoke of the kind of splints he used after the operation. There was no shortening.

Mr. Nunn thought Surgeons hesitated too much in operating on cases of advanced diseases of the hip-joint.

Mr. Holmes said he thought it better to avoid the use of splints altogether. He used a weight to keep the limb quiet, and also a couple of sand-bags. That the limb should be restored to its normal length was neither probable nor desirable. If there was no shortening there would be a weak joint. Mr. Holmes agreed with Mr. Nunn in thinking the operation ought to be oftener performed, as when there were abscesses there was little hope of natural cure. Although he could not confirm Mr. Nunn's opinion as to the slightness of the operation, as several of his patients had died of inflammation following the operation, he had never regretted performing it.

Mr. Barwell said that when there were large abscesses the operation ought to be performed. He supposed the term trifling applied to those cases in which there was dislocation. He could not agree with Mr. Holmes as to the uselessness of splints, and he thought that the amount of shortening necessary was small.

Dr. Andrew showed a specimen from a case of

ACUTE ATROPHY OF THE LIVER.

The patient died jaundiced. He was three days violently delirious, and in this condition he broke two of his teeth. The liver was the only organ noticeably affected. It weighed thirty-one ounces, and contained crystals of tyrosine. The patient had been out of health five or six weeks.

Mr. Henry Smith showed a specimen of

CLOT FROM THE PULMONARY ARTERY.

A negro consulted Mr. Smith for pain in the left side of the back and left side of the abdomen. There was retraction of the belly. Next day the patient felt better, but had no pulse. Brandy was given. The day after he still felt better, but had pain in his joints, and his urine was of a dark colour, but no stone had been passed. There was a little pain in the chest. He died suddenly. A large firm fibrinous clot was found in the right ventricle, and it was continued into the pulmonary artery. There was another clot in the left ventricle and aorta. There was also one in the right auricle. Mr. Smith supposed these clots were the cause of the want of pulse. He spoke of the investigations of Dr. Richardson on the subject. The urine was small in quantity, but contained no albumen.

The President suggested that the clots might have been the effect rather than the cause—*i.e.*, that they were formed during slow death.

Mr. Henry Smith said this view had been suggested to him.

Dr. Brinton alluded to the singular way in which negroes die of slight causes.

In reply to Dr. Cholmley, Mr. Smith said the kidneys were healthy; he had not examined the bladder.

Dr. Semple said he thought coagula in the heart had not received due attention from the Society. He thought too great importance had been attached to them as causes of death. He agreed with Dr. Peacock in thinking that they were rather formed during the last periods of life. In connexion with the subjects of embolism and thrombosis, they were worthy of much attention.

St. Mary's Hospital, Paddington.—The annual festival of this Hospital was celebrated on Thursday last at the Albion Tavern. The Duke of Grafton presided. Subscriptions and donations amounting to upwards of £1100 were announced.

OBITUARY.

JOHN SPURGIN, M.D.

John Spurgin was born at Orplands, in the parish of Bradwell, in Essex, in the year 1797, of a family which had been possessed of that small estate for many generations. He was educated at the Grammar School at Chelmsford, and in the year 1813, having chosen Medicine as his Profession, was entered as a pupil at the United Hospitals of St. Thomas's and Guy's. In 1815 he matriculated at the University of Cambridge, where he became M.D. in due course. He also studied in Edinburgh during several sessions, and then began practice in Guildford-street, London, in 1820. In the year 1853 he removed to Great Cumberland-street, Hyde-park, where he continued the active exercise of his Profession till his long and honourable career was cut short by the lamentable act of violence which we mentioned last week. On the 20th of last September, between 9 and 10 p.m., Dr. Spurgin was returning by the Eastern Counties Railway from visiting a patient at Wanstead. He set out to walk up Bishopsgate-street, but had only gone a few hundred yards "when he was suddenly (to use his own expression) 'butted' by a man, who threw himself head foremost at him, striking him on the chin and breast, and falling on him as Dr. Spurgin fell. The ruffian, placing his knee on the pit of the stomach, snatched at a gold chain and valuable gold watch, and, waving them hurriedly to some behind, rose and commenced running in an opposite direction. After lying stunned for a moment, Dr. Spurgin rose and attempted to follow the robber, whom he still had in sight, when a man suddenly appeared at the corner of an alley and exclaimed, 'Halloo! What's the matter?' 'Why,' gasped Dr. Spurgin, 'that man has just stolen my watch!' 'Oh, has he?' was the reply, and in an instant the unfortunate gentleman was tripped up, and fell prostrate on the flags, sustaining a second time serious injuries. Both miscreants got off scot free; there was no policeman near or in sight—no one to lend a helping hand till it was too late." So says a correspondent of the *Times*.

According to the evidence of his son, Mr. Walter Spurgin, at the inquest, which was held by Dr. Lankester, on Saturday, there were at least six or seven men around him when he was robbed, not one of whom was brought to justice, nor were the watch and chain ever heard of again.

From the injuries received in this encounter Dr. Spurgin never recovered; and, after six months of the acutest suffering, soothed but not remedied by the unremitting care of Dr. Owen Rees, who, with Dr. Watson, Sir W. Fergusson, Mr. Lane, and Dr. Stocker attended him to the end, he died on the 20th of March.

At the time of the accident he was thrown violently on his right shoulder. Immense ecchymosis was produced; but Sir W. Fergusson could detect neither fracture nor dislocation—simply contusion of muscles, and perhaps laceration. He suffered great pain at first for six or eight weeks, although he went out with his arm in a sling, and was even taken to the police-court to see if he could identify some men who had been apprehended on suspicion. After six or eight weeks pain ceased, but his appetite gave way, and he could take no food without dyspnœa coming on. It seemed as if the sympathetic nerve were involved, and with vital powers thus impaired, he gradually sank as it seemed, from inanition. There was no post-mortem; and in default of a better word, his death must be ascribed to "shock" of the nervous system.

The deceased never held any public appointment as teacher in any of the London schools; he was not a voluminous writer in early life, and he had no peculiar theory or speciality, such as is often the means of bringing a man prominently before the public. Yet he soon attained to a large and lucrative connexion. He was Physician to the Foundling Hospital for thirty years, Consulting Physician to St. Mark's and the Skin

Hospital, and to the Eagle Life Office. During the almost half century in which he practised there were few Physicians more widely known, in all ranks of society, or more thoroughly respected. He was a handsome, open-faced man, with a peculiarly kind and intelligent countenance, of middle height, stout, compact frame, and active habits; and his success in life naturally flowed from his peculiar combination of mental and bodily powers, in which good temper, shrewdness, great good sense and sagacity, and considerable power of endurance were prominent ingredients. His was a thoroughly English frame, and English character to match. He was an ardent sportsman, a good shot, and a perfect enthusiast of the rod and line. Besides this he was a man of a singularly ingenious and speculative turn of mind, and was prolific in mechanical contrivances, of which others reaped the benefit. He was inventor and patentee of that "endless ladder" which is now an appurtenance of the scaffolding of all large new buildings, for the purpose of hoisting and lowering materials. He was a capital Latin and Greek scholar, of the old and now almost extinct sort amongst Physicians, and his chief delight and recreation was Latin literature. He delivered the Harveian oration in 1851, and piqued himself with much justice on the classic elegance of its style. With the literature of France and Germany he was not equally familiar, though he had frequently travelled on the Continent. In practice he was himself all over, cool, sagacious, hopeful, never attempting a hazardous *coup de main*, never blindly following a pet theory, but, closely watching his game, he gained the greatest effects by simple, homely, every-day remedies. No wonder that he gained and deserved the confidence of his patients.

Spite of the calm practical exterior, Dr. Spurgin was in his innermost soul largely endowed with the gifts of imagination and philosophical speculation. He was a firm believer in the doctrines of that gifted man Swedenborg, of which the peculiarity is, if we understand them aright, that all the outward and visible creation is pregnant, as it were, with mysterious analogies; that recondite physical and physiological truths are veiled under the moral and religious teachings of the Bible; and that the visible creation is a pattern of moral truths. Hence, notwithstanding the extremely practical style of his Professional work, there was in his mind a deep stratum of meditation on abstract speculative subjects; and thus we are supplied with the key to much that otherwise would be misunderstood in his published works.

The work which most thoroughly requires this elucidation is one published in 1855, entitled "The Physician for All," and dedicated to Lord Palmerston. How odd, it was said, said, that a Physician should write a book, treating on the constitution of the blood and on the treatment of a large number of diseases, and should dedicate it to Lord Palmerston! Time and space fail us for anything like an analysis or epitome, but we may say that under the idea that moral and physical evil are one, Dr. Spurgin's text is, that selfishness is *the* great disease, and that enlightened legislation, and good moral and religious instruction, are the great remedies. "Correct principles of legislation are," he declares, "the chief means of maintaining a healthy constitution of the people." "Moral causes modify the internal organisation as well as the external visage and gait." "Conceive a nation constituted of individuals who, from the least to the greatest, observe God's commandments to do them. Who would say that perfection is not there? Conceive a living body with its innumerable parts performing their functions rightly, who would say that it was unhealthy?" The power of the Creator is to the world what formative force is to the body; animal heat and love of God are one; coldness of love to God leads to a low and cold state first of society, then of individual health. Leprosy disappeared under an improved moral and physical *régime*, so would scurvy if the hateful vice of selfishness could be wiped out of the hearts of shipowners and purveyors who deny their unhappy crews the lemon-juice required to keep them in health. Such, if we understand it aright, is the thread of Dr. Spurgin's work, although the arguments and facts want more lucid arrangement than he has given them. Some half-mystic notions on the value of salts to the blood induced him at one time to bring forward a liquid, called Dr. Spurgin's "Condiment," consisting of a solution of common salt and alkaline phosphates, which he persuaded his friends to take at every meal, under the idea that it would assist digestion and purify the blood, just as the great Lord Bacon believed in the efficacy of nitre. Something of the same speculative vein runs through his "Lectures on the Materia Medica," delivered at the Royal College of Physicians. In a pamphlet, "On the Drainage of Cities" (1858), he urges with great force the necessity of diverting filth from the rivers and applying it to agriculture. Lastly, the "Harveian Oration," 1851, is a truly eloquent description of Truth, and of the means whereby she may be sought.

One passage there is in it which harmonises well with sentiments to which our readers are no strangers. Of investigating truth, he says the method is two-fold—one synthetic; the other analytic. The synthetic deseends from principles and causes to phenomena and effects;—"itaque à prioribus ad postrema. . . . a generalibus ad singularia progreditur; inde ad experientiam quæ priora confirmare possit, tandem pervenit.'

"Analytica contra, a phænomenis et effictibis ad causas adscendit, unde principia evolvt; itaque ab experientia singularium, generalia; ab exteroribus, interiora; a eompositis, simplicia; a posterioribus, priora deducit." The "high priori" method springing from conjecture, is fruitful in controversies and evanescent theories. "Hinc undique errores, fallaces conclusiunculas, dissidia videmus." Would that these words could be pondered by the framers of theories about cholera!

We must not omit to mention that Dr. Spurgin was an original investigator of the temperature of the body in disease, and invented a handy "thermoscope," which he described in the *Medical Times and Gazette*, November 13, 1852.

Such was the active-minded and benevolent Physician who fell amongst the thieves of Shoreditch last September, at a time when, spite of 69 years, his health and vigour seemed to promise many years yet of health and usefulness. Truly such a man's life was too valuable to his family and to society to be lost through want of an efficient police force. On his own principles, we must regard his sufferings and death as evidence of vicious municipal regulations, and of that selfishness which allows the Eastern part of London to be covered with wretched, tortuous, fetid courts and alleys, where few but beasts of prey in human guise do congregate.

THE LATE SIR ALEXANDER MORISON.

But a few days have intervened between the death of Dr. Conolly and the death of Sir Alexander Morison, two names pre-eminently distinguished in the annals of improvement in the treatment of the insane in this country. Sir Alexander Morison was the older man, having attained at the time of his death, on the 14th current, an age only six weeks short of eighty-seven years. Dr. Conolly was fifteen years younger.

Sir Alexander Morison was born at Anchorfield, near Edinburgh, on May 1, 1779. At the High School of Edinburgh he was in the same class with Lord Brougham. In 1798 he took the diploma of surgeon, and in the following year he obtained the degree of Doctor in Medicine from the University of Edinburgh. After a year's probation as a Licentiate he was elected a Fellow of the Royal College of Physicians of Edinburgh in 1801. In 1808 he became a Licentiate of the Royal College of Physicians of London, but not till 1841 did he obtain the rank of Fellow of that College. In 1809 he was appointed Medical Superintendent of a private asylum for the insane in the county of Surrey. About the year 1816 he delivered a course of lectures in Edinburgh on mental diseases, to the excellence of which some surviving members of the Medical Profession can still testify.

In 1816 he was appointed Physician-in-Ordinary to her Royal Highness the Princess Charlotte of Wales, and after her marriage he obtained the like honourable office from her husband, Prince Leopold, the late King of the Belgians, who was further graciously pleased to stand godfather to his infant son. He also held the appointment of Physician to the Duke of York.

In 1827 he was elected President of the Royal College of Physicians of Edinburgh, which office he held for the usual period of two years.

In 1832 he was appointed Consulting Physician to the Middlesex Asylum at Hanwell, and Visiting Physician to the Surrey County Asylum. In 1833 he gave his first course of lectures on mental diseases in London, which course was continued annually for a number of years. In 1835 he was appointed Physician to the Royal Hospitals of Bethlehem and Bridewell, and Consulting Physician to several other asylums for the insane in different parts of England, and in

these he laboured assiduously to promote the comfort of the insane poor.

In 1838, soon after the accession of her present Majesty, he received the honour of knighthood.

After his retirement from the office of Physician to Bethlehem Hospital, he lived chiefly near Balerno, in the parish of Currie, visiting England occasionally in the performance of his duty as Consulting Physician to the Surrey and other asylums. This he did till within the last few years, when the effects of a severe illness rendered it more prudent to remain nearer home. Notwithstanding his great age, he retained his faculties to the last moment of his life.

Sir Alexander's works are numerous, the most remarkable of which is "The Physiognomy of Mental Diseases"—a very valuable book, in which, along with descriptions of the various forms of deprivation of mind, are illustrative portraits from drawings by eminent artists taken from patients in the several institutions with which he was connected.

In 1864, he instituted an annual course of six lectures on mental diseases, under the direction of the Royal College of Physicians of Edinburgh, the first course of which was given in Physicians' Hall last summer by Dr. Seller, appointed by him the first lecturer. He has also established an annual prize to the best recommended male and female attendant in the British asylums for the insane.

Sir Alexander was twice married. His sons have all died before him. He has left a widow, several daughters, and numerous grand-children, to lament him. He is buried in the churchyard of Currie.

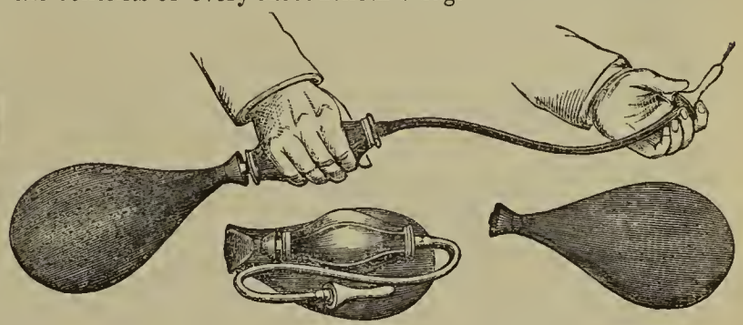
DEATH OF DR. O'REARDON.

Dr. O'Reardon had reached the patriarchal age of 90, and was the oldest licentiate of the Irish College of Physicians. Under the patronage of his uncle, the late Most Rev. Dr. Sugrue, Bishop of Kerry, Mr. O'Reardon entered in 1797 the College of Maynooth, where he received instruction from Dr. De La Hogue, and the Rev. John Chetwode Eustace, author of the "Classical Tour in Italy." A pause in his speech having unfitted him for the pulpit, he relinquished theological for physiological studies, and in 1802 he became a Physician. During this year he published in Latin some Medical dissertations, dedicated to Drs. Clarke and Purcell. Sound sense, free from the theorising flights to which some young Physicians are prone, characterise these productions, while their Latinity is pure and vigorous. In 1803 Dr. O'Reardon proceeded to France, for the purpose of gathering experience at the Hospitals of that city, and of enjoying the advantages of a course of botanical instruction under the celebrated Baron Cuvier. Prolonged hostilities between France and England sprung up shortly after, and Dr. O'Reardon, together with his grand uncle, the General Count O'Connell, of the British service, with whom he resided, were detained in France until the restoration of the Bourbons, nine years later. The longevity of the family is remarkable, General O'Connell having attained the age of 91 at his death in 1834. In 1814 Dr. O'Reardon returned to Ireland, and became Physician to some public institutions, from which he received formal addresses of thanks; but it is in connection with the Fever Hospital in Cork-street with which he will be chiefly remembered. For thirty years he was, with the late Dr. Harkan, its zealous and efficient Medical attendant; but on the reduction of the Hospital grants in 1848 his services were relinquished. The Medical reports of the Hospital, of which many exist, from his pen, attest the unremitting zeal with which Dr. O'Reardon watched over the patients committed to his care. He was also the writer of a small memoir of Kirwan, the eminent chemist, whose friendship he possessed. He was the associate in consultation with Colles, Cheyne, Crampton, and Carmichael; and, although he did not hold quite as high a rank as those eminent men, he largely shared their friendship and high opinion. Dr. O'Reardon was first cousin of the illustrious Daniel O'Connell, whose family Physician he had been. The infirmities of age led to his retirement from the Profession, and a few years ago he removed to Mount Prospect, overlooking the Lakes of Killarney, where he tranquilly breathed his last, almost on the spot where he was born. He had been always remarkable for practical piety, and it may with truth be said that the whole tenor of his long life was one uninterrupted preparation for the next.—*Freeman's Journal.*

NEW INVENTIONS.

SAVORY AND MOORE'S "REPTILE HEART" SYRINGE FOR ENEMA, UTERINE INJECTION, AND BARNES'S DILATORS.

A short time since, when reviewing the Catalogue of Surgical Instruments issued by the Messrs. Maw, we spoke in terms of high commendation of that portable form of india-rubber enema which works by alternate contraction and dilatation, with a valve to direct the course of the current, like a reptile's heart. (We find, by the bye, that Dr. Leared claims the original idea of this instrument, which he says he designed some years ago, to illustrate the action and sounds of the heart.) Messrs. Savory and Moore have devised a new and very perfect form of this instrument, which is made for them by Messrs. Maw, in a very superior style of workmanship and very cheaply. In addition to the bulbed tube, which is the essential part of the machinery, there is an india-rubber bottle, holding about a pint, which can be affixed to the suction tube, so that any one provided with this can put it into his pocket and take a lavement conveniently, in a strange house or hotel, without the trouble even of carrying a jug of water. Then the delivery end can be fitted with a tube for ordinary vaginal injections, and with another longer tube, such as the accoucheur requires for injection of the womb in cases of flooding after delivery. It is also adapted to Dr. Barnes's india-rubber bags for affecting dilatation of the os uteri; and of course would be equally available for a water pessary or for a bag for plugging the vagina in order to check hæmorrhage before delivery. We will not repeat what we have said of the immense contribution to health and comfort effected by these improved india-rubber manufactures; but we will heartily recommend this cheap and compact apparatus of Savory and Moore as an essential part of the contents of every Accoucheur's bag.



MEDICAL NEWS.

Royal College of Physicians of London.—At a general meeting of the Fellows held on Monday, March 26, Thomas Watson, M.D. Cantab., D.C.L. Oxon., was unanimously re-elected the President of the College for the ensuing year. At the same meeting, the following gentlemen, having undergone the necessary Examination, were duly admitted Members of the College:—

Edward Parson, M.D. Lond., 3, York-street, Portman-square; Robert Liveing, M.D. Cantab., 14, Harley-street; William Tilbury Fox, M.D. Lond., 43, Sackville-street.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Bracey, W. A., M.R.C.S.Eng., has been appointed Surgeon to the Birmingham and Midland Eye Hospital.

Budds, W. T., L.R.C.S.I., has been appointed Apothecary and House Surgeon to the Cork South Charitable Infirmary and County Hospital.

Crawford, W., M.D., has been appointed to the commission of the peace for the county of Waterford.

Divers, Professor E., from Queen's College, Birmingham, has been appointed to the Chair of Natural Philosophy at Charing Cross Hospital.

Dolmage, Inspector-General, has been appointed Consulting Surgeon to the Pimlico and Westminster Institute for Diseases of Women and Children.

Morris, J. C., L.F.P.S.Glasg., has been appointed Assistant Medical Officer at the North Wales Counties Lunatic Asylum, Denbigh.

Mucklow, Mr. T. C., has been appointed Assistant Dispenser at the Queen's Hospital, Birmingham.

Owen, Mr. William B., has been appointed Surgeon to the Clergy Orphan School, St. John's-wood.

Sims, Dr. Marion, has been appointed Consulting Surgeon-Accoucheur to the Pimlico and Westminster Institute for Diseases of Women and Children.

Thomason, R., M.R.C.S.Eng., has been elected Visiting Surgeon to the Hereford Dispensary.

Ure, Alexander, F.R.C.S.Eng., has been appointed Consulting Surgeon to the London Infirmary for Epilepsy and Paralysis.

BIRTHS.

Elliott.—On March 21, at North-street, Chichester, the wife of George H. Elliott, M.R.C.S.E., of a son.

Gorringe.—On February 24, at Colaba, Bombay, the wife of Dr. Gorringe, 4th Royals, of a son.

Grace.—On March 10, at Chipping Sodbury, Gloucestershire, the wife of A. Grace, M.R.C.S.Eng., of a son.

Hyde, on February 2, at Aller-cottage, D'Urbans, Natal, the wife of Hyde Clarence, M.D., of a son.

Ryan.—On March 17, at Upper Leeson-street, Dublin, the wife of M. Ryan, M.D., of a son.

Walker.—On March 2, at Walsingham, the wife of W. Walker, M.D., of a son.

MARRIAGES.

Woods—M'Causland.—On March 8, at Birr, Thomas Woods, M.D., to Charlotte Anne, daughter of the Rev. M. M'Causland.

DEATHS.

Arnold, J., L.R.C.P.Edin., of Liverpool, on March 10.

Asbury, Benson V., M.R.C.S.Eng., at Enfield-highway, on March 20, aged 44.

Atkinson, T. P., M.R.C.S.Eng., at Kilham, near Driffield, on March 17, aged 51.

Blackmore, Edward, M.D., at Nelson, New Zealand, on December 6, aged 66.

Board, Walter, M.R.C.S.Eng., at the Rectory, Burnham, on March 9, aged 55.

Bullen, Denis B., M.D , at Ashton Lawn, Cork, on March 21, aged 64.

Crabbe, Benjamin, Surgeon R.N. at Strabane, co. Tyrone, on March 18, aged 32.

Davidge, M., L.R.C.S.Edin., at Clonmellon, co. Westmeath, on March 14, aged 40.

Dodgson, Thomas, M.D., at Skipton, Yorkshire, recently, aged 75.

Fairbairn, William H., Surgeon-Major H.M. Army, at 38, Jermyn-street, S.W., on March 23, aged 48.

Galton, Robert C., M.D., at Hadzor, Worcestershire, on March 22, aged 35.

Hall, David J., M.D., at Eastbourne, on March 23, aged 61.

Mitchelson, William, late Staff-Surgeon E.I.C., at 27, Castle-street, Dumfries, on March 25, aged 68.

O'Reardon, Dr. J , at Mount Prospect, Killarney, on March 14, aged 90.

Parker, John, M.R.C.S.E., at Wincanton, Somerset, on March 24, aged 59.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Builth Union.—The Abergwessin District is vacant; area 68,480; population 3784; salary £42 per annum.

Carlisle Union.—Dr. Walker has resigned the Stanwin District; area 11,730; population 11,677; salary £50 per annum.

Tonbridge Union.—Mr. Dakins has resigned the Third District; area 3184; population 1158; salary £30 per annum: the Fifth District; area 4498; population 1411; salary £30 per annum: and the Workhouse, salary £80 per annum.

APPOINTMENTS.

Basford Union.—Robert H. Sers, M.R.C.S.E., to the Calverton District.

Cambridge Union.—John Buckenham, M.R.C.S.E., M.D. Edin., to the Second District.

Clifton Union.—Joseph J. Evans, F.R.C.S.E., L.S.A., to the St. Phillip and St. Jacob North District; Shirley E. Woolmer, M.R.C.S.E., L.S.A., to the St. Phillip and St. Jacob South District.

Hastings Union.—Henry E. Herbert, L.S.A., to the Third District.

Charitable Bequest.—Miss Maria Renton Tufnell, of Bath, lately deceased, has directed that all her furniture, linen, plate, china, glass, and other effects be sold by auction, and the proceeds to be handed over to the Bath United Hospital, to which excellent institution she further bequeaths, free of legacy duty, the sum of £300.

Arrest of Cattle Importation from Holland.—The step taken by the Government in consequence of a recent reimportation of Rinderpest of stopping cattle traffic with Holland may be expected to produce serious inconvenience. More than half the cattle lately imported have been Dutch, and it is foreign importation alone which has controlled prices in the face of the stoppage of all inland transit of live stock. The *Times* urges on the Government the necessity of adopting measures for slaughtering foreign cattle immediately on their arrival. The great requirement is a dead meat market, which the Corporation of London seem no nearer providing than when, five years ago, Smithfield was voted for the purpose.

Union Chargeability.—The Act for the better distribution of the charge for the relief of the poor in unions has come into operation. It is enacted that from and after March 25, so much of Section 26 of the 4th and 5th of William IV., cap. 76, as requires parishes in unions to defray the expenses of their own poor, whether relieved in or out of the workhouses of the Union, should be repealed, and all the costs of the relief to the poor, and the expenses of the burial of the body of any poor person under the direction of the guardians or any of their officers duly authorised in such Union, thenceforth incurred, and all charges thenceforth incurred by the guardians of such Union in respect of vaccination and registration fees and expenses, should be charged upon the common fund.

Arnfield *v.* Walker.—This case, which was tried on March 22 on the Northern Circuit, is interesting as illustrating the scope of legal reponsibility in cases of injury to the person. The action was brought against a railway contractor to recover compensation for injury sustained through the blasting of rock, whereby a stone flew and struck the plaintiff. Mr. Justice Lush, in the course of the plaintiff's case, said that he should rule that if persons do dangerous work near a public road they are responsible for the injury that results, however carefully they do the work.—Mr. Quain submitted that, as the cutting was authorised by the Act of Parliament, and the blasting was essential to making the cutting, they were not liable if they did the work in a careful and proper manner. His Lordship held that the Act of Parliament made no difference. The jury returned a verdict in accordance with the judge's ruling, awarding heavy damages.

Poisoning by Methylated Spirits.—Dr. Lankester last week held an inquest in St. Giles's on the body of a man who had habitually, for the last two years, intoxicated himself with methylated spirit. This he used to purchase at a chemist's shop, at the rate of three quarterns for three-halfpence. He was also in the habit of eating opium, and had been seen to bite off a large piece of the drug and eat it like an apple. On Wednesday morning the deceased arose from his bed in a maddened condition, and, on the promise of getting him methylated spirit, was induced to walk in the direction of St. Giles's workhouse. On his way he dropped down dead. The evidence of Mr. Bennett, Surgeon of the workhouse, showed that the deceased died of pulmonary apoplexy and effusion of serum on the brain, caused by excessive drinking of methylated spirit. The Coroner remarked that the Government allowed this spirit to be imported free of duty, believing no one could drink it, but here the revenue had certainly been cheated. A verdict in accordance with the Medical evidence was returned.

Discharge of Sewage into Rivers and Brooks.—Goldsmid *v.* the Tunbridge Wells Improvement Commissioners.—The Lords Justices Turner and Knight Bruce have confirmed the decision of the Master of the Rolls in this case. The facts of the case were that a bill was filed by Mr. Goldsmid, of Summerhill, Tunbridge Wells, to restrain the Sewage Commissioners of that place from permitting the local sewage matter to be discharged in a brook called Calverly-brook, or into the waters of the private lake and millstream of the plaintiff, so as to injure the health or otherwise injuriously annoy the plaintiff or his family, or the tenants living on his estate. The Court, after expressing an opinion that in these cases the interests of private individual were not only compatible, but identical with the interest of the public, and after having also explained that the plaintiff was not bound to wait until the nuisance became intolerable before he complained of it, held that the plaintiff was entitled to an injunction to restrain the Commissioners from allowing the sewage matter to be discharged in such a course as to injuriously affect the streams that flowed through his property.

Davison and Wife *v.* the London and North-Western Railway Company.—Northern Circuit, March 23.—(Before Mr. Justice Mellor.)—This was an action to recover damages for injuries sustained by plaintiff's wife on defendants' line. The principal plea was the acceptance of a sum of money, and a promise to pay the expenses of Medical attendance in full satisfaction of all claims. On September 27 Mrs. Davison was a passenger on the defendants' railway, when a collision took place near Preston; the carriage in which she sat was lifted up above the line, and came down

with great violence, throwing Mrs. Davison upon the back, and injuring her leg severely. She was attended by a Surgeon, and for some time was doing well. Subsequently, however, serious injury to the spine developed itself, occasioning partial paralysis of the leg, and incapacitating her from exertion of every kind. It appeared that before the injury to the spine was known the Company's Surgeon prevailed on the plaintiff to accept £51 and the payment of the Doctor's bill, in satisfaction of his claim, and an agreement to that effect was signed. It was contended, however, for the plaintiff that the money had only been accepted "on account," and not as full compensation. His Lordship said the simple question for the jury was, did the plaintiff write the receipt with the full knowledge of what he was about, and did he expressly say at the time that he accepted the money on account. The jury returned a verdict for the defendants.

Scurvy at Sea.—The Medical Officer of the *Dreadnought* reports that from January 1 to March 26 inclusive thirty-nine case of scurvy were admitted into that Hospital. This number represents an increase of more than 90 per cent. over the corresponding months of the last three years. Among records of this disease from the provinces, we have to record the case of a vessel that arrived lately at the port of Bristol, bringing eleven cases of scurvy out of a crew (all told) of twenty-two hands! and of a large ship that reached Hull with twelve cases of scurvy on board, her complement of officers and men consisting of but twenty-eight hands! Numerical facts such as these tell their own tale, and are a standing reproach to the Marine Department of the Board of Trade.

The Workhouse Infirmary of St. George, Hanover-square.—The Governors and Directors of the Poor in St. George's, Hanover-square, have written by their clerk to the Archbishop of York, informing his Grace that the statements made by him at Willis's Rooms on Saturday last, stating the gross neglect of the sick poor and the entire want of any nurses for them in the metropolitan workhouses' infirmaries, having been brought before their Board, the Guardians request that his Grace will visit their infirmaries in Mount-street and at Chelsea, in order to satisfy himself of the falsity of the statements which he has been induced to make public. The Guardians will be summoned to receive his Grace at the infirmary, or, if his Grace prefers it, he can visit the infirmaries unattended at any hour of the day or night that his Grace may think fit.

The Queckett Microscopical Club.—The monthly meeting of this Society was held, by permission of the Council, at University College, Gower-street, on the 23rd inst., a removal from Sackville-street to more commodious rooms having become necessary from the rapid increase in the number of members. Mr. M. C. Cooke read a very practical paper on "Universal Microscopic Admeasurement," the object of which was the advocacy of the universal adoption of the French measurement, with the "millimetre" as the standard for microscopic objects. Mr. Cooke contended that as the French measure was used by the great majority, and that of the "inch" was adopted only by a marked minority of observers, the former was entitled to the victory, especially as it has been already adopted in most foreign countries. A very interesting discussion followed. The proceedings terminated with a *conversazione*. Eight new members were elected, and seven candidates proposed for admission. The offices still remain at 192, Piccadilly.

The Royal College of Physicians and the Committee on the Public Medical Services.—The following resolution, proposed by Dr. Black and seconded by Dr. Sibson, has been unanimously carried by the Royal College of Physicians:—"The Royal College of Physicians of London, in acknowledging the receipt from the Lords of the Admiralty of the 'Report of the Committee appointed to inquire into the whole question of the Rank, Pay, and Position of the Medical Officers of the Army and Navy,' beg leave to convey to the First Lord of the Admiralty and to the Secretary of War the expression of their high gratification with the manner in which their Lordships have responded to the appeal of the College, by appointing a Committee to inquire into the subjects referred to in the Memorials addressed to their Lordships by the College, and by inviting the College to nominate one of themselves to represent them in the Committee. The College also desire to express their satisfaction with the Recommendations contained in the Reports of the Committee. They consider that these Recommendations, whereby the position and pay of Army and Navy Medical officers are materially improved, are well fitted to remove those sources of discontent which the College deemed injurious to the public interest, and will, if carried out, meet with the general approbation of the Profession; and so be the means of inducing a higher class of Medical candidates to seek admission into the Army and Navy Medical Services." Dr. Sibson, in seconding the resolution, said that the excellent part played by the College in this matter would reflect high credit upon the College, and proved it to be what it really was—the leading Medical body in the country. The College in this had looked beyond its own immediate interests, and showed that it had a regard for all members of the Profession, whether they were or not members of its corporation. This was the right and a proud position for the College to assume. The influence exercised by the College with the Government had produced the highest benefits to our Army and Navy Medical brethren. The recommendations contained in the Reports of the Admiralty Committee must meet with general approbation. Thereby the position of Army and Navy Medical officers was much improved, and, besides, a very considerable addition made to their pay. Surely it was no slight matter that an Assistant-Surgeon of the Navy should have his pay increased to the extent of £48 per annum, and that all grades of the Medical service upwards should have likewise a considerable increase of pay. Everything wished for by Medical officers may not be obtained; but certainly, considering the very great improvement made in their position and pay, all reasonable people must allow that a great boon is bestowed by these recommendations upon them. The tact and firmness shown by Dr. Markham in the Committee deserved the thanks of the College. In a settlement of highly conflicting interests, it was simply an act of wisdom to give fair consideration to both sides of the question. It was impossible to disregard the opinions of official minds; but, in any concessions thus made, the right interests and position of the officers have been duly secured to them. Dr. Armstrong, on the part of his Naval Medical brethren, begged sincerely to thank the College for the great services rendered to the Army and Navy by the intervention of the College on their behalf. He supported the resolution with pleasure, and had no doubt that the liberal recommendations contained in the Reports of the Admiralty Committee would be favourably received by Navy Medical officers. Dr. Burrows then, in warm language of approval, proposed, and Dr. Alderson seconded, a vote of thanks to Dr. Markham for the manner in which he had acted as representative of the College in the Admiralty Committee.

St. Pancras Workhouse.—On Tuesday Dr. Lankester resumed the inquest upon the child Elizabeth Thompson Greene, *alias* Adams, alleged to have been "laid out" for dead while alive in St. Pancras Workhouse. The Rev. Mr. Hillocks was examined on the first inquiry, as already reported, and he was not on this occasion submitted to any cross-examination. The pauper witnesses fully established that the child was considered to be dead by the paupers in the ward; that it was bandaged up alive, as described by Mr. Hillocks; and that it was not seen by any official person, even though it had been very ill for days, until Mr. Hillocks went and fetched the superintendent, Mrs. Sansom, who, however, did not even then send for the Doctor. One of these witnesses, a Mary Smith, gave in evidence that she had the deceased child to suckle in addition to her own, and this, she told the Commissioner, though she was ill and scarce of milk. The pauper nurse put the child with her, an milk was allowed the child. The Coroner recalled Dr. Ringer, the Physician, of the University College Hospital, who made the post-mortem, and asked him if he considered the treatment the child had received had caused its death. Dr. Ringer replied that the child was in such a wretched condition that its death was inevitable, but he thought it unquestionable that the bandaging the child up as described must have accelerated its death. At the suggestion of Mr. Ernest Hart, the Coroner asked if a child or any patient in witness's Hospital would be left without being seen by the Medical officer from Monday to Thursday, to which the witness replied in the negative, saying that every patient would be seen every day, and the Coroner emphatically added that in no Hospital in the country would a patient be open to such treatment as this child received in the Workhouse. Dr. Ringer then added that he believed the child had all the attention the Medical officer of the Workhouse could give it, for an Hospital Doctor did not have a tithe of the patients to attend to that the Medical officer of St.

Pancras Workhouse had. Some of the jury expressed their doubts of this, and Mr. Butt, the Medical officer, offered himself for examination. He said he was a duly qualified M.R.C.S., and that having visited the nursery on Monday, he did not find it necessary to go in again until the following Saturday, as he relied upon the superintendent telling him if any of the inmates required his attention, and she told him all were going on well. In reply to questions put by Mr. Hart, through the Coroner, important facts were elicited. The witness said there were at the present time 240 sick persons in the infirmary; 430 aged and infirm women, 212 infirm and aged men, 42 insane men, and 90 insane women, making a total of 1014 persons in the Doctor's hands, in addition to 32 lying-in cases, which made a total of 1042 under the Medical officer's immediate care, and his only staff was another qualified Practitioner. There were, in all, it was elicited, about 2000 persons in the Workhouse, and, in addition to those under the Doctor's immediate care, there were sure to be other cases. Dr. Ringer said a Medical officer of an Hospital would have no more than sixty or seventy cases under him at one time. The jury, on hearing this statement, said it was most important the public should know these facts, and some remarks were made to the effect that the Poor-law Board should not sanction such a state of things. Mr. Hart informed the Court that the Poor-law Board had no power in the matter, which a guardian present confirmed, by saying, "We don't ask the Poor-law Board to sanction what we do." The Coroner said a Medical officer could not be expected to attend to so many cases, and he could not be expected to see the child as it ought to be seen—every day. Mr. Butt said he might add that he did see the ward three times in the course of a week. He saw the ward on Monday, Saturday, and Sunday. Mrs. Sansom, the superintendent, was examined, and she gave the evidence already published—namely, that she did not call the Doctor, and she confirmed Mr. Hillocks's statement in several important particulars, one that the child had been bandaged, another that the pauper nurse had not called her, and that she had scolded the nurse for treating the child as dead, but she excused them on the ground that the child was "all but gone" when it was bandaged. In cross-examination she said she thought the rule to call the Doctor to a dying person or child was generally carried out. She candidly confessed that she was over-worked, as were all the officers, and her case was a sample, she having 156 people to look after, and not a single paid nurse under her. The room was then cleared, and when the court was again opened the jury returned a verdict to the effect that the child died of inanition, and appended the following special resolution:—"The jury are of opinion that great blame is to be attributed to the Workhouse attendants for tying up the jaws of the deceased and treating her as dead for some time before she had wholly expired; that they are further of opinion that there is not a sufficient number of paid Medical attendants and nurses to perform the duties of so large an establishment as St. Pancras Workhouse; and the jury beg to express their approval of the course taken by Mr. Hillocks in bringing the matter before the public."

Treatment of Fever by Acids.—Treatment of Typhus by Acids.—In order to give a fair trial to the acid treatment, so highly recommended by Dr. Murchison and others, I prescribed the nitro-muriatic acid in a considerable number of cases. The theory upon which the use of the mineral acids has been so strongly advocated appears to be beautifully simple—viz., to neutralise the poison of typhus, which is supposed to be present in the blood as a peculiar compound of ammonia; since not only is there an increased quantity of ammonia exhaled by the lungs and the skin, but also the urine and the discharges from the bowels become highly ammoniacal. In the cases so treated, I must confess that I have not met with that very marked amelioration of the disease which many of the writers on fever have ascribed to the administration of mineral acids; and in not a few instances, when given in the proportions prescribed by Dr. Murchison—viz., 20 minims of dilute hydro-chloric acid, and 10 minims of dilute nitric acid, every third hour—I have frequently been obliged to discontinue their administration on account of severe griping and diarrhœa. When the acids are cautiously administered in rather smaller doses, in conjunction with a few minims of solution of muriate of morphia if the bowels be irritable, sweetened with syrup of orange peel, and diluted with water, the draught so formed is generally relished by the patient, and often produces a noticeable effect upon the fever—the most marked improvement being seen upon the tongue, which becomes moist and clean, from being very dry and hard, and covered with a brown fur. In a few cases I gave small doses of permanganate of potash, in order to ascertain if it exercised any antiseptic influence upon the typhus poison. In two of the cases with a very dark petechial rash, it seemed to hasten the disappearance of the eruption. The tongue also began to get clean and moist at an early stage; but as it produced no apparent diminution of the temperature nor of the pulse, and did not shorten the duration of the fever, and as no good results were observed to arise from its administration in the remainder of the cases, I was not encouraged to give it any further trial.—"*Observations on the Present Epidemic of Typhus,*" *by Robert Perry, M.D., Physician to the Royal Infirmary, Glasgow.*

The following are the last week's Cattle Plague Returns.

Note A.—The operation of the Cattle Diseases Prevention Act, 1866, is indicated by the return this week, showing 7220 cattle as "killed," compared with 6132 last week, 5197 the previous week, 1711 for the week ending February 24, and 980 for the week ending February 17.

Note B.—261 Inspectors have not reported this week in time for this return. Of these, 19 reported cases last week—viz., for the county of Chester, 2; Kent, 1; Lancaster, 5; Lincoln, 1; Norfolk, 1; Northumberland, 1; Nottingham, 1; East Riding of York, 1; North Riding of York, 1; and for Scotland, 5. These Inspectors returned 1468 cases last week.

BOOKS RECEIVED.

On the Use of the Chloride of Zinc in Surgical Operations and Injuries, and especially in Operations for the Removal of Cancerous Tumours. By Campbell de Morgan, F.R.S., Surgeon to the Middlesex Hospital, Examiner in Surgery to the Royal College of Physicians. London: Savill and Edwards. Pp. 29. 1866.

*** The author treats his subject under a twofold aspect—as an application after the removal of malignant tumours, for reasons specially applicable to them, and after ordinary operations and injuries, to prevent the decomposition of tissues within the wound. Mr. de Morgan, in the first instance, argues that as "the *original* appearance of cancer in several organs can never be proved," it is at first a local disease, and recurrence is "due to the presence of minute cancer elements which have escaped the knife." That this is the case, he thinks, is "shown by the fact, that after removal of a voluminous breast with only a small tumour imbedded in it, the recurrence frequently takes place along the whole line of cicatrix." (Query, *frequently.*) Mr. Moore first promulgated this theory, and used solid chloride of zinc to the surface of a large wound left after extirpation of a breast. This did well, and led Mr. de Morgan to use chloride of zinc, but in solution, with a similar view, namely, to destroy any floating particles of the disease. He has since used solutions, varying in strength from gr. xx. of chlor. of zinc to xl. He has applied such even to the cancellated ends of bones, and finds they produce little irritation, are not causes of suppuration or sloughing, neither do they retard the cure. They prevent all animal odours and all putrescence within the wound.

The Danger of Deterioration of Race from the Too Rapid Increase of Great Cities. By John Edward Morgan, M.A., M.D. Oxon, Physician to the Salford Hospital, etc. Read at the Social Science Congress, Sheffield, Tuesday, October 10, 1865. Pp. 64. London: Longmans. 1866. 1s. 6d.

*** The author has "been much struck by the singular want of stamina which characterises the poor as a class. Men from whom either healthy offspring or sustained labour might be expected are remarkably rare." Dr. Morgan accounts for this by the excessive drain of the large towns on the agricultural population, by vitiated air, constitutional syphilis, the abuse of alcohol, and by mothers working until pregnancy is too far advanced. The author desires a more careful investigation into the atmospheric changes in the large towns *themselves*, not in some healthy place adjoining, such as Greenwich. He adds seven tables of statistics relating to the population of town and country.

On the Anatomy of Vertebrates. Vol. II.—Birds and Mammals. By Richard Owen, F.R.S. London: Longmans. 1866.

*** A review of this volume and of its predecessor shall appear directly.

The Alkaline Permanganates and their Medicinal Uses. By John Mutter. Pp. 48. London: Churchill and Sons. 1866.

*** This is a warm eulogy of the virtues of the alkaline permanganates which have been brought into use by Mr. Condy. After alluding to the various cases where they have already been found useful, the author suggests their inhalation by the aid of the atomisers of M. Sales-Giron, in cases of lung disease with offensive sputa, in diptheritic and scarlatinal sore-throat, etc.

Successful Removal of the Uterus and Both Ovaries by Abdominal Section, the Tumour, Fibro-cystic, weighing Thirty-seven Pounds. By Horatio Robertson Storer, M.D., of Boston, Surgeon to the New England Hospital for Women. Boston: David Clapp. Pp. 32. 1866.

*** This patient was unmarried, and 47 years of age. She had observed the tumour five years before she came under the care of Dr. Storer. The operation was performed when she was under the influence of ether. Wires were used for ligatures, and the mass was separated by the écraseur. The patient was out of bed on the twenty-eighth day. Dr. Storer adds a minute history of this operation.

Lectures on Animal Chemistry, delivered at the Royal College of Physicians. By William Odling, M.B., F.R.S., Fellow of the College, Lecturer on Chemistry at St. Bartholomew's Hospital. Pp., with Index, 165. London: Longmans and Co. 1866.

*** A course of six lectures delivered at the Royal College of Physicians, with some few additions. It contains a popular view of modern organic chemistry and its relations to physiology and pathology.

On Inhalation as a Means of Local Treatment of the Organs of Respiration by Atomised Fluids and Gases. By Hermann Beigel, M.D., L.R.C.P.L., Assistant-Physician to the Metropolitan Free Hospital, etc. Pp. 200. R. Hardwicke, 192, Piccadilly. 1866.

*** A treatise on the inhalation especially of atomised fluids.

Extracts from Braithwaite's Retrospect.

*** The Messrs. Braithwaite have published in a handy form extracts from their very useful "Retrospect of Medicine," relating to cholera, midwifery, and ophthalmology. Believing that cholera depends on spasm, they recommend chloroform as a remedy. Are they aware whether this remedy has a good reputation among those who have tried it?

On Winter Cough, Catarrh, Bronchitis, Emphysema, Asthma; with an Appendix on some Principles of Diet in Disease. A Course of Lectures delivered at the Royal Infirmary for Diseases of the Chest, by Horace Dobell, M.D., Physician to the Infirmary, etc., etc. Pp. 183. London: Churchill and Sons. 1866.

Observations on Crushing Stone in the Bladder. By George H. Porter, M.D., T.C.D., F.R.C.S.I. Pp. 11. Dublin: Fannin. 1866.

Supplement to the Monthly and Quarterly Returns of the Births, Deaths, and Marriages Registered in Scotland during the Year 1865. Also the Vaccination Returns for 1864. Pp. 44. Edinburgh: Murray and Gibb. 1866.

Memorandum for the Sanitary Committee of the Board of Police, showing the Relation of Epidemic Fever to Overcrowding in Glasgow. By the Medical Officer of Health. (Pamphlet.)

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The *Nightingale Fund* must stand over till next week.

The very able letter of Dr. Bowerbank on cholera in Jamaica is delayed in consequence of the journal going to press one day earlier than usual.

Reviews of "A Treatise on the Principles and Practice of Ophthalmic Medicine and Surgery," by T. Wharton Jones, F.R.S., and "A Textbook of Mental Diseases," by Dr. Max Leidesdorf, are in type. A review of "Statistical Report on the Health of the Navy for the Year 1862," is in the printer's hands. The following papers and reviews will appear immediately:—"Clinical Notes on Diseases of the Nervous System," by Dr. Hughlings Jackson; "On the Mechanical Treatment of Talipes Varus," by F. Clowes, M.R.C.S.; "Notes on and relating to Cholera," by John Patterson, M.D.; "On Lithotomy," by J. McCraith, M.R.C.S.; "On the Occurrence of Amphoric Respiration in Pleurisy and Pleuro-pneumonia," by H. Fearnside, M.B.Lond.; "Comparative Immunity of Rabbits to the Poisonous Action of Atropine," by Dr. W. Ogle; "Cases of Tertiary Syphilis treated by the Zittman Method," by B. Shillitoe, F.R.C.S.; "Use of Opiates in Continued Fever," by Dr. N. G. Mercer; "Amputation at the Hip Joint," by J. Fayrer, M.D.; "Theory of Probability applied to Medical Statistics," by W. P. Hiern, M.A. Review of the last volume of the Medico-Chirurgical Transactions; Cockle, On Intra-Thoracic Cancer; Gamgee, On a Case of Amputation at the Hip Joint, etc.

We are very sorry to see that one of the Medical speakers at the Manchester and Salford Temperance Union meeting so far forgot the rules of propriety as to cast an undeserved slander on the reputation of an eminent Physician lately deceased. That was not a sober speech.

A Novice.—The opportunities are excellent; they only require to be used.

Mr. J. H. Park.—See our advertisement columns of this week.

A Lady who Loves Horses.—We doubt the application of the ether spray to the purpose mentioned. A cold douche of water would probably be better. The ether would hardly, we think, be worth trying.

An Apothecary.—Sir Hans Sloane presented the Gardens to the Society of Apothecaries in perpetuity.

A Member, Greenwich.—Professor Huxley brought his course of lectures to a close on Wednesday last. Professor Hancock will not commence his course until about June next.

L.R.C.P.Lond., Chatham.—Dr. Goulston bequeathed £200 to endow a pathological lecture at the College of Physicians, A.D. 1632. Lord Lumley and Dr. Caldwell founded a Surgical lecture in 1584.

Bibliopole.—The fine library of Dr. Francis Bernard was sold by auction in 1698, and produced £16,000. That of Charles Bernard, the Serjeant-Surgeon, was sold in 1711. The "Spaccio della Bestia Triumphante" alluded to in the *Spectator*, No. 389, was in this collection.

Caius Coll., Cambridge.—Skeletons of that *rara avis* the great auk are preserved in the British Museum and College of Surgeons, where also you can see the eggs. At a recent sale at Stevens's the eggs fetched £30 each.

Tobias Smollet, M.D.—The pay of the Director-General of the Medical Department of the Army is stated in a Blue-book as £1500 per annum. The Director-General of the Medical Department of the Royal Navy appears at £1300 per annum.

The *Staffordshire Advertiser* of March 24 contains a letter from Dr. Bury King, of Stone, complaining of the puffery of M'Dougal's Powder by high chemical authorities, some of whom are said to have a beneficial interest in the sale thereof. We believe carbolic acid to be a capital agent for keeping things sweet. Dr. King, however, wishes not to neutralise, but to destroy putrefaction. "There is only one true, positive disinfectant, and that is oxygen. Even chlorine acts by liberating oxygen from the hydrogen it was combined with (as in water, for instance), and *that* agent, therefore, must be the best disinfectant which contains the largest proportion of oxygen, and being itself susceptible of decomposition, most readily parts with and distributes it. To carry this principle practically out, I know of no agent which can compete with Condy's Patent Fluid."

EARLY EXCISIONS OF THE UPPER JAW-BONE.

Period 1.—	*Acoluthus* (partially)	1693
	Dupuytren (partially?)	1819
	M. Pillet pretend que la malade est allée mourir à la Salpêtrière et qu'une portion du maxillaire avait été conservée (but he is special pleading for Gensoul's priority).	
Period 2.—	Stevens, U. S.	1823
	Rogers, U. S.	1824
Period 3.—	*Lizars* proposed removal of upper jaw	1826
	,, performed it	1827
	Gensoul.	1827
	Lizars, August 1	1829
	,, January 10	1830
	Syme	1829
	It faut ajouter celui que M. Pièdagnel a recueilli en 1818 dans le service de M. Bauchêne et celui que M. Lafont de Nantes vient de communiquer à l'Academies.	
	Velpeau, July	1829

LOCAL ANÆSTHESIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Of course we must take the evidence for this local anæsthesia, but it seems to me that there is not one element of lasting success in it. Cold has been used for this purpose from time to time; the contrivances for its application of course improve, become handier, neater, etc., etc.; but the tissues are "averse to reform, or at least indifferent" (*vide* Horsman), and they are not able to sustain a degree of cold, except where reaction can be but gradual, as in the median line of the body, where both vessels and nerves are very small. No Surgeon will, as a rule, allow the materials he is to work in to be frozen, except in exceptionally healthy subjects, and those might surely have the double blessing of unconsciousness. Freezing so as to induce thorough insensibility in the centres to peripheral injury is only compatible with complete abeyance of life in the peripheral tissues; and if we dare not expose the patient (say his feet) with cardiac or arterial deficiencies to even moderate changes of temperature, how can we subject him in patches to freezing? As the old Scotch ladies say of any new thing, "Yes, sir, it's grand, but it's a havers."

I am, &c. AN EYE WITNESS.

THE REVISED EDITION OF THE PHARMACOPŒIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me through the medium of your excellent journal to offer some suggestions and remarks with regard to the forthcoming revised edition of the British Pharmacopœia.

It has been long known that the application of heat deprives most narcotic and sedative plants to a greater or less degree of their active principles, and that tinct. hyoscy. and tinct. and ext. conii are frequently almost inert. According, also, to a communication from Mr. Donovan which appeared in the *Dublin Medical Press* about eighteen months ago, the lin. aconiti, P.B. (and consequently the tincture also: his specimen, however, might not have been prepared from officinal aconite), is sometimes valueless, while an analogous liniment, prepared from fresh roots, possesses the full virtues of the plant.

In the face of these facts, it would be more satisfactory to the Physician, though perhaps not so convenient for the pharmaceutist, if the preparations of many of our indigenous narcotic and sedative remedies were made from the recently gathered instead of the dried plant.

The spiritus chloroformi is in the proportion of 1 to 19, while the other spirits are 1 to 9. It is weaker than the old chloric ether (which was 1 to 7), not so sweet, and contains too little chloroform to be of much service as a remedial agent.

It is advisable that such preparations as tinctura actæ racemosæ, laricis, veratri viridis, and sumbul be admitted. They are often prescribed, and patients run the risk of obtaining them six or eight times stronger from one place than from another. If not considered worthy of unqualified recognition, they might form part of a secondary list, according to the plan of some foreign Pharmacopœias. A liq. opii sedat. and a good and cheap mist. sennæ co. would also be welcomed by many. Formulæ for approved new chemicals are not so much required, being articles of definite composition.

With regard to nomenclature, would not the terms "hydrargyri subchloridum" and "perchloridum," as applied to the two chlorides of mercury, be less open to objection than those which have been given? They would express their relative position, and could neither lead to mistakes nor inform nervous patients of the remedies prescribed for them. For the last-mentioned reason pil saponis is preferable to pil opii.

I am, &c. J. T.

Poor-law Medical Reform and Vaccination.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall feel obliged by your allowing me through the medium of your columns to inform the Poor-law Medical officers—and I may say the Profession generally, for nearly all Medical men are vaccinators—that the Vaccination Bill will not go into Committee before the first Wednesday after Easter, time amply sufficient for every Medical man in the kingdom to communicate with his member of Parliament. I have sent a copy of the amendments mentioned by me in former communications to every member of Parliament, and have written private letters to about twelve gentlemen in the House. From communications already received, I believe it is intended to permit certain alterations to be made in the Bill, and perhaps Government may consent to pay a portion of the fees, but unless that portion be specially appropriated to the Medical men, it will only be relieving the poor's-rate without benefiting the vaccinator. The Bill will require careful watching, otherwise it will slip through Committee without being materially amended.

The general question of Poor-law Medical Reform must stand over until after the general Reform Bill has been disposed of.

Allow me to tender to Mr. Prowse, of Amersham, the best thanks of the Association, for the exertions he has made in raising the large sum of £92 18s. which he has forwarded to me, and it is now in the bank to the credit of the Association. I am, &c.

12, Royal-terrace, Weymouth, March 24. Richard Griffin.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·290 in. The reading rose to 29·77 in. on Thursday, and fell to 28·90 in. on Saturday.

The general direction of the wind was variable.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 39·3°.

APPOINTMENTS FOR THE WEEK.

March 31. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

April 2. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

Epidemiological Society, 8 p.m. Dr. Mackay, R.N., "On an Outbreak of Dysentery among the Crew of H.M.S. *Conqueror*."

Odontological Society, 8 p.m. Meeting.

Royal Institution, 2 p.m. General Monthly Meeting.

3. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Pathological Society, 8 p.m. Meeting.

4. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Hunterian Society (Council, 7½ p.m.), 8 p.m. Dr. J. R. Bennett, "On Certain Derangements of the Nervous System occasioned by Shock, especially in Reference to Railway Accidents."

Obstetrical Society of London (Council, 7 p.m.), 8 p.m. Dr. Battye, "On Certain Uterine Affections in their Relation to Phthisis." Mr. Robt. Ellis, "On a New Mode of Inducing Anæsthesia by Compound Vapours." Dr. Greenhalgh, "Case of Obstructive Dysmenorrhœa."

Microscopical Society, 8 p.m. Meeting.

5. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Mr. Haynes Walton, "On Detachment of the Retina, their Causes and Treatment, with Specimens."

6. Friday.

Operations. Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Meeting.

Western Medical and Surgical Society, 8 p.m. Mr. J. R. Lane, "On Some Points connected with the Pathology of Syphilis."

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

(Continued from page 304.)

BEFORE we quite leave the shoulder-joint, I have yet a few remarks to make. The grouping which I have adopted is one intended for practical guidance, and I am well aware that I have neglected the distinctions which some very excellent authors have proposed. I have said nothing of fractures through the anatomical neck, excepting to doubt their occurrence. I have omitted to consider the supposed distinctions between impacted fractures external to the capsule and impacted fractures internal to the capsule, nor have we paid any special attention to the fracture so well investigated by Mr. Guthrie and Dr. Robert Smith (of Dublin), in which the greater tuberosity is broken off. Whilst we must admit the possibility of all these several forms of accident, we may be allowed to entertain doubts as to much of the clinical evidence on which they are supposed to rest. The difficulties are exceedingly great, and are such as to lead us to rely with great caution on any other kind of evidence whatever than *the dissection of recent specimens*.

And here, gentlemen, let me invite your co-operation, and let me beg of you to neglect no opportunity for procuring specimens of injuries near to joints. Get, if possible, an account of the symptoms during life, of the position of the fragments after death or amputation, and secure the bones themselves. When you have got your specimen, do not clean it too much, and, above all, keep it as a wet one, and do not cut away all the ligaments and bands of periosteum, and thus destroy half its worth. Specimens of this kind will prove of very great value. It is surprising how few such are to be met with in our Museums. Many of our best are old ones, in which the processes of repair have altogether masked the nature of the original injury, and in these, too, the history of the accident is almost invariably wanting. We need new and better facts before many debated questions of great interest both to the Surgeon and his patients can be set at rest. I am well aware that it is not often that opportunities in this direction occur, but that is only an additional reason why we should sedulously avail ourselves of them when they come. Such injuries are but rarely fatal, and when, perhaps in connexion with some complicated case, death does occur, it is rarely that we can obtain permission to remove the limb or injured joint. As a suggestion in aid of this matter, I may just remark that plaster of Paris offers us advantages which are not generally recognised. By its aid you may easily fill up the cavity left by the removal of a long bone in a way which will escape detection.

To return to our subject. Many of you are aware that year after year in this course of lectures I repeat my scepticism as to fractures through the anatomical neck. In consequence of this challenge, several recent specimens have been kindly brought to me, which were supposed to exemplify this form of injury. In all, however, the fracture was through the tuberosities. Yet I not unfrequently see in our wards cases in which this diagnosis has been given. We have come to believe in it, I think, chiefly through mistakes as to where the anatomical neck really is. Although anatomists are clear enough on this point, yet Surgeons are but too often very vague. Dr. Robert Smith has well pointed out the error of the author of the Surgical Dictionary on this head, who writes, "Indisputable facts prove the possibility of the anatomical neck of the bone being fractured," and then proceeds to record as an example the case of "a lad of 17, in whom the head of the bone was accurately detached from its body by a fracture which *had passed obliquely through the upper part of the tuberosities*." I fully agree with Dr. Smith in the opinion that this was probably an instance of detachment of the epiphysis; at any rate, it is quite clear, on the writer's own showing, that it was not a fracture at the anatomical neck. I need not remind any one here that the anatomical neck encircles the head of the bone, and that only, and includes no portion of the tuberosities. It is intra-capsular, and the portion of bone so broken off would be left loose in the shoulder-joint. That a line of fracture should observe this precise direction, and not branch off anywhere into the adjacent tuberosities, is *à priori* most improbable. It is like Shylock's pound of flesh, very difficult to cut without taking either less or more. For this reason, therefore, I prefer to consider all fractures through the head of the bone, and therefore above the Surgical neck, as fractures through the tuberosities. Of these I am sure you will find great variety—scarcely any two quite alike. Even when the separation observes the line of the epiphysis, as in young persons it frequently does, this line is perhaps but rarely kept in every part. Frequently, and especially so in the aged, the tuberosities are fissured in various directions, and we have two, three, or more fragments.

It is not improbable that in some instances lines of fracture extend into the joint itself, and without much displacement of parts, and thus we may perhaps account for the stiffness and loss of normal motion which not seldom follow obscure injuries to this articulation. One such, I think, we had under our care a few weeks ago. A lad of 15 was admitted for concussion of the brain. When he had regained consciousness he could not use his right shoulder, and there was some swelling about it, though no evidence of contusion. I detected once or twice an indistinct crepitus close to the joint, but could not make out any displacement. When he left us three weeks later the head of the bone was certainly thickened, and although passive motions were quite free, he could not himself use the joint freely.

Dr. Robert Smith, in his excellent monograph, from which I have already quoted, has published a very valuable case in which the greater tuberosity was found separated from the rest of the head, which latter, still continuous with the shaft, was displaced under the coracoid process. The accident had occurred some years before the dissection was made, and the parts were found united only by ligament. I have not met with any case in which I felt certain that this had occurred, nor am I acquainted with any recent specimen of it, but I have seen several of obscure fractures through the tuberosities in which it is very possible that the greater one was detached. You will see that here, as in most other peculiar forms of injury, the practical importance of the lesion concerns rather the degree and character of the displacement than the precise direction of the line of fracture. I have insisted repeatedly that the knowledge of the latter does not necessarily give you the clue to the former. The direction of the violence is of far more importance as regards the displacement than is the line of fracture.

The diagnosis as to the precise direction taken by lines of fracture in any given case is most difficult. I am sure that those who have most frequently had opportunities for dissecting the parts after such diagnosis during life will be the first to admit the difficulties on this score. We can recognise the character and degree of displacement, and may be able to estimate fairly whether the fracture is high up through the tuberosities, or low down in the Surgical neck, but beyond a rough opinion of this kind I am sure we cannot safely go. For this reason, if for no other, then, I think we shall not do well to introduce needless refinements of classification into practice.

We have just remarked on differences of opinion amongst Surgeons as to where the anatomical neck is, but the discrepancy unfortunately does not end here. Different Surgeons apply also the term "Surgical neck" to different parts. In common usage, and I think in most anatomical works, this part is supposed to be that where the tuberosities cease and the bone narrows down to its shaft. But by some very excellent Surgical writers we have the term used as synonymous with the epiphysal line, which, as you know, passes through the base of the tuberosities, and on the inner side constitutes part of the anatomical neck. Thus this same unfortunate epiphysal line has been claimed by some Surgeons as the anatomical neck, and by others as the Surgical neck. I need not say that in using this term I have myself always intended to imply a part of the bone from a third to half-an-inch lower than the line referred to.

I must raise a protest also against the custom which prevails in books of assigning the displacement as a trustworthy guide to the diagnosis of the line of fracture. As I have already stated, the malposition assumed by the fragments depends far more usually upon the direction of the violence than upon the exact part at which the bone has given way. When, there-

fore, you are told that the characteristic symptom of separated epiphysis is displacement of the upper end of the shaft into the axilla under the coracoid, you must receive the statement with much caution. It is true that in fractures of the Surgical neck and in separations of the epiphysis this is a usual direction of displacement, but it is far from invariable. Many of these injuries are caused by violence which forces the upper part of the shaft of the bone in a direction upwards and outwards, and if once it have been driven outwards there it may very probably remain. In a case which we recently dissected of fracture through the Surgical neck the upper end of the shaft was displaced external to the upper fragment, and there it was held, so that we had even on the post-mortem table much difficulty in bringing it into position. The chief means of its retention seemed to be strong bands of periosteum and fascia, which crossed between the two.

Compound Fractures of the Shaft of the Humerus.—I have little to say as to simple fractures near the middle of the shaft of the humerus. They are easy enough to treat. We have, however, recently had some very interesting examples of compound fracture at this part. Their chief interest lies in the support they have given to the practical rule that excision of the end of a projecting bone should be always practised when feasible. In one instance a boy had a severe compound fracture near the middle of the bone, with projection of the ends of the fragments, at a large skin wound. I was called to him in the first instance, and before reducing, I sawed off the end of the upper fragment. I did not, however, take enough away, and subsequently we had great trouble with overlapping of the fragments. Finding that it was impossible to keep them in position, at the end of a fortnight I again turned them out into the wound, detached the periosteum from the end of the lower fragment, and sawed off three-quarters of an inch from its end. After this we had no further trouble, and the arm did remarkably well. I will give you this general rule, applicable not only to compound fractures of the humerus, but to those of all long bones. *Never be afraid to cut bone away. Whenever the ends are displaced into the wound so as to give you a chance, cut them off. You can scarcely take too much. The more you take within reasonable limits the easier will be the subsequent treatment, and the better the ultimate result. But you must leave the periosteum.* If you are careful to leave this wonderful membrane, you may be sure of plenty of new bone, and it will be formed just where it is wanted, and will allow itself to be moulded accurately into shape; whereas the projecting ends of the original bone, if left, are almost certain to be more or less displaced, and to give trouble by projecting into the wound, and to leave thickening and deformity after union is complete. You add nothing to the severity of the case by the free use of the saw; quite the contrary. For some years past I have never neglected a legitimate opportunity for the excision of the ends of the bone in compound fractures with displacement; and whilst I have often wished that I had taken more away, I have never regretted having taken what I did. The inflammation about the injury is usually much less if the ends of the bone be well cleared away in the first instance.

If the fracture occurs near to a joint, there is all the more reason to resect the displaced extremity of the bone.

About two years ago we had an interesting case in Richmond Ward. The patient was a lad of 14, whose arm had been crushed, with severe laceration of soft parts and compound fracture of the humerus just above the elbow-joint. The elbow was displaced backwards, and the lower end of the upper fragment projected into a large wound in the front. I detached the periosteum from about three-quarters of an inch of the end of the latter, and then cut it away. We could now easily retain it in position. The lad made a good recovery, and left the Hospital with the parts soundly healed and a fair amount of motion at the elbow-joint.

Another very similar case occurred four months back, but with the peculiarity that the line of fracture observed for the most part that of the epiphysis.

Compound Detachment of the Lower Epiphysis of the Humerus.—The subject of this case was a lad of 13, who was admitted with a large laceration in front of the left elbow, and the lower end of the shaft projecting into it. From the position of the fracture, and from the character of the exposed fractured surfaces, it was clear that the line of epiphysal junction had been almost accurately observed. There was no difficulty as to reduction; indeed, Mr. Dove had already replaced the bone before I saw it, but, feeling certain that otherwise we should have difficulty at a later stage, I decided to resect the end. This was done, and the fragment I show was removed. Its lower margin is capped with cartilage, that

Fig. 1.

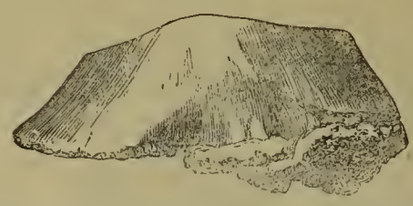

Fig. 1.—Portion of bone excised in case of compound detachment of epiphysis of humerus, natural size. Its lower surface shows the irregularities produced by the adhering fragments of epiphysal cartilage.

of the epiphysis. The removal of this portion did away with all difficulty as to extension of the limb. Had it not been removed the lower end of the upper fragment would have been certain to rest in front of the lower fragment and the elbow-joint, and deformity would have resulted. To effect efficient extension with such injury to the soft parts would have been impossible. After the excision we had no difficulty whatever. The lad now has his elbow bent at right angles, and quite stiff; but he can use his arm well. The anchylosis at the elbow was unavoidable, and must have occurred whatever the treatment had been. A compound fracture at the line of the epiphysis is necessarily a compound fracture into the joint. I show you a section of the lower part of the humerus of a boy of 15 (Fig. 2). You will observe that

Fig. 2.

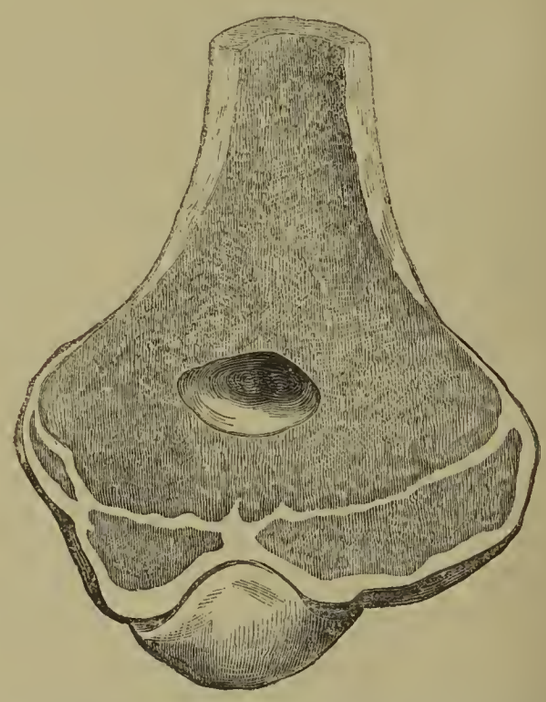

Fig. 2.—Section of the lower part of the humerus of a boy seen from behind. The olecranon is *in situ*, the elbow being bent to the utmost. The olecranon fossa is seen to be half an inch above the epiphysal line. The latter is continuous in a curved direction across from side to side, but the epiphysis is divided by vertical bars of cartilage into three, of which the outermost is the largest, and the inner one much the smallest.

the line of cartilage between the epiphysis (or rather epiphyses, for there are three distinct centres) and the shaft is crescentic, and that at the convexity it passes very near to the joint. Thus, it is very much below the olecranon fossa, and it is barely possible that the joint should not be opened. As is the case in all detachments of epiphyses, the periosteum will be torn off from the lower end of the shaft and left as a sort of cup attached to the epiphysis itself.

I will now relate a good instance of what sometimes happens when the end of the lower fragment is allowed to remain. I have seen several more or less closely similar. In this instance I think it very possible that we may yet decide to reseet the offending bone, as it occasions the boy considerable inconvenience.

Compound Fracture just above the Elbow-joint, with Laceration in Front by the Lower End of the Upper Fragment—Recovery, with some Displacement of the Joint Backwards, and Impediment to Flexion from the Projecting End of the Bone.—Master B., aged 14, fell from a plank about four feet from the ground, and struck his left elbow on a large flint stone. A

compound fracture resulted, the lower end of the upper fragment sticking through a large wound just above, and in front of the elbow-joint. The bone passed through close to the outer side of the artery. The accident occurred in the country, and he was treated by a very able Surgeon. Things went on well as regards union, and at the end of six weeks he came up to his home, and was, on the recommendation of his Surgeon, placed under my care. The wound was now quite healed. There was at first a good deal of thickening about the parts, but this in time subsided.

Six months after the accident the swelling had entirely subsided, and he had good use of the elbow-joint. Pronation and supination were now perfect, and flexion and extension were free, excepting that the former was limited by a projecting piece of bone in front of the joint, which, sticking down in the direction of the biceps tendon, prevented flexion beyond a right angle. The elbow-joint and condyles of the humerus were placed too far backwards, so much so that a curve was distinctly visible in the lower part of the humerus, the projection backwards of the olecranon almost simulating a dislocation. The fragment above mentioned is clearly the lower end of the shaft of the bone. In explanation of its great length, I think there can be no doubt that it includes the internal epicondyle. In no other way could it obtain length enough to act as a prop in impeding the movements of the of the joint. It is clear, also, in comparing the two elbows, that the internal condyle on the injured side is much smaller than the other. The fracture has no doubt been an exceedingly oblique one, possibly with comminution. When the arm is extended, the projecting extremity of the upper fragment becomes merely subcutaneous—indeed, the skin is stretched on it. It is most tempting for removal. The brachial artery can be felt close to its inner side. He can extend fully. The humerus, from acromion to olecranon, is an inch and a quarter shorter in the injured arm than the other. It would appear that the lower fragment taking with it the elbow-joint has been displaced backwards and also rotated inwards.

THE PHYSICAL AND CHEMICAL CHANGES IN LIVING BEINGS FROM A MEDICAL AND PHYSIOLOGICAL POINT OF VIEW.

By Dr. LIONEL BEALE, F.R.S.,

Fellow of the Royal College of Physicians, Professor of Physiology and of General and Morbid Anatomy in King's College, London, and Physician to King's College Hospital.

"Neither formerly nor at this time have men endeavoured to determine or discover the differences in the effects of the vital force and those of the inorganic forces, and their likeness or unlikeness."—Liebig, 1846.

I BELIEVE that all true scientific progress depends upon the temperate but free and open discussion of scientific questions upon which different observers have been led to entertain opposite and conflicting opinions. The very soul of true science is the continual testing of conclusions already arrived at. By this course alone can errors be corrected, and it is mainly by going over scientific ground which is by no means new, and repeating experiments which have been, perhaps, many times performed before, that new facts are demonstrated and new principles discovered. Some scientific men appear to dislike discussion, and are even offended if any one ventures to criticise their observations or to express any opinions opposed to their own. But surely every thorough student of science, so far from attempting to suppress discussion, should encourage it in every way in his power, for he must know that it is almost impossible that the truth of many complex scientific questions can be arrived at without long and patient discussion, in the course of which each statement may be carefully analysed by opponents, and the facts upon which his inferences are based carefully examined. How can science advance without free discussion and free criticism? If a man has honestly worked, he will respect the opinion of other honest workers, though it be opposed to his own; and if objections are raised to his conclusions, he ought to be glad of the opportunity of making his meaning more clear, or if need be, of correcting himself. A man who works thoroughly must feel far more hurt at the trumpery, laudatory, commonplace remarks appearing even in our best journals and reviews at this time than he would be at a good sharp critique, even though it spread out every one of his weak points in helpless nakedness before the world.

For these reasons I have ventured to criticise the observations of many fellow-workers upon matters which have always appeared to me of such very deep interest that it is possible that I may have formed an exaggerated estimate of their real importance, and have concluded their general bearing to be far more extensive than it may eventually prove to be. But however this may be, and however little attention may be given to the details bearing upon the matters in question, I am convinced that no thoughtful Physician or physiologist can accept in their present form the views, I may say, now generally entertained upon the subject of life, and the essential nature of the changes occurring in disease; and I am naturally anxious to show distinctly why these views cannot, in my opinion, be accepted, and to draw attention to the exact points in which they appear to me to fail. This, then, is my apology—if apology be needed—for writing in a manner which some will condemn simply because it is controversial. Those who read these pages must not consider my remarks as an attempt to *review* Odling's "Animal Chemistry." My observations apply only to a very small portion, and that, as regards chemistry, the least important, of my friend's excellent work; but he has from his chemical side called physiologists to account for some of their opinions, and has particularly attacked those who support the "fiction" of *vital force;* and I am desirous of replying to some of his observations, as well as to those of some other chemists and physicists from my physiological side. I shall try, perhaps without much success, to bring out clearly the points in which the observer who regards the question from a physiological and Medical point of view will agree with or differ from him who looks upon it from a purely physico-chemical stand-point.

Chemists and physicists are, and have been, I think, far too much in the habit of writing as if physiologists and Medical Practitioners obstinately refused to accept the views concerning the correlation and indestructibility of force. My friend falls into the same mistake when he states his regret that "certain principles believed by physicists to be fundamental as the laws of gravitation are not heartily and unreservedly admitted by Physicians." I am sure that it is needless to tell us that force is not created, and that, like matter, it is not destructible, and that neither in living nor in dead matter is there any *creation* of force; for no one has asserted that force was created, or that matter was destructible. These truisms have been so diligently and so impressively forced upon us, that it is only right to ask pointedly for references to any physiological or Medical work published during the last quarter of a century in which the author teaches that matter or any form of external force is created in living beings. The real question is, whether there is, in *addition* to external forces, a force or power at work in living things of a nature *distinct from* any form or mode of ordinary force. Heat, light, electricity, etc., manifested in a living organism are clearly of the same nature as heat, light, and electricity manifested out of the body. We know and admit that physical forces are at work in the living body, but ask is there not yet *another internal force* or *power* at work which is not physical or chemical? To which many chemists and physicists would reply "No!" while I would answer emphatically "Yes!" and say that there is evidence of its action, and that the actual phenomena have not been, and in the present state of science cannot be, explained by the action of physical and chemical forces only. We Doctors and physiologists are ready and willing to learn, and most desirous of being taught. We also freely confess our ignorance of much that we ought to know and long to know, but it is really quite unnecessary for chemists to impress upon us the fact that life cannot *create* heat, light, motion, and electricity. Will Dr. Odling point out a single living Physician or physiologist who teaches that life or a living thing ever generated external force?

It is true that some physiologists do speak of these external forces acting in living beings as the vital forces, and Dr. Odling himself says "we might apply the phrase, *vital force*, to the potential energy of so much fat or muscle capable by oxidation of being manifested in the form of external heat or motion;" but the word *vital* thus used is obviously useless, has no definite meaning attached to it, and might just as well be left out of the sentence altogether. If, therefore, the phrase, *vital force*, were thus applied, I think that it would be most incorrectly applied, for the potential energy of a given weight of fat and muscle is the same in a dead body as in a

living one. Potential energy cannot, therefore, be the same as *vital force*, for the *vital force* or *power* ceases to manifest itself when a living thing dies. Dr. Odling says that some physiologists seem to infer that chemists and physicists are insensible to those *important distinctions* existing between living and dead matter, which they, on the other hand, "profess to explain by declaring the former to be possessed, and the latter dispossessed, of vital force." He believes "that chemists appreciate in its fullest extent what may be termed 'the mystery of life.' Chemists and physicists are well assured that, be life what it may, it is not a generator, but *only a transformer*, of external force." Again, what has been said to justify the inference that we supposed *external force* to be *generated* by life or any living thing? But my friend, unlike some who have written from the purely physico-chemical side, has not missed the point upon which some of us differ so entirely from the new school. From that which he advances as the opinion of chemists and physicists, I differ in the paramount importance which I attach to the living thing as a *transformer* of force, and as will afterwards appear concerning the *manner* in which it transforms, and the *principles* upon which the transformation is conducted. But many chemists and physicists, I believe, regard living things as *a result* of the action of ordinary energy upon inorganic matter. The sun "*forms*" the heart, is a formula which expresses this clearly and definitely. But notice the phrase, "*Only a transformer!*" Observe the force of the word "*only*." In a living cell there is *only* a something which transforms external force and rearranges the elements of matter. In fever there is *only* a little peculiar matter deranging the normal chemical changes of the body. In cattle plague there is *only* a little albuminous matter which ferments—all very clear and simple to the chemist, but neither the Doctor nor the Physiologist considers this to be the slightest approach towards a solution of the question. In a laboratory there is "*only a*" chemist who performs operations *more or less (!)* like those in the living cell. The *only* difference is that the something in the "cell"—or rather, in transparent structureless matter—does, without any apparatus or machinery whatever, and at a lower temperature, and in a marvellously small space, and with marvellous speed, much that the chemist cannot achieve with all sorts of complex apparatus, space millions of times as great, and time millions of times as long at his disposal,—and communicates its wonderful powers to new matter into the bargain.

If the chemist admits that living matter possesses a something which dead matter does not possess, and that this something transforms force, and rearranges the elements of matter, he surely admits the existence of a power or capacity which he does not attempt to explain, and which *transforming capacity* was derived from a pre-existing particle of matter possessing similar capacity, and this from one before it, and so on. What is this transforming peculiarity? Whence is it derived? From the external force which it transforms?

If we discuss what is meant by "transformation of external force," and endeavour to ascertain how, and precisely where, the *external force* is transformed, the points to which I have often drawn attention will come out strongly enough. I will not be the one to dispute whether the something in the living cell shall be called the "matter-rearranging and external force-transforming or conditioning property," or "vital force or power." To me the mere words used seem of no importance whatever, provided only we define what we mean, and agree not to use the same word in more than one sense. The real question can be discussed just as well if we call the matter *a*, and the external force *b*, and the force-transforming peculiarity *c*, etc., as if we employ the most complex words and phrases. It appears to me that the whole subject has been much complicated, and the discussion of the various questions rendered much more lengthy and troublesome by the careless employment of ill-selected and often inapplicable comparisons. Chemists have been compared to plants, but it is incumbent upon those who have instituted the comparison to point out exactly in what particulars the chemist is like the plant. "The chemist, *like the plant*, is capable of producing from carbonic acid and water a whole host of organic bodies." "Like the plant!" and yet how different is the plant's way of working from the chemist's way. The more one thinks over the facts, the more one feels astonished that the chemist should not be convinced of the existence of some internal force or power in the plant which more than *supersedes* his intelligence and all his transforming apparatus.

The *plant* may consist of a minute particle of *living*, clear, transparent, structureless, soft, semi-fluid matter, which, under certain conditions, takes up the water and carbonic acid, and the complex organic bodies are *formed*, or form themselves!

Now, let us see how the *chemist* proceeds to form by the synthesis of its component elements such a comparatively simple organic substance as acetic acid. Dr. Odling tells us how Kolbe effected the formation of this substance from carbon by a series of inorganic reactions:—

"Disulphide of carbon, CS_2, was first obtained by the combustion of charcoal in sulphur vapour. This compound was acted upon by chlorine at a high temperature, whereby it was converted into chloride of sulphur and chloride of carbon, CCl_4. Then, by transmission through red-hot tubes, this last product *was transformed!* with evolution of chlorine, into the so-called sesquichloride of carbon, $2CCl_4 = Cl_2 + C_2Cl_6$, and eventually into the so-called bichloride of carbon or tetrachlor-ethylene, $C_2Cl_6 = Cl_2 + C_2Cl_4$. In the course of his examination of this tetrachlor-ethylene, Kolbe observed that by exposure to chlorine in presence of water it was decomposed into a mixture of hydrochloric and trichlor-acetic acids; thus:

Chlor-ethylene.	Water.	Chlorine.	Chlor-hydric.	Chlor-acetic.
C_2Cl_4	+ $2H_2O$	+ Cl_2	= $3HCl$	+ $C_2HCl_3O_2$.

Then, by subjecting this trichlor-acetic acid to the action of nascent hydrogen, he successively converted it into dichlor-acetic acid, $C_2H_2Cl_2O_2$, monochlor-acetic acid, $C_2H_3ClO_2$, and, finally, into normal acetic acid, $C_2H_4O_2$."

What can be more conclusive of the presence of some power in the plant, in obedience to which the elements combine with one another to produce the required compound? The highly complex substance is formed very quickly under conditions so different from those necessary for its production in the laboratory as to render it certain the synthetic processes must be effected in a totally different manner in the two cases. I should have concluded that the chemist would have been led to reflect upon the wonderful and mysterious agency at work in the simple living matter of the plant, by which the same compounds are produced in a manner *so totally distinct from* that in which he is able to produce them. When the chemist has succeeded in forming a little clear, transparent stuff like that in the plant, which will take up water and carbonic acid, and *transform* organic compounds, it will be quite time enough for him to call the plant a "machine" or a laboratory, and talk of the "fiction of vital force" and *artificial processes* of oxidation "more or less similar to the *natural processes* taking place in the animal body." Ought we not for "more or less similar to" to substitute "*totally different from?*"

(To be continued.)

ORIGINAL COMMUNICATIONS.

LOCAL ANÆSTHESIA IN A CASE OF CÆSARIAN SECTION.

By BENJ. W. RICHARDSON, M.A., M.D., F.R.C.P.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

In recording the practical progress of the method of anæsthesia, which I had the pleasure to announce first in the pages of this journal, I could scarcely have a more agreeable task than that which falls to me on this occasion. I have to report the absolute success of the process in a capital, and in some senses the greatest, operation in Surgery—Cæsarian section. As every case of Cæsarian section becomes historical in the widest sense of the word, and as this case will possibly take, even amongst its fellows, an exceptional history, I shall give some attention to the details, in so far as my own part in it is concerned.

On Wednesday, March 28 last, Dr. Greenhalgh asked me if on the following morning I would produce local anæsthesia in the case of a woman whom it was absolutely necessary to deliver by the Cæsarian operation. Dr. Greenhalgh had come to the determination of asking me to make the attempt, after much consideration, and for many reasons based on an able and thoughtful study of the operation. He argued that if the superficial long incision could be made quite painless, and if the closing of the incision with sutures could also be made painless, the patient would, in fact, feel nothing more

than is experienced in an ordinary labour of very brief duration. He argued that the local anæsthetic process would prevent hæmorrhage. He argued that the effect of the cold would produce rapid uterine contraction. Lastly, he felt assured that by the local process the occurrence of vomiting, so frequent after the administration of chloroform, and so troublesome and dangerous, would be avoided. At the same time, the patient herself wished *not* to have chloroform, and expressed that she was in no dread of any degree of pain that did not exceed the pain felt in an ordinary labour. Appreciating the force of Dr. Greenhalgh's arguments, I undertook, therefore, to endeavour to meet his views. I constructed hastily for the occasion a large double spray producer, using a double-necked eight-ounce bottle for holding the ether. I provided a perfect ether, and I employed two hand-bellows to work the spray. With the kind assistance of my friend Dr. Sedgewick, I tested the capacity of the instrument thoroughly. I found that in thirty seconds I could render the whole of the front part of my own arm insensible from the elbow to the hand, and that the same effect could be produced in even a little shorter time on Dr. Sedgwick. We provided for the introduction of the sutures a separate small spray.

The operation was performed on Thursday morning (29th) at 9.30, in the presence of a large number of Obstetricians and Surgeons. On visiting the patient previous to the operation, I found her to be a rather short, stout woman, and apparently about thirty years old. She had had an indifferent night, and her stomach was irritable. She feared, she said, that she should vomit. Her tongue was white and her countenance pale, but her pulse was 74, firm, and steady. Her bowels had been very freely relieved.

She was placed on a short, broad table, and covered with an oilskin sheet or garment, which had an oval opening in it sufficient to expose the front part of the abdomen freely, but no more. This covering was not passed over the face, but was folded neatly over the chest. At her own request a pocket-handkerchief was passed lightly over her eyes as a bandage. The lower limbs were separated, and were allowed to bend over the edge of the table, and were supported by two assistants, who were seated. Dr. Greenhalgh stood in the centre, his assistant in the operation on the left side, and I and Dr. Sedgwick, who assisted me, on the right. The body of the patient was laid in a semi-recumbent position, the head firmly supported with pillows.

Dr. Greenhalgh having indicated to me the line of his proposed incision from the umbilicus towards the pubis, I commenced to narcotise locally in the centre of the space, making the ether tubes bend a little towards each other, and directing the brush of spray about one inch and a half from the skin. In a few seconds I found that the ether was telling on a space full four inches long and two broad; I, therefore, widened the spray by bringing the spray tubes parallel, and I made a gentle movement upwards and downwards, treating the spray as though it were a brush. Whitening of the skin was perceptible at the twenty-fifth stroke of the bellows, but Dr. Greenhalgh wished to widen the line of insensibility a little to the right side, so I lost a few seconds in doing this. At forty-five seconds the insensibility was perfect, and Dr. Greenhalgh made his incision down upon the uterus, dividing the skin and a deep layer of fat with one sweep. I moved the spray in company with his knife, and the uterus was laid bare. During the time the patient reclined absolutely unconscious of the incision; she neither winced nor spoke, her countenance was perfectly placid, and her pulse, which was being observed by Dr. Wilson, of Glasgow, underwent no variation. A breath of ether spray was directed upon the uterus after it was exposed, but, according to our preconcerted plan, the ether was now withdrawn from the open wound, and was directed on the skin surface that had not been divided, on the right side below the level of the umbilicus. The uterus was thus prompted to contract readily.

Having made, also painlessly, his incision into the uterus, Dr. Greenhalgh began to introduce his hand, but was somewhat impeded by the uterine contraction. At this point the patient first showed signs of uneasiness, and she asked of me "What is he doing?" Soon afterwards Dr. Greenhalgh had hold of the feet of the child, and delivered very rapidly and easily. As the child was being expelled—for, in fact, there was an act of uterine expulsion—the membranes gave way, and the liquor amnii escaped freely with some noise. The proceeding caused the patient a start, and she said, in the same voice as women usually speak in labour, and in the same phraseology, "I am sure I shall die." A word from me that she was quite safe, and that the child was born, reassured her; but after the child was removed, and at the moment of the extraction of the placenta, she again complained; she also complained somewhat of sudden pain, evidently from the uterine contraction. The uterus contracted at once so firmly that Dr. Greenhalgh, supported by the opinion of Dr. McClintock, of Dublin, who was present, determined to put no sutures into the uterus. For my part, I do not think the uterine wound could have been found, for the uterus had disappeared below the lower edge of the skin wound, and its muscular fibres were closely knit from contraction.

We waited twenty minutes, or nearly, for any hæmorrhage that might come on in the course of reaction. During this time the patient talked to me as calmly as possible on various subjects, told me of her symptoms, of her previous confinements, of her two children, of the part of Essex she came from, of the distance of her home by rail, of the time it took to make the journey, and the like. Once or twice when the sponge in the wound was pressed a little downwards she said "it was sore," and she thought, as it was all over, she was kept a long time. This expression was rather that of fear that something was wrong than of uneasiness or pain. In inserting the sutures I narcotised for Dr. Greenhalgh with a small single jet, point by point for each needle, and she felt no pain. After the sutures were brought together, however, I having left her, a single fine suture was passed through a part that slightly projected, without narcotism. This suture she felt, and she called out as the needle passed through the skin.

The infant, which seemed to be a little over the seventh month, died about an hour after its birth; but the mother from the time of the operation until now has progressed towards recovery without one untoward symptom. Dr. Greenhalgh's report to me to-day (Wednesday, April 4) is as follows:

"76, Grosvenor-street.

"My dear Richardson,—You will be pleased to hear that our patient is progressing most satisfactorily. She eats, drinks, and sleeps well, is free from pain, is very cheerful, and has had her bowels relieved naturally on more than one occasion. She passes water freely and healthily. The wound has healed by the first intention, and I have this afternoon removed four of the sutures. It would be impossible for any case to do better. Believe me, sincerely yours,

"R. Greenhalgh."

Notes.

In this case local anæsthesia by the ether spray process offered everything that could be desired, and I think was in every sense preferable to general anæsthesia from chloroform or ether. Indeed, Dr. Greenhalgh's foresight in respect to these advantages is not less conspicuous than the skill and precision with which he performed the operation. I say this, not in any way to disparage chloroform in cases where it is really demanded, but as a matter of fact and experience. The advantages of the local method were these:—

1. The operation was painless: the pain that was felt was the pain of labour, and that in the lightest and shortest degree.

2. The patient, prior to operation, was disposed to vomit. Under chloroform she would almost certainly have vomited during the operation; the intestines would thus have been brought into the wound, and the operation would have been prolonged and made more serious. There might also have been after-vomiting. The tendency of the local anæsthesia was to check vomiting.

3. The action of the cold checked hæmorrhage. I do not think three ounces of blood were lost.

4. The action of the cold in producing uterine contraction was in every sense beneficial.

5. The patient was not subjected to shock. I have often, even in deep sleep from chloroform, seen symptoms of shock as the knife entered the flesh, and have felt the heart stop as sharply as though a blow had been inflicted on it. By the local anæsthesia the patient, in her full natural power, was subjected to no kind of cardiac embarrassment.

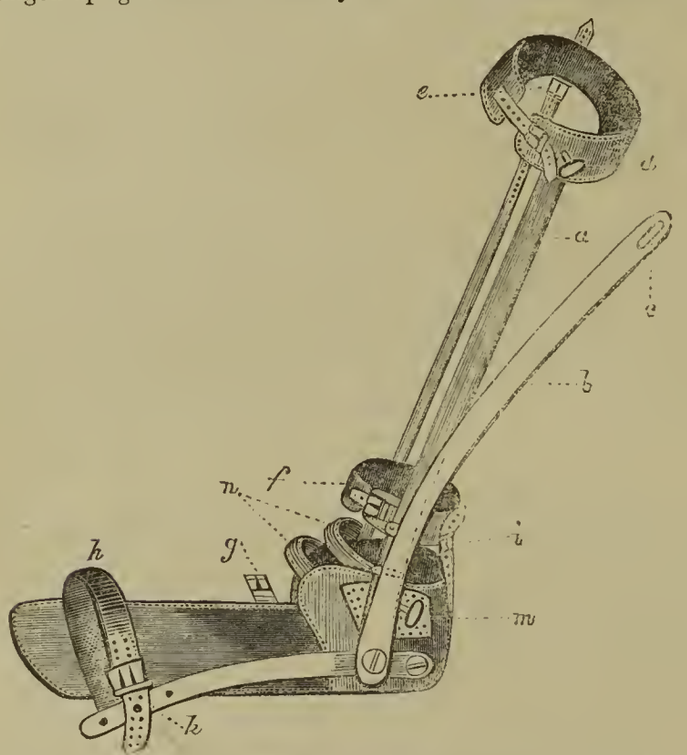
6. The consciousness of the patient was an advantage to the operator. She never was restless, she never moved her body for a moment, and when she was once asked not to bear down with the diaphragm, she obeyed immediately.

7. During the operation there was not the remotest anxiety that the patient would die from anæsthesia.

NOTES ON THE MECHANICAL TREATMENT OF TALIPES VARUS.

By FREDERIC CLOWES, M.R.C.S. Eng.

The treatment of talipes varus has been described so often, so fully, and by so many skilful and experienced orthopædic Surgeons, that it would seem unnecessary to occupy the columns of a Medical journal with any remarks on the subject. My motive for taking such a step is chiefly for the purpose of assisting the inexperienced out of a difficulty which I have myself felt regarding the choice of the best instrument for carrying out the mechanical treatment of this complicated and obstinate deformity. Any one who has access to the various works on club foot will find that each author advises the use of his own instrument, or at least some modification of a well-known one. But as such apparatus are somewhat expensive, it is of no little importance that the Surgeon should select the most effective as well as, if possible, the cheapest. Practised orthopædists cure their cases with any or every instrument; but the inexperienced Practitioner will often fail for want of one which combines simplicity of construction with perfect capability of fulfilling all the requirements of the case. After some experience of other apparatus, I can confidently advise the use of Dr. Little's double hinged upright lever shoe to any one who has an obstinate case



Description of Dr. Little's instrument, double-hinged lever, as made by Ernst, 19, Calthorpe-street.—*a*, the double-hinged lever; *b*, the long lever spring with *c* (the slot), receiving *d* (the swivel) by the long spring being brought owards the calf plate; *e*, the buckle of regulating strap; *f*, the ankle andage; *i*, the buckles for adjusting the latter; *n*, the instep straps; *g*, xtra buckle for instep strap to vary its position; *h*, the toe strap fastened to stud in *k*, the toe spring; *m*, the thumb screw fitting a series of holes for the regulation of the uprights from an obtuse to an acute angle.

of the kind to deal with; and as I have not seen a good figure of this instrument, except in Holmes's Surgery, which may not be in the hands of all my readers, it is here represented. Any one who has treated such affections knows, and he who attempts their cure for the first time will soon find out, that the most important matter in every stage of treatment is always to gain as much as you can, but never to cause greater tension of a part than it will bear; and the want of appreciation of either of these maxims may make the difference between success and failure. Now, this instrument enables us to know exactly, after it has been applied, the degree of power it is exerting in every direction. The twisting of the foot on itself and its adduction at the ankle-joint, are overcome by the upright and horizontal springs and toe-strap, and the degree of tension here may be of course readily felt, as in other instruments. The inverted sole is turned out by the perpendicular spring, and the degree of eversion can be regulated with the greatest accuracy by the strap on the inner side of the leg, so as to take off the spring's action entirely when requisite, converting it into a simple lever. And here you have the same advantage as in the foot-spring of trying the degree of tension after the instrument has been applied. The same power of eversion is obtained in other apparatus by the ratchet-screw, but when applied it is impossible to tell what degree of force is acting. In the last and often most important and obstinate contraction, that of the tendo Achillis and other structures which prevent flexion of the foot, this instrument is peculiarly serviceable. By means of a free joint and a thumb-screw, which fixes the upright at any required angle, the heel may be gradually brought down, and during the early stage (after operation), in the more easily curable cases, too rapid flexion is easily prevented by simply tying it to the thumb-screw to prevent its going forward, or by inserting an additional thumb-screw in front of the lever. In the later stage, when flexion requires to be actively promoted, the free joint allows of motion in the right direction either by the manipulations of the Surgeon or attendant or by the efforts of the child in walking, etc. Indeed, by the systematic use of gentle exercises in this instrument, and inducing the patient to walk in it, some cases may be perfectly cured which would seem to require operation or re-operation, especially when aided by another means suggested by Dr. Little—a wooden or cork wedge under the fore part of the sole of the shoe, so as to raise the toes when standing or walking. The thickness of this may be gradually increased until the natural angle is obtained. Throughout this stage the degree of tension which the thumbscrew is effecting may be readily known, as the free joint allows of motion in the right direction, and thus the orthopædic rate of *arte non vi* can always be carried out. The last, and, perhaps, most important, characteristic of the instrument is the "double-hinged lever," by means of which it can be accurately adapted to the deformed limb without any action on its structures. In every stage of treatment this is useful, as in the application of all apparatus of the kind it is important to get the heel and the whole of the sole of the foot, in close contact with the sole of the instrument. The double-hinged lever allows this to be done perfectly; subsequently, eversion of the foot can be effected to the required extent by bringing the spring to the calf-band and fixing it there, the degree of eversion controlled by the regulating strap, as before described. But it is in the later stages of treatment of obstinate cases that I have found this part of the instrument peculiarly valuable. The thumb-screw remaining in a particular hole in the series, marks a point gained which must not be lost, and the foot can be taken out of the apparatus and replaced, without altering the angle of the upright lever, by simply detaching the spring at the calf-band by means of the swivel when it is taken out, and refixing it thereto when returned to its proper position in the instrument.

Some years ago I was induced to try this apparatus for the cure of a very obstinate case of double talipes varus in a child about four years old, which had been more or less under mechanical treatment by different means from the age of three months.(a) At that time the error was committed of dividing the tendo Achillis before eversion of the feet had been effected, and the consequence was the failure of all subsequent efforts to cure the deformity. In consultation with Dr. Little it was decided to divide all the contracted structures, and this was skilfully and effectually done by Mr. L. S. Little, Surgeon to the National Orthopædic Hospital. But, notwithstanding the use of free tenotomy, considerable time, skill, and patience were required to obtain perfect form of limbs and motion of joints. By the aid of this instrument, however, all this was perfectly effected, and the young gentleman has now acquired such strength and voluntary power in the formerly lame and distorted limb as to well repay all the trouble and expense which has been incurred. In other words, he is cured. Since this case several others have come under my care in which this double-hinged lever instrument has been the most important agent in effecting their cure. Of these I give a short report of the two last.

Case 1.—J. D., aged 18 months, double congenital talipes varus of medium degree. The contracted structures are slightly more rigid in the left than in the right foot. On August 12, 1865, divided tendons of tibialis posticus and anticus in left leg, and afterwards gradually obtained full eversion of foot, etc., by bandage and splint on outer side of

(a) By the kindness and courtesy of Mr. Barwell I was enabled to try his plan of using india-rubber springs, but I failed to do any good by this means.

leg. On September 27 divided tendo Achillis in each leg, and by means of the instrument obtained perfect flexion of feet on November 26. In taking the photograph from which Fig. 1A was engraved, the legs were allowed to hang free, so that the feet assumed their best position, instead of exhibiting that exaggeration of the deformity which is obtained by resting the toes on the ground. In Fig. 1B the feet are represented in a position in which they are readily placed and as readily remain.

Fig. 1.—A.

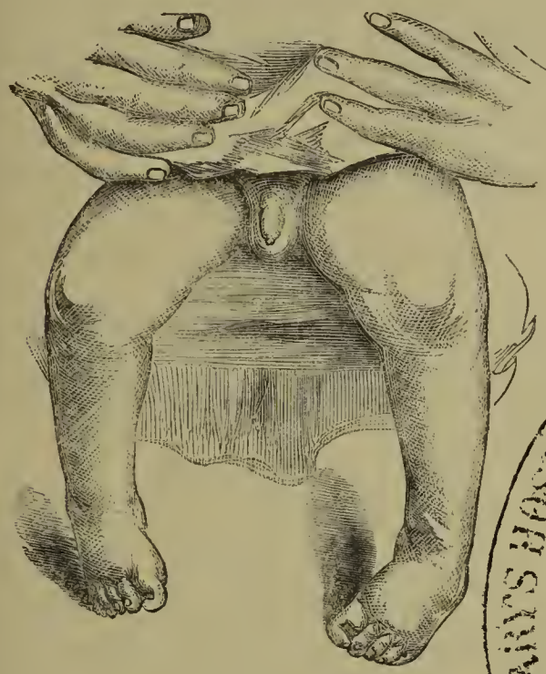


Fig. 1.—B.

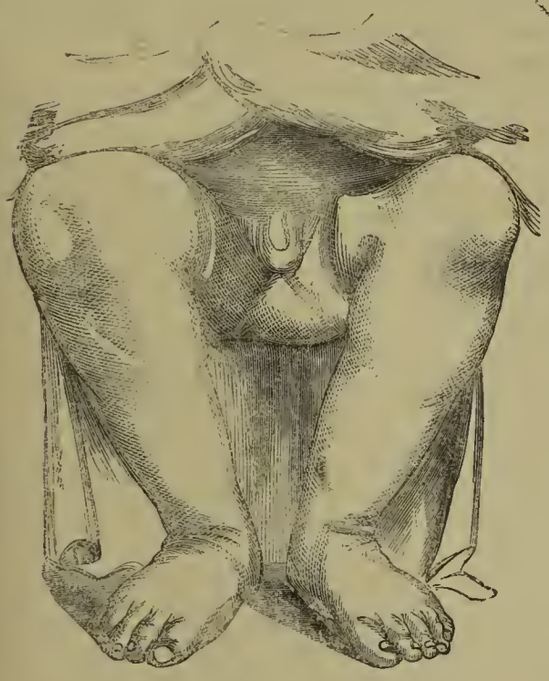
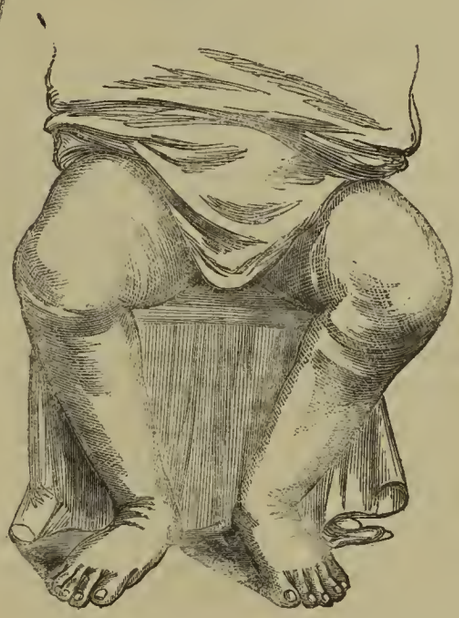


Case 2.—G. B., aged 3 years and 3 months, double congenital talipes varus. Right foot scarcely flexible to right angle with leg, and slightly inverted. Left foot: Heel much retracted, and the foot twisted on itself and inverted, so that the child walks on outer side of dorsum. November 26, 1865.—Applied splint and bandage on outer side of both legs and feet. December 28.—Complete eversion and restoration of form of the feet having been effected, divided tendo Achillis in both legs. On January 28, 1866, flexion of feet was complete.

It will be observed that in Case 1 the tibial tendons were divided in one leg, but not in the other. It so happened that in dividing the tendon of the tibialis posticus of the left leg, the posterior tibial artery was divided; and during the delay occasioned by this accident the adductors of the right leg were perseveringly stretched. They yielded so well as to render the section of their tendons unnecessary; and after the cure was completed this foot was in every respect as completely restored as the other. Profiting by this experience, I tried fully and perseveringly the use of the outside splint in Case No. 2, and although the structures were rather rigid from

Fig. 2.—A.

Fig. 2.—B.



long-continued walking in such an abnormal position, they yielded so as to allow of perfect eversion and restoration of form in little more than four weeks! I cannot but fear that I may have sometimes performed some of those "unnecessary operations" which Dr. Little many years ago so well treated of. At any rate, the inexperienced tenotomist may well try extension before he determines to divide the posterior tibial tendon—the one which is undoubtedly the most liable to non-reunion and other accidents, and the *bête noir* of all incipient orthopædists. I may be allowed to tell this class of Surgeons (of which, perhaps, I am one) that in the later part of this stage of treatment most power is obtained by first bandaging the foot as far as the malleolus; then applying the splint on the outer side of the leg, and by taking a turn with the bandage over it (and thus preventing its slipping forward over the dorsum of the foot), it is kept rather to the back of the leg, while being firmly bandaged to it, and thus great leverage on the foot is gained. This can, of course, be increased to any extent by bending the (well-padded iron) splint outwards, and the use of pads in any required position. This much is certain, that no harm can ever be done by attempting to evert the foot without tenotomy, if only the orthopædic rule be followed of always effecting this eversion

perfectly before dividing the tendo Achillis to bring down the heel. And here it may be remarked that the natural angle of flexion of the foot is often spoken of as if it were a right angle. With the exception of Dr. Little's article in Holmes' Surgery, I can scarcely find in any work any statement of the importance of obtaining (if possible) the full degree of flexion which belongs to a child *of the same age as the patient*, with the necessary caution not to lose the power of *extending* the foot. Another subject of practical importance is the proper use of retentive means after restoration of form and mobility. Few cases are safe without well-made irons from the hips downwards, with free joints at ankle, knee, and hip, well-made boots, and a firm hoop round the pelvis, to prevent inversion until the child has become able to walk correctly. The varus shoe should also be worn at night until the varoid tendency is completely overcome; for here all efforts to cure are made in direct opposition to nature, whose powers, if left to themselves, will ever tend to perpetuate or increase the error into which she has fallen. How different to that large class of cases, more properly called recoveries than cures, in which our duty really is simply to remove impediments to nature's process of restoration.

And a few words on the importance of "early recognition and treatment" of deformities in children. In the first of the above cases, the mother was told by the Surgeon who attended her (a good Practitioner in a country town) that nothing could be done for three or four years, and the case was afterwards rejected at one of our largest provincial Hospitals. The other was taken in hand in infancy by a Liverpool Surgeon. The tendo Achillis was divided, and mechanical treatment used, but imperfectly carried out, and the patient was deserted in the condition represented by the engraving. I have had charge of other cases which have experienced similar treatment, and within half a mile of me is a case of talipes varus in a girl about 12 years old, in which the limb is hopelessly atrophied, who was sent, some years ago, when in a curable state, to one of the largest Hospitals in the North. There she was operated on, but she returned so much the worse for treatment that her parents have determined never to let her be "cut again." A still worse case is that of a young man, about 21 years old, who lives near me. He has a limb so entirely destitute of muscle as to be of little, if any, more use to him than a wooden peg. This is also a case of congenital talipes varus. There can be no doubt that these cases were perfectly curable a few years ago. How much suffering and loss might have been prevented by their early recognition and cure!

More important still (because affecting organs on which life and health depend) are such deformities as curvatures of the spine; and yet I fear that at least one of these deflexions, lateral curvature, is very commonly overlooked in youth, and thus invaluable time is lost. As here, prevention is indeed better than cure—nay, rather, not being cured early, the consequences must, more or less, be endured. In the last few years I have seen several cases in which obscure symptoms of various kinds have been clearly owing to this cause; but the mechanical condition producing them has been entirely overlooked. Among other cases I can call to mind, is one of a lady who has suffered much from many Physicians, and is rather the worse. She is living in London "in the midst of the doctors;" she has consulted obstetricians and chest doctors, and much has been done for the organs they respectively and specially treat; but her symptoms are all caused by lateral curvature, and for this nothing has been done. While writing these notes I was consulted for habitual slight dyspnœa and other symptoms in a child about 10 years old. When undressed, such a decided and severe degree of lateral curvature was manifested as unmistakeably accounted for the symptoms; and yet the Surgeon who had had charge of her (a most competent Practitioner in Scotland) assured the parents that nothing but rest and proper exercises were required to cure her; and it was only by getting the opinion of the orthopædist whose name I have already mentioned more than once, and whom I cannot but call the first in knowledge and skill as well as the founder and earliest promoter of the art and science of orthopædy in this country, that efficient means of cure were resorted to.

When such cases as these are met with in a comparatively small field of observation, proving that in town and country alike such serious causes of suffering and disease are overlooked, I cannot but echo the words of Mr. Brodhurst in his valuable work on curvatures of the spine—"Few subjects in Surgery are perhaps less understood than this of curvature of the spine. It is a subject full of interest, and one which is worthy of much attention." Without exaggeration, indeed, it may be said that the importance of the cure of deformity in youth is *incalculable;* for how great is the influence of such affections on the health, not of the body only, but also of the mind? Many a temper has been soured, many a gentle spirit has been made sad, by infirmities of this kind; and, therefore, who shall say that by curing a physical deficiency the Surgeon may not lessen or prevent a moral failing or vice? And so mysteriously blended and united are physical and mental phenomena—so *certainly* do they mutually influence one another that the healthy education of the soul may be promoted by the sound and normal development of the body, and, if so, who shall say that the effects of our efforts may not be lasting as eternity?

Windermere.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

BIRMINGHAM GENERAL HOSPITAL.

CASE OF UNILATERAL CONGESTION AND SWEATING OCCURRING IN EPILEPTIFORM PAROXYSMS.

(Under the care of Dr. RUSSELL.)

In a late number of this Journal I prefixed to some cases of skin complaint, which probably had their origin in some change in the nerves of the affected part, a brief notice of a case of epilepsy, wherein the state of tonic contraction of the blood vessels, usually supposed to be associated with the epileptic fit, was exchanged for one of paralytic distension, so far, at least, as the external vessels were concerned. Flushing of the face took the place of the pallor which had previously ushered in the epileptic attack, and existed alone without any other epileptic phenomena.

In the following instance similar phenomena were witnessed, but on a far more extended scale, and were united on two occasions with true epileptic symptoms. The whole series of phenomena strikingly call to mind the effects which follow division of the roots of the sympathetic on one side of the body: congestion of the vessels, elevation of temperature, (subjective at least), and exaggerated secretion were present. Had we been able to witness an attack, probably hyperæsthesia and other phenomena would have been observed and not unlikely contraction of the pupil. It is also to be noted that the skin of the affected part, and also the glandular apparatus of the eye of the same side, seem to have been permanently in a state of semi-vasomotor paralysis; their secretions were excited with preternatural facility.

I forbear to speculate on the cause of these peculiar phenomena, whether the stimulus which usually contracts the vessels in the epileptic fit, had produced paralysis of the external vessels by having been rendered inhibitory, either through exaggeration of its power according to the views of Mr. Lister, or through a morbid state of the nervous tissue on which it operated according to the opinion of Dr. Handfield Jones, or whether an influence totally different in its character was concerned.

R. S., aged 38, employed as a night watchman, of healthy family, and tolerably temperate habits, became an out-patient of the Hospital on May 28. His previous history reveals no indication of any disease. He applied on account of two epileptiform seizures which had occurred—the one four months ago, the other a fortnight. In the first seizure he was suddenly attacked with a sense of burning in his left arm, so intense that, as he had just been feeding his engine fire, he looked in his sleeve, not doubting that it had caught fire. At the end of about an hour the sensation "fled up the body," affecting the left side of the face and of the trunk, and also the lower extremity of the same side, and a profuse perspiration broke out over all the hot parts. He walked home; but on his arrival it was found that speech was impaired. He stammered, could not get his words out, and was unable to utter an articulate sound. At the same time, the left side of his face was contracted, and his head was drawn down to his shoulder. It is uncertain whether his left arm and leg were affected with tonic spasm; but most probably they were. Some difference of opinion, too, exists as to whether there was any perspiration on the right side on this particular occa-

sion. He says not. He then became unconscious, purple in the face, and rattled in his throat; but did not bite his tongue. The second seizure was of a milder character, though he would have fallen had he not been supported. He did not then lose consciousness; but in the purple colour of the face, and in the preceding heat and sweating, the attack precisely resembled the former one. He had, however, experienced frequent recurrence of the heat and perspiration, confined on every occasion to the left limbs and left side of the face and body. The recurrence happened first a month after the first fit, and has been repeated often three or four times a-day for several days in succession, but continues generally only for about five minutes; but since the last fit the attacks have been of longer duration—never, however, exceeding a quarter of an hour. He may be free from the attacks for two or three days, and once or twice has been so for a fortnight. The sense of heat has commenced and extended precisely as described above. As the heat reached the face the cheek became much flushed, so that his wife frequently became aware of what was happening by this circumstance alone. The perspiration which accompanied the heat and affected all the left side was most profuse; the moisture poured off him. At the same time, his speech was slightly affected, and he experienced a sense of suffocation which compelled him to spring upright. Generally the attack subsided rapidly on his walking into the fresh air. A slight amount of watering of the left eye accompanies the perspiration, with a little dimness of vision; but he adds that since he has been subject to this affection the left eye is exceedingly apt to water when exposed to chill air, even so much as that tears trickle down his cheek. Moreover, any exertion produces sweating of the left side with preternatural facility. The right side has no share whatever in these phenomena. There has not been any salivation.

He is a healthy, well-nourished, vivacious man. Pupils perfectly normal, vision healthy, surface of skin presents no abnormity, and all of his organs are healthy. The temperature of each axilla is alike, and quite normal. He has greatly improved since he has been treated. The remedies employed have been strict dieting, abstinence from stimulants, the application of a blister to the nape, and alkalies, with bitters, subsequently steel, with aperients.

NATIONAL HOSPITAL FOR EPILEPSY AND PARALYSIS.

SWEATING ON ONE SIDE OF THE FACE IN A PATIENT WHO HAD EPILEPTIC FITS.

(Under the care of Dr. RAMSKILL.)

In connexion with the last recited case we may give another illustration of sweating of one side of the face. This patient was under Dr. Ramskill's care for epilepsy. Dr. Ramskill drew our attention to the odd circumstance that there was sweating on one side only of the patient's face when he exerted himself. To test the truth of the patient's remark he had been sent out to walk briskly round the square. On his return the perspiration was profuse on the right side, and was abruptly limited at the middle line of the nose and lip, but extended very slightly to the left of the middle line of the forehead. On the outer part of the cheek, near the angle of the jaw, the part supplied being a branch from the cervical plexus, there was no perspiration; but the lobulus of the ear, supplied by a branch from the same plexus, was much hotter than that of the opposite side. To see if local stimuli as well as general exertion would produce the same effect, statical electricity was used to each cheek in turn. This was done by Mr. J. N. Radcliffe. It caused profuse perspiration on the right side, and not on the left. The patient looked a healthy man, but we have no details as to nature of his fits; but Dr. Ramskill tells us that the epileptiform seizures did not differ from those of many other patients in whom this symptom was not present.

It is not easy to make out the meaning of this symptom. In some cases it occurs, as Dr. Gairdner has pointed out, with paralysis of the cervical sympathetic from pressure of an intra-thoracic tumour, which tumour is generally an aneurism. In this instance there was no evidence of any such cause. Moreover, the pupil on the side of the sweating was a little larger than on the other side, whereas in Dr. Gairdner's case it was contracted. Some time ago we saw a patient at The London Hospital, under Dr. Andrew Clark's care, who had sweating of one side of the face, along with symptoms of thoracic aneurism. In this case the pupil was contracted on the sweating side. At the same Hospital we saw a healthy-looking woman, 35 years of age, who had this symptom to a well-marked extent, but there was no other discoverable deviation from health. She know nothing of it, and attended for the illness of a child.

Dr. Anstie, in his work on Narcotics and Stimulants, records a very interesting case of sweating on the left side of the face in a child who had epileptic fits. In this case the sweating occurred just before the paroxysm. The child had partial paralysis on the same side of the body, and this side was the one convulsed, or chiefly convulsed, in the fits. In this instance, as in Dr. Russell's case, the symptoms had definite relations, and therefore it has more value than it usually has. The case shows, Dr. Anstie thinks, that the condition of the nervous apparatus is one of paralysis rather than, as would be generally held of such a case, of stimulation. Both fits and unilateral sweating were clearly, Dr. Anstie considers, dependent on distension of the colon with fæces.

THE HOSPITAL FOR CONSUMPTION, BROMPTON.

CASE OF LEFT PNEUMOTHORAX FROM AN OPENING IN THE RIGHT LUNG.

(Under the care of Dr. HAMILTON ROE.)

The following rare case of pneumothorax occurred at this Hospital in a patient of Dr. Hamilton Roe's, with whose permission these notes of it are sent for publication:—

Samuel S., aged 32, admitted July 28, 1865. An ordinary case of chronic phthisis, with a cavity at right apex; harsh breathing, left. The patient slowly got weaker, and in November was much pulled down by diarrhœa, and was confined to bed.

On Wednesday evening, November 29, at 7 p.m., he was suddenly seized with pain in side and dyspnœa; had recently got out of bed. The left side was tympanitic on percussion, and respiration almost absent, anteriorly and posteriorly. Heart displaced; beating under right nipple—(but an imperfect examination could be made, from great distress of patient). Pulse very small, weak, and rapid. Patient died at about 8 p.m.

Autopsy.—A small incision was made through the skin between the fifth and sixth ribs, and a narrow scalpel thrust into the pleura. A current of air escaped, which immediately extinguished a lighted lucifer match held to the opening. The thorax and abdomen were then opened in the usual way, the median incision being extended upwards to the chin. On opening the thorax, the left lung was found to be imperfectly collapsed. At the apex there were some firm adhesions, and about the mammary region there were some longer ones, stretching between the lung and the parietes. The pleural surfaces were glistening and moist. No trace of recent inflammation. The right lung was extensively adherent to the parietes by old adhesions, especially at the upper half. The lungs were raised with costal pleuræ, and removed, with layrnx, trachea, œsophagus, heart, and great vessels, *en masse*. The left lung was then cautiously detached with its bronchus. It was but partially collapsed; posterior lobe most so. A few solid nodules were felt at the apex. This lung was placed in water, and forcibly inflated through the main bronchus by Mr. Williams, my fellow clinical assistant, who was making the post-mortem with me; the whole lung, which was but slightly affected with tubercle (a few nodules only at apex), was perfectly expanded, but no air escaped from any part of its surface. The right lung was then carefully detached from the heart and trachea and found to be extensively solidified; being placed in water, and an attempt at inflation being made, the air was instantly found to escape with great freedom from a point close to entrance of bronchus; the experiment was repeated several times with great care and uniform result. Examination of Lung.—Lung small and tough to feel; at the posterior part of the apex of the upper lobe is an irregular cavity the size of a small orange which communicates externally through the pleura by a well-defined aperture, the tissue and pleura having been, as it were, bored through by a circular canal; the opening is close to the upper division of the right bronchus, but posterior to it. The pleura covering the lung is considerably thickened, the two layers being inseparable; between the perforation and the bronchus the pleura is not thickened, but there is some loose cellular tissue. There were two smaller cavities in lung, which was more or less

*

tuberculised throughout. From the lungs having been separated previously to being inflated, it was impossible to trace the adhesions which had determined the perforation from one lung into the pleural cavity of the other side; but the facts of the air being in the left pleura and the perforation in the right lung were perfectly ascertained. The position of the aperture was in the posterior mediastinum, above the arch of the aorta, in front of the œsophagus and behind the right bronchus, and in this situation the pleura approach so nearly that they might readily become adherent in a state of disease. The lung is preserved, at request of Dr. Alison.

For this communication we are indebted to R. Douglas Powell, M.B., Resident Clinical Assistant.

Dr. Powell adds—"This is probably not an isolated case, though I know of no other on record, some of those cases in which the aperture has not been found having been, very likely, of similar nature, but remaining undiscovered, from both lungs not having been inflated. This would be more likely in cases where death has occurred soon after attack."

TERMS OF SUBSCRIPTION.

Twelve Months (Prepaid) stamped for post £1 10 0
Six Months (do.) 0 15 0
Regularly transmitted by Post throughout Great Britain, and to the most distant of the British Colonies.
The Journal can be obtained of all Booksellers and Newsmen, Unstamped, for £1 6*s. per Annum.*
Post-office Orders and Drafts on Army or Navy Agents, should be made in favour of Mr. James Lucas, 11, *New Burlington-street, W.*

Medical Times and Gazette.

SATURDAY, APRIL 7.

THE MEDICAL COUNCIL RE-ELECTIONS.

The members of the Medical Council, it is well known, are appointed to office for a term of five years, and at the expiration of that time are eligible for re-election. The Council is composed of representatives chosen by the various examining bodies, and six additional ones nominated by the Crown. The Crown nominees are supposed to represent especially the interests of the public Services, the higher scientific grades of Professional position, and the maturer views of those actively engaged in the more ordinary Professional and civil duties.

Now, a vacancy has recently occurred by the expiration of the five years' term of office of one of the Crown nominees. We believe we are correct in stating that the retiring member has been re-appointed. At any rate, the probability of this step being adopted seems to have given rise to discussion as to the advisability of the Crown exercising its power of re-election.

We apprehend that no fixed rule is applicable to the case in point. It is manifestly desirable that any member of the Council rendered unfit for duty, either in consequence of advancing years or failing health, or by neglecting to give a proper amount of attention to the duties demanded of him, and thus disqualifying himself, should retire, and make way for some one more fitted for the post. But, on the other hand, the retiring member may be capable of rendering the most valuable services to the Council; he may have made himself acquainted with all details, which can only be mastered by time, and his compulsory exclusion from the deliberations of the Council would be a very serious loss.

We are, then, of opinion that it is essential to the best interests of the Profession that the Crown hold the power of re-electing the members retiring in rotation from the Medical Council. It is only necessary that Government should be judiciously advised when it is called upon to exercise the prerogative. Our contemporary, the *Observer*, has been very ill-advised, and in the remarks it has made upon the matter has taken (as is the case with most of the political journals when they trespass upon Medical matters) a very superficial glance at the real state of things. It has remarked that, as Medicine is progressive, a succession of new members in the Council is calculated to represent more perfectly the current wants of the time being, and that five years is quite a sufficient time in which to exhaust the stock of advice which any one man is able to give. This supposes that the actual members of the Council are incapable of progress; that they have certain bigoted ideas which they hold once and for ever. Again, the Council meets for about a week once a year, consequently during the five years' term of office each representative has altogether thirty days' attendance, and therefore a working member will, about the time he should retire, be just becoming qualified for further usefulness. Such a man—it may be the best that could be selected, very possibly—should not be lost to the Council.

Our remarks are made in reference to Dr. Sharpey, whose term of office has just expired. He has probably no equal in regard to general acquaintance with all that relates to Medical education, and the amount of sound judgment that he is capable of bringing to bear upon all questions which are entertained by the Medical Council. It will be acknowledged on all hands that his retirement would be an almost irreparable loss.

It has been affirmed that the re-appointment of Dr. Sharpey establishes a precedent which may probably at some time fetter the freedom of the President of the Council or the ultimate usefulness of the latter. This, too, is not true. We call to mind the fact that both the Irish and Scotch representatives are now serving a second term of membership, having been re-elected on a former occasion.

Re-election, however, is a matter entirely beside the question of precedents. If any given member be a useless one, then the sooner he ceases to belong to any executive the better; but if, on the other hand, he be hard-working, judicious, and valuable, it would be suicidal indeed to annihilate his influence by a piece of absurd red-tapeism. No arrangement could be better than that which at present exists. We are as anxious as anybody that the composition of the Medical Council should be keenly debated, and one of the best ways, as far as the Crown nominees are concerned, of securing the most desirable men, is to proffer to the Crown judicious advice when vacancies occur, and such advice has been given on the most recent occasion.

THE THIRD REPORT OF THE CORONER FOR CENTRAL MIDDLESEX.

Dr. Lankester has published a third Report, with statistical tables, by his deputy, Dr. Hardwicke (a). Nothing can be more interesting than these serious histories of our own times, so short, so closely packed with the sins and sorrows of the very people among whom we live. Dr. Lankester has the happy knack of making his reports readable, and yet so admirably arranged that they are handy as pocket dictionaries. There has been a slight decrease in the number of inquests, which may be fairly attributed to a decrease in the crime or culpability which renders them necessary. The decrease was most marked in the months of April, May, June, and July; not from fewer deaths connected with the respiratory apparatus, as might have been anticipated, but owing to fewer cases of nervous diseases and effusions on the brain. Inquests on deaths from natural causes are most frequent in the cold autumn and winter, accidental deaths and suffocation of

(a) Third Annual Report of the Coroner for the Central District of Middlesex, including an Analysis of Inquests held from August 1, 1864, to July 31, 1865. Read before the Social Science Association, March 21, 1866. Dr. W. Farr, F.R.S., in the chair.

children in bed most common in winter, suicides in the first three months of the year, homicide and infanticide twice as common in winter and spring as in summer and autumn. Section III. contains some excellent remarks on the law of *felo de se;* and it is pleasant to see how, even in the ghastly business of investigating suicide with the reasons for self-destruction all too plain, the kindly English natures sympathise with the relatives, and give the gentler verdict of insanity. A marvellous number of infants are smothered in bed. Out of a list of 330 verdicts, we find the result that 113 had died, generally on Sunday mornings, from the pressure of bedclothes or parents sleeping the heavy sleep which follows their weary week of toil or their Saturday night's libations.

Above 200 *fatal cases* were caused by vehicles in the streets of London alone! and it is calculated that for every *one* fatal there are 48 persons injured, who do not immediately die. "The money value of the injury to life and limb in London annually cannot be much less than a quarter of a million." It does seem almost time to prevent "the proud ones who roll along the highways" from crushing pedestrians, who are, however, themselves much to blame, as they behave at crossings as if they were there on sufferance. If they gave up the timid and apologetic behaviour when passing from one pavement to the other, it would make drivers less indifferent and more respectful.

We would especially direct attention to Dr. Lankester's remarks on infanticide. There is one child murder in 20,000 of the population of Middlesex *generally*, and one in 12,000 of the population of the central and western districts. It is calculated that of the mothers many die who have borne and destroyed children undiscovered. The perpetrator of the crime is, "in the great majority of cases, the mother, who is usually employed in domestic service." The conditions necessary for concealing pregnancy can only generally be secured when women are in domestic service, and the crime is seldom committed or attempted when women are sleeping with others. Dr. Lankester adds that "there is no doubt that the kindly and sisterly superintendence of young women living in domestic service by their mistresses would often prevent the concealment and the temptation to destroy their offspring--a crime most frequently perpetrated, not in the homes of the poor, but in the homes of the middle and upper classes of society in England."

Dr. Lankester and his coadjutors seem to have already made considerable progress in carrying out the great objects of the Coroner's Court—the prevention of criminal and culpable death, and arresting the spread of preventible disease.

OZONE.

We promised last week an article on ozone; we proceed to fulfil our promise. For the past few months our Continental neighbours have been making known some valuable additions to the knowledge of this body, to the more interesting of which we shall call attention.

Our readers are probably all aware that the existence of a substance, called by its discoverer *ozone*, was made known to the scientific world by Schœnbein. He did not then isolate it as hydrogen, iodine, magnesium, or other substances have been isolated; nor has he or the other workers at the subject succeeded in doing so since, although more than the quarter of a century has elapsed since its nature first became matter for investigation.

To form it there must, all are agreed, be *oxygen*, but we can hardly say that all are also agreed that there must not likewise be hydrogen, or rather, perhaps, water. On the whole, however, the experiments of Andrews and Tait may be considered as setting the question at rest, at least, so far as this:—From oxygen alone some of the phenomena indicating the presence of ozone can be obtained. The question is not so satisfactorily answered as to whether the substance that is formed in presence of water-vapour, and answering to the tests of ozone, is formed from oxygen only, or from a combination of oxygen and water.

But we must not say more of its nature until we have stated some of the means of obtaining it, or, more correctly speaking, obtaining indications of its existence. If perfectly dry and pure oxygen gas be electrified by passing a series of sparks through it, or, even better, according to Dr. Andrews, by silently discharging machine-electricity through it, ozone is produced. That is to say, the oxygen acquires new properties. It acquires a peculiar smell, such as is observed on standing near a large electrical machine in action, or much like that of a dense fog. It diminishes in volume. It becomes capable of *oxidising* bodies in a way that it could not do before, so that it becomes corrosive, destroying most organic substances, such even as caoutchouc, and acting on metals, even silver, oxidises and decomposes salts ordinarily stable, such as sulphate of magnesia and iodide of potassium, and even combines with the inactive substance nitrogen (in the presence of moisture). It is practically insoluble in water, but is absorbed by it if the water contains a material quantity of organic matter. If the oxygen which has been thus changed is treated with some of the substances affected by it, these active properties disappear, and a great part of the original oxygen employed is left unchanged. But Frémy and E. Becquerel have shown that by electrifying the oxygen in contact with moist metallic silver, or a solution of iodide of potassium, all the oxygen can be so changed as to be absorbed by these substances.

Other methods of forming ozone in the presence of water are by gently heating a mixture of air and ether vapour, or by exposing clean moist phosphorus to the air. In these cases the formation of the ozone seems to be simultaneous with the partial oxidation of the acting substance. It is also formed during the electrolysis of dilute sulphuric acid, or, as it is the fashion to say, of water acidulated with sulphuric acid. And also by the action of sulphuric acid on peroxide of barium, and by other laboratory methods.

It has been shown to be formed during fermentation and the growth of moulds, and it is believed to be very generally produced during oxidation at ordinary temperatures. It, however, can hardly be said for certain that oxidation is a cause of the ozonisation of oxygen, as we know that all the oxidations that do take place are producible by ozone itself, so that it may be that ozone is produced by the contact of oxygen with these bodies, or in other ways, and that then these bodies begin to oxidise under the action of the ozone.

Now, with regard to the test of its presence, there are several, but there is hardly one of them which cannot be challenged as an uncertain indication of it. One of the earliest tests employed, but seldom used now, was a white paper impregnated with sulphate of manganese, an almost colourless salt. This paper is turned brown by the formation of hydrated peroxide of manganese. Another test, proposed by Schœnbein, and the one most in use at present, is white paper impregnated with starch-paste and iodide of potassium. This paper is turned blue, or a colour approaching it, by ozone, potassa being produced and iodine liberated, which then forms the blue compound of starch and iodine. M. Houzeau has introduced, and for a long time employed, strips of wine-coloured litmus-paper, half of each of which only is impregnated with iodide of potassium. This he does because there are other substances that are liable to change the iodised starch-papers by liberating iodine which will not affect these papers. For these other substances liberate the iodine by forming a neutral salt with the potassium, such as acid vapours, chlorine, etc., but ozone does so by forming potassa, which is alkaline. This alkalinity his papers indicate by the part charged with the iodine becoming, under the influence of ozone, blue from the action of the potassa on the violet litmus, and then contrasting with the unchanged colour.

We have already indicated the most striking properties of ozone, but there are still some things requiring notice. By

its powerful oxidising action on organic matter, it quickly purifies air or water charged with organic matters, removing smell and taste from them. Indeed, the most offensive masses of putrid matter lose their offensiveness to the senses by the action of this body. Its active chemical properties render it a powerful irritant to mucous surfaces. By heat ozonised oxygen loses all the properties of ozone, and regains its own; among others, its proper volume.

We have also to say a little concerning the density of ozone. Since oxygen converted, or partly converted, into ozone, contracts in volume, it is evident that ozonised oxygen must be denser than ordinary oxygen. Attempts have recently been made to determine its density, by M. Soret. We must mention that when ozonised oxygen is exposed to the action of iodide of potassium or moist silver, it loses its peculiar properties, except that it does not reassume its original volume, as it does when heated. Further, that the loss of oxygen is accounted for, and the absorption of ozone proved, by the fact that a quantity of iodine chemically equivalent to this oxygen or ozone is set free from the iodide of potassium. It is just possible, it seems to us, that ozone may be a vapour of very low tension, of a highly volatile liquid, which we have not yet been able to get in sufficient quantity in a given space to make it reach the point of maximum density, when formation of liquid would take place. For, then, the slight loss of elastic force by the absorption of it from its mixture with oxygen might well escape observation. However, chemists do not seem to hold this view. The one which has for some years been suggested is that ozone is half as dense again as oxygen. On this hypothesis, iodide of potassium is considered to absorb one-third of the matter of ozone, and to liberate the other two-thirds as ordinary oxygen. This, of course, requires the further admission that the ozone behaves as if formed of two kinds of matter, two kinds of oxygen, and that it is an oxide of oxygen having the formula O_2,O. We shall not pretend to criticise this hypothesis. We refer to it here, partly because M. Soret has attempted to determine the density of ozone, and he finds his experiments confirm the view that three volumes of oxygen are condensed to two. He has discovered that oil of turpentine so acts upon ozonised oxygen as to cause the volume of the gas to diminish, instead of this remaining unchanged, as when iodide of potassium acts upon it. He concludes from this that iodide of potassium decomposes this *compound oxygen*, or ozone, and absorbs part, while turpentine absorbs it wholly. Granting the truth of this conclusion, our readers will at once understand that if, as in the experiments of M. Soret, two measured quantities of the same ozonised oxygen are taken, and the one acted upon by turpentine and the other by heat, that the volume of oxygen equal to the ozonised gas will be learned from the latter action, and the quantity of unchanged oxygen in a given bulk of the gas from the former. The difference between the volume of the original oxygen and that of the unchanged oxygen will give the quantity converted into ozone; the diminution in the bulk of the ozonised gas caused by turpentine will give the volume of the ozone absorbed by it. M. Soret found in this way that the volume of the ozone absorbed by the oil of turpentine was produced from a volume about half as great again of oxygen. Hence he concludes that the density of ozone is half as great again as that of oxygen.

We have so much more to say about ozone, more especially as regards the late controversy as to its existence or not in the atmosphere, that we must reserve this for another article.

A Modest Veteran.—M. Velpeau, on the occasion of presenting to the Académie des Sciences, on the part of its author, a copy of the third edition of Professor Sédillot's "Traité de Médicine Opératoire," stated that he regarded it as the most complete work of the kind that has ever appeared, and the one most up to the progress of science—very superior to the "Traité de Médicine Opératoire" which he himself "committed" some twenty years ago.

THE WEEK.

DR. GREENHALGH'S CÆSARIAN SECTION.

It is unnecessary to call our readers' attention to the case of Cæsarian section described in this week's *Medical Times and Gazette*, and which will be quoted as an historical fact, so long as Medicine shall have a history. It will greatly tend to shake the opinion of some of our conservative Surgical brethren, who believe that although the new method of local anæsthesia may be good enough for small superficial operations, yet that it is insufficient for those of the heroic or capital order. The Cæsarian section is, if any, *the* capital operation. Two lives are at stake. We deeply regret that in this case the child did not live, but certainly all the evidence shows that the safety of the mother was mainly due to, or at least very much increased by, the peculiar action of the new anæsthetic. There was no brain affection, and no vomiting, and the cold helped materially to contract the womb. True, chloroform is not dethroned yet; this woman was plucky and self-possessed, and there was no need of profound unconsciousness; still this operation will give the names of Greenhalgh and Richardson a place in the annals of Medicine, if possible, more permanent than they have already earned.

THE INTERNATIONAL CONFERENCE ON CHOLERA.

Our readers are aware that the sittings of this Conference commenced last month. A Committee composed of Dr. Sotto, Dr. Monlau, Count de Lallemand, Dr. Goodeve, Dr. Mühlig, Dr. Pélikan, MM. Vernoni, Murza-Malkom-Khan, and Salih Effendi, were appointed to sketch out a plan for the guidance of the Conference in its discussions and inquiries. The Report they have presented is an able document, but too long to be transferred in its entirety to our columns. We content ourselves, therefore, with indicating the chief lines of investigation which it recommends. The Committee ranges the questions to be examined under three groups: The first includes those relating to the origin and genesis of cholera; the second those having reference to its capability of transmission and propagation; the third, the great subject of preservation. Under the first head are found such questions as the following:—Is epidemic cholera developed spontaneously, under certain conditions, in European countries, or is it always imported from without? What are the countries in which the genesis of cholera may be incontestably asserted to take place? Does cholera always reign in India, or only at certain epochs and periods of the year, and does it appear with greater violence at certain seasons than at others? Are there certain localities in India in which exclusively cholera is engendered, or which are more favourable than others to its development? Do we know the causes by the concurrence of which cholera arises spontaneously in India or in any other locality, also the circumstances which make it periodically assume the epidemic form? Is there in Hedjaz an original focus of cholera, permanent or periodic; and if so, under what circumstances does it develope itself? Is there reason to fear that cholera may in time acclimatise itself in European countries? How is the immunity which some localities appear to enjoy in the proximity of cholera to be explained? The second group, referring to the transmissibility and propagation of the disease, comprehends a number of questions, of which the following may be taken as examples:—Is the transmissibility of cholera now proved by facts which admit of no other interpretation? What are the principal facts which support this hypothesis? Are there conclusive facts which compel the admission that cholera may be propagated by certain atmospheric conditions—for example, by winds, by the proportion of ozone in the atmosphere, etc.; or rather are there certain cosmo-telluric changes which alone favour its propagation? Can a person coming from a place infected with cholera carry the disease into places free from the disease; and, if so, under what con-

ditions of health does the power of carrying the disease occur? Is the arrival of a single individual affected with diarrhœa sufficient to give rise to the development of an epidemic? Other questions refer to the transmission of cholera by merchandise, water, dead bodies, dejections, etc.; to the influence of different modes of convection, sea or land carriage, roads, railways, steamboats; the effect of the collection and movement of human beings in large masses, as in fairs, pilgrimages, or military operations, on the spread of the disease. The third group on the important subject of preservation, includes comprehensive questions on the value of preventive measures —*i.e.*, public and private hygiene; and on that of restrictive enactments—*e.g.*, quarantine, sanitary cordons, the interdiction of emigration, fairs, etc. Under the head of quarantine, the subject of the incubation of the disease is started. Lazarettos, cholera Hospitals, the disinfection of ships, houses, and goods, the establishment of stations for Medical observation—for example, at Djeddah, Yambo, Suez, Alexandria, and in Persia—are subjects proposed for discussion. The Commission recommend that the questions comprised in the first and second group of their programme should be submitted to a sub-committee of eleven of the members, who are to report the result of their investigations with as little delay as possible. We stated in a recent number that the Conference have adopted the proposal made by the representatives of France to stop communication between the Arabian ports and Egypt in case of another outbreak of cholera amongst the Mecca pilgrims. It is to be seen, however, whether the Porte will have the courage to act on the advice.

MEDICAL INSPECTION OF LONDON WORKHOUSE INFIRMARIES.

The Profession will learn with satisfaction that a systematic inspection of the sick-wards of the London Workhouses is to be made by Dr. Edward Smith, F.R.S. Dr. Smith's testimony will be accepted as that of an acute and impartial man, whose position places him above the temptation to be sensational, and the suspicion of interested motives. It is felt that the Association for Improving the Condition of the Sick Poor in the Workhouses have not acted quite prudently, inasmuch as the speakers at their public meeting displayed a little too much of the advocate, and were too indiscriminate in their censures, and confounded the innocent with the guilty, in order to create a public "sensation." They would have been far more likely to have secured their end had they shown common justice to the West-end parishes, whose treatment of their sick is most generous, and whose Medical officers feel that they have been subjected to undeserved contempt. The Archbishop of York committed the common fault of orators when, in comparing the Workhouse Hospital with the ordinary Hospital supported by voluntary contributions, he dragged forward all the horrors that could be alleged against the former, and all the sentimental exaggerations which novelists urge in favour of the latter. Does his Grace think that there are no discomforts in a voluntary Hospital? or that patients are always well classified? Do we never hear of patients who go in for slight injuries dying of fevers contracted from the occupant of the next bed? As for Mr. Tom Brown, who expressly accompanied the strongest censure of others by the affirmation that he had no personal knowledge of the matter, the less such an advocate is heard, the better for the cause. As it is, a large number of active and benevolent men, who have devoted their leisure for years to the West-end Workhouses, feel themselves insulted quite gratuitously, and the good which is sought has been hindered by want of delicacy and good management. One point to which we invite Dr. Smith's attention is this—What amount of fever and small-pox has been imported into the London Workhouses by the tramps who flocked to them under the Homeless Poor Act? Inspector Farnall, C.B., is surely the last person in the world who ought to throw stones at London guardians.

FROM ABROAD.—THE FRENCH REPORT ON TRICHINIASIS—STATISTICS OF PARIS.

Great alarm having seized the public mind in Paris in respect to the possibility of an outbreak of trichiniasis, the French Government, in place of mystifying opinion as it did with respect to the cholera, has done its best to present the most accurate account of what has taken place in Germany. To this end it promptly despatched Professors Delpech and Reynal to the various districts in which the disease had prevailed, with instructions to put themselves into communication with the most able of the *savants* who have there paid attention to the subject. They have recently returned, and the *Moniteur* has just published an abstract of their report.

According to this, all the epidemics in Germany are extinct or are disappearing; and none of them, with the exception of the last at Hedersleben, where a concurrence of unfortunate circumstances led to most deplorable consequences, have been attended with other than an insignificant mortality. Thus in those occurring at Zwickau, Seitendorf, and Sommerfeld, not a single death took place among 86 or 88 cases. There must surely be some mistake here, as by all accounts some of the epidemics, as that at Hettstadt, were very fatal. All these epidemics arose from eating pork loaded with trichinæ, either raw, smoked for much too short a period, or, more rarely, imperfectly cooked. Pigs in Germany are not infrequently the subject of trichinæ. In about 25,000 examined in Hanover, 14 such were found, and 16 out of 14,000 in Brunswick. The animals or their flesh present no peculiarities in appearance, unless examined by the microscope. This examination is quite conclusive—unless, indeed, the flesh of a diseased animal be chopped up amidst that of numerous healthy ones, when it may escape detection. The evident utility of this examination has induced various governments and provinces in Germany to render it obligatory, as at Hanover, Brunswick, Magdeburg, Görlitz, etc.; and although the butchers in the other parts of Northern Germany have announced that they have their meat carefully examined, the Reporters regard this as altogether destitute of security. The examination to be of real practical utility must be rendered obligatory, however difficult it may be to provide an organisation for this. They see no occasion at present to institute any such examination in France, where neither human nor porcine trichiniasis has yet been met with; and in spite of the exaggerated fears which have of late been excited, they see every reason to expect the immunity to continue. Trichiniasis is now so well defined by its symptoms as to admit of its ready detection, and although it has prevailed and does prevail in Germany, both epidemically and sporadically, nothing analogous has been observed in France. The rats which frequent the sewers, *abattoirs*, etc., in Germany has been found loaded with trichinæ, but the French rats examined by the reporters have not exhibited these parasites. The habits of the two countries are, moreover, so different, for while in Germany the working classes eat the pork either raw or insufficiently prepared, in France they only consume it after being well cooked. Although the Reporters do not recommend an obligatory microscopic examination to be made in France, they recommend that such examinations should, as a matter of investigation, be constituted in some of the towns having *abattoirs* at various parts of the French territory. The heart, liver, kidneys, brain, and fat have never been found to contain trichinæ, so that the most timid may consume these parts without fear.

We may direct our readers' attention to a highly interesting clinical account of trichiniasis by Professor Lebert, of Breslau, now publishing in the *Gazette Médicale*, the material being derived from a small epidemic which he witnessed.

Some interesting statistics have recently been published, showing that Paris is not only progressing in embellishment but in the means of increased viability by reason of the large spaces rendered accessible to the public. Its superficies has increased from 1104 hectares (a hectare being about 2 acres

1 rood English) in the reign of Louis XIV. to 7450 hectares in that of Napoleon III. The Bois de Boulogne alone contains 800 hectares. In 1856 there were 1168 streets and 44 "chemins." There are now 1898 streets and 127 "chemins." The number of boulevards and "places" has more than doubled since the annexation of the ground between the old octroi and the fortifications. Independently of the old "boulevards exterieurs," now a magnificent promenade, and of two parks in process of execution, eight "squares" have been formed in Paris, measuring together 61,284 metres, or more than 6 hectares. The *population* has increased from 530,600 in 1806 to 1,696,141 in 1861; and it is estimated that the new census now being taken will bring it up to 1,800,000. The mean annual number of *births* was 29,016 from 1831 to 1841, and 31,759 from 1841 to 1851. In 1864 they amounted to 53,835. The *deaths* were in that year 8922 fewer than the births. From 1831 to 1850 there was 1 birth for 30 inhabitants, and 1 death for 32. In 1864 there was 1 birth for 31 inhabitants, and 1 death for 35. For the whole of France, according to the last statistics, there is 1 birth in 35 inhabitants, and 1 death in 41. The quantity of butchers' meat consumed in Paris between 1851 and 1854 was calculated at 62 kilogrammes per individual per annum, while by 1864 this quantity had risen to 68 kilos.

THE EXHIBITION OF OBSTETRICAL INSTRUMENTS.

The Obstetrical Society is to be warmly congratulated upon the success of their *conversazione* held last week at the College of Physicians, and the display of obstetric instruments, so fully appreciated by the large gathering of visitors present on the occasion. There must have been some hard work done, to have secured, out of the heterogenous total of contributions, the well-arranged order in which the various objects of interest were displayed; and the Society must not forget that praise is peculiarly due to its President, Dr. Barnes, who was the original projector of the Exhibition. It was through his personal instrumentality that the Library of the College of Physicians was secured, that contributions were obtained from Russia, Italy, and Belgium, and a great many difficulties and doubts dispelled. The Society, no doubt, will find some way of recording its satisfaction at the labours of Dr. Barnes and the committee associated with him. We should be also unjust if we did not specially mention the valuable services of the Secretaries. Amongst those present, in addition to a large number of our well-known London *confrères*, we noticed Dr. Martin (Berlin), Dr. Lazarewitch (Kharkoff), Drs. McClintock, Beattie, and Kidd (Dublin), Dr. Wilson (Glasgow), Dr. Aveling (Sheffield), Dr. Hall (Brighton), Dr. Lumley Earle (Birmingham), Dr. Payne (Wimbledon), Mr. Baker (Derby), Dr. Middleton (Brussels), Dr. Rausch, Dr. Bräumler, Dr. Stillwell, Dr. Bennett (Beamston), and a full attendance of the country Fellows generally. Sir J. Simpson and Dr. Keiller came up from Edinburgh and spent several hours on Wednesday in examining the instruments removed to the Medical Society's Rooms in George-street. We are given to understand that it is the intention of the Society to publish something in the shape of an illustrated report. This will be very acceptable indeed.

We noticed last week the order adopted in the general arrangement of the instruments. How shall we classify the vast array? We think the best plan will be to make a kind of physiological or pathological scheme; to reckon up all the various affections to which the sexual organs of woman are liable from youth to age; and to give with each a slight sketch of the appropriate instruments and appliances that were exhibited.

We will first take the affections peculiar to the unimpregnated state; afterwards the impregnated.

First Division.

Beginning with the *virgin state*, we may mention that marvellous antique machine, in the Archæological series, entitled the *girdle of Venus*, which should rather have been called the girdle of Diana, as it was intended to secure the observance of Diana's law. There is a proverb that love laughs at locksmiths, and in any case we may assert with the poet that it is better to

"Put the padlock on the mind."

The same may be said of gloves to be worn during sleep, secured with padlocks, made at the suggestion of Dr. Brown-Séquard by Mr. Pratt.

For *imperforate hymen*, trocars, bistouries, etc., *passim*.

Vascular tumour at orifice of urethra, caustic, and caustic holders, see *infra*.

Inflammation and Suppuration of Vagina.—Dr. Barnes, a caoutchouc bag for keeping the canal open and the inflamed surfaces asunder, on the principle of giving them rest.

Vaginal Douches.—Dr. Sansom, a self-filling india-rubber bag, with long tube. Messrs. Weiss' "Uterine Douche, 1865;" bag to be suspended; long syphon tube. Self-acting douche by Weiss and Son; like a bidet; the reservoir under the seat, so that patient's weight is made to propel the water. M. Lüer, of Paris, exhibited apparatus for applying pulverised liquids to the vagina and womb.

Womb, Affections of (engorgement, hypertrophy, erosion, ulceration, polypus, and morbid growths).—The *Specula* numbered between sixty and seventy. One which attracted some attention was the small pocket bivalve speculum of Weiss and Son, in which a simple screw mechanism of good strength is so arranged as not to interfere with a full view of the vaginal passage. Amongst others were Sir J. Simpson's trivalve portable speculum; Scanzoni's; a modification of Cusco's, with portable handles, which double up conveniently for pocket use; a portable duck-bill speculum made by Pratt, in which the blade unscrews from the handle part; vaginal retractor or spatula by Fergusson; another by Professor Fabbri; a long vaginal spatula by Jobert de Lambaelle; a curved vaginal speculum by M. Jobert; Maw and Sons' duck-bill speculum; Dr. Tyler Smith's bivalve, made by Weiss; Hilliard's, by Fergusson, forming, when opened by a screw action, the three sides (two lateral and inferior) of a square; a simple *two-bladed wire speculum*, acting on reverse principle to bull-dog forceps, closed by compression for introduction, and opening by its own elasticity, by Mr. Olsen, of Christiania.

There were three *Hysteroscopes*—one by Dr. Tyler Smith, in which the light which entered fell on a mirror at the bottom of the speculum, and was then reflected through a special tube two inches long, which projected as a fixed part from the speculum, and was passed into the uterus, the internal surface of the latter being reflected on to the mirror at the bottom of the speculum. A second was by Krassovsky; a third, a simple bent metallic tube, gradually narrowing, by Grunevaldt.

Dysmenorrhœa.—Uterine Dilatation. Verrier's Uterine Dilator, a straight short vulcanised tube, closed at the top, and with an inch at the top quite thin. This is introduced into the cervix and inflated.

Tents of machine-compressed sponge by Coxeter; laminaria tents, solid and tubular, by Krohne and Sesemann; tents compounded of sponge and laminaria by Dr. Wiltshire, of Islington.

A *tent conductor*, consisting of a central wire in a tube, made for Dr. Barnes by Weiss.

Dilators of the Uterine Cervix.—These may be conveniently classed into four groups. 1. Those which carry out the original idea of Weiss, in which the two halves separate and bow out, though the point remains solid, as in those of Dr. Thompson, Dr. Priestley, and M. Matthieu. 2. Those in which the stem of the dilator is simply split into two, as Mr. Ellis's. 3. Those in which the instrument resembles a split sound, but is jointed at the terminal end to allow of the expansion; to this group belongs Dr. Marion Sims's, the handle of whose instrument is like ordinary forceps. 4. Those in which there is a combination of these two above modes of construction, as Dr. Hamborough's and Dr. Greenhalgh's, both of which have a central bar, or central piece, from either side of which the dilating springs take origin. In all the dilatation is effected by a screw action at the end of the handle. Dr. Bryant exhibited a case of cervix dilators. Dr. Routh a dilator of the female urethra.

Engorgement.—A good many knives of ordinary construction for scarification were exhibited. Especially noticeable were the scarificators of M. Lüer, consisting of a glass speculum, through which passed a moveable knife; an artificial leech made upon a like principle by Mr. Stille, of Stockholm, and the knife of Weiss; also Routh's uterine scarificator by Coxeter

Uterine Sounds.—Of these there were three kinds. *The first*, in which the sounds were all of one solid piece curved to the required shape; *the second*, in which the uterine or terminal part was moveable before the introduction of the instrument, as in instruments by Dr. Sims, and Dr. Haake, of Leipsic; and *the third*, in which the uterine portion was moveable at will, even after the introduction, by means of a screw action at the end of the handle, the most perfect being that of Dr. Lumley Earle, made by Fergusson.

Scoops.—M. Recamier's, exhibited by Luer; Sir J. Simpson's, made by Fergusson, for removing cauliflower excrescences; Sir C. Locock's scoop for soft polypi, and others.

Intra-uterine Syringes (impregnated or not).—A large one of Prof. Lazarewitch, consisting of a curved pipe and a large 10-ounce syringe for the purpose of throwing iced water, perchloride of iron solution, or other fluids into the uterine cavity. Fergusson's — a simple compressible ball with a catheter stem. Dr. Marion Sims'—a long glass tube connected with a syringe, the piston being worked by a screw action. Lüer's—being workable by an ordinary pump piston action, fitted with a *rondeau*, that runs upon the piston-rod to regulate the amount of fluid. There was also a syringe with attached curved tube of Krassovsky for injecting the uterine cavity. Dr. Hennig showed a syringe to draw out any mucus from the uterus—"Tuyau d'aspiration de la Matrice."

Bladder.—A catheter spray producer: quite a novelty, for introducing various solutions into the bladder in the form of spray, or for the purpose of washing out the bladder.

Caustic-holders, etc.—Of these there were eight or nine, including those of Mr. Ellis, Dr. Barnes (consisting of a roughened point, which is charged by steeping it in fused caustic), Sir J. Simpson's (a canula capable of holding the caustic, which is pushed out by a stilette arrangement), and that of Mr. Stille, of Stockholm (made up of coiled solid silver so as to constitute a flexible tube, which can hold a piece of caustic in its end capable of being turned round in any direction). Mr. Stille exhibited a second form for fluid applications. It consisted of a hollow female catheter and a stilette armed with sponge. Mr. Fergusson showed a caustic-holder for use without the speculum. The gas cautery of M. Nélaton, a large caoutchouc bag with a hollow tube or burner, was exhibited by Fergusson.

Hysterotomes and Metrotomes were of various makes. M. Smith, Surgeon in the Army of Christiania, exhibited a double knife with a mechanical dilatorium. Professor Faye, of Christiana, single edged probe-pointed knives of various curves for use with the speculum. A good many were constructed upon the principle of Civiale's urethrotome; such were Routh's, Greenhalgh's, Sköldberg's, and Weiss's. Mr. Spencer Wells's hysterotome cuts as it expands. In most of the instruments exhibited the blades are expanded when introduced, and the cutting effected by drawing the knife downwards. Dr. Sims's instrument can be used either as a double or single-edged knife. Sir J. Simpson's is a single-bladed hysterotome. We noticed Dr. Coglan's double-edged knife with a projecting neck, Whitehead's hysterotome, and others. Dr. Aveling's possesses some special features. In the majority of hysterotomes the blades are protruded, so as to form a triangle with the apex turned towards the handle; in Dr. Aveling's, which is a single-bladed instrument, the blade works on a pivot at the extremity of the stem, and when it is protruded the *base* of the triangle is turned towards the handle of the hysterotome.

The single-bladed form is adopted by Dr. Aveling, in the belief that where there is a double blade the thin healthy part often gets cut through whilst the indurated cervix escapes, and the object in having the blade to open from above downwards and outwards is this, that the diseased structures are incised at the spot where cutting is most wanted, whilst the healthy structures are not damaged.

Medicated Pessaries, vaginal and uterine, shown by Mr. W. T. Cooper, chemist, of Oxford-street, and containing morphia, belladonna, iodoform, iodide of lead, oxide of zinc, borax, opium, matico, tannin, lead, and other medicinal compounds.

Iodised cotton, used by Dr. Greenhalgh.

Carbolic acid, with and without glycerine, by Calvert.

Amongst the instruments used for introducing substances into the uterus, may be mentioned that of Dr. Savage, like a long pair of narrow forceps, forming when shut, at the terminal end, a little hollow tube, which would contain any solid or fluid, and could be opened for the escape of its contents in utero. Dr. Marion Sims' syringe for intra-uterine injection, like an ordinary little brass syringe, to which is fitted a long glass tube. Sir C. Locock's tube glass sponge, for sponging out the os uteri.

Womb, Displaeements of— Prolapse, Ante- and Retroversion—Pessaries.—We saw no globular or any box pessaries save one antique specimen exhibited by Professor Faye, of Christiania.

Pessaries may be divided into 1, the simple contrivances for keeping up the womb by distending the vagina; 2, those which have besides a stem attached to external bandage. For description's sake, in the case of compound pessaries, we speak of that part on which the womb rests, as the receptacle, or *hysterophore;* 3, those provided with intra-uterine stems.

The variety of which the largest number was exhibited was decidedly *Zwancke's*. This we may call the *butterfly pessary*, inasmuch as it consists of two wings, joined by a hinge in the middle, the two wings being capable of being compressed together for introduction, and then of expanding laterally within the vagina, so as to resemble a butterfly with wings expanded. There was Zwancke's pessary with German silver cradle receptacle, modified by Dr. Tanner, and made by Coxeter; one with solid wooden receptacle, by Durroch; the same in vulcanite by Maw, Coxeter, and Pratt. Zwancke's pessary, modified by Professor Giordano, of Turin; one specimen made of zinc and copper wire so as to establish galvanic action.

Hodge's Pessary.—A ring of flexible wire or gutta-percha, bent more or less into the shape of a Jew's harp, or imperfect figure of 8. Modification by Sir J. Y. Simpson; made by Young, of Edinburgh; the inferior loop narrow. Routh's modification, made by W. Russell, 58, George-street, Portman-square; the inferior loop broad; the same in vulcanite, by Mayer and Metzler, 59, Great Portland-street; the same in malleable gutta-percha and in vulcanite, unvarnished, by Russell.

Hodge's Pessary in horseshoe form, ends of the lower loop open.

Meigs's Ring Pessary, made for Dr. Marion Sims, by Mayer and Metzler.

Reid's Spring Pessary, 1840, *by Fergusson.*—V-shaped receptacle of vulcanite, kept open by a spring.

Pessaries consisting of *india-rubber bag*, to be introduced flaccid, and then inflated through tube attached; Dr. West's and Dr. Barnes's varieties, were exhibited by Weiss and S. Maw. (See also dilatation of os uteri, Barnes's bags, and air balls used as plugs.)

Pessaries supported by stem and bandage.—Several old-fashioned varieties in boxwood; some with globular, some with cradle tops, exhibited by Professor Faye, of Christiania.

Professor Lazarewitch's *Redresser for the Uterus.*—A wire loop, covered with thin rubber for receptacle, a curved wire stem, and a wire disc to lie over the pubes, and be supported by a circular bandage. *Duffin's* Pessary.—The receptacle a half sphere of wood, two inches in diameter, perforated with holes; resting on an ivory stem, which again rests on a small wooden disc outside the vulva, to be kept *in situ* by a bandage. *Dr. Fred. Bird's* Pessary.—A vulcanite receptacle one and a-half inch in diameter, with a stem four inches long. *Roper's* Pessary, made by Walters, of 16, Moorgate-street.—A good one; vulcanite receptacle, thin stem, and external wire pad, supported by bandage. Mr. Peter *Magennis's*, made by Pratt, of Oxford-street.—India rubber receptacle, German silver stem, and large outer wire disc to be affixed to bandage. Sir J. Y. *Simpson's* Stem Pessary.—Transverse oval receptacle three inches by two inches. Dr. *Priestley's* Pessary for Retroversion and Anteversion.—A "Jew's-harp" loop supported by straps and bandage. *Coxeter's* Pessary.—A hollow receptacle covered with perforated india rubber, solid curved stem. The same with an air cushion affixed to the top, capable of inflation, by Coxeter. *Priestley's* Pessary for Ante- and Retroversion.—Broad spoon-like bag, capable of inflation, placed before or behind cervix; tube for inflation, double vulcanite stem. *Hysterophore*, by Professor Breslau, of *Zurich.*—Receptacle shape of inverted mushroom, caoutchouc stem and bands. *Nyrop's Pessary*, as given to the poor of Copenhagen.—Concave wood receptacle two and a-half inches in diameter, stem capable of lengthening telescopically, outer wire support to be affixed to bandage. *Calthrop's* Band for Ante- or Retroversion.—A wire loop receptacle covered with sheet rubber, supported on a spring attached to an efficient leather abdominal belt. *Graily Hewitt's* Apparatus for Retroflexion, consisting of hollow distensible rubber bag pessary, on ivory stem two inches long.

Intra-uterine Supports.—Sir J. Y. Simpson's Uterine Stem, in German silver, by Fergusson; the same in wood and ivory, as modified by Professor Martin, of Berlin; in horn, by Pro-

fessor Faye, of Christiania. Sir J. Y. Simpson's, perfectly straight and solid; Balandins, of St. Petersburg, complicated; Dr. Wright's, very simple; the diverging spring is shut or withdrawn by means of a grooved canula, and the little support retains its place by simple elasticity, and no speculum is required for its introduction. In addition, a fourth kind by Dr. Greenhalgh, and a fifth by Tarnovsky may be mentioned.

For Prevention of Uterine Displacements.—Good abdominal or rather pelvic belts, with T strap and air-pad, to press on perineum, exhibited by Salmon, Coxeter, Nyrop, and Russell. A very efficient looking one with Dr. Priestley's name attached.

Subsidiary Apparatus.—Air-syringes to fill india-rubber bags, by Pratt, Sköldling, etc.

Screw for removing impacted pessary, by Fergusson.

In concluding our remarks on the long list of apparatus for palliating uterine displacements, we can but be struck with the carelessness which allows sufferers from "pain in the back," etc., often to go for years without seeking efficient aid; till an over-weighted womb, and distension or elongation of a few muscular fibres induces one of these distressing forms of infirmity, which all these elaborate mechanical contrivances can but make a little more tolerable.

Operations on the Unimpregnated Uterus Generally.—Dr. Marion Sims's reclining-chair, a very comfortable easy chair, for any one; is so balanced that it follows the slightest movement of the patient. Many of these chairs were ordered by visitors from the exhibitors, Mayer and Metzler, 58, Great Portland-street, W.

For drawing down and fixing the womb: a corkscrew tenaculum by Dr. Routh; vulsella of Museux, etc.

A needle-hook, by Dr. Routh, for taking up uterine arteries.

Lint and sponge-holders, by Weiss and Son.

Polypi.—Écraseurs, about thirty in all, most of them working on the ordinary principle of Chassaignac; two, however, were so constructed as to be worked at right angles to the stem, and were exhibited by Dr. Haake, of Leipsic, but in the larger one, the rack being in the middle of the stem, seems to be inconveniently placed; the small one was free from this objection, being worked by a handle placed at the bottom of the instrument. A small one by Maissoneuve, another by Dr. Hicks; and Dr. Sehlberg; a double one by Weiss, securing alternate action by means of a screw; a curved one with friction rollers by Pratt, and Spencer Wells's wire écraseur were among the remainder. Mr. Ellis's galvanic cautery for polypi.

Polyptrite.—Dr. Aveling's polyptrite is manufactured on the principle of a lithotrite; there is a basis like a blunt hook, grooved on the inner side, and into this groove fits the female blade, which has a terminal projecting bar, one and a-half inches long, placed at right angles to it. The hook is introduced over the pedicle, the female blade pressed up towards the pedicle, and then forced home by the working of a screw, as in the original lithotrites; there is no cutting blade, only a crushing one. On the outside of the stem is a flat piece by which the instrument is steadied, so as to prevent its rotation during the operation.

Vulsella were well represented. Dr. Priestley exhibited a complicated pair by Robert, in which a terminal set of teeth could be projected at right angles to the stems after introduction of what looked like a pair of polypus forceps with flat terminal ends. Dr. Greenhalgh's vulsellum has a series of notches on the stem, so as to form several quasi-joints, in which the bottom-like pivot of its fellow fits. In addition there were several four-pronged vulsella—viz., those of M. Melle, and the canular vulsella of Dr. Greenhalgh; then the double hooks of Museux, and Sir J. Simpson's vulsellum, which is made with separate blades on the principle of the forceps, which can be introduced one at a time. Polypus scissors were in abundance. We notice two special ones, in which the cutting part was as near as possible at right angles to the stem. Most operators have experienced very much difficulty in obtaining scissors cutting at right angles. Dr. Hugenberger showed one pair constructed for the purpose of cutting off little pieces of mucous membrane or other structure for examination; and a second and stronger pair, made for Dr. M. Sims, was exhibited by Mr. Pratt. M. Lüer's tumour fixers consisted of a canula with a bell-shaped end; inside runs a stem, at the end of which are two divergent hooks, which can be retracted within the bell-shaped end of the canula. The instrument is applied to the tumour, the hooks protruded, and then the tumour is fixed by a screw-like action. A second pair of M. Lüer's consists of simple open fenestrated blades. Beaumont's instrument for tying uterine polypi. Curved scissors by Mr. Stille, Lüer; and spring polypus scissors of Mr. Harper.

Ovariotomy.—Several complete cases of instruments required in the operation of ovariotomy. One by Messrs. Weiss, made for Mr. Spencer Wells; a second for Mr. Baker Brown, by Mr. Pratt. Several clamps were exhibited; one used by Mr. Brown, when the actual cautery is desirable, opening like a pair of scissors; Mr. Hutchinson's, and that of Dr. Clay; also a pair of forceps for holding the abdominal parietes, exhibited by Pratt. Mr. Chambers has sought to avoid the unequal pressure supposed to be produced by ordinary clamps by the construction of another, in which the two halves open equally in parallel lines by means of a small windlass at the base of one handle; the blades are approximated equally from the top to the bottom, so as to compress the pedicle equally. A third, scissor-shaped, by a French maker, had a semi-circular instead of a straight grip. Mr. Wells' trocar has a fixed vulsellum forceps arrangement on either side of the canula. Mr. Chambers' trocar is furnished with a single set of teeth, which are moveable up and down the shaft of the instrument, for the purpose of enabling the sac to be grasped when it is difficult to withdraw the sac any distance from the abdominal wall. Weiss exhibited a set of Mr. Wells' hollow trocars, with a simple improved Higginson's syringe, by which fluid can be injected into or removed from a sac. Also a neat uterine case, 8 × 3 inches, containing fourteen instruments and two bands, including sounds, knives, needles, hooks, caustic, and lint, and potassa-fusa holders; also a lamp to buckle on the forehead, with a moveable reflector, of use in reflecting light into the vaginal or other canal during operations.

Second Division.—The Married and Impregnated States.

Hymen and Vaginal Orifice Thickened, Rigid; Vaginismus, etc.—The only special instruments noticed were Weiss's three-bladed dilator and three-bladed speculum, made upon the principle of old instruments, and an antique dilator, lent by Mr. Robins, composed of a round tripartite wooden stem, dilatable by a lateral screw action.

Pregnancy, diagnosis of.—Küncke, a double stethoscope—*i.e.*, two india-rubber tubes, one going to each ear, for the detection of twin pregnancy, by comparing the number, force, and place of the two fœtal hearts. Dr. Routh's double stethoscope, with intensifying membrane for getting one sound. Routh's vaginoscope, a curved glass acoustic tube for application to the os uteri.

Pregnancy, Adominal Supporters, Belts, etc.—A good spiral silk abdominal bandage by Russell; also a good stocking for varicose veins of leg. Other bandages by Pratt, Salmon, etc.

Abortion.—Abortion Forceps.—Those of Sir James Simpson, about ten inches long; of Weiss and Son, very thick and strong, with open blades; a small pair of Dr. Cory; those of Lüer, of Paris; and several scoops of Boujalsky, of wood and metal, for the purpose of scraping out the ovum from the uterine cavity.

Induction of Premature Labour.—The fiddle-shaped india-rubber bags of Dr. Barnes, dilatable by water pressure; and a modification or copy almost by Tarnier, of Paris, consisting of a deeply-grooved sound, holding in the groove a piece of india-rubber tubing. The sound is introduced into the uterine cervix, and fluid is then injected up the tube, which dilates at the terminal end in consequence of the greater thinness of its walls there.

Hæmorrhage before Labour.—Braun's eolpeurynter; a folded vulcanised caoutchouc distensible bag, to act as a plug, exhibited by Sköldberg. Another variety by Mr. Stille, of Stockholm, also exhibited by Sköldberg. It is provided with an additional small india-rubber tube, passing through the centre of the air-bag, open at top, and closed by a tap below. By opening this tap it may be known whether hæmorrhage is going on above the plug, without relaxing or removing the latter.

Vaginal bags, distensible by air or water, modified by West, Barnes, etc., and exhibited by Weiss, Maw, and Pratt.

Greenhalgh's expanding felt plug; the felt surface makes it a more efficient plug, and accelerates coagulation.

Labour.—Puncturing the Membranes.—There were several instruments for this little operation. Those of Dr. Lee Dubois consisting of a whalebone flexible stem, tipped with an ivory spear-point. Dr. Braxton Hicks's seemed the least objectionable, the pointed stilette being very small, the inventor relying

upon a slight lateral or scratching movement to effect the rupture of the membranes, so that the child should not in the least be injured.

Fillets.—Of these instruments, almost unknown to London Practitioners, two were shown. They consisted of wooden handles, into which were inserted whalebone loops of sufficient size to go over a child's head. Dr. Radford exhibited one, the other was shown by Dr. Williams, of Wrexham. Some Practitioners prefer the fillet oftentimes to the vectis or forceps, and believe that they are excitors of the reflex muscular action. It is not likely that our shrewd and energetic brethren should be mistaken, still we cannot help remembering the great Dr. Merriman's story of the man who used a fillet, and succeeded in bringing away, not the child's head, but one of its cervical vertebræ.

Obstrueted Labour—Forceps.—These numbered more than 100. "The Chamberlen case," containing three vectes (two combined hooks and crotchets and one simple crotchet) and four pairs of forceps. On one table were shown fifty-five pairs of long forceps, including those of Simpson, Barnes, Greenhalgh, Lever, Oldham, Hugenberger, Levy, Hennig, Martin (of Berlin), Busch, Ramsbotham, Krassovsky (of St. Petersburgh), Churchill (long), Blundell, Roberton, Waller, Murphy, Radford, Boerg, Naegele (two), Caderaehjold (of Stockholm), and those of Richter, with which the present Emperor of Russia was brought into the world. We may give some of the weights of these :—*Long Foreeps.*—Lovati (Assalini's joint), 1½ lb.; Cozeaux, 1¾ lb.; Saxtorph, 1½ lb.; Naegele's, 1½ lb.; Simpson's (long), 1 lb.; Lazarewitch (Assalini's joint), 1 lb.; Simpson's (jointed), 1¼ lb.; Ditto (common, used as long or short), 1¼ lb.; Oldham's, 1 lb.; Simpson's (long, by Maw), 1⅛ lb.; Ditto (by Weiss), 1 lb.; Greenhalgh's, under 1 lb.; Barnes' (Weiss), 1 lb.; Lever's (Durroch), 1 lb.; Boerg, 1 lb.; Radford's (Fergusson), 14 oz.; Levy's (Coxeter), 1 lb.; Sir J. Simpson's (Fergusson), under 1 lb.; Blundell's (Weiss), 1 lb.; Roberton's (Coxeter), 1 lb.; Matthews Duncan's, 1 lb. Sir J. Simpson's forceps are all made with roughened handles, and generally with transverse shoulder-pieces. In Sir J. Simpson's jointed forceps the blade and handle parts are connected very much after the manner of a lady's parasol, and are conveniently made for pocket stowage. Some of the foreign instruments are constructed of one solid piece—*e.g.*, those of Tacitarni, of Naples, working on a common pin screw-joint; of Professor Levy, used in Denmark; Saxtorph and Charriere, Nivet de Clermont, Trèlat, Lazarewitch, Siebold (made thirty years ago and used in Russia by order of the Government), Cazeaux (1835), and Lovati (of Pavia). Most of the forceps are constructed with the ordinary lock joint, two with Assoline's (Lovati and Lazarewitch).

The Short Forceps—about thirty-eight in all—occupied a separate table, and included those of Denman, Graily Hewitt (two), Murphy, Sir J. Simpson, the forceps commonly called English in Sweden (exhibited by Dr. Sköldberg), Jorg's, Naegele's (with bottom joint); those also of Churchill, Trelat, Gayton, Greenhalgh, Chassagny, Beattie, Hamilton, Davis, and Assalini, in which the joint is at the terminal end of the handle, a modification of this being seen in those of Mondolle, where a transverse circular bar at base receives the ends of the two handles. There were also some curiosities in the shape of two pairs of Japanese forceps, the one lent by Dr. Tyler Smith, the other by Dr. Matthews Duncan. They were small, with fenestrated blades; and a small craniotomy forceps of Japanese make. It is imagined that the Japanese may have got some ideas as to the construction of these instruments from the Dutch. There was also a pair of face blades of Dr. Davis's for the position of the face towards the right ilium.

A mechanical apparatus for the extraction of the fœtal head, invented by Dr. Hoffmann, of Molde, in Norway, for the purpose of giving additional power to his own naturally weak arms. The apparatus consists of a forceps with a specially constructed handle, two iron rods, and a windlass arrangement. One of the ends of each rod is furnished with a pad; the other is capable of being connected with the handle of the windlass. The forceps is applied in the usual way. The padded ends of the rods placed one on either side near the inguinal region, the other ends are connected with and converging to the point of the handle, forming together a triangle with the apex at the handle of the forceps, the latter occupying the middle of the triangle. Now the lateral rods afford fixed points near the thighs, and by means of a mechanical windlass arrangement traction is made upon the forceps. The operator takes charge of the forceps, leading it in a proper direction, whilst an assistant turns the winding handle and makes the extraction gently, according to the wish of the accoucheur.

Foot Presentation.—Forceps for holding the child's foot, similar to hæmorrhoidal forceps on a large scale, by Professor Nyrop, of Copenhagen; Lollini, of Bologna, exhibited by Dr. Priestley; and Gronning, exhibited by Professor Nyrop.

Funis Presentation.—Sir C. Locock's instrument for the reposition of the funis, and that of Dr. D. Davis's amongst Dr. Radford's collection.

Impossible Labour.—Perforators.—A great many, too numerous to name in detail, made after the usual fashion. Two special ones attracted attention—the one by Professor Braun, of Vienna, consisting of a large tube containing a circular-toothed saw and screw—in fact, it is a large trephining instrument, worked by a screw; the other, that of M. Lüer, with a bell-shaped end, containing two blades, with a screw in the centre working laterally. The difference between the two consists in this, that when the skull is cut through, in M. Lüer's the blades and screw fly back on account of a specially-constructed screw arrangement; whereas in Professor Braun's, it is necessary to retract the cutting part by reversing the direction of the screw.

Craniotomy Forceps.—About twenty-four in all, including those of Dr. Barnes, Sir J. Simpson (cranioclast), Churchill, Conquest, Hall, Davis, Lever, and Priestley; and the identical craniotomy forceps and hooks used by the late Dr. Merriman during his long course of Midwifery practice. In addition, there was a good display of vertebral hooks, crotchets, blunt hooks, and embryotomy scissors.

Amongst the *Decapitators* may be mentioned that of M. Matthieu, consisting of a canula, freely jointed at the upper end, so that it could be made to assume a curved or straight position. Within this canula ran a knife curved like a blunt hook, which could be projected from the sheath or retracted, when the end of the canula assumed the curved form. It is introduced guarded, and looks like a blunt hook. When applied round the neck, traction is made on the canula, and the knife exposed. After the cutting is over, the knife is readily sheathed before withdrawal. It is simple, and most useful. It could be used for polypi.

Individual Collections of Instruments.—Dr. Cory exhibited some twenty-three instruments, amongst them were the forceps of Levret (1747), three pairs of Smellie (1752), those of Lowder (1771-93), R. W. Johnson, a pair contemporary with Chamberlen (1700), Jacques Mesnard (1741), Burton (1751), and vectes of Lowder, Bland, etc.

Dr. Radford sent a very large number of antique instruments, exhibited on a separate table by themselves. Nine vectes, Ogden's, D. Davis, Bland, and others; about thirty pairs of forceps,—viz., those of Osborn, Smellie (short), D. Davis, Johnston, Bandelocque, Hamilton, Conquest, an antique French pair in two solid halves, Orme (short), Rivers (short), Haighton (long and short); Denman; Bandelocque's pelvimeter; Dr. Davis's funis replacer, crotchets, scoops, blunt-hooks; Davis's osteotomist and his guarded crotchet; Craniotomy forceps of Holme and others. The most curious was an instrument consisting of three blades, which when joined formed by their base (as shanks) a long screw, fitting into a wooden handle accurately wormed to correspond to the tripartite screw stem. Each blade can be introduced separately, the handle then fitted on, and the blades approximated to any required degree. Nothing is known as to the inventor.

Suction Apparatus.—Sir J. Y. Simpson's original bell-shaped, exhausted with attached syringe, was exhibited, and the modification constructed by Mr. Lüer in 1848 for use in craniotomy. Mr. Lüer proposed first to use a species of perforator, then to apply a long glass tube to which is attached an india rubber ring, which should fit closely to the child's head, to exhaust this tube, and thus get away as much brains as possible; then to apply another tube containing at its upper end two projecting arms capable of expanding laterally when introduced into the hole in the skull, and by which means a hold might be obtained in the cranium; then to exhaust again till the head collapsed completely. Messrs. Krohne and Sesemann, of Whitechapel-road, exhibited several complete complete cases of midwifery instruments for ordinary and consulting practice.

Cephalotribes.—Thirty in number; peculiarly novel to the eye of the English obstetrician. Sir J. Simpson's is the only English one amongst the number. At a glance one sees that they indicate a different style of practice—at any rate, of mechanical appliances, adapted to break up the child's head. In all the cephalotribes the screw power is connected with the

right handles, indicating their inapplicability when the patient is placed upon her left side, according to English custom; in fact, they could only be used when the patient was lying upon her back. All have the fulcrum in the centre with the exception of two; viz., those of Assalini and Lazarewitch, which have what is well known as the "Assalini joint." In this case the working power is that of a common screw placed transversely at the centre of the instrument—an inconvenient arrangement, perhaps, in operating, and of deficient power. Some of the cephalotribes have open fenestra, but in the majority the blade is solid. Amongst these formidable instruments was the original one of Bandelocque, presented to the Obstetrical Society by Madame Petit Jean in 1865, weighing 4¾ lb., 21 in. long, with blades 1½ in. wide, by ¼ in. in thickness. One wonders when the head is jammed in the pelvis how such a huge thing could be introduced without producing additional mischief. Sir J. Simpson's, the smallest, about half the size of the other, weighs 1½ lb., and is only 13 in. long; Professor Faye, 20½ in. long and 3 lb. in weight; those of Depaul, Assalini, Martin, 17 in. long, in weight 3 lb. 2 oz., made with open fenestra, and a curve as near as possible that of the pelvis, this being one of the chief points in the construction. There were others in which the two handles were approximated by means of a chain, which attached to a hook at the bottom of the right handle, then ran round a pulley at the end of the opposite handle, and, by means of a screw-like action, ran up along a bar placed parallel to the handle at its inner side, and reached up to near the junction with the blade: it was the transverse screw action prolonged upwards along the handle of the opposite side, so to speak. That of Dr. Etlinger and Hugenberger, 3 lb. 4 oz. in weight, and that of Dr. Braun, of Vienna, acted on this principle. Lazarewitch's smaller instrument weighed 2 lb., Killian's 5 lb. 2 oz. In some of the cephalotribes there was a combined chain-saw apparatus for breaking up the fœtus, as in those of Billi of Milan, Levret, Faye, and Pajot, four pounds in weight. The chain was passed through a little hole in a transverse piece fixed across the widest part of the fenestra of each blade on both sides, forming of course a bridge across the space or area contained by the blades of opposite sides intended for the child's head. This chain, when the instrument is applied, relaxes before the head or body of the child, and forms a loop over it, and by a see-saw action it is made to cut the opposing part through, until of course it becomes tense again, on the principle of the écraseur. Thus it is adapted for piecemeal delivery in cases of arm presentation, when the womb has contracted so forcibly that it is impossible to alter the child's position. The other cephalotribes were those of Martin, Nyrop, Scanzoni, and Hennig. Baron von Huvel's saw forceps, made somewhat on the same principle as the others for cutting the child's head off, the transverse chain-saw, however, remaining tense during the operation, its level being altered upwards or downwards, by a special mechanical arrangement, the pulleys at each side travelling along a groove in the inner aspect of each fenestrum from top to bottom. In some cases a windlass action is substituted for that of the transverse screw in the closure of the handles.

Hæmorrhage After Labour.—Weiss's tourniquet, a broad, concave pad, covered with leather, to compress womb, and a circular abdominal spring. Dr. Priestley's obstetric binder, pressure being made by a tourniquent acting upon a pad in front.

Transfusion Apparatus.—Those of Dr. Martin, of Berlin, consisting of a small curved and flattened cannula and contained trochar, with a simple glass syringe; Dr. Lumley Earle; Dr. Blundell, improved by Fergusson; Mr. Harper, Dr. Graily Hewitt, and Dr. Aveling.

Vesico-vaginal Fistula.—A good many ingenious needles for the operation of vesico-vaginal fistula; a complete case of instruments, by Weiss; forceps for the contortion of thread, by Heppner of St. Petersburgh; Beaumont's needles; Dr. Sims' needles; Dr. Aveling's shot suture; and needles by Dr. Mesterton of Upsala, etc.

Operating Table for Instrumental Delivery, invented by Dr. Howitz, exhibited by C. Nyrop, Copenhagen. A horseshoe table, adapted to support patients' buttocks and feet in the usual Continental dorsal position of delivery; easily folded and carried.

Umbilical Hernia.—Langhardt's umbilical belt exhibited by Weiss—an ivory pad to fill aperture, and hollow well-adapted pads outside with belt; follows movements of respiration. Pratt's simple umbilical belt, with a water pad, affording the equable resistance of fluid pressure. Pratt also exhibited trusses for femoral hernia, in which the pressure was made by means of a water pad, a great improvement upon ordinary trusses.

Support during Labour.—Obstetric back supporter exhibited by Dr. Woodward—a pad for the back, with circular bandage, and rack to increase pressure.

Binders after Delivery.—A great variety by Salmon, Pratt, and Salt, of Birmingham, Dr. Priestley's consisting of stout material cut to a proper shape, and tightened by simple buckles and straps in front.

Ergot of Rye.—Exhibited by Cooper, chemist, 26, Oxford-street.

Instrument for measuring the length of babies, consisting of a board 27 inches long by 11 wide, with a sliding piece at one end like a bootmaker's wooden measure, and a graduated scale.

Lactation.—Bandages for supporting the breast with a large circular water-pad, which adapts itself to the shape of breast. Exhibited by Pratt, of Oxford-street. Various breast pumps, etc.

Feeding Bottles, by Cooper, Oxford-street.

Chloroform Inhalation.—The inhalers were those of Dr. Townley, Dr. Skinner, Dr. Sanson, and Dr. Kidd. Mr. Baker Brown, jun., exhibited his chlorætherine, for use in ordinary midwifery cases.

Instruments for Producing Local Anæsthesia, Dr. Richardson's, with single and double jets. Exhibited by Messrs. Krohne and Sesemann. Also, a probe-shape tube for inducing local anæsthesia about the os uteri, or introducing a spray of any solution into its cavity.

For Resuscitation.—Galvanic coil, by Ladd.

REVIEWS.

A Treatise on the Principles and Practice of Ophthalmic Medicine and Surgery. By T. Wharton Jones, F.R.S., Professor of Ophthalmic Medicine and Surgery in University College, London; Ophthalmic Surgeon to the Hospital, etc. Third edition, recast, much enlarged, and illustrated by numerous additional engravings. John Churchill and Sons. 1865.

The third edition of such a well-known work as that of Mr. Wharton Jones would not require more than a bare announcement, were it not for the fact that the progress of Ophthalmic science since the last edition appeared has rendered it necessary to introduce a very large quantity of totally new matter. A very brief notice of some of the more important of these additions will be sufficient in the case of a book which has been so long before the public.

The chapter on the Ophthalmoscope is completely new. Mr. Jones gives a brief, but clear explanation, aided by diagrams, of the optical principles upon which the instrument is constructed, showing the mode of exploring the fundus of the eye both by the direct and the indirect image. He then describes the healthy, and some of the more important of the morbid appearances which are thus revealed; a more minute description of some of the latter being given in subsequent chapters, in which the diseases in which they occur are the subjects of consideration. The letter-press is illustrated by two of Professor Liebreich's beautiful chromolithographs, reproduced by his permission; as well as by numerous woodcuts, printed in red ink; and the chapter, though necessarily very much condensed, contains a large amount of valuable information.

Another totally new topic in the present edition is the treatment of glaucoma, or, as Mr. Jones prefers calling it, "arthritic posterior internal ophthalmia," by iridectomy. With regard to the pathology of the disease, his views accord, in the main, with those of most modern writers on the subject, being to the effect that the fundamental morbid condition is great venous congestion of the choroid and retina, with effusion of fluid into the cells of the vitreous humour. He makes one suggestion which we do not recollect to have seen before, that in some cases the hardness of the eyeball is due, not alone to intra-ocular pressure, "but also to extra-ocular pressure, arising from a condensation and shrinking, with loss of elasticity of the tissue of the sclerotica." Such cases must, we apprehend, be rare; as with such a sclerotic complication, it would be difficult to explain the complete and rapid return of the normal tension which follows a successful iridectomy.

Mr. Jones is by no means a warm advocate of iridectomy as a cure for glaucoma. He considers the claim which has been set up for the operation as an unconditional cure, as unfounded. He admits that in acute cases it proves a useful auxiliary to

treatment: with regard to such cases it may be said, "*remedium anceps melius quam nullum.*" In chronic glaucoma he believes the result of the operation to be much less favourable, and refers, as a proof of its inefficiency, to the table of cases in the "Ophthalmic Hospital Reports" for January, 1860.

We confess that we cannot see much force either in the facts or in the arguments adduced by Mr. Jones in support of his views, which seem to indicate a reaction against the somewhat exuberant claims which were set up by a few enthusiasts on the first introduction into this country of Professor V. Gräfe's method of combatting a disease of extreme intractibility. We believe that the great majority of Surgeons who have given it an extended and impartial trial are agreed as to the utility of iridectomy even in chronic glaucoma as a means of subduing pain, and of arresting the farther progress of the disease; though, of course, no one expects that any mode of treatment will restore vision where the retina has been disorganised.

It will be observed that the name of Professor V. Gräfe does not once occur in connexion with this subject.

We have been somewhat disappointed with the chapter on cataract. It contains a good deal of new matter, including some very valuable and practical remarks in the form of "General Observations and Questions Regarding the Operations for Cataract." It contains most minute and elaborate instructions for the performance of the old operations; even "reclination," now so rarely adopted, is favoured with seven pages; but the new operations of Schuft and Mooren are merely alluded to in a very few lines, and the operation by suction of Mr. Teale is not mentioned at all. Surely these are grave omissions. No one can be better aware than Mr. Jones that these operations have been considered worthy of the most careful trial, and that they have ultimately been adopted to a very large extent by a large proportion of the most eminent ophthalmic Surgeons throughout this and other countries, and that the literature of the subject, as contained in the British and foreign Medical journals, is abundant and elaborate. Is it right that students who apply to this work for instruction should find long and minute disquisitions upon exploded proceedings, while such operations as those of Schuft and Mooren are dismissed in a few lines, and that of Mr. Teale is suppressed altogether?

But our limits are reached, and our observations must be drawn to a close. There is much in Mr. Jones's book which is well worthy of perusal, even by the most advanced students, though in many instances there clings to it a flavour of antiquity. We would especially direct the attention of our readers to the chapter on the adjustment of the sight and the use of spectacles, in which the recent investigations of Dr. Donders and others are discussed with a perspicuity and thorough knowledge of the subject, which is the result of long and patient scientific research.

The book terminates with an ample glossary, which will be welcomed by those who believe that uncouth combinations of Greek, Latin, or Arabic have any necessary connexion with the study of ophthalmic Medicine or Surgery.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

Edinburgh, March 28.

Although there has been no event of any peculiar Professional interest since my last letter, the ordinary routine of work during the winter has produced matter of sufficient importance to entitle one or two subjects to be selected and chronicled. Many very valuable papers have, during the session, been brought before the Medico-Chirurgical Society, of which, however, it would be impossible to give an extended account. We will refer in detail to only two of these, not only because of the great ability with which the subjects have been treated, but also as they contain matter of a novel and practically important character. A paper was read at a recent meeting by Dr. Sanders, "On a case illustrating the supposed connexion of Aphasia (loss of the Cerebral Faculty of Speech) with Right Hemiplegia, and Lesion of the External Left Frontal Convolution of the Brain." Dr. Sanders introduced his case by an explanation of the title and a reference to the classification of aphasia into *amnesic* and *ataxic;* the former being a loss of speech dependant on imperfect memory of words, and, therefore, a psychical defect; the latter, on loss of speech due to a lesion of the central and supposed cerebral apparatus of co-ordination for the movements of articulate speech. A distinction of comparatively simple application can be drawn from the circumstance that in the former (amnesic) variety there is loss of the power of writing as well as of speaking, while in the latter (ataxic) the patient so far retains a knowledge of words as to be able to write but not to articulate them. The discussion of the etiology of this disease is new to this country. One of the first important steps towards its localisation was made, in 1825, by Bouilland, who referred aphasia to a lesion of the anterior cerebral lobes. M. Dax afterwards limited the cause to disease of the left hemisphere. In 1861, the lesion was still further limited by M. Paul Broca to the "posterior third of the third external or inferior left frontal convolution." Dr. Sanders' case confirms the view of M. Broca. This patient was a domestic servant, Margaret M., aged 43, who was admitted into the Royal Infirmary suffering from defective memory and imperfection of speech. She was described as showing great distress at her inability to articulate distinctly. A curious symptom was the frequency with which she misnamed things and mispronounced words. She called druggist "yollit," and the firm of Duncan and Flockhart, "Doctor and Forrit." When admitted, there was slight paralysis of the right side, and the left pupil was smaller than the right. In a short time the paralysis extended to the left leg, but this was afterwards traced to an obstruction of the left femoral artery, and suggested the idea that the disease in the left cerebral hemisphere might be due to embolism of the artery of the left Sylvian fissure. On one occasion she was asked to sign her name, and wrote the capital "J," but saw her mistake, and made several ineffectual attempts to correct herself, expressing her disappointment by repeatedly exclaiming, "I can't do it; do it." At the patient's death permission was given to examine the brain alone, and here no disease of any description was found, except at the *posterior portion of the external or inferior left frontal convolution*, and also in the left parietal lobe. We believe that Dr. Sanders has the merit of being the first to give a description in Great Britain of a case of aphasia completed by an autopsy. In connexion with this subject, Mr. Turner, the able and popular Demonstrator of Anatomy at the University, delivered an interesting lecture before the Royal Medical Society in which he explained the principles on which were based the subdivision of the surface of the brain of which future cerebral pathology must take cognizance. We believe with Dr. Sanders that these anatomical and pathological investigations, and especially the remarkably beautiful result in asphasia, will necessitate a greater accuracy in future descriptions of changes on the surface of the brain, and, possibly, a subordination to the system of convolutions which we owe to Gratiolet.

A very valuable paper was read at the last meeting of the Medico-Chirurgical Society by Dr. John Duncan, "On the Galvano-puncture of Aneurisms." Dr. Duncan's patient was a man of 45, with a thoracic aneurism, which first made its appearance in 1863, and in November, 1865, was described as covering one-half of the sternum and about a-half of each clavicle, measuring laterally over its highest point thirteen inches, and protruding so far that when the patient sat stooping from weakness his chin rested on it. Its surface was covered with nodulated eminences, several of which increased rapidly until from one a slight oozing of blood occurred on December 2. The father of the author, Dr. James Duncan, had some years ago made a trial with galvanism for the cure of an abdominal aneurism, and the result had been so extremely satisfactory that it was determined to attempt to postpone death for a short time in this case by the same means. Accordingly, on December 3 the first application was made. Two large needles, insulated to about an inch and a-half from their points, were introduced one in each side of the sac, not far from its base, and were so placed that an inch of each must have overlapped, while lying about that distance apart. These needles were then converted into electrodes by being connected with a Bunsen's battery of four cells. A continuous galvanic current was passed through the aneurism for three-quarters of an hour, by which time there was an apparent diminution in the pulsations. The connecting wires were exchanged, so as to make the positive electrode negative, and the negative, positive. After an application of two hours and ten minutes the needles were withdrawn, and it was found that there was a very considerable diminution in the pulsation, and a somewhat alarming accumulation of decomposed gases at the upper part of the sac. On the following evening the galvanic treatment was repeated, a more powerful battery

having been employed, and the application continued for only twenty-five minutes. The electrolytic action was on this occasion very energetic, and tympanitic percussion was obtained in ten minutes at various parts. Although the result of this treatment was extremely encouraging in so far as the risk of immediate death from hæmorrhage was averted, and as the attempt to coagulate the contents of the anterior portion of the sac was successful, the patient gradually sank and died on December 9. The autopsy showed an aneurism which had extended itself to a formidable extent, and demonstrated the power of the galvanic current in coagulating the contents of such a sac. Not less interesting than the narrative of the case was the able summary of the history and prospects of this method of treatment, which occupied the greater portion of Dr. Duncan's communication. The data are as yet limited, but comparing the results of galvano-puncture with those of ligature, as contained in Norris's tables, the disadvantage certainly appears to rest with the latter.

	Total number of cases.	Deaths.	Percentage of deaths.
Ligature . .	579	198	33·1
Galvano-puncture	54	7	12·9

Hitherto it has been found that cures have been most frequently obtained with inflammatory accompaniments, next by immediate and complete coagulation, and, least frequently, by partial coagulation and subsequent fibrinous deposition. It would appear that by a few precautions, the principal being a complete insulation of the part of the needle in contact with the perforated textures, galvano-puncture may be so employed as to avoid the first of these results, and so an important objection to its application may be eliminated. Dr. Duncan concluded by expressing his belief that the operation is one capable of valuable extension, and deserving of more attention than it has as yet received, were it only because of the success it has met with in the hands of Peterquin, Abeille, Ciniselli, and Nélaton.

We feel very much inclined to criticise the title which Dr. Duncan, following the example of previous writers on this subject, has given to his communication. Galvano-puncture, we would submit, suggests the idea of an operation in which the puncture is the main object, and in which this is attained by means of galvanism. This method of treating aneurism consists, in reality, of an application of galvanism to the blood, and the puncture is obviously only a method of gaining access to the blood within a sac. We should suggest, as being more correct and definite, the substitution of electrolysis for galvano-puncture, the former being the usual term to describe that galvanic decomposition which is the object of the operation.

Our Winter Medical Session terminates this week, and an unusually short one it has appeared. The true close of the session will, however, take place on April 2, when the Lord Rector of the University, Thomas Carlyle, is to deliver his inaugural address.

GENERAL CORRESPONDENCE.

"REPTILE'S HEART ENEMA."

Letter from Dr. Leared.

[To the Editor of the Medical Times and Gazette.]

Sir,—In an article in the *Medical Times and Gazette* of Feb. 24 on india-rubber enema apparatus, you speak of a form of the instrument as "workable with one hand, and the construction requiring a simple act of expansion and contraction, like a reptile's heart." Your mention of the heart reminds me of a matter I had almost forgotten, which, is, nevertheless, a somewhat novel incident in its bearing on the "History of Inventions." The application of the principle of the present invention, for which I was indebted to nature, I hold to be mine, and its application to the enema apparatus is curious.

In the beginning of 1855 I was very intent on perfecting an apparatus by which the formation of the sounds of the heart could be demonstrated, and which should be a close copy of the heart itself. There were great difficulties in the way, and a friend advised me to apply to a Paris firm famous for the ingenuity of their work in india-rubber. This I did through their agent, then, and possibly still, in London. I was assured that the apparatus would be perfected as desired. After many inquiries and several months had elapsed without any result, I was informed, however, that my order could not be executed. Very soon afterwards I was not a little surprised to see in the chemists' shops an india-rubber enema apparatus bearing the stamp of the firm to which I had given the order, constructed not only on the principle, but almost identical with my proposed heart-sound apparatus. The only difference was that the diameter of the tube was lessened, and the valvular arrangements were more simple. The very form and size of the propeller or heart were preserved. Copies of the drawing and descriptive letter sent to the Paris manufacturers are in my possession, and afford ample proof of the correctness of the above statements.

I am, &c., Arthur Leared.

March 27, 1866.

THE COMMITTEE OF THE MEDICO-CHIRURGICAL SOCIETY ON THE HYPODERMIC METHOD.

Letter from Dr. R. E. Thompson.

[To the Editor of the Medical Times and Gazette.]

Sir,—The Scientific Committee appointed by the Royal Medical and Chirurgical Society to investigate the physiological and therapeutical effects of the hypodermic method of injection, is desirous of obtaining from the Medical Profession generally, communications of any facts bearing upon the subject, and, knowing your courtesy in matters of this kind, they have directed me to ask you to aid them in their appeal by the insertion of this letter in your columns.

The Committee requests to draw the attention of Medical men to the following points:—Whether the drug acts in the same way by the skin, the mouth and the rectum? Whether the effects are more or less rapid, or energetic, or permanent by the skin than by the other methods of administration? Whether any local effects follow the hypodermic injection?

Communications may be addressed to me at the Society's Rooms in Berners-street.

I am, &c.,

Reginald E. Thompson,

March 28, 1866. Secretary to the Committee.

ADVICE TO CLERGY ON THE TREATMENT OF EPILEPSY.

Letter from Dr. G. Rogers.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the *Church Times* of March 31 I find the following paragraph in that portion of the paper which is devoted to reviews:—

"We desire to call the attention of the clergy especially to a little book which will enable them to suggest a remedy for some of the most distressing cases of illness which they frequently discover among their parishioners. Epileptic affections have been long considered usually incurable. Mr. Baker Brown, F.R.C.S., the eminent Surgeon, has discovered and applied with great success, at the London Surgical Home for Gentlewomen and elsewhere, a Surgical remedy for certain forms of epilepsy and kindred diseases. He has published through Mr. Hardwicke a little volume of cases, which prove incontestably the success of the treatment, and which the clergy will be doing a service, especially to their poorer parishioners, by bringing under the notice of Medical men, any of whom can, if possessed of ordinary Surgical skill, perform the operation with but slight assistance."

It says little for the judgment of the editor of a religious journal, who, by the way, is alway falling foul of those who pronounce shibboleth somewhat differently from himself, that he should in this direct manner aid in diffusing advertisements of books relating, however innocently, to sexual disorders, when the Medical press has so strenuously exerted itself to check this evil, and thus to further the great interests of morality. Observe, I am not involving in this charge the writer of the little book. He is an eminent Surgeon, and if honours are worth anything, his prove him such, for they occupy fifteen lines of the title-page. But brilliant as is his operating skill, and philanthropic as are his endeavours, "dictated by the loftiest and most moral considerations," to interest "philosophical and charitable minds"(a) in his plan of treatment, I, for one, think any one is mistaken, however well meaning, in bringing "spiritual advisers" to take part in this "vast and important consideration affecting

(a) Pp. 12—13.

the well-being of the whole human race;"(b) whereas every one who reflects calmly upon the matter knows that it is one exclusively appertaining to Medical "advisers."

How are the clergy to "suggest a remedy," as the sapient *Church Times* reviewer puts it, or to bring cases under the notice of Medical men, unless, at great risk to their own moral well-being and well-doing, they vex the minds of their "poorer parishioners" (not the richer ones, mind you) with prurient inquiries, to which even those alleged to exist in manuals of confession are purity and incorruption? In perusing Mr. Baker Brown's treatise I find (p. 13) the name of Dr. Rogers amongst other gentlemen who have been led to adopt the views and treatment therein detailed. I will only add, in conclusion, that this gentlemen is not, Sir, your obedient correspondent, G. Goddard Rogers, M.D.

Grosvenor-street, April 2, 1866.

THE DOSES OF MEDICINES.

Letter from Dr. C. R. Bree.

[To the Editor of the Medical Times and Gazette.]

Sir,—It is impossible for one moment to admit the extraordinary plea set up by Dr. Farre that the doses of medicine in his posological table are those of Dr. Pereira, and not his. Turning to the title-page of his book, I find "Arranged in conformity with the British Pharmacopœia, and adapted to the use of Medical Practitioners, chemists and druggists, and pharmaceutical students."

According to Dr. Farre's plea, then, he is to "arrange" and "adapt" Pereira's Materia Medica according to a work which has altered the strength of the medicines; and yet the doses are to remain as fixed by Dr. Pereira. On consideration, I think Dr. Farre will admit that such a plea is untenable. For all practical purposes—for the use of "students," "chemists and druggists," etc., Dr. Farre's table is new; and coming before the world under the authority of one of the editors of the British Pharmacopœia, I must be altogether excused if I demur to Dr. Farre's refusal to accept its responsibility.

Last week there was a trial at Brighton, in which a chemist was charged with causing death by giving thirty drops of the tincture of aconite by mistake. The symptoms were those undoubtedly of poisoning by aconite. One of the Medical witnesses swore that ten drops might cause death under certain conditions of the heart. But suppose Dr. Farre's table had been produced in court, wherein the dose is given as ♏v. to xv., would there not have resulted one of those clashings of Medical opinion which lawyers so delight in exposing? Again, Dr. Nevins is a lecturer on Materia Medica and Therapeutics, and a well-known authority. In his Analysis of the British Pharmacopœia, p. 147, I read—"*Belladonna Extractum:* Dose, gr. $\frac{1}{6}$ to gr. $\frac{1}{2}$. *I have seen violent effects follow the last-named dose.*" Surely it would be a reasonable inference that in this case double the dose would have caused death, and yet, on turning to Dr. Farre's table I find—"Ext. Belladonnæ, gr. 1 to 3," without any comment. In the case of death from gr.j., would any judge allow Dr. Farre to put in the plea of irresponsibility, because Dr. Pereira wrote the dose, and not himself?

Let us take the alkaloid of belladonna—atropia. Dr. Farre says the dose is that of Pereira, but, for the reason above stated I must decline to accept this excuse. Turning to the English edition of Trousseau, by Dr. Bazire, p. 96, I find the distinguished French Physician stating that the treatment which for years he has found most useful in epilepsy is that which begins with $\frac{1}{100}$th of a grain of atropia once a-day.

Dr. Farre gives the minimum dose as $\frac{1}{30}$th of a grain—more than three times the dose proved to have been successful by Trousseau. Surely comment upon such a discrepancy is unnecessary. Dr. Farre asks me what I think of Dr. Pereira ordering ♏x. to ♏xx. of the t. lobelia to children two years old. I answer that I have seen ♏x. every four hours produce violent sickness and collapse in an adult in twenty-four hours, and therefore I designate Dr. Pereira's dose to children as altogether unjustifiable, and that to adults dangerous to life, as the inquest upon the victim of a celebrated quack abundantly proved.

Let me give an ideal, though far from improbable case, to illustrate the great danger which may be caused to human life by the use of Dr. Farre's posological table. Suppose one of the men who spend their days and nights in any way except hard work during their London student's life manages by cramming to get through his examination, and is sent for post haste to take the practice of a brother Practitioner just dead in a rural district. Let us suppose that after a hard day's work a messenger arrives to say that his wife "has a great pain at her heart and is very bad"—a not uncommon message in country places. Our new Practitioner, in the course of his cramming, remembers aconite having been recommended for cardiac pain, and he finds the remedy among his defunct friend's drugs, properly labelled "Tinct. aconiti." But the dose? He is uncertain—"had got it up, but forgot it again." So the last new work by the editor of the British Pharmacopœia is consulted, and he finds the dose ♏v. to ♏xv., and as the poor woman is "very bad" he will send her the medium dose, ten minims. Now, it so happens that our friend's predecessor was a Scotchman, and always used Fleming's tincture—a name which probably his successor never heard of. The tincture is made up and delivered, labelled "A dose (ten minims) to be taken every two hours." Now, I ask, is such a case possible? If it is, which I firmly believe, then would that poor woman's life be sacrificed because the dose of the tincture of aconite was given without any explanation as "from five to fifteen minims" in the posological table attached to Pereira's Materia edited by Dr. Farre. That such a lamentable result should happen, no one, I am sure, would regret more than that gentleman.

Again, suppose a young "Medical Practitioner" in every respect well educated, or a "chemist and druggist," or a "pharmaceutical student," were to be called upon to prescribe for a case of asthma or dyspnœa. They have all read that lobelia is a valuable medicine in such cases, but having no practical experience themselves, they refer to Dr. Farre's posological table, and seeing the dose of the æthereal tincture of lobelia inflata is there stated to be from f. ʒj. to f. ʒij., they immediately order the drug in these doses. Will Dr. Farre or any other Practitioner of experience in the United Kingdom deliberately state such practice is free from risk?

I need not go over the old ground of colchicum and strychnia, I have only again to repeat my firm conviction that 15 or 20 minims of the former and $\frac{1}{40}$th of a grain of the latter are the proper minimum doses of these drugs.

Dr. Farre has made a greater mistake than I did when I spelled oxide as it used to be with a "y." Dr. Christison in his Dispensatory gives the dose of pil. colocynthidis et hyoscyami as it is made with socotrine aloes, whereas the new pill to which I alluded is made of Barbadoes aloes, and I am indebted to Dr. Christison for one of the most useful prescriptions in practice for that compound as it is ordered in the British Pharmacopœia, and of which I took down the dose in 1859 of gr. 2 to 4 from Dr. Christison's own lips.(c)

In conclusion, let me observe that I could extend these remarks to a very great length, for there are very many similar cases to those which I quoted at random equally faulty,—such as the minimum doses of acid. hydrochlor. dil., ♏xx.; acid nitrici dilut., ♏xv.; ammoniacum, gr. x.; balsum Peruvianum, ʒss.; borax, ʒss.; ergot, gr. v.; extractum nucis vomicæ, gr. $\frac{1}{2}$; hydrarg. c. creta, gr. v.; liq. ammon. acetatis, f. ʒj.; misit. ferri co., ʒj.; ol. crotonis, ♏j.; pulv. ipecac. c. opio, gr. v.; spt. ether nitrici, f. ʒj.; spt. ammon. aromat., f. ʒss.; spt. chloroformi, ♏xx.; syr. ferri iodidi, ʒss.; syr. scillæ, f. ʒj.; tinct. benzoini co., f. ʒj.; tinct. camph. c. opio, f. ʒj.; tinct. digitalis, ♏x.

I trust, however, that the new edition of the Pharmacopœia, notwithstanding the remarks of Dr. Farre, will contain a posological table which will, at least, tell us how we are to prescribe the preparations which the Committee have altered in strength, and that in such a table there will be a sufficient range between the minimum and maximum doses as will conduce on the one hand to the safety of the public, and, on the other, will enable the Practitioner to modify his dose in the direction which his knowledge and experience will permit him, and that such a table will reflect more credit upon its compilers than the literary productions of the General Council have hitherto done. I am, &c.,

Colchester, March, 1866. C. R. Bree, M.D. Edin.

Académie de Médicine.—M. Richet has just been elected into the Section of Operative Medicine, in place of the late M. Malgaigne, by 53 votes of 73 voters present.

(b) P. 13.

(c) Of course this was before the publication of the British Pharmacopœia; but the composition of the pill was exactly the same as that introduced by Dr. Christison into the British Pharmacopœia.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 13, 1866.

Dr. Alderson, F.R.S., President.

A paper, by Dr. John Caddy, Surgeon R.N., was communicated by Dr. Hodgkin, on some

NOTES AND OBSERVATIONS ON FEVER DURING SERVICE ON BOARD H.M. SCREW CORVETTE, "PYLADES," ON THE WEST COAST OF MEXICO IN THE YEAR 1860. (WITH MAP.)

After referring to the previous services of the *Pylades* at Calcutta at the time of the Indian Mutiny, and the subsequent beneficial change produced on the crew by the climate of Vancouver's Island in 1859, the author gave a statistical statement of the fever cases on board when, on the west coast of Mexico in 1860, and drew inferences as to the greater liability of attack in the ratio of greater age, and of the excess in length of the sickness when treated on the coast to that treated in the ship. The climates and geographical position of Mazatlan, Panama, La Paz, Guaymas, San Blas, etc., and the comparative lengths of their dry and rainy seasons, were then described. The *Pylades* arrived at Mazatlan in January, 1860, and details were given of the first cases of remittent fever which occurred on board as they entered the Mexican tropics. Numerous cases of continued fever followed after February 21, which were considerably added to by the occurrence of duties which involved much solar exposure, and the constant alternate landing of officers and men for duty on shore at San Blas, up to the beginning of June. The number of cases increased during the short passages between Mazatlan, La Paz, and Guaymas, up to the end of September; but from that time the men's health improved as the cool season advanced. The author then described the general symptoms seen in patients when first attacked, and the usual course of those developed as the fever increased. Only one case proved fatal. Black vomit was of rare occurrence, it being unknown in the fevers at the commercial towns of San Blas, Mazatlan, and Guaymas. The author, in describing his treatment, which proved most successful, included fresh breathing-air, personal ablution, close cutting of the hair, full supply of cooling drinks (those made with the mineral acids being preferred), pouring of sea-water on the head, mustard sinapisms and chloroform liniments, and the giving of sesquicarbonate of ammonia in conjunction with chlorate of potash early in the fever, the ammonia having been suggested to the author by a previous West Indian experience in 1845-47, and at Calcutta in 1858. With the cessation of active symptoms, quinine and iron usually and speedily concluded the treatment of the cases. The value of the above treatment, the author said he had been able to confirm by a subsequent ten months' service in the Gulf of Mexico in 1862, and again among the West Indian Islands in 1863 in H.M. screw frigate *Phaeton*. Details followed of the total number and length of cases of fever in these latter expeditions, and a summary of other diseases, which made up the total of 518 cases of sickness on board the *Pylades* in 1860, concluded the paper.

The President said the disease could not have been grave, or the treatment must have been very good to have resulted in so great success. There had been no autopsy to confirm any opinion as to the type of the fever.

Mr. Gaskoin thought papers on fever sent by Surgeons from remote parts of the world were most welcome contributions. He supposed the fever in Dr. Caddy's cases was remittent, as during recovery it assumed an intermittent type, and there were as complications hemi-crania and paralysis. It was not clear to what this fever could have been due. Attention had recently been directed to the effect of "coaling" under an ardent sun as a possible cause of fever. Mr. Gaskoin concluded by saying that a few months ago he saw in St. George's Hospital cases of spotted fever treated by ammonia, and that—whether the ammonia was theoretically wrong or not—the patients thus treated did well.

Dr. Caddy said his object was to bring forward the treatment by ammonia as treatment against that by calomel every four hours. The calomel treatment produced hypercatharsis and retching, and these were supposed to be symptoms of the disease. His treatment by ammonia had been suggested by the valuable researches of Dr. Richardson. He (Dr. Caddy) had observed that cases of tropical fever—the so-called yellow fever being an exaggerated type of tropical fever—terminated sometimes by serous apoplexy. In ammonia a readily absorbable pabulum was supplied to the blood; it stimulated the heart and arteries without exciting the brain.

Dr. Henry G. Wright asked if the author had noticed any difference in the fevers in different races of men. He (Dr. Wright) had crossed Panama in 1852, whilst the railway was making. There was a Hospital for Chinese coolies, who died at an enormous rate. They, however, would not stay in the Hospital, but went out into the woods to die. He had asked the Doctor, an American, if he had observed any difference in the symptoms when the fever attacked a Chinaman or a native. The only thing was that the Chinese did not suffer from headache, and this might be explained by the fact that a Chinaman always walks about with his head uncovered, unless he can afford the luxury of an umbrella.

Dr. Caddy said he had had no experience of fevers attacking Asiatics.

Dr. Webster said that cases of fever on board ship were milder than cases on shore. This had been remarked in many parts of Europe. He instanced the yellow fever at Lisbon.

Mr. Spencer Wells said most Naval Surgeons would differ from Dr. Webster, as they frequently observed that men newly arrived in places where any disease was endemic, suffered much more severely than the acclimatised inhabitants. Many instances could be referred to where sailors suffered severely from remittent and intermittent fevers soon after arriving in places where the residents were quite unaffected. Then with regard to the coolies in Panama, rather than accept the explanation of the difference in the symptoms of fever being due to the covering or non-covering of the head, he should think the question one of race and climate. When any endemic, epidemic, or contagious disease appeared for the first time in any of the chief varieties of the human race, the mortality was much greater than when it attacked a race of men who had been protected by a previous attack, or had inherited some protection from forefathers who had suffered.

Dr. Wright said the inhabitants of Panama were chiefly emigrants from the United States.

Dr. Pollock considered that the author's cases illustrated a form of gastric remittent fever with which he had formerly been familiar when practising in Rome, and which appeared to him to be dependent on malarious influences less powerful than those which determined the more perfect forms of tertian and quotidian. The Roman fever was characterised by great prolongation, many cases lasting from forty to sixty days, by daily exacerbations without distinct remissions, and by marked irritation of the gastro-intestinal mucous membrane, shown by vomiting, diarrhœa, and a morbidly clean and red glazed tongue. Above all, there was much intolerance of drugs. Dr. Pollock had lost many cases by an over-active and so-called "heroic" treatment in the early days of his practice, and had in the latter years of his residence in Italy often declared to the friends of the patient that he felt bound to abstain from prescribing. Quinine was only tolerated when the gastric irritative symptoms had manifestly subsided, and the type of fever was much less under the control of ante-periodic remedies than the more defined intermittents. The treatment described by the author (ammonia in effervescence with citric acid) did not appear to Dr. Pollock to be identical with that by uncombined ammonia, which possessed directly stimulating properties little likely to meet the requirements of the case.

Dr. Caddy said that at first he gave the ammonia with limejuice, but afterwards unmixed. He had observed that the acetate of ammonia purged; the citrate agreed well.

Medical Charities.—The following Medical institutions will benefit under the will of Miss M. F. Woodburn, of Kensington-park-gardens, lately deceased, viz.:—The Hospital for Consumption, Brompton, £1000; St. Mary's Hospital, Paddington, £500; the Metropolitan Convalescent Institution, £300; the Sea-side Convalescent Hospital, £300; the City of London Hospital for Diseases of the Chest, £300; the Notting-hill and Shepherd's Bush Dispensary, £300; the Royal National Sea-bathing Infirmary, £200; the Westbourne Dispensary, £200; and the Kensington Dispensary, £50. All legacies to the above and other institutions not strictly Medical benefited under the will to be paid free of legacy duty.

OBITUARY.

DR. DELATTRE, OF DIEPPE.

La Vigie de Dieppe reprints an account of this lamented Physician, from the graceful pen of his friend and Medical adviser, Dr. Moriarty. Dr. Delattre took his degree in Paris in 1822, and practised for nearly twenty years in Dieppe. He was Professor of Agriculture, of Physics as applied to the Arts, ex-director of chemical works at Fontenay-aux-Roses, and member of many learned societies. He published a classical Medical dictionary, dedicated to the late Duke of Orleans, and made discoveries in therapeutics. Some one has said that a Doctor should be learned and honest. Dr. Delattre was both, and in a larger sphere he would have been a remarkable man. He lived simply, was habitually silent and diffident, but his shyness, the attribute of true genius, did not lessen his merit. But you required to know this guileless man intimately to appreciate the depth of his learning and the versatility of his genius. He was an indefatigable worker, and Dr. Moriarty thinks, from conversations he had with him, must have left a mass of unpublished materials. He died from cardiac disease. "It was," says Dr. Moriarty, "evident that the long and fatal malady was near its end, and there was something grand and edifying at this solemn moment in the peace with which he awaited death with manly courage and Christian trust. At the last moment he bade farewell to his daughter as naturally as if he were setting out on a journey." As is well known, he devoted his time and learning with prodigality to the public service, and his death is a serious loss to the town and neighbourhood of Dieppe.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 29, 1866:—

Henry Burrill Glaister, Southwell, Notts.; James Webb Booth, Queen-street, Huddersfield; Henry Warlow, Haverford West; George Cooper Sanders, Earlswood, Red-hill, Surrey; John Henry Simpson, County Asylum, Gloucester; William Gillett, Westminster.

The following gentlemen also on the same day passed their First Examination:—

Lancelot Newton, St. Bartholomew's Hospital; Lawrence Clapham, St. Bartholomew's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BEAMISH, M., M.D., has been elected Vice-President of the County and City of Cork Medical Protective Association.

CLAYWORTH, C. C., L.R.C.P. Edin., has been appointed House-Surgeon to the London Hospital.

HARRISON, Mr. REGINALD, has been appointed Junior Surgeon to the Liverpool Northern Hospital.

LYONS, R. D., M.B., F.K.Q.C.P.I., has been appointed to the Richmond Hospital, Dublin.

M'CORMACK, M. J., M.B., has been appointed Medical Officer of Health for the Borough of Southampton.

ROBERTS, F. T., M.B., B. Sc. Lond., has been appointed Physician to the Liverpool Northern Hospital.

BIRTHS.

CHRISTIE.—On April 1, at Pembroke House, Hackney, the wife of T. B. Christie, M.D., of a daughter.

DUNLOP.—On March 29, at Holywood, County Down, the wife of A. Dunlop, M.D., of a son.

HUBBARD.—On March 27, at 22, Ladbroke-gardens, Notting-hill, the wife of W. Hubbard, L.R.C.P., of a daughter.

NEILSON.—On April 2, at Blairgowrie, N.B., the wife of James Neilson, of a son.

NOWELL.—On March 19, at Cornwall Villas, Westbourne-park, the wife of A. H. Nowell, L.R.C.P. Edin., of a son.

SEALY.—On March 20, at Oakland's-park, Weybridge, the wife of G. J. Sealy, M.D., of a daughter.

SMYLY.—On March 28, at 8, Merrion-square, North Dublin, the wife of P. C. Smyly, M.D., of a son.

MARRIAGES.

BOLTON—ORPEW.—On March 27, at Queenstown Church, A. J. Bolton, M.B., Assistant-Surgeon R.N., to Geraldine Francis, third daughter of the late T. H. Orpew, M.D.

LATHAM—O'HARA.—On March 21, at Ballymoney, T. Latham, M.B., to Anne, daughter of C. O'Hara, Esq.

WILKINSON—LEADBEATER.—On March 22, at the Cathedral, Manchester, T. J. Wilkinson, L.R.C.S. Edin., to Miss Jane Leadbeater.

WISE—SHARP.—On March 29, at St. Margaret's, Plumstead, A. Wise, M.R.C.S., to Marie Jane, eldest daughter of John Sharp, Esq.

DEATHS.

BECKETT, A. R., L.F.P. and S. Glasg., at Liverpool, on March 10, aged 28.

BROWNE, ROBERT CAVE, M.D., at Barnet, on March 22, aged 66.

CAMBRIDGE, Dr. S., at Cheltenham, on March 19, aged 94.

DAVIES, SAMUEL S., M.R.C.S., L.S.A., at Pembridge, Herefordshire, on February 12.

HAWKINS, JAMES, L.R.C.P. Edin., at Newport, Monmouthshire, on March 21, aged 52.

HEMPHILL, Dr. S., at Spring-hill, Co. Tipperary, on March 17.

MACKENZIE, W., M.D., late of E.I.C.S., at 14, Carlton-terrace, Edinburgh, aged 86.

MAY, W., M.D., at Madeira, on March 21, aged 56.

MELSON, JOHN WALLER, B.A., M.R.C.S., at Birmingham, on March 21, aged 23.

THOMSON, E. D., Army Medical Department at Gibraltar, on March 6, aged 32.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

St. Austell Union.—The St. Blazey District is vacant; area 4990; population 7564; salary £20 per annum.

Clitheroe Union.—The Clitheroe District is vacant; area 17,634; population 7744; salary £30 per annum.

Haslingden Union.—The Haslingden District and Workhouse are vacant; area 4659; population 10,320; salary £30 per annum.

Marlborough Union.—Mr. David P. Maurice has resigned the First District; area 28,271; population 7182; salary £100 per annum.

Newport Union (Monmouth).—The Western District is vacant; area 29,856; population 22,536; salary £56 per annum; also the Workhouse, salary £24 per annum.

Wincanton Union.—The Wincanton East District is vacant; area 15,435; population 5164; salary £86 per annum; also the Workhouse, salary £19 per annum.

APPOINTMENTS.

Birmingham Parish.—Jabez Jackson, L.S.A., L.F.P. and S. Glasg., L.M., to the Fourth District.

Chertsey Union.—John P. Hunt, L.R.C.P., Edin., L.R.C.S.I., L. Mid. Dub., to the Windlesham District.

Portsea Island Union.—John F. Pritchard, M.R.C.S.E., L.S.A., to the Kingston District; Frederick Page, M.D. St. And., F.R.C.S.E., L.S.A., to the Workhouse.

Rochford Union.—George F. B. Willing, L.R.C.P. Edin., M.R.C.S.E., L.M., to the Great Wakering District.

Wincanton Union.—Samuel S. Larcombe, M.R.C.S.E., L.S.A., to the Castle Carey District.

DR. RICHARDSON.—This gentleman gave the first of a course of six lectures on Physical Researches into Pathology and Therapeutics at the Royal College of Physicians on Wednesday last, to which course any member of the Profession will be admitted on exhibiting his personal card.

PROFESSOR W. HERAPATH ON RINDERPEST.—Professor W. Herapath, of Bristol, has addressed a letter to the *Times* stating that he had made a chemical examination of inflamed tissues from two cows just slaughtered on account of commencing Rinderpest, and that he found that "the blood, the mucous surfaces, and the adherent matters were alkaline, and the alkali was ammonia;" and he thereon suggests a theory of infection, "as the volatile ammonia would carry the poison into the atmosphere;" and a theory of treatment. Our readers will not need reminding that there is nothing new in the suggestion of a super-ammoniated state of the blood in some exanthematous fevers. Doubtless Professor Herapath has communicated his observations to the Cattle Plague Commission, or to some scientific journal, as well as to the popular daily paper.

THE HOUSE OF CHARRIERE, OF PARIS.—This celebrated Paris Surgical instrument maker, so well known all over Europe, having met with an irreparable loss in the death of his son, in whose favour he had retired from business, has just disposed of his important establishments to MM. Robert and Collin, formerly his pupils, who have already acquired a great reputation with the rising generation of French Surgeons.

SUSPECTED POISONING.—At Malmesbury, in Wiltshire, a series of extraordinary disclosures have just been made. A widow lady named Perring lately resided there with one daughter, who is not yet 18 years old. Last October there came to Malmesbury a young man, who gave the name of Fuller, and was engaged as assistant in a Surgery. Soon after he eloped with Miss Perring, and was married to her at Chel-

tenham. A few weeks ago it was discovered that Fuller, as he called himself, forged a cheque. Further inquiry showed that he had already married two women, both of whom are alive. For the two bigamous marriages he was committed for trial last week; but there yet remains a more serious inquiry to be completed. Mrs. Perring died a few days ago, after a short illness, which commenced only a few days before the discovery of the forgery. It is proved by her daughter that Fuller gave her medicine, and a post-mortem examination revealed that an active poison, such as chloride of mercury, had been administered to her. The contents of the stomach and intestines have been sent to Dr. Herapath, of Bristol, for analysis.

Royal Institution of Great Britain.—At the general monthly meeting on Monday, April 2, 1866, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair, John Curwen Christian Boyd, Esq., Charles Browne Cornish-Browne, Esq., Walter Thomas Fawcett, Esq., Mrs. Bridget Margaret Sortain, Calvert Toulmin, Esq., were elected members of the Royal Institution. The special thanks of the members were returned to the donor of the following addition to "The Donation Fund for the Promotion of Experimental Researches:"—E. O. Tudor, Esq., £20. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

London Workhouses.—The public will be glad to learn that the Poor-law Board has instructed their Medical officer, Dr. Edward Smith, F.R.S., in conjunction with Mr. H. B. Farnall, C.B., to inspect the Infirmary wards of all the metropolitan workhouses, and to inquire and report upon the existing arrangements for the care and treatment of the sick poor. They have also requested those gentlemen to suggest such remedies for any existing evils in the several workhouses as may be fitted to render the care of the sick satisfactory. It cannot be doubted that with such an official inquiry the truth will be ascertained, and it is to be hoped that the guardians will receive the recommendation with the intention of rendering the treatment of the sick poor in workhouses all that can properly be desired.—*Times, April 5.*

Local Anæsthesia by Dr. Richardson's Method in Orthopædic Surgery.—We have not previously reported any cases in which the new method of producing local anæsthesia has been tried in orthopædic Surgery, although, *à priori*, it would occur to the Surgeon that such operations were well fitted for it. We now learn that this expectation is correct. At the National Orthopædic Hospital on Tuesday, the 27th ult., the usual operating day, local anæsthesia by Dr. Richardson's method was tried by Dr. H. Dick and Mr. Little. The first case, one of Dr. Dick's, was a contracted knee after disease of the joint. The hamstring tendons required division. On division of the semi-tendinosus and semi-membranosus no pain whatever was felt. In dividing the biceps, where deeper puncture was necessary, some pain was felt by the patient. The results were still more satisfactory in a case of Mr. Little's where the tendo-Achillis was divided. Etherisation here was applied on both sides of the tendon with two separate etherisers, so that the whole of the skin covering the tendon on either side was blanched. Mr. Little divided the tendo-Achillis in three separate patients, all of an age capable of expressing and describing what they felt. All the operations were painless. If it is possible to draw a conclusion from this small number of cases, it is that the division of tendons near the skin can be performed without pain, and in the division of tendons more deeply seated, the pain of the puncture in the skin can be avoided,—in itself no small gain.

The Lord Rector of the University of Edinburgh on Health.—Towards the close of the characteristic address with which Mr. Carlyle edified and amused the Edinburgh students on the occasion of his installation are the following remarks, which, we believe, are based on as sound ethics as physiology:—"Finally, gentlemen, I have one advice to give you which is practically of very great importance, though a very humble one. It is in the middle of your zeal and ardour—for such, believe, will be sufficient in spite of all the counsels to moderate it that I can give you, and I have no doubt you will have among you people ardently bent to consider life cheap, for the purpose of getting forward in what they are aiming at of high—and you are to consider throughout, much more than is done at present, that health is a thing to be attended to continually—that you are to regard that as the very highest of all temporal things for you. (Applause.) There is no kind of achievement you could make in the world that is equal to perfect health. What are nuggets and millions? The French financier said,—'Alas! why is there no sleep to be sold?' Sleep was not in the market at any quotation. (Laughter and applause.) It is a curious thing, that I remarked long ago, and have often turned in my head, that the old word for 'holy' in the German language—*heilig*—also means 'healthy.' And so *Heilbronn* means 'holy-well,' or 'healthy well.' We have in the Scotch hale; and, I suppose, our English word whole—with a 'w'—all of one piece without any hole in it—is the same word. I find that you could not get any better definition of what 'holy' really is than 'healthy'—'completely healthy.' *Mens sana in corpore sano.* (Applause.) A man with his intellect a clear, plain, geometric mirror, brilliantly sensitive of all objects and impressions around it, and imaging all things in their correct proportions—not twisted up into convex or concave, and distorting everything, so that he cannot see the truth of the matter without endless groping and manipulation—healthy, clear, and free, and all round about him. We never can attain that at all. In fact, the operations we have got into are destructive of it. You cannot, if you are going to do any decisive intellectual operation—if you are going to write a book—at least, I never could—without getting decidedly made ill by it, and really you must if it is your business—and you must follow out what you are at—and it sometimes is at the expense of health. Only remember at all times to get back as fast as possible out of it into health, and regard the real equilibrium as the centre of things. You should always look at the *heilig*, which means holy, and holy means healthy. Well, that old etymology—what a lesson it is against certain gloomy, austere, unæsthetic people, that have gone about as if this world were all a dismal prison-house. It has indeed got all the ugly things in it that I have been alluding to; but there is an eternal sky over it, and the blessed sunshine, verdure of spring and rich autumn, and all that in it too. Piety does not mean that a man should make a sour face about things, and refuse to enjoy in moderation what his Maker has given."

University of Edinburgh.—The Degree of LL.D. Conferred on Professor Huxley and Dr. Rae.—On the occasion of the installation of Mr. Carlyle as Rector of the University, amongst the gentlemen presented for the honorary degree of Doctor of Laws were two who were originally trained as members of the Medical Profession—Professor Huxley and Dr. Rae, the Arctic explorer. We subjoin the speeches in which Professor Muirhead recounted their claims to academical honour when presenting them to the Vice-Chancellor:—Professor Muirhead, in presenting Mr. Huxley, said: I present to you, Mr. Vice-Chancellor, as judged worthy by the Senate to receive the honorary degree of Doctor of Laws, Mr. Thomas Henry Huxley—(applause)—a Fellow of the Royal Society, Professor of Natural History at the School of Mines, and Hunterian Professor of Comparative Anatomy in the Royal College of Surgeons of England. Trained to the Medical Profession, Mr. Huxley became in early life an Assistant-Surgeon in the Royal Navy; and it was while serving in that capacity in one of her Majesty's ships, then engaged in a survey of the coasts of Australia and New Guinea, that he acquired his unrivalled knowledge of marine zoology, and vindicated his claims to be regarded as one of the most accomplished naturalists of the day. (Cheers.) His appointment, on his return to this country, to the Chair of Natural History in the Government School in Jermyn-street, gave him an opportunity of turning his attention to palæontological inquiries; and the results of his labour in that field are embodied in a series of valuable and most interesting papers descriptive of various extinct forms of animal life. (Cheers.) As Hunterian Professor in the College of Surgeons of England, he has delivered several courses of lectures on the comparative anatomy of the vertebrata; lectures which, not less than his contributions to the transactions of learned societies, testify his remarkable perspicuity and his rare power of discriminating the relations of structure in complicated forms of animal life. (Cheers.) Professor Muirhead, in presenting Dr. Rae, said: I next present to you, Mr. Vice-Chancellor, as also judged worthy by the Senate to receive the same honour, Dr. John Rae, a Fellow of the Geographical Society—(applause)—and a graduate in Medicine of this University. Entering life in the Medical service of the Hudson's Bay Company, he was soon afterwards transferred to its ordinary service, and before long attained the rank of one of its chief factors. In that capacity he had the command of several exploring expeditions in high latitudes—in the course of which, travelling sometimes

in boats, sometimes in sledges, sometimes for weeks together on foot, he and his companions endured hardships and surmounted obstacles such as it has been the lot of few to encounter. On none of those occasions did Dr. Rae allow any opportunity to escape him of advancing our knowledge of the geography, meteorology, and natural history of the far north-west and frozen regions; and it is not to be forgotten that he it was who first obtained definite information of the fate of Sir John Franklin and his gallant comrades—(loud cheers)—and indicated the locality where three years later their remains were discovered by M'Clintock. (Applause.) Very recently, Dr. Rae has been engaged in a Government survey of a telegraphic route from Canada to Vancouver's Island, over the wild country of the Rocky Mountains—an enterprise in which he completely succeeded, although the occupation of a considerable part of the route by savage tribes has caused the construction of the telegraph to be in the meantime suspended. (Cheers.)

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending March 24.	Week ending March 17.	Week ending March 10.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

Note.—39 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Berks, 1; Salop, 1; Bucks, 2; Cambridge, 1; Chester, 2; Cumberland, 1; Essex, 1; Hereford, 1; Huntingdon, 1; Lancaster, 1; Lincoln, 7; Norfolk, 2; Northampton, 1; Oxford, 1; Stafford, 1; Yorkshire, 6; and Scotland, 9. These Inspectors returned 1215 cases last week.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

In consequence of the pressure of matter this week, many Communications, articles of interest, and Reports of Societies are postponed.

Mr. John Adams's Clinical Lecture on Lithotomy shall appear directly.

A Third Year's Student.—Dr. Guy's.

N.B.—Lallemand, Perrin, and Duroy. The elimination theory does not hold water. *Some* is eliminated doubtless, but the quantitative test fails.

Dr. W. B.—The autograph of Albinus is of great rarity, according to Pettigrew. A memoir of this distinguished Anatomist appeared in the *Medical Times*, vol. XI., p. 150.

St. Thomas.—The Académie Royale de Chirurgie de Paris was opened in 1731, and Cheselden was elected the first corresponding member of it in the ensuing year.

W. A. P.—Dr. Henderson's paper "On New Specific Remedies for Gonorrhœa" appeared in the *Medical Times and Gazette* of June, 1865. Galvanism in the cure of Graves's disease is noticed in Ranking's "Abstract" for 1865, vol. xlii., p. 85.

Bibliopole.—An index to the *Times* for 1862 and 1863 was published by Freeman, of Fleet-street; copies are in the Library of the College of Surgeons, where also the newspaper has been filed for many years past. Write to the Secretary.

A Medical Churchwarden, Kennington.—The credit is unquestionably due to Mr. George Alfred Walker, a retired member of our Profession. You will find an account of the other circumstance referred to in old Stow's Chronicle, p. 409, who states in his quaint language that the body of a man hanged for felony was begged by the Chirurgeons of London in 1583 or 4, to have made of him an anatomy. After he was dead, to all men's thinking, cut down, stripped, laid naked in a chest, thrown in a car, so brought from the place of execution through the Borough of Southwark and City of London to the Chirurgeons' Hall, near unto Aldersgate; the chest being there opened and the weather extremely cold, he was found to be alive, and lived to the day next following, and then died.

The Cattle Plague.—A correspondent would be glad to know whether the mineral acids have been given to cattle in the water which they drink to act as a preventive when the disease breaks out in a herd. If the Rinderpest bear any analogy to scarlatina, small-pox, or diphtheria, the nitro-hydrochloric acid would, perhaps, be the best preventive, but sulphuric acid is more of a tonic, but possesses less febrifuge properties.

Erasures from the Medical Register.—We have been requested by Dr. John Burton, of Walsall, to publish the following extract from a letter of Dr. Francis Hawkins. We regret that Dr. Burton has been annoyed by the publication of the list of erasures from the Medical Register, one of the persons erased by the Council bearing his name. Of course the publication of the list is necessary on public grounds, but we should scarcely have thought it possible to confound any respectable Practitioner with persons so punished.

Copy extract of Dr. Hawkins's Letter dated April 3, 1866.

"Since you ask for particulars as to that person with a view to publication, I do not feel justified in furnishing any which the Medical Council has not already published. I can only say that the entry of that person's name was thus made in the Register:—

"'1859, January 1. Burton, John, Bulter-row, Gloucester. In practice before August 1, 1815.'

"On the 13th of June, 1859, that entry was erased by order of the Branch Medical Council for England, because 'it was proved to the satisfaction of the Branch Council that the said John Burton was not entitled to be registered, and that the entry of his name on the Register had been fraudulently or incorrectly made.'

"I am, Sir, your obedient servant,

"(Signed) FRAS. HAWKINS, Registrar."

THE ALLEGED CASE OF MANSLAUGHTER AT MIDDLESBOROUGH.

Some of our readers may need reminding that in this case an indictment was brought against William Simpson, the unqualified assistant of Mr. Richardson, of Middlesborough, for the manslaughter of a man named Jenkinson. Jenkinson was suffering from stricture of the urethra, and died from rupture of the canal and extravasation of urine. It was alleged that the accused had caused the man's death by neglecting to use the catheter and by treating him solely by the administration of saline medicines. As the Medical evidence in the report, which has reached us from a local paper, is passed over as unfit for publication, we are unable to give anything more than an outline of the case. It will be sufficient to add that the trial took place before Mr. Justice Keating, and was terminated by the jury unhesitatingly returning a verdict of "Not guilty." We have a few words, however, to offer on the ethical aspect of the case. Mr. Richardson was absent during the progress of the patient's illness, and could not therefore be responsible for its result, except inasmuch as he was responsible for the competence of his representative. It is only fair to Mr. Simpson to state that he voluntarily retired from the management of the case on Monday, and the friends of the patient do not appear to have obtained any other Medical assistance until the following Thursday, when the patient was dying. Mr. Husband, who was then called in, was, we think, quite justified in expressing an opinion that the man ought to have been relieved by operative procedure. The thing was self-evident, and we do not think that a Medical man is restricted, by any rules of Professional etiquette, from expressing a judgment, when a patient's life has been at stake and the plain rules of Professional practice have not been followed. If Mr. Husband were instrumental in obtaining an inquest, as it was hinted at the trial, we can but regret it. It is sufficient for a Medical man to express his opinion in his Professional capacity. We do not think that he is required to set the law in motion, for the purpose of visiting with pains and penalties the shortcomings of the representative of a brother Practitioner. Mr. Husband, however, in his evidence, denied that he had taken such a course. He stated that, although he wished for an inquest, he did not write to the Coroner to procure one, nor take any step beyond the fact of "giving a sort of certificate." We give him full credit for the truth of his assertion, and are sorry that any expressions he may have used should have given any colour to an opposite theory of his conduct.

POOR LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been received by me towards the funds of the Association:—Hinnell, E. J., Thingoe, 5s.; Morris, R. T., Wigan, 20s.; Green, H., Lexden and Winstree, 10s.; Lys, D. F., Blandford, 5s.

By Mr. Prowse: James, J., Bristol, 10s.; Wraith, J. H., Over Darwen, 10s.; Probert, J., Mertbyr Tydvil, 10s.; Allday F., Merthyr Tydvil, 10s.; Dyke, T. J., Merthyr Tydvil, 10s.; Rees, M., Merthyr Tydvil, 10s.; Roberts, B., Eastbourne, 5s.

RICHARD GRIFFIN.

WHAT IS THE USE OF THE SAFFRON IN THE PIL. ALOES C. MYRRHA, AND OTHER PREPARATIONS OF THE PHARMACOPŒIA?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The pil. aloes c. myrrha of the Ph., is one of the most useful aperient pills, especially for females, we possess; but the pill is rendered bulky and disgusting by the saffron contained in it. I am informed by a pharmaceutist that saffron is an expensive article, and as it possesses no Medicinal properties, why is it permitted to clog the above-named pills and other preparations of the Pharmacopœia?

The day is past for colouring and disguising our remedial agents, and let us hope that the revisers of the new Pharmacopœia will bear in mind that simplicity in the art of compounding should not be overlooked.

I am, &c., A PHYSICIAN.

COMMUNICATIONS have been received from—

A Physician: John E. Gross, Esq.; Dr. Markham; M. C. Mitra, Esq.; Apothecaries' Hall; R. E. Thompson, Esq.; Armstrong Todd, Esq.; British Medical Association; J. Laidler, Esq.; Dr. Laycock; Western Medical and Surgical Society; Dr. Durgan, R.N.; J. Munday, Esq.; R. Griffin, Esq.; H. B. Condy, Esq.; The Royal Medico-Chirurgical Society; J. N. Vinen; Dr. Burter; Obstetrical Society; Ethnological Society; Dr. H. Fearnside; Mr. J. Hutchinson; Dr. Lionel Beale; Dr. B. W. Richardson; Dr. C. R. Bree; Dr. Silver; Dr. Tilbury Fox; Dr. Hughlings Jackson; Mr. J. Chatto.

BOOKS RECEIVED—

The Pharmaceutical Journal—Flint's Physiology of Man—Leared, On Imperfect Digestion—Gibbs, Remonstrance respecting the Vaccination Bill of 1866—Annual Report of the Cumberland and Westmoreland Lunatic Asylum—The Eleventh Annual Report of the Manchester Medico-Ethical Association—Tilbury Fox, On Leprosy, Ancient and Modern—Spencer's Elements of Qualitative Chemical Analysis—The Archives of Dentistry, vol. i.—Watt's Dictionary of Chemistry, part 33—The Edinburgh Medical Journal, April—The British and Foreign Medico-Chirurgical Review, April—Condy, On the Purification of Water and Air—The Westminster Review, April.

NEWSPAPERS RECEIVED—

The Dublin Medical Press—The Stockton Gazette—The Sunday Gazette—The Edinburgh Daily Review.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN MARCH, 1866.

The following are the Returns of the Metropolitan Association of Medical Officers of Health:—

	Total Solid Matter per Gallon.	Loss by Ignition.(a)	Oxydisable Organic Matter.(b)	Hardness.	
				Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	..	..	..	..	..
West Middlesex	20·25	0·86	0·48	13·6	3·5
Southwark and Vauxhall.	20·72	1·01	0·49	14·1	4·0
Chelsea	19·99	0·94	0·41	12·8	4·0
Lambeth	20·29	1·01	0·56	13·7	3·1
Other Companies.					
Kent	24·78	1·11	0·05	18·6	7·0
New River	21·44	1·29	0·24	15·8	6·8
East London	23·25	1·14	0·41	16·5	4·5

(a) The loss by ignition represents a variety of volatile matters as well as organic matter, as ammoniacal salts, moisture, and the volatile constituents of nitrates and nitrites.

(b) The oxydisable organic matter is determined by a standard solution of permanganate of potash, the available oxygen of which is to the organic matter as 1 is to 8; and the results are controlled by the examination of the colour of the water when seen through a glass tube two feet in length and two inches in diameter.

VITAL STATISTICS OF LONDON.

Week ending Saturday, March 31, 1866.

BIRTHS.

Births of Boys, 1082; Girls, 1025; Total, 2107.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·909 in. The mean daily reading was above 30 in. on three days of the week. The barometrical pressure was 29·10 in. on Sunday, and it was 30·05 in. on Monday and Friday.

The general direction of the wind was W., N.W., and S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 40·2°.

‖ The returns from Edinburgh and Glasgow not having been received in time for insertion in the above table, averages of the returns of the six previous weeks have been substituted for the correct numbers.

APPOINTMENTS FOR THE WEEK.

April 7. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

9. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

10. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Ethnological Society of London, 8 p.m. John Crawfurd, Esq., President, "On the Invention of Writing Materials;" "On an Ancient Hindoo Sacrificial Bull, with Inscription, Found in the Northern Island of the New Zealand Group."

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

Royal Medical and Chirurgical Society, 8½ p.m. Dr. Morehead, "On the Pathology of Pneumonia;" followed by Mr. Gaskoin, "On Continued Syphilitic Inoculation," or Mr. A. Durham, "On the Radical Cure of Hernia."

11. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Royal Institution, 3 p.m. Professor Du Bois Reymond, "On Muscular Contraction."

12. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

13. Friday.

Royal Institution, 8 p.m. Professor Du Bois Reymond, "On the Time required for the Transmission of Volition and Sensation through the Nerves."

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

ON

GENERAL AND LOCAL CHEMICAL AND MECHANICAL DISORDERS ARISING FROM ERRORS OF CHEMISTRY IN THE DEVELOPMENT AND REPAIR OF THE BODY.

By H. BENCE JONES, M.D., F.R.S.

Part IV.—Lecture XI.

(Continued from page 333.)

The three actions of supply, assimilation, and removal which constitute nutrition are usually so closely dependent and interwoven that no separation between them can be made, and the result of these actions, whether in excess or in deficiency, may each be summed up in a single word. For example, an increased supply of blood, increased assimilation, and slightly increased removal, constitute hypertrophy. Whilst the diminished supply, and lessened chemical action, and more or less diminished removal of disintegrated matter produce simple atrophy, or atrophy with more or less degeneration, according to the nature of the substances—(as, for instance, fatty and calcarcous matters) which remain unremoved in consequence of the suboxidation occasioned by the diminished supply of blood.

I shall now take the conjoint effect of these three actions, and I shall try to bring before you one or two chemical diseases and the secondary mechanical disorders which are thus produced.

Among many diseases from which I may select, I shall take simple hypertrophy of the prostate on account of the very marked mechanical disease which springs from the primary chemical error of nutrition.

"Simple enlargement of the prostate," says Mr. Paget, "consists of increased gland cells and muscular fibres with masses of new-formed tissue within and without the gland. These prostate glandular tumours are composed of simple tissues like those of the gland itself. The gland cells and muscular fibres are not to be distinguished from those of the gland itself. They are masses of new structure, resembling the prostate embedded in the proper substance of the enlarged gland. Near the enlarged prostate similar detached outlying masses of new substance like tumours in their shape and relations, and like prostate gland in tissue, may sometimes be found. A very large specimen was taken from a man, 64 years old, and who for the last four years of his life was unable to pass his urine without the help of a catheter. He died with bronchitis, and a tumour, measuring $2\frac{1}{2}$ inches by $1\frac{1}{2}$, was found lying loose in the bladder, only connected to it by a pedicle moving on this like a hinge, and when pressed forward obstructing the orifice of the urethra. Now, both in general aspect and in microscopic structure this tumour is so like a portion of enlarged prostate gland that I know no character by which to distinguish them."

The immediate result of this growth is that the urine cannot flow out; it is mechanically stopped in a greater or less degree, according to the amount of the impediment. The mechanical disease then begins to produce its effects. These are altered pressure of the urine on the bladder and altered chemistry, in consequence of more or less of the urine being retained in the bladder.

In a previous lecture I have brought before you the phenomena of the fermentation of the urine. Even in perfect health whilst the urine is in the bladder, chemical changes are going on, although they usually escape our notice; but when a little of the urine is continually left in the bladder, then the internal chemical action becomes very evident. The increase of time during which the ferment can act on the urea, the production of vibrios, the increased chemical action going on in the prostate, these sometimes very slowly, sometimes very rapidly, according partly to the amount of acid that passes from the kidneys, set up ammoniacal urine, and then the chemical action of carbonate of ammonia on the urine and on the mucous membrane has to be added to the original chemical disease.

Meanwhile the mechanical pressure of the urine has been more or less effective, and helps to increase the chemical action on the mucous membrane. Each time the bladder contracts the pressure temporarily rises in intensity, and slowly increased nutrition of the different tissues and increased oxidation in them is set up; this insensibly passes into peroxidation, and the chemical action of the carbonate of ammonia not only adds to the inflammation, but alters its products, so that mucus and pus can no longer be recognised, but a gluey, ropy, adhesive matter, even more adhesive than the stringy alkaline secretion from the throat and nose is produced. The ammoniaco-magnesian phosphate crystallises in and upon this matter, and the granular phosphate of lime increases its consistence, so that a mechanical irritation, or even a fresh mechanical obstruction to the passage of the urine, is added to the fearful sufferings which a small chemical error of hypertrophy originally set up.

If you look at the treatment of this disease, you will soon see how the mechanical secondary disorder constitutes the important part of the complaint. Without a mechanical remedy almost no good whatever can be done by treatment, and when the catheter is used scarcely any other treatment is required.

During the gradual increase of the hypertrophy an increased action may suddenly come on from internal or external causes; for example, from excessive acid or other chemical irritant formed in the kidneys and passing into the bladder; from cold applied to the skin. From substances in the blood passing into the structure of the prostate, increased flow of blood to the hypertrophied part takes place, and this may reach to any amount of congestion and inflammation; an immediate stoppage of the flow of water is the result, and when this happens, recourse must be had the same day to mechanical relief, and very often from that date the catheter must be always passed, more or less frequently, according to the degree of wrong chemistry that exists. If the ammoniacal urine be not drawn off sufficiently often, diffusion takes place into, and perhaps even through, the mucous membrane of the bladder. The phosphatic salts are found not only adherent to the bladder, but even deep in the structure of the mucous membranc. The putrid urine passes through into the blood, and thereby a general state of poisoning may be produced. This has been also called uræmia, and by some persons ammoniæmia, but the experiments of Hammond, in the *American Quarterly Journal of Medical Science*, vol. xli., p. 55, 1861, show that putrid urine acts much stronger as a poison than carbonate of ammonia, and it is highly probable that among the offensive matters in putrid urine some more poisonous substance than carbonate of ammonia or urea may bc formed. Certainly the poison differs from those higher compounds which cause death in the so-called uræmia of Bright's disease.

If, instead of hypertrophy, I take an example from atrophy, which depends on diminished supply and lessened chemical action, and more or less diminished removal of disintegrated matter, you will see an opposite chemical error of nutrition, giving rise to secondary mechanical or chemical diseases far more serious than the primary complaint.

I will shortly bring before you senile gangrene and apoplexy from diseased blood-vessels, both of which arise from a slowly acting error of nutrition, suddenly giving rise to a chemical or mechanical disease, which often rapidly ends in death, or when this is not immediately produced, the effect of the diseases in causing general or local loss of power is only very partially removed.

No part of the body is exposed to greater continuous action in proportion to the supply of blood to its structures than the arteries. From the semilunar valves to the arterial capillaries the structures of the air vessels are exposed to mechanical pressure comparable with the pressure of the atmosphere. Thus in man the pressure in the aorta is equal to one-third the weight of the atmosphere. It has been found to bc 9·7 inches of mercury. In the brachial artery it is equal to one-sixth, or 4·5 inches of mercury. Down to the capillaries this pressure is continuous, lessened by the friction of the blood in vessels. This pressure and friction have a direct influence on the chemical actions of nutrition and oxidation which take place in the coats of the arteries. When the pressure in the arteries is increased, the actions of nutrition and oxidation must be increased also, and with long-continued action a state of pertrophic action and peroxidation must be produced, giving rise to thickenings of the different coats, which entirely alter the chemical changes going on in them. Hence errors of disintegration arise, and suboxidation and subtrophie action readily occur. The acids that ought to be produced to dissolve the earthy matters are no longer formed; the fatty

matters no longer are oxidised, and hence fatty and earthy substances accumulate, and the healthy tissues are not formed. If the nutritive fluid be loaded with fatty matter, or if the supply of oxygen be deficient from any cause, or if the conditions on which the oxidising and nutritive actions depend be lowered, the errors of disintegration will more rapidly arise.

Wherever the arterial textures are injured or destroyed, there the mechanical pressure from within is less capable of being resisted, and rupture is ready to occur at the place of least resistance, and when any slight extra pressure is made the vessel breaks. If this happens in the brain a mechanical blow and a rupture of the nervous structures is produced, and paralysis is the result, the muscles being cut off from the action of the will. When the rupture is large, and the quantity of blood effused great, the pressure on the nerves that regulate the motions of the heart and muscles of respiration soon put an end to life.

When the smallest branches of the arteries are much thickened the supply of nutritive materials and the supply of oxygen to the textures beyond these arteries is interrupted. The day before the senile gangrene begins, the arteries supplying the part are nearly, if not quite as diseased as the day after when the mortification has commenced. The altered action in the textures begins only when the diminution of nutritive material has reached to a degree that alters the chemical actions of the part, or when the diminished amount of oxygen produces the same effect. From one or other or from both of these causes the part becomes livid, and gradually darkens until it becomes black; as the oxidation is stopping it becomes cold, and the accumulation of carbonic acid and the stoppage of the circulation render the nerves insensible. The stagnant blood exudes its serum under the cuticle, where there is least resistance, and the fluids gradually evaporating, leave a black brown mass in which vibrios are produced, and putrefaction is set up, varying in its products with the dryness and the temperature of the part.

The further a part is from the centre of the circulation the more the force of the blood is diminished by friction, and the more readily will the altered vessels cause gangrene to be set up. Thus the extremities are the seat of the disease, and in the toes the greatest loss of chemical action takes place. Around the dead part the obstruction causes an opposite action; increased flow of blood and increased chemical action amounting even to inflammation, occurs. At the part where the dead nerve joins the living structures the most violent pain may be produced, and this become so severe that perfect rest and the strongest opiates alone give any relief. The progress of the mortification can only be stopped by keeping up the temperature, promoting the circulation by position, and making the blood as abundantly nutritious as possible.

Very much less serious errors of repair than those which I have mentioned may produce most remarkable general and local chemical diseases. Debilitating climates and hereditary subtrophic actions give rise to results at places of greatest pressure and least resistance, which, but for the striking phenomenon produced, might almost escape notice. In such a structure as the kidney it might almost be expected that from the immense pressure in the arterial vessels albumen, if not blood globules, would constantly be forced through the dialysing membrane. In the renal artery the pressure cannot be much less than one-sixth of the weight of the atmosphere, and a considerable portion of this falls on the malphigian tuft, and has to be resisted by the walls of the vessel which separate the blood from the urine. If by subtrophic action this membrane is made less resisting, albumen may be forced through; when the pressure is increased, blood-globules may pass into the urine; and when the pressure is diminished, the blood-globules first, and then the albumen may disappear. So also in other parts of the kidney, where there is less pressure than in the tufts, as in the capillaries on the tubes in the medullary structure, a subtrophic action in the textures may allow an increased pressure in the capillaries to force out substances which would not escape if the dialysing membrane were thicker. From one or other of these places fat, albumen, and blood-globules may pass into the urine, and constitute the complaint known as chylous urine, which is worthy of a few minutes' attention, not only as an example of increased pressure producing wrong chemistry of the urine, but also because it furnishes the most striking contrast to Bright's disease in its course, and in its secondary diseases.

In chylous urine the daily loss of albumen may be as much, or even considerably more, than in Bright's disease, and yet the complaint may last for a quarter of a century, whilst the patient may continue his work, and, if he were blind, might know nothing of his ailment except by a feeling of more or less general debility. No secondary diseases are produced, no accidents occur except that sometimes so much fibrin may escape from the blood into the urine that it may cause the contents of the bladder to coagulate, and thus give rise to a mechanical impediment to the escape of the urine. The distention and obstruction may cause much pain and distress for a day or two until the clot shrinks, and the fibrin loses its cohesion and gradually breaks up and is passed away in the urine. Throughout the course of the disease there is usually no dropsy and no uræmia. The poisoning of the blood, which commences with the alteration of the different structures in Bright's disease, never takes place in chylous urine. The structure of the kidneys may let one or many of the constituents of the blood out when the pressure is increased, but the alteration does not keep the uriniferous substances in the blood.

In the *Medico-Chirurgical Transactions* for 1850 you will find the history of a patient who has now been under my observation more or less frequently for sixteen years. I shall here only bring before you the evidence of the effect of pressure in causing the altered chemistry of the urine.

The first specimen of urine I saw "was made at 9·30 a.m., one hour and a-half after breakfast, the patient remaining in bed. It was clear, acid to test paper, not light coloured; sp. gr. 1022·5. It did not coagulate when boiled and when nitric acid was added; but the acid made the colour deeper. On the surface there was a slight appearance of oil; one or two blood globules were also seen." "The second specimen was passed at 11.30 a.m., two hours after being up. It was of a yellowish-milk colour, quite thick, and spontaneously coagulated, so that it could not be poured from the bottle. The specific gravity was 1017·0. It was very feebly acid to test paper. Nitric acid and heat gave a considerable precipitate. Under the microscope I saw blood globules in some quantity. No trace of oil globules, but a large quantity of very minute molecular matter, scarcely resolvable by a magnifying power of 320 times. No trace of casts of the ducts could anywhere be found. Little films of coagulum could be seen, containing many blood globules. Treated with ether, the etherial solution was clear; the urine below was cloudy, but on long standing became clear. The etherial solution on evaporation gave a great mass of oil globules, but with the microscope no decidedly crystalline fat was seen."

In the *Philosophical Transactions*, Part II. (1850), you may see some further experiments on the influence of rest and motion in lessening or increasing the albumen in the urine previous to or after food was taken:—

Last food was taken at 5.15 p.m. yesterday. He laid in bed this morning till 9.30 a.m.

10 p.m. last night.—Urine milky.

6.40 a.m.—Urine yellow, slightly milky, acid, contained a little albumen.

8.10 a.m.—Urine clear, healthy looking, made just before breakfast, which consisted of boiled milk (a pint), with sago and bread with a little butter; the specific gravity of the urine was 1021.3; it gave no coagulum with heat and acid.

9.30 a.m.—Urine opalescent, but not spontaneously coagulable; specific gravity 1019·0; gave a considerable precipitation with heat and acid.

12.30 a.m.—Urine milky; spontaneously coagulated.

Contrast this with the following day, when he got up earlier and breakfasted as before, though half an hour later:—

Last food was taken between 5 and 6 yesterday. He got up this morning at 6 a.m.

10 p.m. last night.—Urine milky.

2 a.m.—Yellow milky urine, acid, slightly coagulating with heat and acid.

6 a.m.—Urine quite clear, healthy looking, acid, contained no trace of albumen; specific gravity 1026·4.

7.30 a.m.—Urine opalescent, feebly acid. Gave a large precipitate with heat and acid; contained multitudes of healthy blood globules, but no casts. Specific gravity, 1018·8.

9 a.m.—Urine opalescent; by 12 became a solid jelly, alkaline. This was passed just before breakfast.

11.30 a.m.—Coagulated spontaneously to a strong unclear, slightly milky jelly.

Experiments on other days gave the same results, showing that when he remained in bed the urine was clear, and did not contain albumen, and when he got up the albumen, fibrin, and blood globules passed into the urine before food was taken; so that I frequently determined beforehand whether the

urine before breakfast should be albuminous or not by directing the patient to get up and move about early, or to keep very quiet in bed. And by keeping him in bed all the day the urine throughout the whole day was very slightly albuminous.

Fifteen years after these experiments I have the following note:—

4 p.m.—Very milky urine. Specific gravity, 1031.

10.30 p.m.—Urine has slight milkiness. Specific gravity, 1029·5.

6.40 a.m.—Clear urine; specific gravity, 1020; contains no trace of albumen.

8.30.—Breakfast; up early.

9.15 a.m.—Urine clear; considerable precipitate with heat and acid. Specific gravity, 1023·0.

This influence of rest and of motion to me indicates that the disease depends on some slight alteration in the structure of the kidney, dependent upon some slight change of nutrition, which remains without perfect repair for years. Even with a slight increase of pressure the altered mechanical condition immediately affects the chemistry of the urine, and this to a degree resembling the wrong chemistry of the most serious Bright's disease, but none of the complications of Bright's disease occur; and sometimes, without any assignable reason whatever, or by the aid of strong astringent medicines, as gallic acid in large doses, the wrong chemistry will entirely disappear, and for a time at least the dialysing membrane appears to be sufficient to resist any pressure that it has to bear without admitting any of the proper constituents of the blood to pass through.

In order to show you how vast this subject of errors of chemical repair is, I must very briefly close this lecture with a sketch of one other chemical disorder arising from the injurious action of a chemical substance affecting the growth of the epithelial textures of the body. I allude to chimney-sweep's cancer produced by the action of soot.

The most violent opponent of spontaneous generation never can believe that any germ passes in with the soot, nor is it conceivable that any nervous or vascular action can transform an epithelium cell into a cancer cell. Whether the epithelial cancer be superficial in the vete mucosum; or deep, commencing in the epithelium of the sebaceous or sweat glands of the scrotum, or in the epithelium of the hair tubes, it consists in no error of oxidation, but in an entire change in the chemical growth of an epithelial cell.

It was for a time considered that a characteristic form of cell, a so-called cancer cell, marked this altered growth; then it was believed that an error *loci*, a peculiar birth-place, gave rise to it. The cellular tissue produced it. A corpuscule of the cellular tissue became an epithelial cancer cell. Most recently Dr. Thiersch has stated that the disease comes from the loss of the right balance of pressure between the epithelium and the stroma of the skin. The necessary equilibrium is destroyed by insufficient growth of the stroma; this gives rise to the peculiar increased development of the epithelium.

Although any peculiarity of form as characteristic of cancer is given up, and we no longer recognise it by fusiform, caudate, multinucleated, or polygonal cells, yet it is by no means unlikely that chemistry will detect some difference of substance; for the growth, propagation, and consequences of an epithelial cancer cell prove that it differs from an ordinary epithelial cell, and this difference of action probably is connected with a different chemical composition.

Not only does the soot act on the scrotum, but it even acts on the hand, and the pressure of the pipe on the lip or of the finger and thumb during shaving, and the lessened actions of declining years, all may lead to an altered epithelial cell growth. The cells no longer become healthy texture, but like pus cells they grow and multiply and oxidise and decay. Wherever a cancer-cell forms it begins its increased chemical action of nutrition, and it easily sets up peroxidation, and this adds the effect of ordinary inflammation to the altered nutrition of the part. At first, or indeed at any time, the increased flow of blood may cause all or any of the healthy structures to increase; thus the epithelium, the papillæ, the blood vessels may grow or waste, according as the nutritive fluid is attracted by growth or retarded by pressure. Even in the arteries themselves these changes may be observed, the inner epithelium coat may become thickened. The middle muscular coat may be still more developed and the outer coat of thickened cellular tissue may be extremely enlarged; after long-continued pressure the outer coat becomes fatty; the form of the vessel may be so changed that it becomes triangular instead of round. Generation presses on generation, and the multiplied growth exerts a pressure on all the neighbouring textures; so that increased action is accompanied in places by decreased action, and disintegration and suboxidations occur. The pressure destroys not only the healthy increased growths, but the very cancer cells themselves, so that they, in the places of greatest pressure, waste, become horny, fatty, or even earthy before they entirely disappear.

The abnormal growth takes the place of the healthy structures, and more especially in the deep-seated form of epithelial cancer, a single cell, or possibly even a nucleus, or a granule, or a possible cell, grows into an afferent lymphatic vessel, and is immediately carried to the gland. There it is stopped, and there it goes through the same series of actions as it would have gone through in the skin—at first, pertrophic and peroxidising actions, to be followed by subtrophic and suboxidised results, whilst rapid increase of epithelial and cellular growth goes on until a particle spreads into the efferent lymphatic, from whence it passes to any organ, and sets up a new colony, going through the same cycle of actions as it would have gone through in the skin.

At present, no medicine is known which can keep up the healthy formation of the epithelial texture, or which is able to stop the too prolific growth of the cancer cells. The chemical or mechanical removal of every outlying cancer cell alone can afford a respite, and in a few cases of epithelial cancer may give a perfect cure of the disease.

ORIGINAL COMMUNICATIONS.

LITHOTOMY IN SMYRNA.

By JAMES McCRAITH, M.D., F.R.C.S.,
Surgeon to the British Seamen's Hospital, Smyrna.

To the eighteen cases of lithotomy, as reported in the *Medical Times and Gazette* of July 2 and July 9, 1864, I have to add six additional cases since then, all of which have been successful, making two actual deaths in twenty-four cases—one of these deaths, as I then explained, ought not to count. I am induced to report these latter cases on account of the interest which I conceive attaches to two of them,—to one on account of the very large size of the stone removed by the "median" operation, the age of the patient (65 years), and the very satisfactory result; the interest in the second case is, the stone was encysted for a space of fourteen years, during which all the symptoms were more or less in abeyance, but recurred after this long interval with terrible violence, driving the poor patient to submit most willingly to any operation giving him a chance of relief.

I beg leave to make some remarks on the case of the old man with the very large stone:—

The calculus weighs 4½ ozs., is of a pear-shape, slightly flattened. Its chemical composition is given in the accompanying table. Assisting at the operation were Drs. Wood, Chasseau, and Edward McCraith. One would naturally suppose that such a large stone must be easily found and indicated by the sound, yet such is by no means the case, and for the following reasons, I believe:—The stone fills up the bladder, being moulded to its shape; if water be injected it will be forced into the upper part of the bladder, and the sound passing behind the stone is engaged in folds of the bladder; it cannot move freely, and it is impossible to get anything like the sensation which a moderate-sized stone moving freely in the bladder gives when struck by the sound. It will only be when jerking the sound towards yourself that you get the sensation of a foreign body being in the bladder, and you are then doubtful if it may not be a large tumour which you have in hand; a little manipulation, however, will give evidence of its being a stone. The above facts may, perhaps, be diagnostic of a very large stone. The time during which the symptoms may have existed will be no indication of the size; this very large stone was only eighteen months in forming, the symptoms dating only for that period. The calculi of urates or phosphates form quickly; the oxalates are very slow in being formed.

The old man was well, and left for Candia (his home) in three weeks. It is No. 34 in the table.

The points of interest about the second case which I will notice are the following:—The patient, 25 years of age, suffered severely from symptoms of stone when 3 or 4 years of age. This suffering continued for a couple of years, and then

gradually eeased (the stone bccoming encysted), to recur after sixteen or eighteen years, and then so severely as to make the patient submit to any operation. The three cases of encysted stone which have fallen under my observation were diagnosticated as such from the rectum. In this country it would appear that encysted cases are not rare, and the eyst was in the neck of the bladder in each case. Reasoning theoretically, it should always be so, as the stone must be driven into such a state (encysted) in an empty state of the bladder, when of course it lies at the neck, and being grasped spasmodically it must be driven forward into the neck, and the cyst there found. The body of this stone is of a longish pigeon's egg shape (this was eontained in the eyst) ; then a neck or stem surmounted by a button-shapcd body, flat on the top. This latter was contained in the bladder, and being struck by the sound gave me the idea that there were two stones, one encysted and the other free, and I gave such as my opinion to my *confrères* assisting at the operation. In operating I quickly came on the encysted part, and on pulling on it gradually it broke off at the neck, leaving the head or button-shaped part in the bladder. The eyst only was divided, and I had to enlarge the small opening into the bladder with a button-pointed bistoury and my finger as director to get this part away. The entire proceeding took less than a minute. The patient took nearly two ounces of ehloroform on this occasion, and also, when sounded three or four weeks before, he required the same amount. Prescnt at this opcration : Dr. Wood and Dr. Nazick. No urine passed by wound after thc seventh day.

You will allow me to make a few observations which I conceive may have some importancc with regard to the question of median or lateral operation. All my later cases are of the median category. In encysted cases I suppose all will agree that the median is alone applicable. The stone is fixed in the centre or median line in a cyst; you cut on it direct and bring it away ; the communication between this cyst and the bladder is in the median line ; you evidently can get at this, and if necessary enlarge it, much more conveniently from the centre. There is no qucstion of this in my mind. The median should alone be performed in all the encysted cases I have scen.

Now, as a general question, the chief advantage claimed for the lateral is the greater space it allows for the extraction of large calculi. The first case detailed in this paper is a proof that space enough can be made by the median operation for any calculus which can be met with in the general run of eases, this being far beyond the usual size of ealeuli, and yet extracted without much difficulty, and with perfect and quick cure. It is, therefore, a practical answer as to the space to be given by the median, being enough for all praetical purposes. But I eonceive the median has other and great advantages over the lateral, which, if I am right, should decide the question at once in its favour. They are the following :—During the operation, 1st, the Surgeon knows exactly where to make his incisions ; nature has marked the line—no small advantage to one who has not had much experience. 2nd. The incisions are direct into the bladder ; the manipulation of instruments therein, on that account, either to seize a small stone or broken pieces, is much easier ; the washing out of *débris*, and the escape of blood, elots, and the flow of urine are facilitated. 3rd. You cut much more easily and securely on the groove in the staff when the latter is held centrally, than when held slantingly, as it must be in the lateral opcration—a most important step in the operation thereby facilitated. 4th. You run little or no risk of arterial hæmorrhage ; the pudie being safc, and no risk of dividing a large branch elose to the point of origin, which may happen in the lateral. 5th. The vasa deferentia are safe, and the testicle consequently not affected ; I have seen severe inflammation of testicle after the lateral. 6th. In extracting a large stonc, as in the presont instance, I think the dilatation of the parts more easy ; and should some laceration take place, I consider it much less injurious whcn in the centre, between the lobes of the prostate, than when taking place through the lateral lobe ; there is less risk of infiltration. But after the operation there is one advantage gained by the median, which, if it be acknowledged by the Profession, should decide in its favour. It is this :—The parts, when healed, are in a normal state, because in the median no muscular fibre need be divided ; they may simply be separated, and no nerve is cut across its centre ; whereas in the lateral all the muscles are divided more or less, and one—the transversalis —is cut quite across ; and the cut ends of a muscle so divided tend to kcep the wound open, and the muscle itself can never be normally restored ; the functions, therefore, of those delicatc parts are more or less interfered with ; the result, incontinence of urine, or permanent fistula—derangement, in fact, of the functions of the part. After the median, none of those risks exist, and, in fact, in my twenty-five cases I have had very quick cures, and no resulting inconvenience. Table of last seven cascs is given below :—

No.	Weight.	Dimensions.	Shape.	Composition.	Age.	General Appearance.	Result.
31	ʒiss.	$1 \times \frac{3}{4}$ inches.	Flat oval.	Urates and oxalates.	5	Concentric layers	Cure.
32	ʒss.	$1 \times \frac{1}{2}$	Long oval.	Phosphates.	11	Shining long crystals, standing on end, like No. 3 in former list.	Cure.
33	ʒiij. ʒij.	$1\frac{1}{2} \times 1\frac{1}{8}$	Irregular square, and curlish, like a piece of mortar.	Oxalates, fortification character on section, urates on outside.	30	Irregular squarish, like a piece of mortar.	Cure.
34	ʒiv. ʒiv.	$3\frac{3}{8} \times 2$	Long, roundish.	Urates and oxalates.	65	One end larger than the other.	Cure.
35	ʒij.	Broken in extraction.	Roundish.	Urates.	9	Do.	Cure.
36	ʒiij.	$1\frac{5}{8} \times \frac{6}{8}$ Head, $\frac{7}{8} \times \frac{5}{8}$, flat. Body, $1\frac{1}{4} \times \frac{6}{8}$ Neck, $\frac{3}{4} \times \frac{2}{8}$.	Long, oval, round body, with a neck at one end surmounted by a button-shaped head.	Urates body, phosph. head.	25	—	Cure.

NOTES ON, AND RELATING TO, CHOLERA.

By JOHN PATTERSON, M.D.

After more than half a century the Medical world is beginning to acknowledge that little, if any, advance has been made in the treatment of cholera, and that at prcsent it is the opprobrium of the Profession. This disease has been treated in every country, under every known condition of climate, in every rank of life, and with every application that enlightened and suggestive minds produced. With all these facilities for observation and treatment, it does seem strange that no remedy should have been discovered, and that the nature of the disease has not been elucidatcd. Surely the time has now come when we are justified in asking what must be done to satisfy the public mind that we, as guardians of the public health, have done all in our power to discover the origin and nature of this scourge of the human race, and that we have, as is our duty, pointed out to the heads of the various Governments the course to be adopted for the public welfare ? These questions are now being asked, and soon, probably, our Profession will be invited to give a clear exposition of its views of this disease at the International Sanitary Congress. In what position are we to comply with such an invitation ? Have we any clear idea to express as to its nature or treatment ? Can we answer that our treatment has been based upon any sound principle of pathology, or shall we confess that every one of us has acted on a very vague idea of the nature of the disease he has been called upon to treat, and has applied remedies on a purely empirical principle ? Serious questions these ; yet most surely they are being asked, and demand our careful consideration. There certainly has been no lack of zeal and industry on our part as a body. Would that we could add the results were more satisfactory ! The various theories of the day of the nature and manifestations of this disease, the diverse and often startling plans of treatment suggested and applied, the still fearful mortality, give too direct an answer to these questions. Shall we now quietly sit under the dogma that no treatment, no specific, has been, or ever will be, discovered for a pestilence ; or shall we own that our researches have not been conducted in such a way, or our treatment applied in such a manner, as a sounder pathology might suggest ? What has been the object of treatment for the last fifty years ? To check diarrhœa and vomiting by opiates and astringents, in spite of

the positive evidence that this is seldom accomplished; to stimulate the liver to secrete, and anxiously watch for the coloured motion, which is the indication of improvement, as if it were a certain result of the medicine, when more likely it is the first indication of the general returning vitality, which permits the organ to resume its natural function, and which, in cases of recovery without medicine, is equally well shown, and which never takes place till the reaction from collapse, however mild that may be, begins to show that the system is recovering from the shock which caused the first disturbance. To apply warmth and external frictions (which is certainly the only part of the treatment that looks efficacious), in conjunction with diffusive stimuli, to produce heat where there is cold, and to stimulate the visibly flagging powers of life, although this has not always been done with due regard to the principle on which it should be applied. These principles of treatment have guided the mass of the Profession in every country; and what have we to show for it? Simply that no definite knowledge of the value of any medicine has been obtained in spite of the variety of treatment, inasmuch as no cases were treated without external stimulation being applied at the same time, and the probability is that this was the most efficacious; that often the after-consequences of many of the medicines have been injurious; that, until within a very short time, we have had worse than ridiculous statistics of the results of treatment in various countries, arising either from the desire of some to gain a fleeting reputation by pretending to cure, or, perhaps, believing they really did cure, by forms of treatment daily practised for simple diarrhœa; that our knowledge of the contagious and infectious character of the disease is as limited as ever, no two men holding the same opinion; lastly, we have the same fearful mortality as when the disease first appeared. That this is not an exaggerated picture four fearful experiences of cholera in England and Egypt prove. Every form of treatment suggested I have seen tried, and by Practitioners of every civilised country. The honest opinion, of all whose opinion was worth having, is, that Medical treatment has done little. What, then, remains for us to do? To re-open the subject, and endeavour to obtain some clue to the nature of the poison which causes this disease, and its *modus operandi*, either on the nervous system directly or through the blood; to ascertain by careful and scientific meteorological observations, and by chemical analysis of the air the relations that varying atmospheric conditions bear to its progress; to ascertain what peculiar affections of the nervous system attend these varying conditions of atmosphere, which all admit prevail at these periods of epidemic, and which are more marked in warm climates. We have seen the great advances made in England alone in the study and treatment of fevers from opening out a new field of inquiry, and basing our treatment on certain known pathological conditions, modified by external conditions of climate, food, etc., after many years of what seemed a profitless discussion. Can we not do the same by this fearful pestilence which continually revisits us? It seems now certain that we must disassociate certain fixed ideas as to the nature of cholera. It must be considered something more than purging and vomiting, that being but secondary, and either an elimination of the *materies morbi* which should be checked, or a simple mechanical transudation which cannot be checked until the vital power of the mucous membrane is re-established. The able papers of Dr. George Johnson on this subject, embracing the former view, are suggestive of inquiry. I cannot, for one, as yet, agree with him, as they do not sufficiently explain the nature of the nervous shock, which I have shown, in a previous paper, constituted a marked feature in a recent epidemic, which, from its very severity and clearly-pronounced characters seemed to throw a clear light on the operation of the poison; nor do I think, with such a condition of the blood as Dr. Johnson supposes exists, that the cerebral functions would be so perfectly clear as they are in cholera.

This very marked condition of perfect intelligence has not been sufficiently considered as likely to throw light on the disease. It is more consistent with a diseased condition of part of the nervous system, especially the ganglionic, which we believe may receive impressions and not affect the brain, than with his theory of a blood disease. It is, however, probable there may be a close connexion between the two. The great restlessness and anxiety of many cholera patients, throwing themselves about so unceasingly is more indicative of sudden depression of the nervous system than that irritable restlessness induced by loss of blood or alteration in its quality. The collapse of pestilential cholera is also different from the collapse of excessive diarrhœa and vomiting. The sudden shrinking which we observe when there has been no great waste of the fluid of the blood, the extreme corrugation of the skin and contraction of the subcutaneous tissues, by which the capillaries are acted upon, seem to indicate something of the nature of shock, and show an action of the sympathetic system on the general circulation, which is also conformable to our notions of its action on the arterial system in preserving its healthy tone. Some of these conditions seem incompatible with the theory of Dr. George Johnson of infected blood, and are respectfully submitted for his consideration and inquiry. It is only from a careful consideration of such facts by such a man that we shall arrive at any useful conclusion, and I desire to provoke a new spirit of inquiry, that useful and philosophic spirit of inquiry which consists in something more than each man telling how many cases he has cured by such and such a treatment, which, when his neighbour tries it, is found useless, and brings us into notice rather as charlatans than sound pathological and physiological inquirers. The time is near at hand when we shall be called upon as a body to give some useful account of our labours. The International Sanitary Congress cannot but desire to take the opinions of scientific Medical authorities of the various countries of Europe, and then submit to the whole world the conclusions they have arrived at. It is probable the Commission may decide on certain sanitary precautions for Europe; how far these shall be based upon scientific Medical conclusions, or simply upon the experience and observation of shrewd outside observers, must necessarily depend upon the account we have to give of ourselves.

The great Powers of Europe have suddenly come to a resolution to try and prevent the progress of cholera—to shut it up, as it were, within certain limits, and prevent its spreading to Europe. What are the probable means at hand to carry out this very laudable intention, and what are the data they will act on? Are there really any definable limits to this disease? If so, it must have frequently overstepped them. Is our knowledge of the varying conditions of atmospheric temperature, electrical tension, development of ozone and other climatic conditions, so perfect as to determine those epidemic constitutions of atmosphere, and enables us to limit or arrest them by any system of quarantine? Can we say that cholera is infectious or contagious, and that such measures will have effect? Much attention has, of late, been directed to Egypt as the source of this malady. The pilgrims have been considered the importers, therefore by stopping the pilgrims bringing it to Egypt, its progress towards Europe will be prevented. But the pilgrims come to Egypt every year, and they do not bring cholera with them. The pilgrims come too from India; others, not pilgrims, also come from India, China, Cochin-China, and places where cholera is ever present. Do they ever bring it with them? In the early part of the year 1865, cholera was known to be gradually spreading from place to place along the shores of the Red Sea, long before any idea of the pilgrims bringing it ever entered the minds of people, keeping then as erratic a course as it has since done. If the doctrine of contagion and infection holds good, why did it leave some places untouched, in a straight line with others that were severely affected? On the other hand, how explain its locating itself in several places, giving apparent evidence, if one did not carefully examine it, of communicability; or, against the generally received opinion, attacking, as if *par preference*, the young and healthy and temperate, whilst the aged and weak and the hard-living escaped? It may be well worth our consideration what answers we are prepared to give to such questions.

The opportunity should not be lost of the present Congress. What cannot be done by the Medical Profession unaided may be done by the assistance of the various Governments. What is needed? A regular system of meteorological and chemical observations of the most accurate kind in India, China, and Cochin-China—at the places where cholera is known to take its rise. For the various Governments to have properly qualified persons, at home and abroad, provided with instruments and everything necessary to carry on an extended course of observations in the intervals of epidemics, and, when the disease appears, to carefully note its line of march and the varying circumstances likely to have a bearing on it.

To have some able pathologists and physiologists to watch the disease carefully, and make accurate post-mortem examinations, and to give them opportunities of studying the disease under circumstances likely to eliminate sources of error; not to leave this work altogether to the unaided zeal of

common meteorological observers, and to the anxious and over-taxed mind of the practising Physician. Something of this kind is certainly wanted, and will probably do more good to mankind at large than what is likely to result from any local quarantine, which can rarely be properly enforced, and which almost all are interested in evading. And it really does not look like a bright idea to suppose that a local quarantine in Egypt will limit a disease like this, which is generally believed to be dependent on atmospheric conditions, operating over a large space, and often in several places at once on the same continent. If quarantine has to be applied for this purpose, the most natural way of imposing it would seem to be that of trying to limit the disease to the countries where it is generated—the Indian continents—not an easy matter certainly—but for the European Powers to try and keep it away by placing one way of communication in quarantine and leaving the others open, even allowing for a long sea voyage, seems strange enough. These reflections on cholera have arisen during a tour through Europe, and from conversing with my brethren in various countries on the nature and treatment of cholera, and from observing everywhere how little prepared we are, as a Profession, to answer the questions likely to arise. Lastly, from the humiliating feeling that so many years' experience has not enabled us to alleviate much the fearful scenes many of us have lately been called to witness, and from the desire to stimulate a spirit of earnest inquiry as to the nature and conditions of this fearful plague, and to discover some remedy.

Cairo, Egypt.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. MARY'S HOSPITAL.

ABSTRACT OF CLINICAL LECTURE ON A CASE OF PARALYTIC CONTRACTURE AFTER FEVER.

(Under the care of Dr. HANDFIELD JONES.)

F. R., aged 12, an emaciated boy, was admitted under my eare December 30, 1864. He had been ill about four months, had passed through a severe fever, in which there had been much diarrhœa and bed-sores had formed on hips. Sinee this illness he has never been able to stand. As he lies in bed he has evidently almost complete paraplegia; can only just stir his feet a little. The right knec is very much flexed, and the left somewhat also. He can use his hands and arms freely now, but some time after the fever was unable to use his left hand and forearm; the right upper limb has never been affected. The sensory power in the lower limbs is disordered, the right is hyperæsthetic; he cannot bear to have it touched or stirred; if it is, he feels pain all up the limb. The left is in a similar state, but not so badly affected. Sphincters have never been paralysed. On trial the muscles were found very insusceptible to the interrupted eurrent. Appetite good; bowels regular; sleeps fairly; pulse very feeble. Urine neutral, pale, specific gravity 1015, not albuminous, deposits a notable quantity of pale flocculent sediment, which contains numerous cast-like objects of granular appearance and various size. The urine was in the same condition and deposited the same sediment fourteen days later, when the casts found in the sediment were made out to consist of a central cylinder of organie matter clustered over with refracting granules, which disappeared with effervescence when nitric acid was added, and were therefore probably carbonate of lime. On one occasion, some days previously, a cast was seen covered with minute oxalates. Hc was ordered gr. v. of citrate of iron and quinine and cod liver oil, which he took till February 1, when the former was replaced by strychniæ gr. $\frac{1}{20}$. The dose of this was raised after ten days to gr. $\frac{1}{16}$. On February 1 I made a note "that he has still very feeble power over his lower limbs, but moves his legs much more than his thighs; the sensory power appears perfect." Improvement to a notable extent had evidently taken place. On the 11th I noted that his right leg was rather stiff in the mornings, but he moved it as well as the other in the evenings. On the 18th the report is, "Urine pale and elear, specific gravity 1007, slightly acid. Right lower limb is nearly rigid in a semi-flexed state; very slight passive movement can be made at the knee-joint; the calf muscles are tense and also the extensors of thigh, but the muscles on the posterior aspect of thigh are tolerably lax. The left lower limb can be almost perfectly extended. Both are quite moveable at hip-joints. Both feet feel equally cold, but above the ankle the right limb is distinctly eolder than the left. Sensation is good, and equal in both legs. Complains of pain only in the right groin. No pain at all felt when spinal column is percussed. Looks well in face. Pulse weak." Ordered pot. iod., gr. iv.; ammon. carb., gr. ij.; tinct. cinchonæ, ʒj.; aq., ʒj., ter die. Pt. c. oleo.

February 28.—Cannot stand alone, but ean get along by himself with erutches; the right knee is still stiff, and he has but little power over the leg; his face looks bright and rosy. Urine pale and clear, specific gravity 1012. On closer examination it appears that it is the calf muscles especially which prevent the right leg from being straightened. They are felt tense and resisting, while the long flexors of the thigh are lax. Chloroform was now administered, and he was rendered quite insensible. The orbicularis palpebrarum did not act at all; the arms were lax for a short time, and fell when raised as inert masses, but the tense condition of the calf muscles (gastrocnemii) never changed at all. When the knee is flexed the muscles become lax enough, but are rendered tense by extending the joint. He was ordered ant. pot. tart., gr. $\frac{1}{6}$; liq. opii sed., ɱij.; M. C., ʒj., ter die. Pt. c. oleo.

March 4.—When lying on his back he can kick vigorously forward with his left foot (the knee being bent), but cannot do the same with his right; can just stand alone.

8th.—Is improving; ean extend the leg on the knee; ean kick with the right foot. Urine deposits phosphates copiously. Pt. c. mist, quater die. Pt. c. oleo, ʒij. ter die. Warm hip bath with douche to back every night.

15th.—Improves; can hobble about pretty well without crutches, but cannot yet stand on the right leg alone. While he is having the hip bath and douche to the loins the right lower limb becomes much straighter, as the sister reports.

22nd.—Some sickness produced by the antimony, thc dose having been increased to gr. $\frac{1}{4}$. Omit it. Pt. c. oleo, ʒj., ter die.

29th.—Walks about quite well without a stick, but the calf muscles still retain the knee-joint in a slightly flexed state; he can extend and flex it up to a certain point, but the extension is incomplete. Has had for the last three nights a large Pulvermacher's chain applied from the hip to the calf; it causes a pricking sensation, but there is no ulceration. Girth of right thigh = 13 inches, of left at corresponding part $13\frac{3}{4}$. Urine specific gravity 1028, turbid with lithates, not albuminous. Atropiæ gr. $\frac{1}{64}$, injected subcutaneously into ham. Pt. c. oleo. Ferri citratis, gr. v.; acidi hydrocy. dil., ɱiij.; tinct. calumb, ɱx.; aq., ʒj., ter die.

April 12.—He can walk and run now; the right knee is not quite straight, but very nearly; he can stand on the right leg alone. Discharged.

Remarks by Dr. Handfield Jones.—There can be no question in this instance that the palsy was the result of the fever. The impairment of nutrition which the disease so commonly induces affects sometimes one part, sometimes another more gravely. Generally, the more peripheral parts, the muscles of the limbs, or the skin, suffer, while the central and more important organs escape. It is well known, however, that the heart is often gravely affected, and we have recently had a very good instance of this occurrence. Some of you will remember the youth who lay for two or three weeks, after his fever had apparently ceased, with a most feeble pulse, an imperceptible cardiae impulse, and an all but extinct first sound. For many days 15 oz. of brandy taken with milk daily seemed no more than sufficient to keep up his feeble circulation, though his general muscular power was not so much impaired as to prevent him from changing his position in bed, and the skin retained its vitality, for he was free from bed-sores. Turning to the nervous centres, we find that a previous attack of fever has not unfrequently been recognised as the eause of such disorder of the brain as has issued in some form of insanity. Drs. Bucknill and Tuke state from 2 to 3 per eent. of the admissions are due to this agency, and that the mental malady is more apt to occur after typhus than after typhoid, and in this case is less curable also. In children, they add, it is not uncommon for illusions or extreme nervousness to last for some time after the attack of fever, but they pass away commonly as the strength is restored. M. Thore(a), in a paper on the relations between chorea and insanity,

(a) *Annales Med. Psychol.*, March, 1865.

observes that a severe typhoid fever, complicated with cerebral symptoms, constitutes a serious predisposition to lesions of intelligence. There is at present a girl, aged 25, under my care in Victoria Ward, who has passed through a severe attack of typhoid, in the course of which she became extremely deaf, and had also a good deal of noisy delirium. The fever has long been at an end, but, though she is quieter than formerly, her deafness persists, she does not regain flesh or strength, and appears rather to be gradually wasting away—so much so that I made an examination of her chest recently with the expectation of finding some evidence of tuberculosis in progress. Concurrently with this general *dèpèrissement*, her brain seems to be undergoing atrophy, she has a semi-demented aspect, refuses food, and passes all her evacuations in bed. Her pulse is, indeed, very feeble, but not at all more so than it is in many sick persons whose cerebral functions are performed very differently. No doubt can exist that in this instance an originally not over strong brain has been so depressed by the fever process in its functional power that there is much ground for fear that it will never recover, but lapse still further into a condition of hopeless structural decay. The persistent deafness is no doubt owing to a like state of the auditory nervous apparatus. In the case of the boy which I related at the commencement of this lecture, the spinal cord failed to maintain its nutrition, while the brain resisted the depressing influence. The spinal centres of the lower limbs seem evidently to have a less vigorous and enduring life, and, therefore, to be more liable to succumb to morbid agencies than those of the upper. While superior paraplegia from spinal disease is infinitely rare, inferior is abundantly frequent. This may be in part due to the greater length of space between the volitional centres and the inferior than between them and the superior; but that this cannot be the chief cause is shown by a case recorded in my Lumleian Lectures, in which two tumours situated on the pons Varolii caused paralysis of the lower limbs, while the upper almost entirely escaped. Moreover, in the disease termed "locomotor ataxy" the wasting changes are most advanced in, or may even be confined to, the lower enlargement of the cord. In reflex paralysis the lower limbs are much more often affected than the upper; and the same is true, I think, of myelitis and white softening. Rokitanski, speaking of apoplexy of the cord, says that in adults it is confined to the lumbar portion. The failure of nutrition and of functional power in the cord could not have advanced so far as to produce actual dilapidation of structure, I think, as in that case recovery would not have ensued so completely. I regret very much that the record of the case is not so clear as could be wished with respect to the period when the shortening of the muscles first appeared. My own impression certainly is that it did not exist when he was admitted, but the sister's testimony was decided the other way. However this may be, it is plain that in the later stage of the disease we had to deal with a real shortening of the muscles attached to the tendo-Achillis, and not with a spasm only. This state was materially amended by exercise and by passive extension of the joints, which was frequently performed. What is the exact condition of the muscles which thus shrink and shorten when paralysed from disease of their animating nerves, we do not know, but it may be surmised that some alteration occurs in the sarcous elements approximating them to the condition of ordinary fibrine, which, as we know, has a marked tendency to retract and draw together. The indications of treatment were tolerably plain, tonics and restoratives were evidently necessary at first; but at a later period, though cod liver oil was still beneficial, it was clear that we should have gained nothing by persevering with strychnia. On the other hand, I incline very much to believe, though I would not speak too positively, that the small doses of antimony which we administered were really of much service. At any rate, improvement, which was at a standstill just before, went on very fairly after the use of this drug was commenced. Ackermann's observations go to show that antimony has the effect of diminishing very much muscular irritability; and it is conceivable, therefore, that it may be of service in states where the muscular tissue has a tendency to pass into a state of permanent and increasing contraction. Mr. Holmes Coote states that antimony in small doses, continued for many months, together with purgatives and stimulating embrocations to the limbs, constitutes the best treatment for infantile paralysis—a disease not altogether dissimilar to that which we have now before us. The persistence of the rigidity during chloroform anæsthesia, and the lax state of the muscles when the knee was flexed, seem to me to put it out of the question that the contraction was dependent on existing irritation of the nerves; yet I do not well know how to reconcile with this the statement made by the sister that during the warm bath and spinal douche the limb became much straighter. In all case of paralytic rigidity or contraction, passive movements of the limb should be practised diligently. I have heard of very unexpected results being thus produced. Steady perseverance in this proceeding may enable us to dispense with division of the tendons.

ROYAL FREE HOSPITAL.

CASE OF IMPACTED FRACTURE OF THE NECK OF THE FEMUR—RECOVERY WITH FIRM UNION, AND A FREELY MOVEABLE JOINT—LIMB SLIGHTLY SHORTENED—CLINICAL REMARKS.

(Under the care of Mr. GANT.)

This case is the continuation of a series of interesting cases on injuries and diseases of the hip-joint, which have been under Mr. Gant's care at the Royal Free Hospital, and reports of which have appeared in the columns of this journal. Last year, four consecutively successful cases of excision of this joint were communicated, as illustrations of what he appropriately terms "Pathological Operative Surgery,"—so named, as indicating the kind of knowledge which originally suggested all such local and limited operations, instead of amputations, for diseases of the joints otherwise incurable; and, moreover, as representing the guidance of pathology generally, in the design and performance of operations which characterise modern Surgery.

The following uncommon case—for the particulars of which we are indebted to Mr. Hackney, House-Surgeon to the Hospital—well exemplifies the suggestiveness of pathology in the *diagnosis* of an obscure form of injury to the hip:—

Respecting the diagnosis of the case, Mr. Gant remarked that early detection of the kind of injury much concerned the credit of the Surgeon, as well as being of great consequence to the patient. The interest of both turned on the fact that impacted fracture might be overlooked, and the symptoms attributed to a sprain of the joint, an oversight which would inevitably entail incurable lameness to a far worse extent than pertains to the injury itself.

The presence of extracapsular fracture *without* impaction cannot be mistaken. All the symptoms are exaggerated, so to speak, to the highest degree—the shortening of the limb, possibly to the extent of two or three inches; the complete eversion; the flattening of the hip, masked only by the severe contusion which generally accompanies the injury as caused by direct violence; the crepitation when the limb is drawn down and rotated inwards; the mobility of the great trochanter when it can be felt; the utter helplessness of the limb, and the extreme pain, which indeed renders inexcusable much, if any, manipulation in search of the local symptoms referred to, for the aspect of the limb itself and its diminished length, coupled with the contusion of the hip joint, are together sufficient evidence as to the kind of injury. Intracapsular fracture, *without* impaction, is recognised by the same symptoms, only in a lesser degree, particularly with regard to the contusion, which is generally conspicuous for its absence. But here, with impacted fracture, we noticed the absence, or nearly so, of all the symptoms enumerated, except shortening of the limb, and this only to the extent of about half an inch in the first instance. All the other symptoms were reduced to their lowest degree, so as to almost escape observation; yet this very negation of the usual symptoms suggests our diagnosis. Observing some degree of shortening after recent injury; without eversion of the limb, or scarcely any; without alteration of the contour of the joint itself, or scarcely any; without perceptible crepitation or alteration of mobility at the seat of injury, and without much power to raise the limb; then we have before us a case of impacted fracture. The pain and partial inability to use the limb may point to sprain as the kind of injury which the hip joint has sustained, but the shortening without the concomitant symptoms of fracture assure us of the presence of an *impacted* fracture.

The diagnosis between impaction within and without the capsule is of no practical consequence.

W. C., aged 48, labourer, admitted October 4, 1865, was knocked down by a drunken man in the street. He (the

patient) fell on the pavement, striking his right hip, and with the leg twisted under him. On attempting to arise, he found he had no power in the right leg, which felt, as he described it, a "dead weight" to him. Any attempt at moving it also caused great pain in the hip.

He was brought to the Hospital, and on examining him in the recumbent position, the following symptoms presented themselves. The limb is slightly shortened—not more than half an inch less in length than the left—and it is slightly everted; but there is no marked flattening of the joint, the great trochanter being quite perceptible, although a little higher in position than on the left side; nor, on the other hand, is there any notable contusion or swelling. No crepitation or preternatural mobility can be felt on rotating the limb and grasping the trochanter. Lastly, there is not total inability on the part of the patient to use his limb. He can lift it off the bed to a height of some inches, and lower it again pretty steadily, though the movement is evidently attended with great pain.

The limb was allowed to remain at rest for two or three days until the immediate effects of the injury had passed off, and the hip would bear the pressure of a splint.

October 8.—It was noticed that the limb had shortened upwards of half an inch more, making the whole extent of shortening upwards of an inch. It was also then specially noticed that the shortening could not be altogether overcome, and the limb brought to its proper length, by extension.

A long splint was applied with a perineal band, and by tightening this occasionally to increase the extension, the limb was gradually brought down to only half an inch of shortening, which was the length finally attained at the end of a month. When the splint was removed a gutta-percha splint was then moulded to the hip, and a starched bandage applied over it. The patient was allowed to get about with crutches. Nothing worthy of note occurred afterwards.

December 5.—The patient can bear his weight partly on the limb, and can swing it freely, but soon becomes tired. His general health and strength, which were feeble before admission, have now much improved under the influence of good living, quinine, and cod liver oil. In this state, or a better, as to use of the limb, he left the Hospital on December 28.

SATURDAY, APRIL 14.

DEATH-RATES.

An able writer (whose hand we fancy we recognise) on the "Fallacies of Sanitary Statistics," devotes some space this month in the columns of a contemporary to strictures upon a "statistical delusion" involved in the practice of quoting "what are supposed to be local death rates."

The writer we refer to objects to the publication by the Registrar-General of the rates of mortality of the twelve towns which are given in the weekly return for London, on the ground that "the proportion which the deaths occurring in a very limited period of time in any town or district bear to its assumed population is no true test either of the salubrity of the place or of the longevity and healthiness of its inhabitants;" and he asserts, in fact, that the publication of anything beyond the number of deaths registered in those places weekly and quarterly, leads to "mischievous absurdity."

Now, whilst we have no intention of taking upon ourselves the defence of a department so well able to hold its own as the one in question, we are nevertheless prepared to challenge the wisdom of the attack to the extent of retaliating that a mere comparison of the deaths registered in a town with those of another town, irrespective of the proportion which they bear to the population out of which they occur, would be a "statistical delusion" of the wildest kind.

Objection is further made to "two curious assumptions: first, that an annual death-rate may be calculated from the mortality of any single quarter: and, secondly, that the population has uniformly increased since the last census at the same rate as during the whole decennium before that census;" and the writer refuses to "admit that such results so obtained have any right to be termed death-rates."

Is not this just as if one having paid £2 10s. as the interest on the loan of £100 for six months should object to have it noted that the *rate* of interest was £5 per cent. per annum?

In point of fact the writer would place us in this difficulty: For the last three months, in a certain town of 500,000 inhabitants, the weekly deaths have not unfrequently exceeded the births registered; whilst in another town of 200,000 inhabitants the births have been largely in excess of the deaths during the same period. By what standard are we to measure the relative mortality of these two towns if we are precluded from placing them on a uniform basis by ascertaining in both cases the proportion of deaths to population? And as in the computation of interest the rate per cent. *per annum* is invariably quoted, why should not the same rule be applicable to death rates? We simply make use of a common denominator which is sufficient for all practical purposes.

The writer is equally hypercritical in his conception of "curious assumption" No. 2, for as it would be absurd to assume a stationary population when everything proved the contrary, there is no alternative but to make the "curious assumption" that the increase is regular in its progression.

We take the death rates which are published weekly as a means whereby we can judge of the relative healthfulness of the several towns; but neither we nor any person at all acquainted with the subject would dream, when we see it stated that the *annual* rate of mortality in a given week, say in Liverpool, was 57 per 1000, that it was thereby implied that throughout the year 57 deaths would actually occur to every thousand persons living. *If* that rate prevailed for a year, it would be an absolute fact, but as it is hypothetical the rate is relatively understood.

The Registrar-General does not, as far as we know, claim for these death-rates any higher position than this: that by assimilating places of different degrees of population to one general standard in that respect, a view of the general mortality rate of the towns is obtained which is thus fairly comparable. But this general view is without prejudice to more minute inquiries into the causes of divergence in the constitution of those towns, either as to locality, age, sex, or condition of the inhabitants. The mortality-rate of a town undoubtedly depends very greatly on the character of its population, and if hordes of uncleanly Irish families were to be accumulated in the most healthy localities of England, the effect of such a change of inhabitants would soon be apparent in the increased death-rate of those localities.

When the elaborate organisation dreamt of by the writer we have quoted is *un fait accompli*, we shall, perhaps, learn much that is at present obscure as to the remarkable difference in the death-rates under apparently similar circumstances; but we would have him bear in mind that public departments are not yet omnipotent, and that many things which are well known to the officials to be desirable, are under present arrangements impracticable.

ATMOSPHERIC OZONE.

In speaking of ozone last week, we referred to its action on iodide of potassium as having been adopted as the test of its presence. Many of our readers, we are sure, have made use of ozone test papers to detect the presence of ozone in the atmosphere. At any rate, the action of the atmosphere on these test papers forms a part of nearly all meteorological observations. These papers are usually white paper which has been impregnated with starch and iodide of potassium. When ozone comes in contact with them, it colours them, in consequence of the reaction between the starch and the iodine set free from the potassium salt by the ozone. Now, these papers are influenced by the atmosphere in the same way as they are by undoubtedly ozonised air. May we not, therefore, consider that ozone is in the atmosphere, when the test papers are affected by it? That we may has been the general conclusion for years. But there are further reasons why this conclusion has been come to. Electric currents passed through air produce ozone, and we may fairly suppose, therefore—nay, more, we can hardly help admitting—that as there are so often variations in the electrical condition of the air, and discharges of lightning through it, ozone must be often found in it. Again, it is found that during slow oxidations at ordinary temperatures ozone is produced, and as these are constantly going on around, we may also suppose on this ground that ozone is always being produced in the atmosphere.

With regard to the test paper indications, however, there are other substances which may occur in the atmosphere capable of causing the liberation of iodine and its consequent action on starch. There is another reason for doubting the correctness of the indication of these test papers, which is the inexplicable irregularities of the variations in the quantity of atmospheric ozone recorded by them. In fact, after ten years' ozonometric observations, Admiral Bérigny stated, through M. Frémy, to the French Academy of Sciences, at its meeting on November 27, his serious doubts of the existence of ozone in the atmosphere at all. M. Frémy, on this occasion, commented on the very doubtful character of the evidence of its existence in the air. He looked upon the oxidation of silver as the only certain test of its presence, and he had repeatedly exposed metallic silver to the air without obtaining any indication of it. We are very far, he said, from being acquainted with all the substances suspended in the air. And may not iodide of potassium, he asked, become alkaline or liberate iodine by other means than that of ozone? What was the use, he said, of test papers which were affected, not only by ozone, but by the oxides of nitrogen, by peroxide of hydrogen, by formic acid, by essential oils, by acids, by particles of dust, &c., all of which, particularly in a wooded district, may be present in the atmosphere?

The result of this legitimate attack upon the theory of atmospheric ozone has called forth important replies from M. Houzeau, a French chemist, who has for years been engaged in investigating the subject. He admits that many substances capable of affecting the iodised starch papers of Schœnbein may be in the atmosphere—such as those above mentioned, as well as chlorine, bromine, and particularly iodine, the existence of which in the atmosphere has been demonstrated by M. Chatin. He shows the fallacy of M. Frémy's silver test by the fact which he has himself demonstrated, that actually ozonised air sufficiently diluted does not affect silver, although still far richer in ozone than the atmosphere is ever found to be. He considers that Schoenbein's test papers, which Admiral Bérigny employs, are certainly open to the objections of M. Frémy, and has for a long time employed papers of his own (which we described last week), made of wine-red litmus-paper slips, half of each of which has been impregnated with iodide of potassium. The potash formed by ozone then turns the part of the paper prepared with the iodide blue, while the other part preserves its colour in contrast. Iodine, chlorine, acids, etc., do not affect this paper, so that its ozone indications are of much greater moment. He referred to the results of his experiments he had laid on a former occasion before the Academy, which proved that the statement that the oxides of nitrogen which might be present in the air would turn his paper blue by forming an alkaline nitrite with the potassium of the iodide was incorrect. When oxides of nitrogen turned the iodised litmus paper blue it was due to ozone produced during the oxidation of binoxide of nitrogen. As far as the atmosphere was concerned, at the times when it was very active towards his test papers no oxides of nitrogen could be detected, and when it was artificially impregnated with oxides of nitrogen it did not affect his papers.

From the evidence of his papers M. Houzeau said he was far from sharing the doubts of Admiral Bérigny, who had employed iodised starch papers, inasmuch as that after ten years' experience also, he had not met with the discordant results and incomprehensible contradictions which had so discouraged Admiral Bérigny. There was no scientific reason for not admitting the existence of ozone in the air, and he had, he stated, never despaired of solving the doubts on the subject. This was on December 18.

On February 26 he laid before the Academy an important memoir, in which he states the conclusions from his observations to the following effect:—1. The principle acting on the test papers is a normal constituent of the atmosphere in our temperate climates, circulating freely in the open country. 2. Its proportion varies according to certain meteorological data. 3. Various causes favour its manifestation. These are winds and aqueous vapour: either of these may not singly affect the test papers. This is explained by the well-known chemical fact that moisture is essential to many chemical reactions. But when, in spite of agitation of the atmosphere, and sufficient moisture in it, the iodised litmus papers are not affected, it is because of the presence of an acid principle in the atmosphere, the existence of which has been already announced by him. 3. The established difference between the chemical activity of the air of towns and that of the country is very simply explained by the observed difference in the renewal of air in the two cases. In the country, the circulation of the air is free; in towns, it is impeded by the houses and other buildings. Consequently, with the same amount of active principle, the air of the fields ought to prove more active than that of the towns, since, in the same time, more air comes in contact with the paper. Hence the more exposed the test paper is, the more rapidly it is found to turn blue. 4. But, besides these almost purely mechanical influences on the mobility of the atmosphere, there are also natural causes, the action of which is more especially chemical, for they enrich the atmosphere itself with the principle which gives it chemical activity. These are storms, waterspouts, and hurricanes. The influence of these meteorological phenomena on the active properties of the air extends at times to great distances, and often even into regions where their existence remains unknown. Most frequently, however, the announcement of the great atmospheric perturbation by the iodised litmus papers is accompanied by other most characteristic signs, such as gusts of wind, a clouded sky, showers, and fall of the barometer. The author here gives some striking meteorological evidence of this, but too long for us to abstract.

Thus, the author remarks in conclusion, is resolved the meteorological part of the problem which has for so long a time divided philosophers.

Concerning the chemical part of the problem, the author adds in a note the peculiarly interesting fact which he had just then discovered, that by condensing the vapours of the atmosphere there is obtained a liquid possessing all the properties of the peroxide of hydrogen discovered by Thénard. He expressed his hopes of obtaining sufficient of the substance for analysis. If he does, we may hope soon to have evidence which may be said to prove and disprove at the same time the presence of ozone in the atmosphere; for atmospheric ozone

*

has been by some regarded as modified oxygen, while by others it has been looked upon as a peroxide of hydrogen.

THERMOMETER IN DISEASE.

We propose to continue an account of the information the thermometer affords us in cases which simulate phthisis. A patient presents himself with the following physical signs and symptoms :—There is general bulging of the chest, the antero-posterior diameter of which is much increased, the back is much curved, and the costal angle is very obtuse. The lower ribs are almost horizontal, and the lower interspaces are much widened. The expansion movements of the chest are greatly lessened. The heart is seen beating at the epigastrium. By percussion we learn that the chest is too resonant, and that the area of percussion resonance is much increased, encroaching on the heart and liver dulness. The respiratory murmur is everywhere weak. Respiration is divided, and expiration much prolonged, and there is heard over the whole chest some sonorous and submucous rhonchus. The patient has lost flesh greatly ; his pulse beats too quickly ; his appetite is lessened, and he sleeps badly at night. There is profuse muco-purulent and nummulated expectoration, and he sweats profusely. The other organs of the body are healthy. What have we here ? Is the patient tubercular, or can we explain his symptoms in some other way ? The bulging of the chest, the obtuse costal angle, the horizontal position of the ribs, with widening of the intercostal spaces, with increase of the antero-posterior diameter of the chest, prove that the capacity of this cavity is much increased. His chest has assumed in many respects the form that occurs when a deep inspiration is taken, but this is habitual with him. It may be termed the inspiratory chest. What diseases will produce this enlargement of the chest ? The three diseases that will cause such distension are emphysema, pleurisy, and pneumo-thorax. If the two latter complaints were the cause of the signs and symptoms in such a patient as that described, the disease must be situated on both sides, and to have caused so much enlargement they must have also pressed and caused collapse of the lung. With such a condition of things the patient could not live. Thus these two diseases may be excluded from the diagnosis, and such a chest of itself becomes diagnostic of emphysema. Emphysema, also, will account for almost all the remaining physical signs. In this condition of lung the air vesicles are much distended, and thus the lungs are much enlarged. The amount of air contained in them relative to the solids of the lung is increased. This increased amount of air, with increase of the size of the lung, explains the increased clearness of the percussion note and the increase of the area of resonance. But such lungs have also lost much of their elasticity ; but this elasticity is one of the chief factors causing expiration, thus the expiration is retarded, and the respiration becomes divided. The vital capacity of the chest is greatly lessened, and the amount of tidal air is diminished, and hence the respiratory murmur is weakened. Thus all these signs are sufficiently explained by the emphysema present ; and further, we can only conclude from the rhonchus that the patient has some bronchitis. But does such a patient merely suffer from emphysema and bronchitis ? Can these diseases account for the symptoms given, or must we accept some other disease to be present to account for them ? If such disease be present it is probably phthisis, for the other organs of the body are healthy, Is the absence of physical signs sufficient to preclude the possibility of tubercle being present in the lungs ? Certainly not, for with such signs as those given, and with them alone, cavities of considerable size may exist in the chest—nay, more, tubercles in considerable quantity may be scattered throughout the lungs, and yet give no evidence of their presence, or if they do give rise to any signs, the only one present may be submucous rhonchus ; but this may also be due to simple bronchitis. Can the symptoms present be accounted for by the bronchitis ? In many cases of simple bronchitis such symptoms are present. The profuse expectoration exhausts the patient. By the frequent cough the sleep is broken, and from want of sleep the appetite is greatly impaired, thus affording an additional cause for the loss of flesh and general weakness. We have already seen that weakness may quicken the pulse, and cause profuse sweating. Nevertheless, such symptoms are quite sufficient to justify the fear that tubercle is being deposited in the lungs, for such a deposition may be going on, and yet no other signs or symptoms than those given above be present. How are we to decide to which of these diseases the symptoms are to be ascribed ? We have seen that the deposition of tubercle always produced an abnormal elevation of the temperature. *In bronchitis of the kind described the temperature is normal.* It is true, at the very commencement of an attack of capillary bronchitis, the temperature is much raised, but this elevation only continues five or six days, and then subsides again. Thus, when bronchitis has lasted some time the temperature is normal. The thermometer, therefore, affords us the information we require. If the temperature be normal the patient is not tubercular ; or the converse case may be met with in which with the symptoms and signs given above, an active deposit of tubercle is taking place.

It is highly important not to confound these two diseases, for the latter is usually quickly fatal, whilst the former often subsides, and the patient may survive many years. If the temperature be elevated, and if the elevation continues for many days, it becomes almost a certainty that tubercle is being deposited in the lungs.

Other conditions may sometimes occur and render the diagnosis of phthisis difficult or impossible.

The following case, narrated by Dr. Bateman, Physician to the Norfolk and Norwich Hospital, illustrates one source of difficulty:—"A patient, aged 32, was admitted into Hospital. He had been ill two years. Twelve months previous to his admission he spat about a teaspoonful of blood, and for six months he had suffered from a slight cough, with some expectoration and dyspnœa. On admission the first and principal symptom which attracted attention was a stridulous noise with his breathing, as if something was pressing on the recurrent laryngeal nerve. There was slight cough, with some expectoration. Expansion on inspiration was deficient under both clavicles, but percussion was fairly resonant. The respiratory murmur was covered by a loud stridulous noise, evidently conducted from the larynx. There was considerable obstruction to the entrance of air into the lungs. He spoke in a whisper. He had no difficulty in swallowing, and there was no numbness nor pain in either arm. The right pupil contracted more sluggishly than the left. His digestive functions were healthy. A laryngoscopic examination revealed an œdematous condition of the glottis. *The temperature of the body was taken. This varied from* $101\frac{2}{5}$ *to* $101\frac{4}{5}$. Much doubt existed in respect of the nature of the disease ; whether it was simply local and situated in the larynx, or whether the patient was the victim of a mediastinal tumour or of tubercular deposit in the lungs. The elevation of the temperature, which continued during the time he was under observation, negatived the two former suggestions, and rendered it highly probable that tubercle was being deposited in his lungs. The obstruction in the larynx increased to such an extent as to render laryngotomy necessary. Air was thus freely admitted into his lungs, and the stridulous noise was removed. After the operation moist crackling was heard at the left apex, and he died with all the symptoms of pulmonary phthisis about seven weeks after the operation." The patient was under observation for about three months.

The German Hospital.—Mr. Hermann Otto Post, lately deceased, has bequeathed £100 to the above institution.

THE WEEK.

POISONOUS WATER.

What killed Dr. Hodgkin? Impure water. We wonder that travellers do not carry with them a little bottle of solution of permanganate of potass—a few drops of which would speedily purify any water. A friend of ours, who has just returned from India, tells us that he has derived the greatest benefit from its employment. At stations where the water was turbid, and tasted and smelt of decaying organic matter, he found the addition of a few drops of the solution of the permanganate made it in a few minutes as clear and sweet as spring water.

HÆMOSTATIC AND CAUSTIC ETHER SPRAY.

When a principle is once established in practice, it is remarkable in what a number and variety of ways it developes itself. This is specially the fact in respect to Dr. Richardson's process for producing local insensibility to pain by means of ether spray. We learn now that Dr. Richardson is pursuing a series of new inquiries by which he will be able to combine styptic and caustic substances with the ether. He expects in a few days to present to the Profession a hæmostatic spray which will combine, when it is directed on the bleeding surface, the constringing effect of the extreme cold with the styptic qualities either of tannin or of perchloride of iron. He also expects to have an ether containing an active caustic by which, when the part subjected to the spray is made insensible by cold, the structure will be destroyed and easily removed. We shall, of course, in forthcoming numbers, describe these processes in detail; meanwhile we report them as in progress, and wish them every success.

HOW TO PROMOTE VACCINATION.

There are two ways in which we may endeavour to promote universal and efficient vaccination of our population. One we will call the English, or autonomic; the other the foreign, or bureaucratic. The first proceeds on the assumption that most people do of their own accord what is for their advantage to do. The second takes for granted that they need compulsion and people to look after them. To apply this to vaccination. It is to the interest of every Medical man to look after his own patients and to keep them in his own hands. Hence it is argued that if every Medical man were made virtually a public vaccinator, and were to receive payment from the State for every patient whom he successfully vaccinated, that the natural impulse to look after his own interests would induce every man to hunt up and vaccinate every vaccinable child. A very able and well considered scheme on this principle by Dr. Lilley, of Lambeth, was laid before a public meeting at the Freemasons' Tavern on the 10th, with Dr. Richardson in the chair. There was this further feature in Dr. Lilley's proposition—viz., that no charge should be made in any case for the act of vaccination, but that every Medical man should receive a small fee (1s. 6d.?) for the act of registering each successful case.

This proposal, however, was rejected by the meeting in favour of one to the effect that Mr. Bruce's Bill, now before Parliament, is a great improvement on the existing laws, though it still requires modification. We are almost sorry to say it, still the fact of the necessity of arrangements for arm-to-arm vaccination, for keeping up a regular weekly succession, and for not only not resorting to dried or preserved lymph, but for excluding the lymph from sickly, scrofulous children, with ill-developed vesicles, make it expedient that the vaccinator should not only do the operation regularly, but also in a large number of children. We are compelled, therefore, to agree with the majority of the meeting, in favour of public vaccinators, and not too many of them. There were several important suggestions brought forward by the gentlemen present; for instance, that the minimum fee should be 2s. 6d.; that the same sum should be allowed for revaccination; and likewise in cases in which these careful vaccinators had proved the insusceptibility of the patients to the disease, The onus of registering the certificate of successful vaccination to lie on the parents. On this point we are quite in unison with a very able letter addressed to the Chairman by Mr. Felce, of Launceston. Make the registration of vaccination compulsory, and the population will be protected; and there will be no more outcry about compulsory registration of vaccination than there is of births or deaths.

Mr. Jay related a crucial case in which arm-to-arm vaccination of an adult succeeded after "points" had thrice failed. It was the general opinion that the conduct of public vaccinators afforded no ground for "jealousy" on the part of private Practitioners. Considering how frequently of late we have heard from good observers accounts of the degeneration of the vaccine vesicles, and the probable effects of our present unpreparedness in the event of a small-pox epidemic, we were almost shocked to hear from Dr. Blackman that in his neighbourhood vaccination is performed gratuitously by unqualified persons, especially in hundreds of instances by a chemist, for the sake of the custom which is thus obtained. Dr. Richardson, while expressing his belief that Dr. Lilley's suggestion deserved consideration, agreed that Mr. Bruce's bill was an improvement as far as it went, and although at one time opposed to compulsory vaccination, he had seen reason, from its success on the Continent and in the farms of some American States, to alter his opinion. A correspondent informs us that the "farms" in America, to which Dr. Richardson alluded, are analogous to our Workhouses, "but very well conducted, so that there is never any degradation in a person having been born in them." All the inmates are vaccinated by the Medical man.

DR. SALISBURY ON THE INFLUENCE OF LOW ORGANISMS IN PRODUCING DISEASE.

Dr. Salisbury, the Professor of Physiology, Histology, and Pathology in Charity Medical College, has recently made some novel observations "On the Cause of Intermittent and Remittent Fevers, with Investigations which tend to prove that these Affections are caused by certain species of Palmellæ." It appears that during the month of May, 1862, ague was peculiarly prevalent in the malarial district of the Ohio and Mississippi valleys, and continued to show itself during the months of July and August. Dr. Salisbury, obtaining a hint from former observations, was induced to institute some experiments for the purpose of determining the special condition of the emanations from the damp malarial grounds. He noticed that the damp season had been followed by a peculiarly dry time, so that the place that had been especially swampy became dry, the little streams much lower than usual, and the action of the sun was intense upon those parts of the exposed soil before covered with water. The succeeding drought ushered in intermittent fever, which attacked "nearly every family on ague levels." Dr. Salisbury began by instituting a careful examination of the first and morning expectoration of patients ill with the intermittent who had been constantly within the influence of malarial emanations, and detected a large and varied amount of low forms of life, algæ, fungi, animalculæ, desmidiæ, and others. He then attempted to show whether the presence of any of these was characteristic and constant, or whether they were all accidental, and concluded from his inquiry in different districts that the only bodies found constantly, and in any amount, were "minute oblong cells, either single or aggregated, consisting of a distinct nucleus, surrounded by a smooth cell-wall, with a highly clear apparently empty space between the outside cell-wall and nucleus," probably, according to Dr. Salisbury, not fungoid, but algoid, in all likelihood palmellæ. These were not found above the level at which

ague was noticed; all the other forms of low life, however—the diatoms, desmidiæ, and fungi, etc.—were detected everywhere beyond the ague limits. Having, then, found these bodies constantly present, it became necessary to discover their source. He suspended pieces of glass 16 inches by 22 inches, about a foot above the ground, around the stagnant pools and marshy malarial places, and left them there all night, and in the moisture condensed upon the under surface no palmelloids were discoverable, but they existed in plenty on the upper side of the glass slide.

Dr. Salisbury states that on walking over one particular peaty bog he noticed a peculiar dry state of throat. To this spot, which had been freshly broken up, he often repaired, and upon it he observed what looked like whitish mould or salt. Over this the glass plates were suspended, and, curiously enough, there were detected after a while these palmelloid bodies on the *under surfaces*, and on microscopic examination the white mould of the bog turned out to be composed of palmelloid bodies and mucidenous fungi.

This led to the institution of a series of experiments, which showed that,—

1. Cryptogamic spores are carried aloft above the surface at night, in the *damp exhalations* which appear after sunset; they fall again after the sun rises.

2. These bodies rise from thirty-six to sixty feet, never above the summit of the damp night mists or exhalations, and intermittent fever observes the same limits in its occurrence.

3. The day air of ague districts is free from the "bodies" in question.

It appeared further that evening visits to the "peaty bogs" were followed by the presence of the palmelloid bodies in the expectoration.

There would appear also to be a relation between the peaty bogs and ague districts, the former being a feature in the topography of the latter. It is asserted also that in some cases when large excavations have been carried on, ague has appeared in districts where, up to the time of the excavations, it had been quite unknown.

These palmelloid bodies, Dr. Salisbury declares, are never found except in aguish districts, but are developed as the dry warm weather of spring and summer evaporates the surface water, and begins to dry up the recently exposed soil of rich, humid, low grounds and peaty bogs in certain localities," when "a peculiar white green, or yellowish or greenish white, or brickdust powder will be noticed making its appearance upon the surface."

It seems strange, too, that the examination of the urine of aguish patients should establish the fact that ague plants, the same as grow upon the ague soil, are constantly developed in the system of the intermittent fever patients, and that the urinary organs constitute one important outlet for the elimination of this fever vegetation.

Dr. Salisbury states also that he obtained a quantity of the peaty earth, placed it, in a neighbourhood where ague was unknown, near an open window of a room where two young men slept, and he declares that on the fourth day the glass suspended over it was covered with spores; and on the twelfth day one, and on the fourteenth day the other young man, had intermitent of a tertian type.

It would be well that some one set to work and put to severe test in our own country these remarkable observations of Dr. Salisbury.

PATERSON *v.* SOMERS.—ACTION FOR LIBEL.

A TRIAL has been just concluded before the Lord President of the Court of Session in Scotland, in which Dr. Paterson, of Glasgow, sought damages from the proprietor of the *Morning Journal*, a Glasgow daily paper, for a libel which appeared in that paper during the early stage of the inquiries in the Pritchard case. It appears that the suspicions of the authorities in reference to Pritchard were first aroused by an anonymous letter which was sent to the Procurator Fiscal. This letter was signed "Amor Justitiæ," and simply drew that functionary's attention to the fact that Dr. Pritchard's mother-in-law and wife had died suddenly and unexpectedly, under suspicious circumstances, at his house in Sauciehall-street. In reference to this letter another letter appeared in the *Morning Journal* which contained the alleged libel. It was written by a friend of Dr. Pritchard's, who at that time believed in his innocence, and the following was the passage of which Dr. Paterson complained:—

"The whole matter lies in a nutshell. An anonymous letter is written by some moral coward or other, who either hazarded a stab in the dark, or whose love of justice did not conquer his sense of modesty—a man who, no doubt, does 'good by stealth, and blushes to find it fame,' a blush, doubtless, of deservedly deep scarlet. Well, this anonymous communication is traced to its source, and the writer must, of course, adopt the letter, and stand to it. Then the apprehension of the gentleman named or alluded to in it is a natural result, and the post-mortem examination, the scrutiny in his household, and all that has since taken place, follow in natural sequence; and here the affair rests. But it is not a little strange that a whisper of 'antimony' should have been heard about the County Buildings before even the examination was commenced. Why, what was Dr. Paterson about if he knew anything about antimony being administered? Was he not called in his Professional capacity, and entitled therefore to speak with a voice of authority as to what should be administered, and what withheld; and if administered against his advice, and he saw or suspected anything wrong, why did he not at once deem it his duty to boldly protest, or immediately communicate with the authorities? But we have not yet heard that he has adopted the anonymous letter referred to. It cannot be denied that his position in the case does not, *primâ facie*, appear either lucid or pleasant, and this he must feel himself, and actually too. Dr. Paterson should really clear himself as regards this anonymous letter; and the public, seeing that it was the primary cause of the arrest and the subsequent events, should withhold its opinion, give the accused fair play, and calmly wait for more light."

The case for the prosecution was that this paragraph evidently assumed Dr. Paterson to be the author of the anonymous letter, and branded him as a moral coward, who either hazarded a stab in the dark or whose love of justice did not conquer his sense of modesty. Dr. Paterson, however, totally disclaimed the authorship of the letter to the Procurator Fiscal, and it was proved at the trial that the real writer was Dr. Alexander Greenlees, who sent it to the authorities in consequence of what he had been told by Dr. Paterson. The jury returned a unanimous verdict for the pursuer, thus establishing the libel, but assessing the damages at one farthing. We think that justice was completely asserted by the finding of the jury, and we would suggest that the public and the Profession have heard quite enough of Dr. Paterson's connexion with this horrible tragedy.

FROM ABROAD.—REVACCINATION IN THE PRUSSIAN ARMY—CATSUP AND CAT SOUP—THE PARIS FACULTY OF MEDICINE.

THE annual report on the vaccinations practised in the Prussian Army during 1865 has just been published. During the year 65,776 soldiers were either vaccinated or revaccinated, 56,895 of the number having distinct scars from former vaccinations, 6143 with indistinct scars, and 2738 exhibiting no marks at all. These 65,776 vaccinations ran a regular course in 41,334 individuals, an irregular course in 8326, and were unsuccessful in 16,166. These last were vaccinated again, and with success in 5469 instances, so that the total of successful cases amounted to 46,803. The number of true vaccine pustules produced were as follows:—From 1 to 5 pustules in 24,154, from 6 to 10 in 13,830, from 11 to 20 in 8075, and from 21 to 30 in 744. Among the soldiers successfully revaccinated there occurred during the year 3 cases of varicella, 6 of varioloid, and 1 of variola. Thus the proportion of completely successful revaccinations amounted to 62 per cent., and, in-

cluding those in which the vaccination was not followed by regular vaccinia, 71 per cent.,—a proportion very similar to that which has been observed during the last ten years. Notwithstanding the frequent occurrence of variola amongst the civil population during the year, to the contact of which the soldiers were more or less exposed, there occurred only 69 cases of any form of pock. Of these, 35 (2 cases of varicella, 30 of varioloid, and 3 of variola) occurred in soldiers not yet revaccinated; 24 cases (4 of varicella, 18 of varioloid, and 2 of variola) in persons revaccinated without success; and 10 cases (3 of varicella, 6 of varioloid, and 1 of variola), as already stated, in those who had been successfully revaccinated. These cases were of a very slight description, only one person dying during the year, and he succumbed to a catarrhal affection, during the progress of which variola appeared.

The Bermondsey pig-liver catsup case has given rise to an amusing mystification in the Paris journals. Increasing in its proportions as it migrated through these, we find the following as the latest edition in the *Union Médicale*:—

"An Impossible Broth.—Can it be believed that it has been recently proved that in an eating house of great renown in London, enormous quantities of a soup which has become highly popular is prepared simply with half putrid cats' livers?"

Evidently here our word catsup has been transmogrified into soup of cat, and the liver derived from the same animal, in order to give a proper degree of *vraisemblance*. But really, after all, our neighbours may fairly have the laugh at us, for certain it is that had this disgusting case occurred in France, no fine-drawn legal plea would have enabled the perpetrator to escape the penalty for making his beastly concoction upon the plea that it was intended not as an article of food, but as a condiment! The fact that it was destined for the human stomach would have amply satisfied the French legists. What the decision of the Court of Queen's Bench will be, after the learned discussion which is to take place there, is far more problematical.

The following is a list of the Professors at the Paris Faculty of Medicine for the summer course, which commenced on April 6:—Medical Natural History, Professor Baillon; Physiology, Longet; Accouchements and Diseases of Women and Children, Pajot; Therapeutics and Materia Medica, Trousseau; Legal Medicine, Tardieu; Pharmacology, Regnauld; Surgical Pathology, Gosselin; Pathological Anatomy, Laboulbène, as substitute for Cruveilhier; Medical Pathology, Béhier; Hygiene, Bouchardat; Clinical Medicine, Bouillaud, Guillot, Grisolle, and Piorry; Clinical Surgery, Dolbeau, as substitute for Jobert, Laugier, Velpeau, and Nélaton; Clinical Midwifery, Depaul; Clinical Lectures on Diseases of the Skin, Hardy; Clinical Lectures on the Diseases of Children, Roger; Clinical Lectures on Diseases of the Eye, Foucher.

PARLIAMENTARY.—SURGEONS IN THE GUARDS—THE CATTLE PLAGUE—OYSTER CULTIVATION—EPPING FOREST—THE MORTALITY AT HONG KONG—THE VACCINATION BILL.

In the House of Commons on Monday, April 9,

Mr. O'Beirne asked the Secretary of State for War whether the system hitherto followed in promoting Assistant-Surgeons to Battalion-Surgeons in the Foot Guards had not been regimental; whether there was any intention to change that system; and, if any change was to be made, under what Warrant?

The Marquis of Hartington said that up to the year 1858 the system of the promotion of Assistant-Surgeons to Surgeons in the Guards was undoubtedly a regimental system. In that year, however, a Warrant was issued which conferred several pecuniary advantages upon the Medical Department, and that Warrant also enacted that the mode of promotion as a general rule should be by seniority in the service. In 1860 a question arose as to whether the provisions of this Warrant would apply to the Surgeons of the household cavalry, and, after consideration, it was decided by Her Majesty, on the recommendation of the Commander-in-Chief and the Secretary for War, that in the household cavalry and the Guards also, in consideration of the Surgeons having accepted the Warrant, and being in the enjoyment of the advantages conferred upon them by it, the mode of promotion enacted by that Warrant should be carried out in both services, to the extent that the promotion from the rank of Assistant-Surgeons to Surgeons should not go in the regiment, but in the brigade. Until within a few days no case had occurred in the Brigade of Guards under the new system; the alteration, however, was not a recent one, but dated as long back as 1860.

In answer to a question by Mr. Read, Sir G. Grey said that the temporary provisions of the Cattle Disease Act—those affecting the slaughter of cattle—which were to expire on the 15th of April, would continue in operation till the 10th of May.

Mr. Hunt called attention to that portion of the Report of the Sea Fisheries Commissioners which, with the view of promoting the cultivation of oysters, recommends the appropriation of public grounds in estuaries and other places for the formation of oyster beds. He suggested the passing of a general Act for this purpose.

Mr. Gibson replied that the Government were fully alive to the importance of promoting the cultivation of oysters in the way suggested, and had a Bill under consideration which, when matured, would, as he believed, carry out the objects in view, and meet all the difficulties of the case.

The Chancellor of the Exchequer moved a string of resolutions on the Crown Lands Act, as a preliminary to the introtion of a Bill for the better management of the Land Revenues of the Crown. Among other provisions he explained that the Bill would transfer the forestal rights of the Crown over Epping Forest to the Board of Works.

On Tuesday, April 10,

Sir R. Anstruther gave notice that on May 11 he would call the attention of the House to the proposed alteration in the system of promotion among the Medical officers of the brigade of Guards, and move for a copy of the Warrant or order of 1860 under which such change was to be made, and for copies of any communications from the War Office or Horse Guards to the officers commanding the three regiments of Guards, intimating the proposed change of system to the officers affected by it.

On the motion of Colonel North, the Select Committee on the subject of mortality amongst the troops in China was nominated as follows:—Colonel North, Marquis of Hartington, Lord Hotham, Mr. Baxter, Mr. Adderley, Lord Frederick Cavendish, Mr. Roebuck, Colonel Percy Herbert, Mr. Dalglish, Lord Henry Percy, Mr. Calthorpe, Major Anson, Lord John Hay, Mr. Trevelyan, and Major O'Reilly.

In the House of Commons on Wednesday,

Mr. H. Bruce, in moving the committal of the Vaccination Bill, after sketching briefly the history of vaccination, and the legislation in regard to it, and quoting copiously from numerous Medical returns and reports to illustrate its efficacy in checking the spread and virulence of small-pox, described in detail the defects of the present system, which the Bill was intended to remedy. The Bill, he explained, besides consolidating the existing law, would enable the Poor-law Board to re-arrange districts and revise contracts periodically; it would provide for more complete and permanent registration, and would give increased facilities to boards of guardians to enforce a universal system of vaccination.

Mr. Henley, in criticising the Bill, pointed out two principal defects—the want of security for a due supply of healthy lymph, and the inadequate payment of the Medical officers, to which last cause he attributed the comparative failure of the system of compulsory vaccination.

Sir R. Peel agreed with Mr. Henley in censuring the niggardly payment allowed to the vaccinators, and enumerated nine or ten clauses in the Bill which he predicted would be inoperative. He suggested that it should be postponed to give time for further consideration.

Mr. Lewis moved that the Bill be referred to a Select Committee, and this amendment was seconded by by Sir J. C. Jervoise, and supported by Lord Henley, Mr. Barrow, and other members.

After some further discussion Mr. Bruce, having replied to various objections, accepted the amendment, and the Bill was ordered to be referred to a Select Committee.

REVIEWS.

Statistical Report on the Health of the Navy for the Year 1862.

One can never open a volume of these Naval Reports without being struck with the large amount of Professional knowledge and scientific research which is devoted to the public service by the Medical Officers serving in various parts of the world. There is always, too, something to be found which is of general Professional interest in the midst of much that naval officers alone will in all probability be disposed to dwell upon. To the latter class these reports are invaluable, since they place these gentlemen, whose life on unhealthy stations is neither an easy one nor unendangered, in possession of the experience gathered by their predecessors, and deposited here in a condensed and available form for their information and guidance. A naval officer now can feel that wherever he may be sent he is visiting no place the Medical topography of which is unknown, and that he has, while availing himself of the legacy of those who have been there before him, the comparatively easy and promising task of following up by his own researches the observations recorded for his use.

In reviewing the present Report, we shall follow the same rule which we have previously adopted—namely, to select for special remark those portions which have a more general pathological or etiological interest. Before doing this, however, there is one point which we should like to suggest to Dr. Mackay, as the editor of the Reports, and that is the admirable opportunity there is for determining the period of incubation of certain maladies, the result of the introduction into the system of a specific poison. We may mention scarlatina as one of these, and we confess to a little disappointment at not finding in his report upon the outbreak of this disease in the *Boscawen* training ship the date of the first case that succeeded the arrival on board of the boy in the desquamative stage on October 27. We cannot have too many such observations recorded.

A confirmation (if any such was needed) of the connexion of enteric fever with sewage emanations is furnished abundantly by the returns of the Surgeons serving on the Mediterranean station. It is endemic in most of the large towns on the seaboard where the sewerage is generally defective, and it is especially prevalent in Malta, where the sewage of a densely populated district is actually discharged into the dockyard creek. The disease is in the habit of appearing in ships shortly after mooring near the open mouths of the drains, disappearing soon after leaving. This fever is of considerable urgency, and causes the largest amount of the mortality on the station. We are told, moreover, that the men serving on Mediterranean stations suffer much from a species of general cachexia characterised by steadily progressive debility, for which change to some other station is the only effectual remedy. There are many matters of far less national importance than the health and lives of our seamen which occupy (and shall we say waste?) the time of Parliament.

The beneficial operation of a strict supervision of brothels receives a striking illustration also upon this station. At Malta and Corfu, where this regulation is effectually carried out, venereal affections (originating at these places) are scarcely ever met with. During a period of twelve months, during which the *Marlborough*, with a complement of 1145 men, was stationed at Malta, only twenty-three cases of syphilis and four of gonorrhœa were observed, notwithstanding that the men had as much leave as they cared to have, and never went on shore without plenty of money in their pockets. During the quarter ending March, 1862, only four fresh cases were returned, and only two of these had any reference to Malta. Of the other two one had contracted the disease at Naples, where only a nominal surveillance is exercised, and where "privilege leave" is sure to be followed by a large accession of venereal cases.

We pass on now to the North American and West Indian station, in the report from which we find the following crucial proof of the infectious character of yellow fever:—"Nothing could better illustrate the advantages to be derived from a rigid quarantine in the prevention of the spread of yellow fever than the history of the epidemics in these three vessels (the *Peterel*, the *Landrail*, and the *Rinaldo*). The *Landrail* and the *Rinaldo* had been for some time stationed at New Orleans during the hottest and most sickly month of the year, the thermometer in the shade ranging during their stay between 88° and 92°; during this time the city was occupied by large bodies of Federal troops, who being chiefly from the Northern States were altogether unacclimatised. From the great trade which exists between New Orleans and those localities in the Gulf of Mexico where yellow fever most frequently prevails, it is constantly having that pestilence imported into it. To guard against so disastrous a visitation at such a time, the Federal authorities had taken the wise precaution to institute such stringent quarantine laws that no vessel that had been near an infected port was allowed to proceed above the quarantine anchorage (which is situated about fifty miles below the city), and for thirty days no communication was allowed to be held with the shore. The wisdom of this precaution was exemplified by the fact that, although yellow fever was raging at Key West and at Pensacola, a town only about 100 miles from the mouths of the Mississippi, it did not make its appearance in New Orleans during the whole of that year. Some cases of severe remittent fever did exist in the city, as will always be the case in such a locality in summer, but of specific yellow fever there was none. At Key West, on the other hand, where the season had been an unusually healthy one, and no yellow fever existed either in the town or in the vicinity, a collier barque which had been visiting infected localities had been obliged to put in on account of her leaky condition. She had had a severe form of fever on board during her passage from Havana, it appeared, and she was consequently placed in quarantine, and the sick were landed. One died, and the others recovered, and the Medical officer having asserted that the cases were not yellow fever, she was very soon allowed pratique and a new crew placed on board of her. On the arrival of the *Landrail* and *Rinaldo* at Key West, the former vessel proceeded to coal from this barque, and on the day following that on which the two vessels were placed alongside each other for that purpose, one of the new crew of the barque was seized with fever, of which he died on shore in a few days. The *Rinaldo* and *Peterel* likewise coaled from this barque, and within a few days all these vessels were visited with yellow fever. On shore the fever immediately afterwards broke out in the small town there, and also amongst the Federal troops holding the place. It spread with great rapidity and violence, and caused a large mortality."—P. 98.

A very interesting account is to be found in the report from the Cape of Good Hope Station of the fever which attacked the expedition engaged in transporting Dr. Livingstone's steamer, the *Nyassa*, up the Zambesi and Shire, on the West Coast of Africa. The *Gorgon* furnished the assistance requisite for this purpose, and the Surgeon to whom we are indebted for the account of the outbreak, Dr. David Ramsay, accompanied the expedition. We recommend naval officers proceeding to this station to study this admirable history, which may be taken as applicable generally to remittent fever as it appears in inter-tropical rivers. All we can do is to quote Dr. Ramsay's experience of quinine as a prophylactic, and we do so mainly because he seems to place a limit to its efficacy, which, if confirmed by future experience, it will be well to keep in mind. He says—"All these cases occurred while the men were using quinine as a prophylactic, in doses of three grains daily, the same as Dr. Livingstone has always used, and which was as much as my stock of quinine could afford. I regret much, however, that I could not give the full dose—eight grains a day—as it was such an excellent opportunity to try the efficiency of the remedy. But I doubt much its efficacy when it has to be continued so long, for in the *Pioneer* there are one or two men who have been in the habit of taking daily enormous doses of quinine, from ten to twenty grains; and these have suffered from the disease quite as much as the others. . . . Now, with regard to the fever itself, so fatal to some persons, and so innocuous to others, we have seen that though taking quinine regularly every day, only six out of fifty-four escaped it; not one of the *Pioneer's* crew, nor of the ladies escaped it, making the total number of attacks seventy-three out of seventy-nine within two months. . . . Many of these cases were very severe, attended with delirium and extreme prostration; yet we have not lost a single man." Another observation of the intelligent Surgeon of the *Gorgon* will interest syphilographers—namely, the immunity of Tamatave and its neighbourhood in Madagascar from the infecting variety of syphilis. The cases observed among the men were "so slight and easily cured as not to require entry on the sick-list. They were all of the soft, suppurating, and non-infecting species. Of these seven appear in the return, being cases of inflamed sores, produced by neglect and want of cleanliness. It is remarkable that constitutional syphilis seems to be unknown, not merely at Tamatave, but up the country, and at

Antananariso. Yet the Rimerisi, or prostitute class, at Tamatave compose almost the whole female population; and among no people can morality be less regarded than the Hovas and Betsimasaraka."—P. 194.

An illustration of the deleterious influence of bad water in the production of diarrhœa, dysentery, cholera, and remittent fever, together with the etiological relations of these diseases, is supplied by the Surgeon of the *Euryalus*, serving upon the East Indian and China station. In a few days after the arrival of the ship at Hong-Kong "diarrhœa broke out among the men to a rather alarming extent. I attributed the cause of the complaint," says the Surgeon, "to the water supplied to the ship by the contractor, who supplied it from a reservoir situated in a paddy field. The field was manured with human ordure and irrigated with the water which was ultimately supplied to the shipping. The Japanese inhabitants of a neighbouring village were seen to wash their soiled linen in the same reservoir." But this is not all. The ship having arrived at Shanghai in a very satisfactory condition, the expeditionary forces, consisting of 211 officers and men from the *Euryalus*, together with a number of men belonging to the Commissariat, Medical, and Military Train departments of the army, started for Kahding on the morning of October 22. "They proceeded in flat-bottomed boats along a shallow river, which was muddy and unwholesome. They lived in these boats, which came to an anchor at night, and drank freely of the river water. Not a case of sickness occurred among them until the night of the 25th, at 10 p.m., when the first case of cholera appeared. How did they contract the disease, the incubation of which in any case must have been limited to within four days after leaving the ship for the first time since we left Plymouth? Was it communicated to them by infection? They had no intercourse with the Chinese; they were not even allowed to enter within the walls of the captured city. The only medium of infection was confined to the 'chops' which carried them, and which were propelled by Chinamen; but their decks had been previously cleared of all articles of clothing belonging to the Chinese crew, among whom there was no trace of disease at the time. Besides, there were a number of men belonging to the Commissariat, Medical, and Military Train departments of the army, who were equally exposed in the boats to the same influence as our men; but the latter fact would militate equally against any other theory as to the cause of the outbreak except that of its being propagated through the medium of the river water. These men had taken the precaution of carrying with them a supply of good water from Shanghai, where they returned on the morning of the 26th inst. . . . It did not appear that there had been a single case of choleraic diarrhœa even among them. . . . . In a few days after the return of the men who had been on detached duty to the ship, another formidable disease broke out among them—viz., dysentery—and it was remarkable how the cases of choleraic diarrhœa, and two even of cholera, merged into dysentery. . . . Fever, both of an intermittent type and a formidable remittent fever, appeared about the same time in the ship as dysentery. The fact that many of the cases of the latter complaint were accompanied by paludal fever, and that the two diseases appeared at the same time among that part of the crew who had been on detached duty, led me to think that the fever and dysentery were produced by the same cause, and must have been taken about the same time. . . . I am inclined to believe that the malarious poison, as well as the choleraic poison, was conveyed in this instance through the medium of the river water, which the men freely drank of. . . . In regard to the incubation of these diseases, it may be remarked (as before noticed) that cholera appeared within four days from the 22nd of October, the day on which the men left the ship; and that dysentery and remittent fever appeared within eleven days after that date, the first cases of dysentery and remittent fever having appeared on the 2nd of November."—P. 229.

We need only add that the report of each station is accompanied by an outline map of the principal localities on the seaboard.

MUNIFICENT GIFT.—Mr. Peter Pantia Ralli, of 5, Connaught-place West, Hyde-park, a Greek merchant, has just presented to the committee of King's College Hospital, through Dr. Priestley, the sum of £6000, for the purpose of establishing a ward for sick children in that institution. The ward is to be called the "Pantia Ralli" ward, in memory of the late Mr. Pantia Ralli, the father of the generous donor. It will contain about a dozen beds.

GENERAL CORRESPONDENCE.

LESSONS FROM THE CHOLERA AT JAMAICA.

LETTER FROM DR. BOWERBANK.

[To the Editor of the Medical Times and Gazette.]

SIR,—Humanly speaking, there seems little doubt but that, ere long, this country will again be visited by epidemic cholera. It behoves us, then, to prepare to meet the enemy. If experience during the previous attacks of this dire disease has not taught us how to cure it, still I believe we have learned the necessity of trying to ward off its ravages by sanitary measures, the propriety of avoiding certain forms of treatment, and have been made aware of the necessity of exercising great caution ere we commit its apparent victims to the grave.

My experience of this disease was obtained during the epidemics of 1832 and 1849 in this country, and more especially in the island of Jamaica during its outbreaks there of 1850 and 1854.

In the epidemic in Jamaica in 1850 it was computed that 40,000 persons died of cholera, being in the proportion of one death to every ten inhabitants. An excellent report on this epidemic was drawn up by Dr. Gavin Milroy, who was sent out at the time as Medical Inspector by the Government.

From my own observations, I believe that cholera cannot be kept out or excluded from a district or a county by any so-called quarantine restrictions. I consider such restrictions to be useless, and worse than useless, as costing money to carry them out, but more especially as inspiring false confidence and preventing or cramping the adoption of other and more reliable measures of prevention.

I have had no proof that any of the visitations of cholera I have seen were traceable to importation by a particular vessel; but I have known cholera introduced into a district and an island, and the disease not extend itself; thus, at any rate, proving that something more than mere introduction of the disease was necessary to its extension, and over which quarantine restrictions could exercise no influence. That cholera attacks certain districts or places, certain towns and streets, certain houses and rooms, and during the prevalence of an epidemic nestles there, I am confident, and I believe that in every such instance a bad sanitary status will be found to exist.

The great preventives of cholera and all other epidemic diseases are pure air, pure water, plenty of daylight, and cleanliness in its widest acceptation. Where these essentials to health exist, cholera may come, and may proclaim its presence by the occurrence of diarrhœa, borborygmi, cramps, and other well-known symptoms, and it may seize as a victim a person predisposed to disease by intemperance or depression of body or mind, but here it will not nestle.

During the epidemic of 1850, I have known towns and villages nearly depopulated; whole yards and houses, ships in port, swept clean, and not an inmate left to tell the tale. But in all such cases neglect of sanitary measures and the open violation of Nature's laws explained the cause. It will thus be seen I am of opinion that we have no power to exclude epidemic cholera. This mysterious visitor will come to our shores in spite of us; but we have the power to lessen its ravages and to deprive it of its sting, and in effecting this we at the same time adopt the best means to rid us of those less dreaded (because more familiar and slower in their course) but more fatal scourges of our population, typhus and typhoid fever, and the entire class of tuberculous disease.

"Prevention is better than cure." In no instance is the truth of this adage more obvious than as regards a visitation of epidemic cholera. Experience in all parts of the known world has taught us that its ravages may be lessened or prevented by judicious sanitary measures; but that where these have been neglected, for a time at least, after its advent, this disease resists or is but little amenable to curative treatment. In case of the outbreak of cholera in a notoriously unhealthy district, I believe, as regards the mass of the people, instead of, as hitherto, adopting the house-to-house visitation system and the unprofessional and wholesale administration of medicines, it would be far better that arrangements should be made to transfer the inhabitants, or as many as possible of them, to another place, even though it should be requisite to provide tents or to allow them to remain uncovered.

If the Government could be persuaded of the truth of what I have stated, and if they would act upon it as regards sanitary measures in general, and the removal of nuisances, and the bettering of the habitations of the poor, and if the upper and middle classes of society, instead of being compelled by legislative enactments, would bestir themselves, and for their own safety adopt the necessary preventive measures as permanent and not temporary ones, there is little doubt that cholera and the whole class of epidemic and zymotic diseases would become less fatal and their attacks less frequent.

Hitherto, on the outbreak of a cholera epidemic, panic has always prevailed, and has, I believed, caused almost as many deaths as cholera itself. There can be no doubt that depression of spirits and fear during the prevalence of cholera is a predisposing cause. The best remedy for this evil is that the people should be made to understand the nature of the disease, and how each of them, individually and collectively, can assist in preventing it.

I have seen much mischief done by persons on the outbreak of cholera epidemics altering their mode of life, especially as regards their food and drink. I have known many to give up particular articles, as fish, vegetables, etc., others to stop meat, wine, malt, to which they were accustomed, and others again to partake most freely of spirits to which they were not accustomed. I believe the best and most proper plan is to live as usual, of course avoiding the use of any article which is known to disagree or which is likely to do so, such as long-kept or tainted meats, etc. On no account should any person on such occasions reduce their diet too much. Of the two errors this is the greatest.

I have known persons very much alarmed by the occurrence of borborygmi or slight cramps to fly to the physic bottle and to produce real illness by the use of purgatives or the abuse of opiates. I fear the common practice of prescribing for one's self and for others at these periods has tended very much to swell the list of deaths, and that many fall victims to poisonous doses of opium, lead, etc. On one occasion an old gentleman, hearing that sea water had been used as a remedy in the treatment of cholera, made sure that it must also be a preventive. He, therefore, before breakfast, went down to the sea-shore and drank off two large tumblers. He was attacked with diarrhœa, and for some hours his life was despaired of.

On such occasions, of course, it is of little use to tell persons not to be unnecessarily alarmed when they imagine that they are in the very grasp of the dreaded disease. But I think that it is the duty of members of the Medical Profession to do all they can to induce the people to make themselves acquainted with a disease over the prevention or lessening of which they themselves have so much influence, and which, for a time at least, after its outbreak is so little amenable to medicine or the Medical art.

As regards the prophylactic treatment of cholera, so cried up by some, I must confess I have no faith in it. I have heard of persons taking daily doses of tincture of rhubarb, chalk mixture, preparations of opium, etc., but I should very much doubt the efficacy of such; the only practice of this kind which appeared to me to be of service was the wearing of a flannel band round the abdomen, especially by persons predisposed to attacks of diarrhœa. With this exception, I believe the best treatment of the kind is to avoid all known causes of disease, and humbly to place our confidence and our trust in the goodness of an all-wise and all-merciful Creator.

As far as my experience goes, I believe many of the worst forms of cholera took place without any premonitory symptoms or diarrhœa, and there is no doubt that in the most violent cases of this disease, known as "cholera sicca," there are no alvine dejections at all.

In many cases I have known borborygmi and cramps of the feet and hands to be very troublesome, and to occur several times a-day, but not requiring any particular treatment. I myself during the outbreak of the epidemic in 1850 was much troubled with these affections.

As regards the attacks of diarrhœa so prevalent during the visitations of cholera, I have seen all sorts of treatment employed—as mercurials, opiates, ipecacuanha, the mineral acids, laxatives, antacids, and astringents; and I have seen each and all succeed and fail in checking the disease; in cases in which the looseness was troublesome and continuous, tending to dysentery, not infrequent after an attack of cholera, I have found strychnine of much service, either alone or in combination with iron. In prescribing strychnia in such cases, I generally gave it according to Marshall Hall's formula. In the majority of cases of diarrhœa I think a little ginger tea with a few grains of carbonate of soda, with attention to diet, proved sufficient. If there was pain, a few drops of some preparation of opium were added. In such cases, too, chloroform and chlorodyne prove of service; but in all cases, even of diarrhœa, the treatment should be suited to the particular case.

As to the treatment of cholera, my experience is, that at the commencement of an epidemic the majority of cases die, and appear to be unamenable to any curative treatment. I have seen drugs without number tried, and have heard each and every one cried up for a time as a specific and certain cure, but have seen them again fail and put aside. I have seen and tried small and repeated doses of calomel; also large doses of the same; also small and monstrous doses of acetate of lead, the mineral acids, the alkalies, opiates, quinine, ipecacuanha, belladonna, mineral and vegetable astringents, cajuput oil, croton oil, castor oil, turpentine, creosote, nitrate of silver, sulphite of magnesia, tartar emetic, mustard, table salt in large doses, "Stevens' saline powders," charcoal, chlorate of potash, Eupatoria or bitter bush, the fresh juice of the aloe, and many others; spirituous stimulants to intoxication, carbonic acid gas, the so-called "Liverpool mixture," and other boasted formulæ, warm baths, hot-air baths, external frictions, enemata of all kinds, saline injections into the veins; —but, nevertheless, I fear the results have been very unsatisfactory on the whole. Few of the first cases got well, and if they did I could not satisfy myself that their doing so was the result of what they had taken. I am quite certain that in the epidemic of 1850 I saw much mischief done by the use of spirituous stimulants and of opiates; so that in the epidemic of 1854 I almost entirely banished these remedies from my practice. Calomel and other mercurial preparations are, in certain cases and at certain stages of the disease, useful; but they have no specific effect, and in the hands of the unprofessional are calculated to do more harm than good.

I think I have seen more good to arise from the use of Stevens' powders than from any other mode of treatment—in fact, in 1854 I confined myself chiefly to this. Having read of the use of sea-water in the treatment of cholera, and from the difficulty of getting the saline powders prepared in sufficient quantity, Dr. Campbell and myself were inclined to give sea-water a trial among the prisoners of the General Penitentiary in Kingston. We had buckets of sea-water brought from a distance from the shore, and this well iced by pieces of ice thrown into it was doled out in small quantities to the sufferers; they drank it greedily, and strange to say of the seventeen cases who took it all recovered. Unfortunately it was not tried till towards the decline of the epidemic. In almost every case after the fourth or sixth dose the alvine dejections became tinged with bile, as also the contents of the stomach vomited.

From the result of this experiment, I made up my mind, in case of another epidemic breaking out during my time, that I would give sea-water a fair trial; and, indeed, should I suffer from the disease, I would from my own experience trust to the saline treatment, or, if I could get it, to sea-water well iced. The native nurses appear to have a great objection to allow the patient water to drink. I have frequently witnessed the most terrible sufferings from this cause. I may mention that in both the last epidemics I have witnessed I had great difficulties to encounter. The black prisoners for the most part fancying, that as the white population did not suffer in an equal degree with themselves they were being poisoned, often refused to submit to treatment; and again, in private practice among the negroes, great difficulty was often experienced to get them to take or to administer the remedies prescribed; partly because panic-stricken, at the mortality around them, they were ready to sit down and meet their destiny. The negroes of Jamaica, as a class, are fatalists. Often has it been my lot to witness a patient neglected and left to sink, and on remonstrating with relatives and friends have been coolly told—"Massa, what de use? him time da come." Again, there is a very prevalent notion among them that all the medicines ordered by Doctors are either emetic or purgative in their effect; it is, therefore, often impossible in cases of diarrhœa, cholera, or dysentery, to get the medicines regularly given, the patient and his friends declaring that the purging is from the physic. Another popular and most mischievous fallacy among them is, that in such cases the use of farinaceous articles of food as arrowroot, pap, etc., turns to water in them, and increases the evacuations, and that hard food, as they call it, as green roasted plantains, yams, and cocoes, have the contrary effect. In the wards of the Hospital

of Kingston it is a common practice for poor debilitated, miserable creatures in the last stage of dysentery to refuse the diet ordered for them, and to importune the nurses and other attendants with their dying breath to give them one meal of plantain, yam, and salt fish.

In very many cases of cholera in Jamaica, after the patient had battled through the disease, he has died from the effects of a heavy meal off some fat greasy soup.

In the prisons and Hospitals, whenever such patients refused to submit to treatment or to take the medicines ordered for them, the rule was to put the mattress on the floor and to lay the patient there, placing by his side a bucket filled with ice water and a tin pannikin. For the most part, these patients received little or no further care; certainly they were not rubbed and covered up with blankets as the more tractable were. But my experience was that the majority of those thus left to their own resources got well.

My experience in Jamaica convinced me that during cholera many persons were buried alive. I say this advisedly, having myself seen cases of persons alive being considered dead. At the Cholera Hospital, in Spanish Town, in the year 1850 the attendants, to save themselves the trouble of carrying the dead down the steps, were in the custom of laying a plank along the steps, on which they placed the body, allowing it to glide to the bottom. On one occasion, as I was going up the steps, the body of an old man, supposed to be dead from cholera, slipped past me, head down; in doing so I was struck by the appearance of his eye, and on examining him I found he was alive; he soon, however, died. I thought at the time rather from concussion of the brain than from the effects of cholera.

In another case a man was placed in a badly-made coffin (luckily for him), and had been taken to the burial ground; while there, waiting to be buried, the sexton, a very heavy man, sat down upon the coffin to eat his lunch; the yielding of the top of the coffin pressed upon its contents, and the man groaned aloud, much to the surprise and horror of the sexton.

In another case a female was placed as dead in a coffin, and the person in charge, in nailing it up, awkwardly drove a nail into her hip, after which the coffin was placed with a number of others in the dead-cart, and taken to the burial-ground. Here she was found to be alive, and for some years after appeared as a crippled beggar in the streets of Kingston.

Other cases of premature coffining occurred, and I fear many were consigned to an untimely grave. As a member of the Board of Health, I did my best to check this by having a rule framed that all persons taken for burial should be placed for a given time previously to being buried under a shed, but the fear of contagion and infection, I fear, prevented this being carried out.

The idea that the dead body was more contagious than the living one was very prevalent in Jamaica, and gave rise to several shocking and revolting acts. On one occasion, as reported, a woman was attacked with cholera, and her husband appears to have remained with her till symptoms of sinking made their appearance. He then dug a grave, and having tied a rope round her neck he left her, and when he thought she was dead, by means of the rope he dragged her to the grave and covered her up. Again, this notion led friends to remove the apparently sinking patient from his comfortable bed, and to lay him on the ground; the idea being that if he died on the bed it would be necessary to have that destroyed. I have even known the last moments of a dying person taken up in having the body bedaubed with whitewash, for the purpose of preventing contagion after death. In one instance, the proprietor of a breeding-pen recommended his people to clean up their huts and yards, and to whitewash the walls, and to enable them to do this he procured a large quantity of lime and brushes, which he distributed gratuitously. This whitewashing was very much talked of, and Quashie became impressed with the idea that whitewash was the cure for cholera. A young man on the property one day made his appearance and requested to be supplied with some lime, as his father was taken ill. This was given to him, with instructions to use it freely. A few hours after he returned, stating that his father was worse, on which the owner of the property accompanied him to see the old man. On entering the hut he was surprised to find that the walls were dirty, and had not been whitewashed. On remarking this to the young man, he remarked,—Oh, yes, he had washed him well, and so saying pointed out the poor patient lying on the floor thickly smeared over with lime.

While writing this a Medical friend who was in Jamaica during the epidemics I have alluded to, mentioned to me that he was one fine morning called to see a man who was said to have had an attack of cholera. On visiting him he found him sitting up with a pipe in his mouth. The wife stated that he had been attacked on the previous evening, and that during the night she thought he was dead; but that in the morning she found he had come to life again. (No doubt, he observes, his death during the night saved his being buried.) On visiting this man he was recovering from the stage of collapse, and expressed great hunger, and a desire for soup (*i.e.*, a thick, heavy pottage or mixture of fat pork with yams, cocoes, etc.). He was warned not to take anything of the kind, but to confine himself to a little simple diet. He took his own way, and on his Medical attendant calling the same evening he found him dead.

Such, Sir, is a very hurried statement of my experience as to cholera. I regret I have not my notes by me. If you think it worthy of a place in the *Medical Times and Gazette*, you are welcome to it.

I am, &c.

London. L. Q. Bowerbank, F.R.C.P.E.

THE RECENT OBSTETRICAL EXHIBITION.

Letter from Dr. Robert Barnes.

[To the Editor of the Medical Times and Gazette.]

Sir,—I should ill satisfy my sense of what is due to others if I did not beg of you to allow me the opportunity of sharing much of the credit you assign to me for the organisation of the obstetrical exhibition, soiree, and dinner, with my fellow-labourers. It cannot be necessary to say that the gathering together and arrangement of a collection of instruments so vast, varied, and instructive entailed labour enough to call for the zealous co-operation of several heads and hands. The conversazione committee, including the honorary secretaries, Drs. Meadows and Murray, Dr. Tyler Smith, Dr. Hicks, Dr. Greenhalgh, Dr. Graily Hewett, Mr. Traer, and Mr. Gaskoin, worked almost unremittingly, and in the most admirable spirit; but I am sure I express the opinion of all when I say that the chief praise is due to Dr. Meadows. To say that he worked with unwearied activity and energy is to fall very short of his desert. Without an intimate knowledge of the subject, marked ability in organisation, tact and promptitude in foreseeing and removing difficulties, much work would have been futile. These higher qualities Dr. Meadows displayed in a remarkable degree, deserving and commanding the success achieved in this arduous and most useful undertaking.

I am, &c.,

Finsbury-square, April 10, 1866. Robert Barnes.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 27, 1866.

Dr. Alderson, F.R.S., President.

A paper by Mr. T. Holmes was read on

A CASE OF LUMBAR COLOTOMY (AMUSSAT'S OPERATION), SUCCESSFULLY PERFORMED FOR THE RELIEF OF A VESICO-INTESTINAL FISTULA.

Ulcerated openings sometimes take place between the bladder and either the large or small intestines, which have no connexion with previous stricture of the gut, still less with cancer. In those cases in which the fæces come from the lower bowel, and are consequently more solid, great suffering is produced, and the formation of calculus in the bladder becomes exceedingly probable. In such of these cases as are not dependent upon malignant disease, colotomy, by diverting the fæces from the fistulous channel, may possibly enable the latter to close, and is at any rate necessary in order to relieve the sufferings caused by the fæces passing into the bladder. The author read the notes of a case in which communication existed between the bladder and some part of the bowel above the rectum and in which Amussat's operation was performed eight months since; the patient being now in good health, and in a condition of tolerable comfort, with evidence of con-

siderable contraction, if not complete closure, of the fistula. References were also made to some other cases of communication between the bowel and the bladder, with a view to support the opinions here put forward and the treatment adopted in the above case; and also with a view to the diagnosis of the seat of the communication with the bowel when out of reach of the ordinary means of examination.

Mr. Solly thought the Society was indebted to Mr. Holmes for his case. The Profession was not fully alive to the value of Amussat's operation in cancerous diseases of the rectum, and the case related would improve our knowledge of the operation in those malignant diseases. One peculiarity of interest in it was, that the operation was performed when the colon was not distended, which rendered the proceeding a difficult one. In his (Mr. Solly's) cases the intestine was full, and the operation very simple and easy. He would inquire whether the cavity of the abdomen was opened before the colon was reached?

Mr. Holmes Coote said that very few Surgeons had had personal experience of Amussat's operation. He had not operated upon the living, but had on the dead subject. The proceeding when the colon was distended was simple and easy; not so when, as in Mr. Holmes's case, the intestine was in a state of collapse. The case was interesting from the complete relief afforded to the patient, and from the fact that the disease was of a non-malignant character. Did the ulceration arise from tuberculous deposit, which might be only of temporary existence, and a complete cure follow?

Mr. Curling said that the remark made by Mr. Holmes Coote, a Surgeon to a large Hospital, that he had not yet had occasion to perform colotomy, seemed to confirm the observation of Mr. Solly, that the operation was not sufficiently appreciated by the Profession as a means of giving relief in many cases of painful disease. In the interesting case which had just been read, no doubt could exist as to the propriety of opening the lumbar colon, and as to the great advantage which might result from such a proceeding. We had only to contrast the great misery, ending in death, which existed in the case communicated by Mr. Morgan to the last volume of the Society's *Transactions*—in which the ileum opened into the bladder, Surgery being powerless in affording relief, with the comparative comfort and relief from all suffering now enjoyed by Mr. Holmes's patient,—to conclude that, in this instance, the operation was a triumph of Surgery. In his (Mr. Curling's) opinion, the principal interest of the case consisted in the diagnosis which had been so carefully and successfully made—in determining, chiefly from the solid character of the fæces which passed from the bladder, and from the free escape of urine by the rectum, that the opening from the bowel was in the larger bowel low down. He would endeavour to follow the author of the paper in confining his observations relating to colotomy to cases of non-malignant disease without obstruction. He believed that there were many cases of the kind to which this operation was applicable—cases of inveterate stricture of the rectum, with ulcerations and mucous growths, attended with an exhausting discharge, the patients going from Hospital to Hospital for relief, leading a miserable life, and ultimately dying of the disease. Mr. Pennell, whose interesting case of colotomy had been alluded to by Mr. Holmes, in his paper communicated to the Society sixteen years ago, remarked that he would have recourse to this operation in every case of incurable stricture of the rectum, which produced severe suffering, and was beginning to destroy the health and undermine the constitution. He (Mr. Curling) was not aware that this suggestion had ever been acted on, until six weeks ago, when he was induced to perform the operation in the London Hospital on a man only twenty-seven years of age, who had an obstinate stricture, and a diseased state of rectum such as he had described. The man was not pressed to submit to the operation, but when the circumstances of the after-condition were fully explained to him he begged to have it done. He recovered favourably, and under tannic acid and chloride of zinc injections the discharge from the rectum was greatly reduced; but it was too early to speak of the effect of diverting the channel for the fæces, and of other treatment, in bringing the rectum into a more healthy state. Colotomy was supposed to be a dangerous as well as a difficult operation. When performed in consequence of obstruction arising perhaps from cancerous disease, and delayed to the latest period, being resorted to only as a *dernier ressort* after a stoppage of three or four weeks, the operation was necessarily fatal in many instances. Owing perhaps to accidental circumstances, it had fallen to his lot to perform an unusual number of these operations. His experience extended to fourteen cases; eleven he had performed himself, and he had assisted in three other cases. Now in nine the operation was undertaken to relieve obstruction, in all from carcinomatous disease; five were fatal, and four recovered; but in none of the fatal cases could death be said to result from the direct effects of the operation. In the remaining five cases, in which there was no obstruction, the operation was performed to relieve the distressing symptoms of disease in the rectum. All of them recovered favourably. So that with this experience we are justified in saying that colotomy is not attended with any great danger. He had not met with any serious difficulty in opening the colon in the cases where no obstruction existed. He attached great importance to securing the bowel to the margins of the wound in the skin, so as to bring the gut near the surface, and to prevent feculent matter escaping into the sigmoid flexure below, as this was liable to be a source of trouble. He trusted that the satisfactory result of the author's case, and the discussion which had taken place that evening, would tend to remove much of the prejudice which existed against colotomy, being assured that it was capable of diminishing suffering and prolonging life in many cases of serious disease.

Mr. Holthouse could confirm the observations of Mr. Curling as to the great depth of the bowel from the surface in many of these cases, as well as to the necessity of securing the edges of the intestinal opening close to the cutaneous one. He (Mr. Holthouse) had had some experience in the performance of Amussat's operation, and nothing was more striking than the difference of depth at which the colon was situated in different cases. When this intestine was distended above the seat of operation, it pressed towards the surface, producing such a stretching and apparent thinning of the superimposed structures that a trocar might be thrust at once into the bowel without any fear of wounding the peritoneum. In other cases, on the contrary, the colon was empty and contracted, sometimes not larger than the finger, and lay at a great distance from the surface. This was the condition of the patient in the last case operated upon by him, and which indeed somewhat resembled that of Mr. Holmes, inasmuch as a communication had formed between the intestine and the bladder. With the view of acquiring a correct knowledge of the relative anatomy of the parts concerned in this operation, and the appearances which indicate the proximity of the colon, Mr. Holthouse some years ago made a number of dissections of the region implicated. The parts were dissected both from before and from behind, and the following was the mode of proceeding:—The abdomen being opened and the small intestines removed, a long carpet-pin was thrust directly backwards through the descending colon, one inch above the crest of the ilium, till it emerged through the skin in the loin. Taking the average of the cases examined, the lower end of the kidney was found to be two-thirds of an inch above the transfixed part of the colon, and internal to it. The intestine itself lay on a layer of fat and the anterior lamella of the lumbar fascia, which separated it from the quadratus muscle. In performing Amussat's operation, therefore, after cutting through the skin and subcutaneous tissue, together with the superficial muscles, one arrived at a very strong dense fascia (fascia lumborum) connected with the internal oblique and transversalis muscles externally, passing beneath the outer margin of the erector spinæ and in front of the quadratus. On dividing this and the last-named muscle, a layer of fat or omentum-like structure, which varies in thickness, comes into view, and immediately behind this is the uncovered portion of the colon. Mr. Holthouse regretted, with previous speakers, that colotomy was not more frequently resorted to, and, when performed, that it was not done earlier. He had on several occasions recommended its performance, but it was either declined or put off till too late. The case of Mr. Gracie (Mr. Pennell's patient), which had been referred to by Mr. Holmes and Mr. Curling, was a striking example of what the operation could effect. Mr. Holthouse had had the advantage of seeing that gentleman when he was in London some years ago, and as evidence of the completeness of his recovery it might be mentioned that he was in the habit of walking from his lodgings in Piccadilly to the Docks and back again without experiencing any inconvenience. His chief anxiety was lest the artificial anus should close up.

Mr. Curling rose again to state that he had under his care in the London Hospital, at the present time, two patients upon whom he had performed colotomy: one, to whose case he had already adverted; and another, a young man aged twenty,

with cancerous disease of the rectum without obstruction. And he should be happy to show the cases to any Fellows interested in the subject. He would also add that he had once operated in a case of extreme lateral curvature of the spine, and had succeeded in reaching the bowel above the anterior-superior spinous process of the ilium without opening the peritoneum.

Dr. Marcet related a case of obstruction of the intestine, which was removed by injections of large quantities of olive oil.

Mr. Holmes then replied. He said that the peritoneal cavity was not opened in the operation. The difficulty in reaching the colon depended upon its being in an abnormal position—quite different, indeed, from its ordinary situation; but he succeeded in reaching it in the mode described in the paper. Usually, as the colon was distended, there was no difficulty in finding it, and this without opening the peritoneum; though this cavity had in many instances been laid open in this operation, and often without the knowledge of the Surgeon. He thought with Mr. Coote that the case was one of ulceration of tubercular deposit, a form of disease by no means rare. He agreed that many cases in which Amussat's operation might be performed, with the result of prolonging life and affording much comfort, went now from Hospital to Hospital, and were submitted to instrumental and other interference. Occasionally, in these cases, the comfort of the patient was dreadfully interfered with from the difficulty of fitting an instrument to the opening, and from the constant escape of fæcal matter and its offensive odour. When the bowels acted at regular periods, and the pad could be well adjusted, the patient experienced much comfort.

OBITUARY.

DR. THOMAS HODGKIN.

We regret to announce the death of Dr. Hodgkin, in his 68th year, which occurred from dysentery, on the 5th of April, at Jaffa, to which place he had proceeded in company with Sir Moses Montefiore for the purpose of still further advancing the interests of the suffering Jews. It was only a few months ago that he succeeded, in conjunction with Sir Moses, in inducing the Sultan of Morocco to make important concessions to his Jewish subjects. He graduated at Edinburgh in 1828, and his thesis was not only characterised by his devotion to that branch of Professional science to which he afterwards devoted so much time and energy—the department of morbid anatomy—but was remarkable for the purity of its Latin. His early life called for the continuous care of his highly intellectual parents, for he was a seven months' child, and he never attained to anything like vigour of constitution; but his physical growth was outstripped by a development of remarkable mental power, to which his whole life bore testimony. He was elected Licentiate of the Royal College of Physicians, London, 1825, and Physician, Curator of the Museum, Inspector of the Dead, and Professor of Morbid Anatomy at Guy's Hospital. To have occupied such a position he must have possessed not only strict anatomical knowledge, but an amount of special scientific and general information which few men attain. His classified catalogue of the Pathological Museum of Guy's Hospital is a masterpiece of talent and industry. On the formation of the University of London, he was appointed by Earl Russell the first Senator, and was empowered to organise that University to which he never ceased to give his untiring attention. St. Thomas's Hospital, under difficulties, sought Dr. Hodgkin's assistance, and he reorganised the Medical staff, taking upon himself the responsibility of Curator of the Museum and Lecturer on the Practice of Physic. With this vast labour on his hands, he never lost sight of those studies which were dear to him. His valuable works on the Morbid Anatomy of the Serous and Mucous Membranes and on the Influence of Physical Agents on Life must always be works of reference; but he was as great at the bedside as in the study; and as a diagnostic Physician he was not surpassed.

We have now to speak of him as a naturalist and philanthropist. His love of Nature was such that there was scarcely a department in natural history that he did not cultivate; and his knowledge of languages, commanding, as he did, Greek, Latin, Italian, French, and German, all of which, with the exception of Greek, he spoke fluently (and speaking Latin is a rare attainment now) rendered his correspondence both extensive and valuable. As a philanthropist he has of late years more particularly distinguished himself. His love of natural history centered itself—master as he was of geography—upon the study of the uncivilised races of man; and if he was not the founder, he was mainly instrumental in establishing the Aborigines' Protection Society, and through the formation of that Society Ethnology took its place in science.

Dr. Hodgkin seems to have foreseen the cause of his own death; he maintained for years that the sigmoid flexure of the colon was diseased, and he was a great sufferer from this cause, though his sufferings were known only to his amanuensis. His most important works were written under extreme suffering, according to his usual custom, between six and eight o'clock in the morning, while reclining in bed.

Dr. Hodgkin was a member of the Senate of the University of London, and intimately connected with almost all the scientific bodies in this country. In addition he was member of the Lyncean Academy of Rome, the Physico-Critical Academy of Sienna, the Philomathic Society of Paris, the Royal Society of Medicine at Marseilles, the Society of Natural Philosophy and Medicine of Heidelberg, the Academy of Natural Sciences of Philadelphia, the Massachusetts Medical Society, the Geoenian Society of Catania, the Iatrophysical Society of Palermo, the Sandwich Islands' Institute, etc. His writings were of most extensive character, distributed through periodical literature both at home and abroad. We may mention amongst the most valuable of his works the following:—"The Pathology of Serous and Mucous Membranes," "Classified Catalogue of the Museum of Guy's Hospital," "The Means of Preserving Health," "The Influence of Physical Agents on Life."

NEW INVENTIONS.

REW'S PREPARATIONS OF CARBOLIC ACID, CARBOLIC INHALER, AND APPARATUS FOR MAKING EFFERVESCENT BEVERAGES.

Mr. Rew, of Regent-street, seems to have been working for a long time at preparations of carbolic acid, in order to render this powerful agent more available for the treatment of disease. In the first place, there is an aromatised solution of carbolic acid, in which the inventor has striven to "cast a perfume" not on the "violet," but on the somewhat pungent and refractory antiseptic. Secondly, there is a new inhaler, in which the necessity for heat is done away with, for the volatile acid is carried up and inhaled at the ordinary temperature of the room. It may be remembered that the mere use of steam, or other heated vapour, is disagreeable to some patients, and prejudicial to others; consequently that a means of adding a tonic and balsamic ingredient to air of the ordinary heat may have great advantages. Thirdly, there is a lozenge impregnated with carbolic acid, of which the writer will only undertake to say that it is not more disagreeable than other medicated lozenges, and that he has heard patients compare it to paregoric and bitter almonds, thus indicating the kind of flavour it possesses. These lozenges and other preparations are available in cases of stinking breath, relaxed mucous membrane, ulcerated lungs, and the like; but there is one malady for which we do not see them recommended, but for which they surely should have full trial, and that is whooping cough. They *ought* to do good in this *opprobrium medicorum*; whether they will is another question, which we leave to be decided by experience.

The last apparatus on our list is one for making gaseous water, cheaply and easily, in a convenient vessel for table use, and one which has not the remotest possible chance of blowing up, or of spurting its contents over the costly toilettes of the fair sex. The vessel is double bodied; one part holds a solution of acid, the other a solution of alkali. The spout is single, so that the liquids combine and foam in issuing forth, even as oxygen and hydrogen do in the oxyhydrogen blowpipe. The contrivance is simple, but clever and effective for all that.

Hydrophobia from the Bite of a Badger.—M. Selle, at one of the recent sittings of the Turin Academy of Medicine, gave an account of an old woman who was attacked and severely bitten by a female badger, infuriated by the loss of its young. She was taken to the St. Giovanni Hospital and treated for her numerous wounds, but she died at the end of a month, having manifested during several days the symptoms of well-marked hydrophobia.—*Gaz. Méd.*, April 7.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 10th inst., and when eligible will be admitted to the Pass Examination:—

L. J. Moseley, A. H. Baines, C. J. Sells, F. S. Daldy, Charles Munden, J. G. Carruthers, W. B. Lewis, C. J. Worts, George Stokell, W. J. Bennett, and J. W. Barry, students of Guy's Hospital; William Kipling, John Lloyd, J. J. Bingham, William Price, and David Havard, of University College; C. H. Joubert de la Ferte, Inman Welsh, Friend Lewin, and T. A. Roberts, of St. Mary's Hospital; R. C. Sanders, W. H. Causton, and George Salt, of the London Hospital; W. J. Barkas, T. O. Wood, and J. T. Parkinson, of Newcastle; W. A. Cox and Edward Jackson, of St. George's Hospital; T. W. Lee, of St. Bartholomew's Hospital; H. L. Snow, of Birmingham; and William Dobson, of Leeds.

The following gentlemen passed their Examination on the 11th instant, viz.:—

Edward Hewer, R. M. Bradford, J. T. Williams, Thomas Smith, Richard Samuel, H. L. Williams, C. B. Crowfoot; and N. H. Jarvis, students of St. Bartholomew's Hospital; George Andrews, Richard Rendle, R. L. Wilson, J. G. Wiseman, J. B. Saundry, Frederick Taylor, and Edward Sunderland, of Guy's Hospital; A. H. Buck, Adam Wilkinson, and William Powell, of the Charing-cross Hospital; Edward Stephens and William Younghusband, of Liverpool; J. R. Haynes and C. C. Winkworth, of the Westminster Hospital; H. E. Hetling and T. D. Saunders, of Bristol; George Thompson, of Leeds; F. W. Wimberley, of the Middlesex Hospital; John Bately, of Birmingham; and Clement Dukes, of St. Thomas's Hospital.

The following gentlemen passed their Examination on the 12th inst.:—

William Roche, John Curnow, A. F. McGill, Daniel King, William Webster, and W. B. Kendall, students of King's College; John de Liefde, T. W. Joy, F. W. Sabzmann, Branford Edwards, R. M. Cole, and Charles Higgins, of Guy's Hospital; J. A. Lormier, Alexander McGregor, John Gosse, D. H. B. Anderson, and John Giles, of St. Bartholomew's Hospital; William Anderson, N. C. Dobson, and John Fairbank, of St. Thomas's Hospital; Alfred Hollis, J. J. Levindell, and Walter Maine, of the Middlesex Hospital; J. G. Black, of Newcastle; B. P. B. Burroughs, of Bristol; Anthony Foster, of Leeds; and Evan Williams, of Dublin.

It is stated that out of the 108 candidates who offered themselves for the Primary Examination, no less than 22 failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their studies for three months.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 5, 1866:—

William Thomas Cassel Pratt, Newport, Monmouthshire; Alexander Thorburn Macgowan, 5, Caversham-road, N.W.

The following gentlemen also on the same day passed their First Examination:—

George William Barroll, St. George's Hospital; John Bately, Sydenham College, Birmingham.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BOTTLE, A., M.D., has been appointed Senior Resident House-Surgeon to the Leeds Public Dispensary.

BUTLER, T. M., M.R.C.S., has been appointed an Honorary Assistant Medical Officer to the Surrey County Hospital, Guildford.

COOKSON, E., L.S.A.L., has been appointed Resident Assistant House-Surgeon to the Leeds Public Dispensary.

DE TATHAM, H., L.R.C.P., M.R.C.S., has been appointed to the office of House-Surgeon, St. Mary's Hospital.

ELLERTON, JOHN, M.D., has been appointed Surgeon to the North Riding Infirmary, Middlesbro'-on-Tees.

FISH, R., M.R.C.S., has been appointed Assistant-Surgeon to the London Rifle Brigade.

GRUBB, R. T., M.R.C.S., has been appointed House-Surgeon to St. Mark's Hospital.

HAYWARD, SIDNEY, M.D., M.R.C.S., has been appointed Honorary Medical Officer to the Royal Pimlico Dispensary and Lying-in Charity.

MORTON, J., M.B., has been appointed an Honorary Assistant Medical Officer to the Surrey County Hospital, Guildford.

MUSHET, W. BOYD, M.B., M.R.C.P., has been appointed Physician to the North London Hospital for Consumption.

PAGE, W. J., M.R.C.S., has been appointed Surgeon to the Peckham Rye Dispensary.

RIGDEN, G. W., M.R.C.S., has been appointed House Surgeon to the Taunton and Somerset Hospital.

SCHOLLICK, T. J., M.R.C.S., has been appointed Honorary Assistant Medical Officer to the Surrey County Hospital, Guildford.

SIMPSON, J., L.R.C.P.Edin., has been appointed to the Leith Hospital and Edinburgh Humane Society and Dispensary.

VEITCH, WILLIAM YOUNG, L.R.C.P. Edin., has been appointed House-Surgeon to the North Riding Infirmary, Middlesbro'-on-Tees.

BIRTHS.

ADAM.—On April 2, at 137, Princes-street, Edinburgh, the wife of H. Adam, Assistant-Surgeon, Madras Army, of a daughter.

BUCHANAN.—On April 7, at 63, Harley-street, the wife of G. Buchanan, M.D., of a daughter.

CALDWELL.—On March 28th, at Dreghorn, Ayrshire, the wife of J. Caldwell, L.R.C.P.Edin., of a daughter.

FITCH.—On April 5th, at Chaddesley Corbett, near Kidderminster, the wife of F. Fitch, M.D., of a son.

FITZPATRICK, JOHN.—On March 31, at 39, Elgin-road, Kensington-park-gardens, the wife of John Fitzpatrick, M.D., Retired Surgeon-Major Madras Army, of a son.

GAMGEE, J. S.—On March 31, at Birmingham, the wife of J. S. Gamgee, M.R.C.S., of a daughter.

GELL.—On March 27, at Great Ayeliffe, the wife of A. S. Gell, M.R.C.S., of a son.

HARVEY.—On April 7, at 31, Grosvenor-street, the wife of John Harvey, M.D., of a son.

MACANN, A. B.—On April 5, at 22, King-street, Portman-square, the wife of A. B. Macann, M.R.C.S., of a son.

MORPHEW.—On April 8, at Sevenoaks, the wife of A. Morphew, Staff-Surgeon, of a daughter.

PERKINS.—On April 2, at Bentinck-terrace, Regent's-park, the wife of R. H. Perkins, Surgeon Bengal Army, of a son.

RUSSELL.—On April 5, at Accrington, Lancashire, the wife of W. S. Russell, M.R.C.S., of a son.

SLYMAN, W. D.—On March 29, at 18, Warden-road, Kentish-town, the wife of W. D. Slyman, M.R.C.S., of a son.

MARRIAGES.

DRAKE—ELLIOT.—On April 4, at All Saints', West Ham, T. Drake, M.R.C.S., to May, daughter of W. Elliot, M.D.

DUNCAN—THOMSON.—On April 4th, at Mains Tillicoultry, John Duncan, M.D., of Edinburgh, to Jemima, daughter of Alexander Thomson, Esq.

PUGSLEY—OATWAY.—On April 5, at Old Cleeve, Somerset, L. Pugsley, M.R.C.S., to Susannah Risdon, daughter of the late R. Oatway, Esq.

WARD—BURNAND.—On April 10, at Cuckfield, W. P. Ward, Surgeon, Royal Artillery, to Eleanor, eldest daughter of H. Burnand, Esq.

WELCH—SLATER.—On April 10, at St. James's, Clapton, Charles H. Welch, L.F.P.S. Glas., of Cambray-villa, Clapton, to Ellen F. Slater, only child of the late Isaac Slater, of the Cape of Good Hope.

DEATHS.

ALLARDYCE, JAMES, M.D., at Cambray place, Cheltenham, on April 6, aged 84.

BABINGTON, BENJAMIN GUY, M.D., at 31, George-street, Hanover-square, on April 8, in the 73rd year of his age.

BRYDONE, J. M., Retired Staff-Surgeon, R.N., at Petworth, Sussex, on March 29, aged 86.

CHEESEWRIGHT, W., M.R.C.S., of Sturminster Newton, Dorset, on March 28.

FINCH.—On April 9, at Slough, W. Finch, L.F.P.S. Glasgow, aged 34.

GALINDO, R. M., M.D., M.R.C.S., at 19, Noel-street, Islington, on April 7, aged 72.

HARLAND, W., M.D., at Scarborough, on April 6, aged 79.

JONES, W., M.D., at Lutterworth, on March 27, aged 86.

MOSELEY, F. X., M.D., F.R.C.S., at Seymour-street, on March 31, aged 61.

WOODWARD, HENRY, M.R.C.S., at Bicester, Oxfordshire, on April 4.

WOOTTON.—On April 9, at Harrold, Bedfordshire, W. Wootton, M.R.C.S., aged 63.

WYLIE, JOHN DICK, M.D., Civil Surgeon, at Nynee Tal, North-west Province, India, on February 19.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Chard Union.—Mr. G. R. Burt has resigned the First Ilminster District; area 7032; population 4608; salary, £68 8s. 4d. per annum.

Driffield Union.—The Kilham District is vacant; area 13,880; population 2035; salary £16 per annum.

Hartley Wintney Union.—Dr. Ebenezer Diver has resigned the Heckfield District; area 7759; population 1492; salary £70 per annum.

Keynsham Union.—The Workhouse is vacant; salary £50 per annum.

Uppingham Union.—The Barrowden District is vacant; area 16,874; population, 3887; salary £45 per annum.

Wrexham Union.—Mr. J. F. Churchill has resigned the Fourth District; area 15,941; population 3299; salary £25 per annum.

APPOINTMENTS.

Kidderminster Union.—Cecil Webster, M.R.C.S.E., L.S.A., to the Bewdley District.

Louth Union.—William D. Ditchett, M.R.C.S.E., L.S.A., to the Louth District and the Workhouse.

Newcastle-upon-Tyne Union.—Thomas C. Nesham, M.D. Edin., M.R.C.S.E., L.S.A., to the First District. John Hawthorn, M.R.C.S.E., L.S.A., to the Fourth District.

Pontypridd Union.—David W. Davies, M.D. and M.C. Aberd., to the Llantrissant District. Henry N. Davies, M.R.C.S.E. L.R.C.P. Edin., L.M. Lond., to the Cymmer District.

Totnes Union.—Thomas E. Owen, M.R.C.S.E., L.S.A., L.M., to the Stoke Gabriel District. Augustus Newman, M.B. Oxon., M.R.C.S.E., L.S.A., L.M., to the Townstal District.

Whitechapel Union.—Septimus Swyer, L.R.C.P., M.R.C.S.E., L.S.A., L.M., to the Spitalfields District.

THE LATE DR. BENJAMIN GUY BABINGTON, F.R.S.—Our readers will receive with deep regret the news of the death of this accomplished Physician, which took place on April 8 at his residence, George-street, Hanover-square. Dr. Babington's name will be always connected with epidemiological science. His translation of "Hecker's Epidemics of the Middle Ages," and the foundation of the Epidemiological Society, of which he was President, gave the first impulse to the special study of widely-spreading diseases in this country. We shall give a biographical notice of Dr. Babington's career in our next number.

CHARING-CROSS HOSPITAL.—We have to announce the appointment of Professor Divers, M.D., of Queen's College, Birmingham, to the Lectureship on Natural Philosophy in the Medical School of Charing-cross Hospital.

OFFICERS OF THE HUNTERIAN SOCIETY FOR THE SESSION 1866-7.—*President*—Stephen H. Ward, M.D. *Vice-Presidents*—S. W. Devenish, M.B.; Sigismund Sutro, M.D.; Thomas B. Crosby, M.D.; D. De Berdt Hovell, Esq. *Treasurer*—William Cooke, M.D. *For the Oration of* 1867—W. Sedgwick Saunders, M.D. *Librarian*—Robert Fowler, M.D. *Secretaries*—H. I. Fotherby, M.B.; W. Allingham, Esq., F.R.C.S. *Council*—Robert Barnes, M.D.; Henry Blenkarne, Esq.; Thomas Brown, Esq.; Thomas Bryant, Esq.; P. Lodwick Burchell, M.B.; Thomas Mee Daldy, M.D.; Esquire Dukes, Esq.; J. Hughlings Jackson, M.D.; G. Lightenberg, M.D.; C. F. Maunder, Esq.; W. S. Saunders, M.D.; Alfred Smee, Esq., F.R.S.

THE Odontological Society held its monthly meeting at 32, Soho-square, on the 2nd inst. Dr. Rottenstein, of Paris, sent for exhibition a stomatoscope for illuminating the mouth as well as the larynx by galvanic means. A paper was read by Mr. Sydney Longhurst on "Lateral Abnormalities." The irregularities of the lateral incisor teeth, the frequent additional number, their absence, their being occasionally germinated, and their tendency to produce abscess of the palate, were the chief points considered.

THE OPHTHALMOLOGICAL CONGRESS FOR 1866.—Professors von Jäger, senior, Arlt, and Gulz, as the official managers of the next Congress, to be held in Vienna, have issued a cordial invitation to the ophthalmologists of all countries, assuring them that a rich material awaits their inspection at Vienna, where every attempt will be made to render their stay profitable and agreeable. The first general meeting of the Congress will take place August 25, at the Academy of Sciences.

DEATH OF A VETERAN.—Mr. J. M. Brydone, Surgeon R.N., died at Petworth on the 29th ult., aged 86. He was at the battle of Trafalgar, and never had a day's sickness till within a fortnight of his death, with the exception of an attack of yellow fever.—*Guardian.*

IT is officially announced that a separate department has been formed for the transaction of business relating to the cattle plague, under the superintendence of Colonel Harness, R.E., C.B., at 7, Westminster-chambers, Victorial-street, S.W.

CLOSURE OF A HOSPITAL.—The Roman Catholic Hospital of St. John and St. Elizabeth, Great Ormond-street, which was founded in 1856, has just been closed by the unanimous resolution of the Committee. Want of funds was the ostensible reason for closing it. Sir George Bowyer has circulated a letter amongst the subscribers, in which he condemns the management of the charity by the Committee, and stigmatises the closing of the Hospital as "cruel, unwise, and mischievous."

THE PUBLIC MEDICAL SERVICES.—From the report of the committee on Army and Navy Medical officers' affairs it appears that the total number of candidates examined for the Army Medical Service since 1856 is 922. Of these 713 were passed and 209 rejected. The total number of candidates examined for the Naval Medical Service since 1856 is 596, of whom only 389 were found qualified. During the past year there were only 17 candidates, of whom seven were rejected. That the public Medical Service is distasteful to the Profession is shown in the small number entering, and in the large number of resignations after, as since 1850 up to the present time no less than 137 Medical officers have left the Royal Navy, and during the same period 117 have voluntarily left the Army, even after 17 years' service. The average age of Army Assistant-Surgeons on promotion to the rank of full Surgeon, for the last 11 years' has been 33 years, and the average length of service $9\frac{1}{2}$ years.

A LUNATIC AND HIS KEEPER DROWNED.—On Friday afternoon, while a number of the patients of the Abbey Lunatic Asylum were employed working in an adjoining field, it was discovered that a patient named Thomson, and one of the male attendants, named Lachland Vas, were missing. Search was immediately made, when the cap and wig of the keeper were discovered floating in an old quarry hole partially filled with water. After a few hours spent in dragging the hole, both of the bodies were brought up. It appears that Thomson (who was a dangerous and at some times almost ungovernable patient) had made an attempt to escape from the keeper, and being acquainted with the ground had leaped over a fence into the quarry. Vas followed, with the intention of rescuing him, but not being aware of the depth of the water, they were both drowned.

LONDON SUPER-MARE.—Few of those whose avocations do not lead them to visit the poorer parts of this wealthy town would imagine how great and serious has been the neglect of the fundamental conditions of public health. Not only is there a very general absence of drainage and very deficient water supply, but the accumulation of refuse and filth, the overflow of cesspools and closets, the absence of domestic arrangements of a kind essential to decency and health, and the accumulation of water in yards and cellars are all to be found in numerous localities—tending alike to the promotion of fever and epidemic diseases.—*Sixth Annual Report of the Brighton Ladies' Sanitary Association.*

HYDROPHOBIA.—A fatal termination of the bite of a dog has occurred near Manchester. In August last Mr. Charles Budd, a clerk employed at the Manchester and Liverpool District Bank, was bitten by one of his own dogs, a bull terrier, which, as it had exhibited signs of madness, he was about to shoot; but before he could do so, it flew at him and inflicted a wound on the leg. He continued at his business up to Monday last without any alarming symptoms being developed, but on that day he complained of a strange feeling, and on asking a drink of water from the housekeeper, he found he could not swallow. On arriving at his home in Withington the same evening, he experienced equal difficulty in swallowing a glass of porter which was offered to him, though suffering from intense thirst, and all the indications of hydrophobia quickly supervened. He grew rapidly worse, and died on Wednesday night, with all the symptoms attendant on hydrophobia.—*Manchester Courier.*

HEAVY RAILWAY DAMAGES.—In the case of Elkington *v.* London and North-Western Railway Company, which was tried at Gloucester on April 6, the plaintiff was high bailiff of the County Court at Birmingham; the salary attached to his office is £1200 per annum. He was travelling to London on February 3, and when near the junction at Rugby the train in which he was was run into by another train with so severe a shock that the train was sent from the rails on to the sleepers. He felt that his back was hurt, but, nevertheless, went on to London. When he got there he sent for his father-in-law, Dr. Elkington, and he found himself too ill to perform the duties of his office three days afterwards. On the part of the plaintiff, Dr. Elkington stated that he was suffering from a nervous shock to the brain, and had indications of paralysis and that his spine was injured. Mr. Cheshire said there was a slight extravasation in the right eye, arising from a shock received by the retina in the accident. Dr. Bell Fletcher thought there was a general affection of the nervous system of the brain and spinal marrow. Dr. Gilchrist, of Torquay, saw a general disturbance of the nervous system, and Mr. Erichsen a subacute inflammation of the brain and irritability of the spine, with paralysis of the legs. On the part of the defendants, Dr. Heslop, of Birmingham, thought that, though there was a general disturbance of the nervous functions, there was no organic disease of the spine or brain. Dr. Blount agreed with him. Mr. Haynes Walton, Mr. Pemberton, and Sir W. Fergusson gave evidence in support of the theory that the plaintiff's injuries were temporary, and not permanent. Verdict for the plaintiff, damages £3500. In the case of Hubbert *v.* Lancashire and Yorkshire Railway, tried at Liverpool, April 4, the action was brought to recover damages for injuries sustained in a collision which took place on the defendants' line at Wigan on June 20 last. The negligence was not disputed, and the inquiry became an assessment of damages. The plaintiff is a draper carrying on business at Birkenhead, and on the day in question he had taken a second-class ticket from Liverpool to Manchester. On his return journey, when the train got to Wigan, a second train ran on to the same line of railway, and

both came in collision with each other and with a coal train. The consequence was to inflict most serious damage upon the plaintiff, resulting in paralysis of the right leg, and inability to transact or attend to business. The plaintiff at the time of the accident was a young man of 34, with a wife and children, and a thriving business. Medical evidence was given to show the grave nature of the injuries sustained by the plaintiff; also evidence that his income from his business amounted to £340 per year; and the jury found a verdict for £4000. In the case of Perelle *v.* the Great Western Company, tried at Liverpool on April 7, a ship chandler claimed damages on account of injury of the spine. The jury returned a verdict of £1600 damages. In the case of Vowles *v.* the Great Western Company a verdict of £700 damages was obtained, the plaintiff having sustained fracture of the leg. In the case of Sewell and Wife *v.* the South Devon Railway Company, the action was settled for £550.

At a meeting of the Yorkshire Registrars of Births and Deaths, held at Leeds on March 10 to take into consideration the New Vaccination Bill introduced by Mr. Bruce into Parliament, Mr. J. K. Heaps in the chair, the various clauses of the New Vaccination Bill having been read, it was resolved, "That this Meeting considers that the Remuneration Clause, No. 23, is very unsatisfactory." The Clause is as follows:—"Every registrar shall keep a book in which he shall enter minutes of the notices of vaccination given by him as herein required, and also register the certificates transmitted to him as herein provided, and shall at all reasonable times allow searches to be made therein, and upon demand give a copy under his hand or under that of his deputy of any entry in the same, on payment of a fee of one shilling for each search and sixpence for each copy; and every registrar shall receive a fee of one penny in respect of every child whose birth he shall have registered, and in respect of whom he shall give the notice, as aforesaid, and another fee of *Threepence* in respect of every such child whose certificate of vaccination he shall have registered as herein provided, and he shall receive a fee of *One Penny* in respect of each child whose certificate of vaccination he shall have registered without having registered the birth: provided that no fee shall be charged for any search made by a public vaccinator or any officer of the guardians, authorised by them to make such search, or any Inspector appointed by the Poor-law Board or the Lords of Her Majesty's Council." It was resolved, "That in the opinion of this meeting the remuneration should be *Threepence* for giving the notice and entering the particulars required in the Vaccination Book, and the further sum of not less than *Twopence* for completing the entry on receipt of the vaccinator's certificate."

The following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked.			2. Result of reported Cases from the Commencement of the disease.

Note.—19 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Chester, 1; Lancaster, 3; Lincoln, 4; Northampton, 1; Stafford, 2; East Riding of York, 1; Metropolitan Police District, 3; and Scotland, 4. These Inspectors returned 290 cases last week.

Treatment of Fever by Sulphites.—In No. 51 of the *Glasgow Medical Journal*, October, 1865, there is a communication by Dr. De'Ricci, of Dublin, in which he advocates the use of sulphites and hyposulphites in the treatment of zymotic diseases. "Physiology," he says, "leads us to believe that all zymotic diseases depend on a fermenting or catalytic principle in the blood. Chemistry teaches us that in the presence of sulphurous acid and the sulphites no catalytic action can take place, and practical experience confirms the teachings of science, by showing us palpably that zymotic diseases, even in their most virulent forms, become completely neutralised by this remedy." This discovery he ascribes to Professor Giovanni Polli, of Milan. I may here remark, that it is much to be regretted that Medical men are so frequently in the habit of making such unqualified assertions respecting the use of various remedies. One might suppose that with such a remedy in hand the treatment of fever would become a very simple matter indeed—neutralise the poison, and, as a natural consequence, the fever must cease. Being satisfied that the bi-sulphite of soda—the preparation chiefly recommended—is, at all events, innocuous, I determined to test its efficacy in typhus. After carefully watching the progress of at least a dozen cases in which scruple doses of the bisulphite of soda were administered every three or four hours, I am led to the conclusion, that in typhus fever, at least, no amelioration of the disease is produced by it; as to its action in scarlatina, small-pox, and puerperal fevers, for which it is so highly lauded in the paper just referred to, I am not prepared to speak, having had no experience of it in such cases. Had I been so rash as to have given an opinion upon the use of the sulphites without giving them a full trial, I might have fallen into the mistake of supposing them capable of completely neutralising the poison of typhus, because in one of the first patients who got this treatment, there was a very remarkable fall of the pulse, accompanied with an unusual defervescence or diminution of temperature on the eighth day of the fever. In none of the other cases did I observe the smallest degree of benefit from the use of the bisulphite of soda; all I can say is, that while it does not appear in the slightest degree hurtful, it is by no means an agreeable Medicine to the poor patient.—*Observations on the Present Epidemic of Typhus, by Robert Perry, M.D.*

BOOKS RECEIVED.

The Australian Medical Journal. August, 1865. Melbourne: Wilson and Mackinnon.

*** Dr. Burn Malcolm gives a case of empyema cured in a novel manner. The affection was on the left side, the patient was extremely exhausted, the heart displaced, and by the end of a month there seemed no resource, save paracentesis. But the risk of tapping was too great, and the following ingenious method pursued:—There was already an opening between the pleural cavity and the upper and front part of the lung, and when the man leaned forward he expectorated profusely. Dr. Malcolm asked himself "Why not turn the man upside down, and allow the pus to escape through the opening already made?" He was made to hang his head over the side of the bed, when about a quart of horribly offensive pus ran out of his mouth. This was repeated night and morning, perseveringly but cautiously, the pus was gradually drawn off, the heart began to return towards its normal condition, the lung to expand, and in twenty-two days there was no further need of a Doctor. In another month he was out driving, with his chest wonderfully little fallen in, and now weighs fourteen stone. There are cases of hydatids by Mr. MacGillivray; a case, by Mr. Butler, of intestinal obstruction, with recovery after fourteen days, and expulsion of a gangrenous portion of small intestine seven inches long; and a paper, by Dr. Neild, on feigned hæmoptysis.

Bathing: How to do it, When to do it, and Where to do it. By Edgar Sheppard, M.D. 2nd edition. Pp. 39. 1866. London: Hardwicke.

*** Dr. Sheppard has used the Turkish Bath in the treatment of cases at the Colney-hatch Lunatic Asylum with "unqualified success." Its power in many forms of disease, especially in melancholia, has been found most remarkable; sleep is induced, morbid fancies dispelled, and the violence of acute mania mitigated. It softens the dry skin and gives out the odour by which "you may smell a madman anywhere," and gives satisfaction to the patient. Dr. Sheppard enters into his subject with the enthusiasm of a Turk or an Urquhart, and we recommend our readers to study this pamphlet.

The First Annual Report of the Hankow Medical Mission Hospital, in connexion with the Wesleyan Mission Society, under the charge of F. Porter Smith, M.B.Lond., M.R.C.S., from July 1, 1864, to June 30, 1865. Pamphlet. Presbyterian Mission Press, Shanghai. 1865.

*** An exceeding interesting pamphlet, showing that the benefits to be derived from this Medical mission are highly appreciated by the Chinese. From its earnest and scholarly tone it leads us to expect longer and more valuable communications from Dr. Porter Smith.

Traitement des Maladies des Voies Respiratoires par l'Inhalation des Emanations des Epurateurs, du Gaz D'Eclairages; Reproduction Chimiquement et Physiologiquement identique des Mêmes Gaz dans la Chambre d'un Malade à l'aide d'un Nouveau Liquide qui en est la Synthèse, le Gazeol. Préparé G. M. Burin de Buisson, Laureat de l'Academie de Médécine de Paris. Paris: Victor Goulz. 1865. Pp. 16.

*** Has a list of volatile substances which may be inhaled in diseases of the respiratory apparatus, as whooping cough, and a description of the manufacture of gazeol, a fluid having ammonia for its base, which evaporates spontaneously at a temperature of 15° to 24° Centig., and fills the atmosphere of the sick room, according to the patient's pleasure.

Annali di Médicina Pubblica Igienica, etc. Firenze. No. 3.

*** The sanitary papers are continued. Professor Luigi goes to the physiology chair of Bologna. Dr. Francis Cami has left a large sum to endow a deaf and dumb asylum at Monga. The municipality of Ancona has given silver medals to fifteen Army Surgeons for services during the cholera epidemic. Signor Thuri, Professor in Verona, believes he has discovered the art of propagating the different sexes at will.

What Food to Eat? By M. W. Ireland, M.D., late of H.M. Bengal Army. 1s. Pp. 52. London: Pitman.

*** Dr. Ireland, we regret to observe, is incapacitated by a wound received in India from the active duties of his Profession. He is already well known as the author of several popular works on general subjects, and the present essay, which is learnedly and pleasantly written, discusses and describes the questions of food and eating always interesting to omnivorous man, and important in their relations to public health and public institutions. We recommend this essay to our readers.

Local Museum Notes.. No. 1. Pp. 16. Edited by the Treasurer of the Wimbledon Local Museum. (Communications may be addressed to the Editor, Beech Holme, Wimbledon-common, S.W.) London: Hardwicke. 1866.

*** The object of these "Notes" is to recommend a practical plan for the commencement of any local museum.

Reports on the Extent and Nature of the Materials Available for the Preparation of a Medical and Surgical History of the Rebellion. Philadelphia: Lippincott and Co. 1865.

*** This handsome quarto volume, abundantly illustrated with woodcuts and coloured engravings, gives, as it were, a *precis* of the whole Medical history of the late American Civil War.

The Chemist's Desk Companion. The Year-Book of Pharmacy: a Practical Summary of Researches in Pharmacy, Materia Medica, and Pharmaceutical Chemistry during the Year 1865. Edited by Charles H. Wood, F.C.S. London: Churchill and Sons. 2s. 6d. Pp. 175, with index.

*** A most useful book. For half-a-crown, all the novelties in therapeutics, in the manipulation of remedies, tests for poisons, etc., that have appeared in English and foreign journals during 1865.

Thoughts on the Value and Signification of Statistics. By Daniel Noble, M.A., M.D., F.R.C.P. Read before the Manchester Statistical Society, January 10. Manchester. 1866.

*** Is a highly successful effort to bring out the true function of statistics in thoughtful inquiry.

Bulletin de l'Academie Royal de Médicine de Belgique. Nos. 5 and 8.

*** Dr. Hyernax communicates some curious obstetric notes.

Rhinoscopy and Laryngoscopy: their Value in Practical Medicine. By Dr. F. Semeleder. New York: W. Wood and Co. Pp. 191.

*** Translated from the original German by Dr. Edward T. Caswell.

A Radical Operation for Procidentia. Read before the New York Obstetrical Society, Dec. 28, 1864. By Dr. Thos. Addis Emmet. New York: Bradstreet. 1865.

*** Very similar in its details to the proceeding of Dr. Marion Sims.

De la Résection du Genon. Par M. León de Fort, in the memoirs of the Society of Surgery of Paris.

*** Shall receive a notice in a subsequent number of this journal.

Nouveau Traitement de l'Angine Couenneuse, du Croup et des Autres Localisations de la Diphthérie par le Baume de Copaiba et le Poivre Cubèbe Medication Antieatarrhal, Substitutione Genéral. Par M. H. Tridean d'Audouillé (Mayence). Paris: Baillière. 1866. Pp. 32.

*** The author and his friends seem to have used copaiba in croup with great success.

The Endoscope as an Aid in the Diagnosis and Treatment of Disease. By Francis Richard Cruise, B.A., M.D. Dublin, etc., etc. Dublin: Fannin. London: Longman. Edinburgh: Maclachlan and Stewart. From *Dublin Quarterly Journal* for May, 1865. Pp. 43.

*** The endoscope—"What," said one of his pupils to M. Desormeaux, "is the use of it?" "It enables us to see parts which, without its aid, are wholly beyond the reach of vision." It is well described by Dr. Cruise.

Contributions to Practical Medicine and Surgery, including the Treatment of Cancer, Stricture of the Urethra, Rheumatic, Neuralgic, and Epileptic Affections, and of Surgical Hæmorrhage. By James Arnott, M.D., late Superintending Surgeon St. Helena. 2nd edition. London: Churchill and Sons. 1865.

The Sanitary Condition of the Poor in relation to Disease, Poverty, and Crime. By B. Baker, M.R.C.S. London: W. Tweedie. 1866. Pp. 30.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The Workhouse Infirmary Movement.—We said last week that Dr. E. Smith's position, as Medical Inspector of the Poor-law Board, "placed him above the temptation to be sensational, and the suspicion of interested motives." We did not mean to imply that any one connected with the movement for reforming Workhouse Infirmaries was actuated by interested motives; neither can any such construction be fairly placed upon our words.

Mr. Campbell De Morgan's case of Injury of the Brain shall be put in at once.

Palperro, Cornwall.—The egg of the great auk is very scarce; some were recently sold at Stevens's for £30 each. Consult Yarrell's Birds.

A Third Year's Student.—Under the circumstances mentioned by you, we have no doubt a declaration made before a magistrate by either of your parents will satisfy the authorities.

Jackson.—The result will be declared at a meeting of the Council next week, and the subjects of the new essays made known.

Dr. Farr's Calculation of the Progress and Decline of Rinderpest.—In the *Medical Times and Gazette* of March 17 we published a full account of Dr. W. Farr's calculation of the progress of the Rinderpest, and we gave the figures, which, in full reliance on the soundness of his data, he believed would represent the numbers of fresh cases in the succeeding weeks. It was there stated that "stamping out measures" might be expected to produce a more rapid decline than the calculated one. Every calculation refers to fixed data. Shift your data, and the result *cannot* be the same. In this case the substantial truth of the calculation is shown by the fact that the decline began before the legislative measures were brought into full activity.

Early British Skeleton.

In the autumn of last year, in order to erect a new and permanent viaduct across the Derwent valley, near Malton, the North-Eastern Railway Company commenced the formation of cofferdams on each side of the river. In the first formed, on the Malton side, as reported at the time, after ten feet of the fluviatile post-tertiary clay had been excavated, a three-feet bed of alluvial silt was entered, which abounded with water, and caused the cofferdam to burst. Beneath this sand was the Kimmeridge clay of the Vale of Pickering, and upon it, at a depth of thirteen feet, the femoral and pelvic bones of a human being were thrown out, the skull then being left within the piles forming the dam. An enlarged dam having been formed, operations were re-commenced last week, when the skull so much desired was fortunately obtained, and is now deposited in the collection of pre-historic *crania* of the Rev. William Greenwell, of Durham. The bones, from long steeping, have become blackened and devoid of lime, resembling leather more than bone, and are much impregnated with vivianite. The body has been that of a male of small stature, apparently from 40 to 45 years of age. The teeth have all been present, and are not much worn, but the sagittal suture of the skull is almost obliterated, and so is the coronal suture. It has been supposed that the body was one of an early British race, but the skull is not at all typical, and not in the least like those obtained from either the long or the round barrows of the Britons. It is very broad in the occipital region, and rather narrow in the frontal; but the main characteristic is flatness. Mr. Greenwell says the skull is very like some he has from a Kentish Roman cemetery, but is relatively broader in the occipital region. He can offer no conjecture as to race, but the supposition that the man may have been a dependent on the Romano-British camp at Malton, probably an auxiliary. This view is strengthened by the finding, in another excavation, but on the other side of the river, and also below the clay and silt, a rudely-formed vessel upturned. This is about six inches high, and is irregularly hand-made, entirely without ornament, but is not like British ware at all. The material is more like the ordinary bluish Roman pottery, and is hard-baked, but there is neither the form nor finish of Roman ware, nor any trace of the potter's wheel. The shape is that of the "food vessel," and if Romano-British, is extremely rude indeed. Up to the present time no further object has been found. The skeleton and the pot seem to have reference to the same date, being both found at the same depth (10ft. clay and 3ft. silt), both also being below the bed of the river Derwent considerably. During the human period there has been considerable alterations in the geological deposits on the surface, as was recently illustrated by the section of the cutting for the Norton drainage close by, where an ancient (supposed) British trackway was found beneath water-borne sand and gravel. The local antiquaries and geologists consider that the skeleton and urn mark the level of the British period, and that the super-imposed beds have been left by the river accumulations since that period. A look-out is being kept for any objects likely to give further light.—*Times*, April 10.

The Alleged Case of Manslaughter at Middlesborough.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In your last number it is intimated (upon what authority I know not) that I was instrumental in setting the law in motion. This I beg most distinctly to deny, also to inform you that the "colour" so appropriately referred to, was imparted to the affair by a perverted report of a conversation which took place between myself and another person.

April 9, 1866. I am, &c., Edward Husband.

*** Our notice was founded on the report of the evidence given at the trial. We quoted Mr. Husband's statement that "he did not write to the coroner to procure an inquest, nor take any step beyond the fact of giving a sort of certificate." We stated that we accepted in full Mr Husband's account of the matter.

Late Menstruation?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Knowing that you are always desirous of making anything peculiar in the Medical line public, should you think the following worthy a space in your valuable journal, I give it for your approval. I was called in to a patient in her 77th year suffering from uterine hæmorrhage, which had produced great exhaustion, and upon inquiry I found that she had regularly menstruated monthly up to the present time; the discharge lasted four to five days, and then left her, as it would in its natural course with a person of younger years, but that this time the hæmorrhage had been so severe that alarming symptoms had shown themselves. I ordered her the same astringent as I should in similar cases, and, I am glad to say, with the same beneficial result, and she is now quite well. I am, &c.

J. Whitehead, M.D.

10, Park-place, Liverpool-road, Islington, April 4.

The Amended Vaccination Act.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—It is to be hoped that this bill will provide for the enforcement of vaccination by some responsible executive, which is not at present the case. All Medical men must more or less feel the want of obtaining fresh lymph in their own neighbourhoods, and their dependence on dry lymph from London. And why? People in general disregard the Act, and vaccination seems very little influenced by it. If the Act were enforced, I conceive, children being vaccinated in succession, we should always have lymph at hand, and the children could be properly looked after, —which they cannot be now,—often vaccinated in multitudes, under a

visitation of small-pox. One evil attendant on this is that many children, from imperfect examination, break out in skin complaints, and the parents, in consequence, give cow-pox a bad name, and become averse to vaccination. The Act has not been carried out because nobody was specially called upon to do it, and individuals would be naturally unwilling to act. I have always thought the Boards of Guardians the most proper persons to enforce the Act, for they appoint vaccinators and registrars under it; and if they were legally charged with this duty, I can see no reason why vaccination should not go on satisfactorily to the Profession and the public. A meeting respecting Mr. Bruce's bill I see is advertised for the 10th inst., Dr. Richardson presiding, when I trust the question I refer to will receive attention. I am, &c.

A Country Practitioner.

Acupressure.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In your last number you have inserted some cases of acupressure, and perhaps you will allow me to call your attention to a case that occurred to myself some little time ago. A patient was brought to me who had, in bottling some wine, broken the bottle and divided his ulna artery. The hæmorrhage was most alarming, and being single-handed, I found it impossible to secure the ends of the artery. However, it occurred to me to pass a hare-lip pin deeply through the tissues and transversely to the course of the artery, and then pass a thread round the needle in the ordinary figure-of-8 manner. This entirely controlled the bleeding, and in the course of a few days the man was perfectly well, no swelling or inconvenience resulting. I have reason to know that this satisfactory result was lasting, and not temporary. The case is peculiarly valuable to Practitioners who are deprived of Professional assistance when such accidents occur. I am, &e.

20, Kingsland-crescent. William Hewitt.

An Asylum for an Imbecile Child.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Can you, or any of your numerous readers, help me? I have a son between 14 and 15 years of age, who, though not an idiot, is yet mentally very imbecile. He can write a little (from a copy), can spell easy words, is fond of figures, and never tired of watching the movements of clocks, watches, or mechanical apparatus; is good tempered and amiable, requires close watching in his habits, as regards personal cleanliness, and commonly wets his bed at night; his health is not robust, though he is rarely ill, and is then very patient.

I should be glad to place him in any good institution where his mental weakness would be relieved. I do not stand in need of other help than advice, being able to meet any reasonable expense; but I do not know of any institution of the kind except those of a benevolent character; and to those I am not entitled. If you will direct my attention to any that are well conducted, and fitted for a boy of the grade to which he belongs, I shall be very much obliged. I am, &c., M.D.

COMMUNICATIONS have been received from—
The Royal Institution; W. Hewitt; H. Matthewson; A Surgeon; A Country Practitioner; H. A. P.; N. B.; Apothecaries' Hall; Dr. Charles Kidd; Dr. N. G. Mercer; B. Ball; Dr. Fotherby; Cork Medical Protective Association; E. Husband; J. M. Goodiff; J. E. Morgan, M.D.; Dr. Bence Jones; Dr. E. Fleming; Professor Laycock; Dr. Ballard; Dr. Hughlings Jackson; Mr. E. Bellamy.

BOOKS RECEIVED—

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·573 in. The barometrical reading increased from 29·26 in. on Monday to 29·89 in. on Friday.
The general direction of the wind was variable.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 49·8°.

APPOINTMENTS FOR THE WEEK.

April 14. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.
Royal Institution, 3 p.m. G. Scharf, Esq., "On National Portraits."

16. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.
Medical Society of London, 8 p.m. Clinical Discussion. Dr. Broadbent, "On Chorea."
Royal Institution, 3 p.m. Professor Du Bois Reymond, "On Muscular Contraction."

17. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.
Pathological Society, 8 p.m. Meeting.
Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

18. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.
Hunterian Society, 8 p m. Dr. J. Braxton Hicks, "Remarks on the Local Treatment of Malignant Diseases of the Uterus."
Royal Institution, 3 p.m. Professor Du Bois Reymond, "On Muscular Contraction."

19. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.
Harveian Society of London, 8 p.m. Dr. H. C. Stewart, "Some further Remarks on Embolism of the Great Vessels of the Heart."
Royal Institution, 3 p.m. Professor Frankland, F.R.S., "On the Non-metallic Elements."

20. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.
Royal Institution, 8 p.m. G. Macfarren, Esq., "On the Music of the Church of England."

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

(Continued from page 361.)

Dislocation at the Elbow backwards—Dislocation at the Elbow forwards—Dislocations of the Radius only forwards—Lateral Dislocations at the Elbow—Fracture of the Coronoid Process—Fracture through the Humerus, just above the Elbow.

When after injury to the elbow you find the olecranon prominent behind, the forearm shortened, and the tendon of the triceps curved and conspicuous, you know at once that one of two lesions must have occurred. Either the bones have been dislocated or a fracture has occurred just above the joint. You put a finger upon the tip of the internal condyle and ascertain its position in relation to the olecranon, and your differential diagnosis is made. If a dislocation, the olecranon will project beyond the condyle; if a fracture, the two will still keep their normal position in regard to each other, being almost on the same level. The diagnosis may be strengthened by several other valuable symptoms. If there is fracture, the motions will be abnormally free, you can either extend or flex the arm as you like; if dislocation, the patient will prefer a position between extension and a right angle, and the movements practicable without force will be very limited. The deformity is greater in dislocation, whilst in fracture you will usually also be able to obtain the decisive symptom of crepitus. Lastly, you will observe the relations of the head of the radius to the external condyle, and if dislocation be present, you will easily feel the projecting end of the former below and behind the joint; this last is usually a most conspicuous symptom. Again I have to urge that the diagnosis is of the utmost importance both to your reputation and your patient's welfare, and if by reason of the muscularity of the arm and the swelling which has resulted you cannot appreciate the points satisfactorily, give the patient chloroform, and do not rest till you are quite certain as to the nature of the injury with which you have to deal.

If a dislocation at the elbow be overlooked in the first instance, it is improbable that it will ever be reduced. During the next fortnight the swelling will probably be such as to prevent any rectification of the error in diagnosis, and after that period, if discovered, the error will be for the most part irremediable. I have often seen the reduction of dislocations backwards at the elbow attempted after periods varying from three to eight weeks from the injury, and I scarcely recollect a single instance of success; on the other hand, the reduction in recent cases is usually easy.

Amongst the more rare events in relation to the common dislocation backwards at the elbow which I have to mention are two cases in which the bones slipped out again after reduction. If we consider the formation of the elbow-joint, the height of the coronoid process, etc., we shall be prepared for the general result as to displacements—that after reduction there is no liability to return of deformity. The latter is, indeed, usually, and very rightly, held to imply the probability of fracture either of the end of the humerus or of the coronoid process. In the two cases to which I refer, however, I am convinced there was no fracture of moment.

The first case was that of a man of about 30, who was brought to me at the Hospital by Mr. Griffiths, of Hoxton. The accident had occurred a few days previously. Mr. Griffiths told me that he had diagnosed dislocation by the usual signs, and had effected reduction with tolerable ease, but the deformity had recurred. Although the parts were now much swollen, yet I felt no hesitation in agreeing with Mr. Griffiths in the opinion that the injury was an ordinary dislocation backwards and without fracture. I could not detect crepitus. We again reduced, and again the bones slipped back when the flexion of the forearm was remitted. On a second trial we effected reduction, and carefully kept the elbow bent at an acute angle. This time the bones were retained in position. The forearm was not allowed to be brought down for upwards of a fortnight, and the subsequent progress was, I believe, quite satisfactory.

A few months after I had seen the case above mentioned, a man was brought into the Hospital under my care who had dislocated his left elbow ten days previously. As the House-Surgeon had failed to reduce by the usual method, after a vigorous trial, we had the man into the theatre and gave him chloroform. I now succeeded in getting the bones well reduced, and the motions were perfectly restored. Having requested the House-Surgeon to satisfy himself that reduction was complete, he proceeded to extend the arm, and at once exclaimed, "The bones have slipped out again!" All the symptoms were reproduced. I reduced again, and, for experiment's sake, again extended the arm, and found them again slip back in the most definite manner. No crepitus could be detected, and as difficulty in reduction had in the the first instance been encountered, it is very improbable that fracture existed. We now reduced for a third time, and keeping the elbow well bent, no further displacement took place. The man did perfectly well. We were careful not to allow him to extend his arm for several weeks afterwards. Probably in both these cases the coronoid process was unusually low, and the ligaments torn to an unusual extent. It is quite possible that the extremity of the coronoid may have been broken off, but of this I did not detect any evidence. The cases are valuable in support of the clinical rule to keep the elbow bent after reduction of this dislocation, and also to examine the position of the bones carefully at the end of a week, so as to guard against the possibility of a recurrence of displacement.

Amongst the very rarest of dislocations is that of both bones of the forearm forwards.

Dislocation at the Elbow forwards.—It might indeed have seemed almost impossible that this displacement should occur; yet some well-accredited reports of cases are in print. Dr. Hamilton refers to eight cases, and to these I now have to add another. I do so on the authority of my friend and late pupil, Mr. E. Greenaway, by whom the case was examined and the dislocation reduced. Mr. Greenaway informs me that the symptoms were very definite, the forearm lengthened, the condyles of the humerus prominent below and behind the olecranon, the projection of the latter bone being quite lost. On bending the limb the bones slipped into place almost spontaneously. The motions of the joint were quite restored after reduction, and the man did well.

The accident had occurred from a fall in a bar-room in which the extremity of the elbow was struck.

If you will look at the bones, or still better, at this dissected specimen, you will see that extreme flexion is almost the only position in which this dislocation could occur. Supposing a man to fall heavily backwards with his elbow bent to the upmost, and to strike on the end of his olecranon, you will see that it is easy to understand how the weight of his trunk received by his humerus might displace the latter over the tip of the olecranon. If he were at the same time clinging to something with his hand the dislocation would be yet more facilitated.

In the cases described by writers the amount of displacement appears to have varied much. In some the olecranon had slipped high up over the inner or outer condyle; in others, as in Mr. Greenaway's, its end rested against the articular end of the humerus.

A few years ago I saw a man who had just been admitted under Mr. Curling's care with a compound fracture of the humerus into the elbow joint, and with dislocation forwards at the latter. In this case the end of the olecranon was exposed to view, and rested in front of the humerus, but the condyles of the latter had been crushed, and the damage to the parts was so extensive that displacement in almost any direction would have been possible.

Dislocations of Radius only forwards.—This accident is not very rare, and when it does occur is almost always attended by fracture of the ulna, and is a consequence of direct violence. In a few instances it may possibly occur from falls on the hand. Its reduction is usually easy, but to keep it in place is often difficult. If it is overlooked in the first instance, and the fracture of the ulna allowed to unite, the forearm will be shortened, and reduction almost impossible. Ten years ago I admitted a man at the Metropolitan Free Hospital who had just been discharged from one of our largest charities after a complicated injury to his forearm. He was a most

unruly and violent fellow, and I have no doubt had in the first instance resisted examination. His arm had been very much swollen, and the swelling was now, at the end of four weeks, only beginning to subside. I found evidence of a fracture of the ulna near its middle with overlapping, and of dislocation forwards of the radius. The head of the latter could be easily felt in front of the external condyle. Under chloroform, by traction on the forearm, I reduced the displacement, and we then put a pad over the head of the bone in front, and kept the elbow bent at a right angle. The bone, however, again slipped, and on two later trials I obtained only the same temporary success. Thinking that the biceps might be the cause of displacement, I next divided the tendon of that muscle. Still, however, I could not by any contrivance keep the bone in place, and was at length obliged to let the man leave the Hospital in *statu quo*. His chief inconvenience was inability to flex the arm beyond a certain point a little short of a right angle. I am convinced that one impediment to reduction was the shortened condition of the ulna.

Of *lateral dislocations at the elbow* I have little to say, except to urge the great advantages which accrue from the use of chloroform both in the correct estimation and in the treatment of these complicated forms of displacement.

I have had but one opportunity for dissecting a recent lateral dislocation of the elbow. The case was that of an adult and very muscular man who had died of injury to the head. Mr. Dawson, the House-Surgeon in office, had reduced a dislocation outwards of the left elbow, but on the post-mortem table we could easily reproduce the displacement. The bones could be made to pass either outwards or inwards, and when pressure was made to effect reduction it was quite as probable that they would pass too far, into the opposite form of dislocation, as that they would stop in the normal position. When displaced inwards the sigmoid notch of the ulna rested against the inner condyle, and the bones were twisted, so that the head of the radius was below the level of the articular extremity of the humerus, and the finger could be pressed into its shallow cavity from behind. When displaced outwards the sigmoid notch rested against the trochlea for the head of the radius, and the latter projected beyond the external condyle; there had been no displacement backwards; the lateral ligaments, both external and internal, were completely torn away, and there were several rents in the anterior ligament. Small portions of cartilage were broken off from several places on the head of the radius, the coronoid process, and the head of the humerus. The orbicular ligament was entire; it had been so much stretched, however, that it allowed the radius to leave the ulna for a considerable extent. Even when complete reduction was effected, the head of the radius projected below the articular surface of the humerus, and required to be pressed into place. This condition might have been very puzzling after reduction during life, and might have led to the suspicion that the reduction was incomplete.

I have never had an opportunity for dissecting a recent specimen of *fracture of the coronoid process*, nor have I ever, with any great confidence, diagnosed this injury in a living patient. It is, I think, a plausible conjecture that in many of the examples of dislocation backwards at the elbow, so frequent in children, the cartilaginous extremity of the coronoid is broken off. It would be impossible to diagnose such a condition of things, since no crepitus would be produced.

Case of Dislocation Backwards at the Elbow, in which very free Movement was Permitted, and Reduction was very Easy.—Probable Fracture of the Extremity of the Coronoid.—A case of dislocation at the elbow which I examined a week ago—through the courtesy of our House-Surgeon, Mr. Dove—was, in some respects, peculiar. The patient was an adult man who had fallen some little height, and struck and twisted his right arm. The deformity was conspicuous. The man supported his right forearm with his left hand, and held it at an obtuse angle, and declined to make any attempt to move it. The olecranon projected a little, and it was nearly double its normal distance from the inner condyle, whilst there was a remarkable hollow between the latter and the tendon of the triceps. The head of the radius could be felt to the outer side and behind the outer condyle; but it did not appear to have completely left its articulation—*i.e.*, it was not quite behind. Taking the forearm into my hand, I found that the bones at the elbow moved with the greatest ease, and that the olecranon could be pushed almost an inch further back with very slight force. I thought also that I detected crepitus in the joint, and in this opinion Mr. Dove concurred. We conjectured from the ease with which the ulna slipped backwards, that the coronoid process must be broken off; a supposition which was favoured by the fact that when first we examined the part, the olecranon, although considerably displaced outwards, was but very little backwards. In order to examine the state of things more carefully, we put the man under chloroform; I then confirmed the observation as to the great ease with which the olecranon could be made to project backwards. Suddenly, whilst I was examining the position of this part, and, perhaps, making a little pressure on it, complete reduction occurred. The freest normal movements were now practicable, and no re-displacement took place, nor could we now elicit crepitus. I think it probable that the case was one of incomplete dislocation backwards and outwards, with fracture of the extremity of the coronoid process. Had the base of the coronoid been broken through, the arm would scarcely have borne the free movements which we made after reduction without a recurrence of the displacement.

Fracture through the Humerus just above the Elbow.—When fracture occurs just above the elbow joint the displacement is almost always of the elbow and lower fragment backwards. This leaves the lower end of the shaft of the humerus resting on the coronoid process, and allows of simulation of the symptoms of dislocation of both bones backwards. Occasionally, however, the displacement is the reverse, the upper fragment being behind the lower one. Of this we have a specimen in the Museum, and I show you a second from my own collection. I have already alluded to the means of diagnosis when the displacement is the usual one (of the elbow backwards), but must now say a few words respecting the treatment. These cases are not of very infrequent occurrence, and are very difficult to manage. Often most unsatisfactory results are obtained. I can call to mind at least half-a-dozen cases in which adults have come into this Hospital during the last few years with an arm rendered almost useless by mal-union of this form of fracture. In several the inconvenience has been such that we have seriously discussed the expediency of an excision, and the dread of pyæmia and erysipelas has been the only deterring motive. These patients always have the elbow at an obtuse angle, and are quite unable to bend it to right angle, the arm consequently being useless for a majority of its employments. In one case which tempted me much to an excision the arm was at a very obtuse angle, in fact almost straight. The man was a German gold-digger from San Francisco, where the accident had occurred. As I found on experiment that he could still handle a spade vigorously with the injured arm, I told him that it was not worth his while to run the risk of an operation, and there was clearly no room for any other treatment. The impediment to flexion is the mass of bone in front of the elbow, partly the end of the upper fragment displaced forwards, and partly new bone effused about it. The triceps has little or nothing to do with the deformity, and I cannot think that in any of the cases which I have seen division of its tendon would be of any benefit.

Diagram of malposition of fragments after transverse fracture through the humerus just above the elbow joint. Displacement of forearm and lower fragment backwards, the lower end of upper fragment resting on the coronoid process.

The knowledge that this kind of malposition is apt to occur and to be permanent, leads us to careful consideration of the best plan of treatment. First, I think we must acknowledge that if a transverse fracture has occurred just above the joint,

and the fragments have been displaced from each other, a real reduction—in the sense of making the fragments again fit each other--is scarcely to be hoped for. Extension with much force is the only agency which could effect this, and without it they are certain to overlap. Now, such extension could be made only in the straight position, and if this is used the fragments will be at right angles to each other ; for the muscles attached to the condyles will always maintain the lower fragment erect in the greater sigmoid notch, and at right angles to the shaft of the ulna. Here, then, are our Scylla and Charybdis. If we flex the elbow, the bones will overlap ; if we extend, they will be mal-placed in a yet more serious manner. I think that clearly the less evil attaches to the flexed position, and that we ought to take care to keep the arm well bent, maintaining as much extension as we can in that awkward position. If union with overlapping occurs (as it will do almost necessarily), at any rate, the elbow will be in the most useful position. Of course you will warn the patient that the accident will entail permanent consequences, which he must make up his mind to. Very often these injuries are complicated by vertical lines of fracture through the lower fragment. The rule that the elbow should be put up well bent is only absolute when the fracture is transverse. When it is oblique, sometimes a different position may be better. Of this I will relate an instance in the next lecture.

(To be continued.)

THE PHYSICAL AND CHEMICAL CHANGES IN LIVING BEINGS FROM A MEDICAL AND PHYSIOLOGICAL POINT OF VIEW.

By Dr. LIONEL BEALE, F.R.S.,

Fellow of the Royal College of Physicians, Professor of Physiology and of General and Morbid Anatomy in King's College, London, and Physician to King's College Hospital.

(Continued from page 362.)

Plants and animals have been oftentimes compared to machines, but no one has yet taught us in what particulars the plant or animal is like the machine. For my part, I cannot discover the slightest resemblance in origin, form, composition, or mode of action. I have looked over and over again at the matter of the living plant and animal in which or by which the wonderful changes characteristic of it are effected, but I have seen nothing save a little transparent, structureless, colourless, semi-fluid stuff. I even see this move, and while under my observation various substances of complex chemical composition may be formed through its agency. It may increase in size, and I may see it divide and subdivide so as to give rise to others like itself. But how it *moves*, how it *grows*, how it *forms*, and why it *divides*, I cannot tell. I know it does not move like a machine, for it moves in any and every direction, and every minute portion exhibits movements of its own accord, not by being pushed or pulled by others. Nor does it *grow* like a crystal, for the stuff of which it is made cannot be detected in the solution around it, nor is the matter deposited particle after particle upon the surface. Nor does it produce chemical compounds like the chemist, for there is nothing like a laboratory, chemicals, apparatus, or chemist there. It may be childish in me to attribute this *movement*, this *growth*, this *formation*, and this *multiplication* to some mysterious force or power, or agency, of the nature of which I know nothing, and to call it *vital power*, because it works in *living* matter only ; but is not anything better than leading people to imagine that you have explained to them the whole matter, when you have really given no explanation at all, and do not understand the thing you have attempted to explain? The words *machine*, *mechanism*, *machinery*, certainly might be applied to soft, colourless, structureless, growing, moving matter ; and watches, and mills, and steam-engines might be called "living things," but it is not easy to see what would be gained. At any rate, the same term ought not to be applied to that which lives, and moves, and grows without our help, and came from something which did the same before it, and to that which was constructed by us and cannot make another like itself, and has no power to move itself.

It would be absurd to point out the various attributes which belong to the thing machine ; but I may be permitted to draw attention to the essential actions in which living matter differs entirely and absolutely from every kind of machinery whatever. In order to avoid giving any special name to this matter, we may call it *a*. It *grows* by taking up pabulum different in composition from itself, and converting it into matter like itself. This pabulum shall be *b ;* and, thirdly, the clear, transparent, colourless structureless stuff, *a*, may become converted into matter which may exhibit distinct and peculiar *structure*, and characters and properties, resident neither in *a* nor in *b*. This matter which is *formed* shall be *c*. Now, *b* cannot become *c* without *a*, and *a* comes from pre-existing *a*. There is nothing that has ever been made by the chemist or machinist which possesses the properties and powers of *a*, neither is it likely that anything of the kind will ever be made by either of them. The mere suggestion of such a thing is as monstrous as it would be to talk of the possibility of a watch making another watch like itself from the solutions of the metals entering into its composition. Nothing that we make can make another thing like itself. Of the chemical composition of this matter *a* we know absolutely nothing ; for if we attempt to analyse it, it becomes changed, and we examine, not the living growing matter itself, but *substances resulting from its death*.

The chemist boasts that ere long every animal and vegetable principle will be built up artificially in the laboratory, although he has not yet succeeded in ascertaining the composition of the most important substances which are to be obtained from *all* living organisms. There is not a living thing from which a substance having the reactions of albumen cannot be obtained, and nothing like albumen has been prepared artificially. Surely the facts do not at all justify the confident boastings in which many chemists and physicists have recently indulged. The step from that which has been actually achieved to that which it may be possible to effect, is, it seems to me, far too wide to be bridged over in our time ; and is it not probable that its width will seem to increase as science gradually reveals to us little by little the vast and increasing extent of that which is really interposed?

If "the constructive power of chemical art" be "*unlimited*" there can be no doubt of the chemist's ultimate ability to reproduce "all animal and vegetable principles whatsoever," but is it not rather early in the day to talk thus confidently? One of the lowest, simplest things in nature is the common yeast fungus. It forms a clear, transparent matter, which chemists have termed "cellulose." What substance yet produced in the laboratory by synthesis approximates to this, the product of the lowest, simplest plant? But my friend, like many who have written from the same point of view, manifests an indisposition to discuss the nature of the changes which occur in the simple cell. "However valuable might be the study of the more minute and elementary forms of life," etc., there are, on the other hand, some *great truths* which can "only be appreciated by comparing the most highly specialised forms of life with one another, not in their minute details, but in their broad general features." The new philosophy deals only in broad generalities. It is advanced as the philosophy of the general, and its supporters invariably avoid "minute details." It is the philosophy of mass, and has nothing to do with the characters of the particles of which the mass is made up. By statements about *broad general features*, the mind of the reader is cleverly led away from the consideration of the real question. He is asked to consider what is taking place in a fully formed plant or complex animal, but is never told what occurred in this same plant or animal before it reached its fully developed form. He is told about the great truths which apply to the plant or animal as a whole, which nevertheless cease to be truths at all when applied to the several parts of which the whole is made up.

Now, if it were possible to divide the simple from the specialised—if the lower forms of life and the higher were separable by any distinct line of demarcation—if we could really account for the changes taking place in any one part of a living thing of the $\frac{1}{100}$ of an inch in its extent, such a course might be supported by mere argument, but the facts of the case render the position taken up absolutely untenable.

There is not one portion of a living thing much more than $\frac{1}{500}$ of an inch in diameter, in which living matter cannot be demonstrated, and in this living matter changes occur which physics and chemistry do not explain. In every change characteristic of living things this living matter takes a part. Chemists and physicists cannot imitate the changes because they cannot imitate what takes place in the living matter. In the formation of every tissue, in its disintegration, in its repair, living matter is concerned. Nor does the slightest morbid change

take place without the phenomena occurring in the living matter of the part being modified. No formation of structure, no action occurring in the structure after it has been produced, no secretion can be accounted for without considering what goes on in living matter. In every form of inflammation, in every kind of fever, in hypertrophies, in atrophies, in every general disease, and in every local disease, this "living matter," which physicists and chemists completely ignore, plays or has played a most important part.

It is very well for the advocates of the new doctrines to laugh at physiologists and Physicians, but it would be better if they would come into our work-rooms and wards and meet the difficulties in the face. Let them observe the movements in some of the simplest living things, as an amœba, and then explain to us if they can how these movements occur. The movements and multiplication of a monad, the movements and multiplication of a pus corpuscle, seem beneath the notice of the new philosophy. Grand indeed must that philosophy be which solves all the great wonders of the universe, and tells us how worlds and suns and systems and faunæ and floræ are formed, but cannot teach us how a trumpery monad "grows" and gives rise to a number of other monads like himself, or explain why movements occur in a living amœba, or white blood corpuscle, or pus corpuscle, and not in a dead one. It is not surprising that the advocates of such a philosophy should have made vigorous efforts to shunt the vital question off the main line of intellectual inquiry; but hitherto neither the force, dexterity, nor combinations employed have been sufficient to effect the purpose.

My friend seeks support from Mr. Mill, who says that for a long time "fictitious entities continued to be imagined as means of accounting for the more mysterious phenomena; above all, in physiology, where, under great varieties of phrase, mysterious *forces* and *principles* were the explanation, or substitute for explanation, of the phenomena of organised beings." Here, however, is a physiological *hypothesis* which Mr. Mill considers "well calculated to light the path of scientific inquiry!"—"that the brain is a *voltaic pile*, and that each of its *pulsations* is a discharge of electricity through the system!" And here is the observation advanced in support of it—"*It has been remarked that the sensation felt by the hand from the beating of a brain, bears a strong resemblance to a voltaic shock!*" (a) The path of scientific inquiry may have been sadly darkened in times past by mysterious forces and imaginary entities; but what, I would ask, has physiology gained from hypotheses supported by such observation as this, and what is it likely to gain?

For my part, I only desire to have that which has been stated to exist—the "machinery" of the cell or living thing—shown to me, or to be taught how I may demonstrate it for myself. I have sought for it long and diligently, and under great advantages, but, in vain. I have found nothing, save a little transparent, structureless, colourless, semi-fluid, moving matter. If it is by this that force is "conditioned" in living beings, the mode of "conditioning" is essentially different from that of any machinery I am acquainted with. The matter is not *machinery*, and the "cell" is not a *machine*. But still, if any one can explain the phenomena occurring in living matter as in that of a fungus, or an amœba, or in a cell of any healthy or diseased tissue, by any laws of physics and chemistry only, I pray him to do so at once, and simply, that I may learn, and then impart my knowledge to my pupils without exciting in them the reflection that "there is such a thing as a man endeavouring to persuade himself, and endeavouring to persuade others that he knows about things when he does not know more than the outside skin of them; and he goes flourishing about with them."

The old College of Physicians in Warwick-lane, which was built by Sir Christopher Wren, is to be pulled down in a few days.

The International Statistical Congress. — This important body, which has held its meetings successively at Brussels, Paris, London, Vienna, and Berlin, will assemble in the ensuing autumn at Florence, under the presidency of the Prince Royal. The Italian Government has nominated a numerous Commission, upon which are placed six Physicians, to make the necessary preparations.

ORIGINAL COMMUNICATIONS.

NYCTALOPIA, WITH PARTIAL DEAFNESS, IN FIVE CHILDREN OF THE SAME FAMILY.

By THOMAS LAYCOCK, M.D.,
Professor of the Practice of Medicine and Clinical Medicine; and Lecturer on Medical Psychology and Mental Diseases in the University of Edinburgh.

My friend, Mr. Alderman Richardson, Surgeon, of Stockton-on-Tees, asked my opinion lately on the cases of five children of the same family affected with nyctalopia and with dulness of hearing from infancy.

The eldest was a healthy, rather handsome, young lady of 17, who, since the age of 12 years, has experienced a difficulty in distinguishing objects so soon as twilight came on in the evening. Previously during the day she can see perfectly well. She had been somewhat deaf in childhood, but her hearing had gradually improved as she got older. No morbid change of any kind could be discovered in either the organ of vision or of hearing.

The second case was that of a boy, aged 15, who, like his elder sister, had imperfect vision when evening twilight came on, and experienced difficulty in consequence in going about. His hearing was more impaired, but not seriously.

The third was a boy, aged 13, of a nervous, timid disposition, pale and delicate-looking, who had nyctalopia to the same extent as his elder brother and sister, but who was much more deaf. Beyond a free excretion of cerumen, nothing was discoverable in the ears, nor was the throat affected.

The fourth case was that of a girl, aged 10 years, healthy in appearance, but with deafness and nyctalopia like her younger sister.

The fifth case was also a girl, aged 7 years, who is extremely deaf, and has had nyctalopia for the last two or three years in the same way as her elder brother and sisters. She also suffers from severe attacks of ophthalmia during the prevalence of cold north-easterly winds.

What was the cause of these conjoined defects of vision and hearing? Five other children of the same family, living under the same roof, were wholly exempt from them. The defects were first noticed in all the cases at periods of dentition; so that it seems probable they are in some way connected with development. There was no reason to think that the organs of vision and hearing were at all involved in any constitutional inflammation or degeneration. The ears and throat appeared to be healthy in all, and the ophthalmia to which the youngest was subject seemed to be due simply to irritability of the conjunctiva. I had not the opportunity of examining the eyes of these patients by means of the ophthalmoscope, nor during the accession of nyctalopia. But the fact that during the day the vision in all was in every respect satisfactory, precluded the idea of any organic defect whatever, and led to the conclusion that the nyctalopia was due either to a defect of accommodation, or else to some retinal change of a purely functional character, or to both. As it seems necessary to class the two defects together in connection, I incline to think that both are due to a paresis of the muscles of accommodation of hearing and vision induced temporarily in vision by defect of the stimulus of light at sunset. So far as I am aware, the group of cases is unique in Medical literature, and may serve to try the ingenuity of our scientific oculists.

4, Rutland-street, Edinburgh.

CASE OF

INJURY TO THE BRAIN, WITH DEATH FROM EXTRAVASATION OCCURRING TEN DAYS AFTER THE INJURY.

By CAMPBELL DE MORGAN, F.R.S.,
Surgeon to the Middlesex Hospital.

In the *Medical Times and Gazette* of January 13 last, I reported a case of injury of the head, in which symptoms of an anomalous and severe character came on suddenly some hours after the accident, the man being up to that time apparently free from any cerebral injury. The ultimate recovery

of the patient, James H., left the question as to the nature of the injury and the cause of the symptoms one of conjecture. My own impression was, that a trifling injury had been done at the time of the accident to the base of the brain, probably in the neighbourhood of the pons Varolii, and that at the time of the occurrence of the cerebral symptoms a slight effusion of blood had taken place.

A case has recently come under my notice which, I think, throws light on the one referred to, and is of great interest in itself.

A gentleman, aged 40, was brought into the Middlesex Hospital on New Year's day, in this year. It appears that he had been confined to his room for some weeks previously owing to an injury to the leg. He went out for the first time on the day of the accident, felt faint, and fell with his face on the pavement.

When brought to the Hospital the limbs were rigidly flexed, and the lids tightly closed. This state very speedily passed off. He was not insensible, and could be made, with some difficulty, to answer questions. He was irritable, and complained of pain in the head. Retching and vomiting were present. The right malar bone was beaten in. There was slight bleeding from the nose, and ecchymosis of the right upper eyelid. The pupils were normal, and acted freely. The pulse was very feeble. There was no paralysis of any part of the body.

From the 1st of January to the 10th his condition was so generally uniform that it would be a waste of space to give a daily report. He was sensible, talking readily, and for the most part correctly, but complaining of confusion of ideas. It may be mentioned that he was a gentleman of considerable attainments and mental power, and he felt greatly distressed at his being unable to control his attention. At times he wandered, but was at once brought to his senses by being talked to. He was generally restless, especially at night, and liked to have some one sitting by him constantly. At times he complained much of headache, and was seldom free from an unpleasant sensation in the head. There was not the slightest indication of paralysis or loss of sensation in any part of the body, nor did any tendency to rigidity recur. The pulse usually ranged from 70 to 80; it was weak, and occasionally irregular. The bowels were always obstinately constipated.

So little was there of any marked indication of cerebral injury that on the 9th he was lying in bed on his back, and reading the newspaper, which he held up before him with both hands. He complained that he could not fix his attention on what he read, but it kept him quiet.

On the night of the 9th he was restless, as usual, but in other respects in much the same state as on the previous nine days. On the morning of the 10th, at 9 a.m., he became rapidly insensible; the countenance was blanched, the limbs perfectly relaxed. There was some paralysis of the left side of the face at first, but it was soon lost in the entire relaxation or paralysis of the whole muscular system, save that of respiration. The pupils were dilated, the right more so than the left; the pulse was small and irregular, and the surface cold. In this state he remained—the respiration becoming stertorous, and the surface getting colder—till 4 p.m., when he died. The remarkable appearance about him was the extreme flaccidity and loss of tone of all the muscles. No difference existed between the two sides. There was not the slightest trace of reflex action in any part. Even the respiratory muscles were involved in this loss of power; the breathing was carried on almost entirely by the diaphragm. The rapid and general cooling of the body, although well covered with bed clothes, was very remarkable.

A post-mortem examination was made by Dr. Cayley, to whom I am indebted for the account, twenty-two hours after death. There was no effusion between the dura mater and the bone. The outer surface of the right hemisphere was covered by a soft recent black clot, spread out as a layer on the arachnoid. It extended to the under surface of the middle lobe, and was not distinctly circumscribed. There was also a small quantity of loose black clot and fluid blood beneath the arachnoid in the meshes of the pia mater; this extended across the base of the brain to the left side. On the under surface of the right middle cerebral lobe, close to the fissure of Sylvius, the cerebral substance for a considerable space appeared soft and discoloured, and on making an incision a large cavity was found immediately beneath the surface filled with loose black clot mixed up with lacerated brain substance. At one point the blood had escaped into the Sylvian fissure, which was filled with it, and it had passed beneath the arachnoid over the side of the hemisphere, and across the base to the left side, and backwards over the pons and medulla oblongata, which, especially on the right side, were covered with loose clot. Large quantities of fluid blood welled up from the subarachnoid space of the spinal cord when the head was depressed. The brain substance for some distance round the clot in the middle lobe was softened, and of a yellowish pink colour. Hyperæmia extended from this softened substance as far as to the inferior parts of the corpus striatum and thalamus; there was no hyperæmia on the left side. Microscopical examination of the reddened parts near the clot showed great engorgement of the capillaries and intermixed with the nerve elements were large numbers of compound granular cells. The capillaries and arteries themselves appeared normal; there were a few small patches of atheroma in the basilar and intracranial carotid arteries. The right malar bone was depressed, and there was fracture at the inner angle of the lower margin of the orbit. There was no fracture of the base of the skull.

This case, I believe, illustrates the very interesting one to which reference has been made. That the cerebral injury took place at the time of the accident, and not at the moment of the accession of the fatal symptoms, does not admit of a doubt; and yet for nine days the symptoms were only such as might follow slight concussion; they were not, at any rate, with the exception of the transient and general rigidity of the limbs, indicative of lacerated brain. On the tenth day a vessel gave way, and extensive and rapid extravasation took place. We can readily conceive that with a minor degree of injury in the same situation there might be traces of it as slight as those which existed in the case previously recorded; and supposing that instead of the great extravasation which took place in the present case a trifling amount of blood had been suddenly extravasated in the same situation, we should probably have had symptoms of much the same character and severity as were present when James H.'s attack took place some hours after the injury. That in his case congestion and inflammation may have subsequently set in, as suggested by Dr. Brown-Séquard, is highly probable, but I cannot but think that the first seizure was due to some more rapid cause—such as effusion of blood.

The present case is of practical interest in itself, as showing how slight may be the symptoms even when a severe injury is done to some part of the brain. The existence of large compound granular cells, mixed up with disorganised brain substance, showed that the disorganisation had been of some days standing. The piece of brain so injured was at least as large as a large nut. Whether the whole of this was lacerated at the time of the injury, or there had been extension of disorganisation afterwards, still we have the fact of the existence of a considerable lesion of the brain, with very slight and by no means characteristic symptoms.

The symptoms which followed the extravasation are worthy of comment. At the moment of the attack, and for a very brief space of time afterwards, there was paralysis of the left side of the face. This corresponded with the time when the effusion was limited to the right side; but the effusion must very rapidly have extended to the opposite side and into the subarachnoid space of the cord. The paralysis then became general, and it was more complete than I remember ever to have seen. The singularly flaccid state of all the muscles of the face and limbs, the rapid loss of temperature, and the total absence of any reflex power, were, I think, due to the general pressure on the cord and medulla, more even than to that on the brain. They were more marked than is seen in cases of intra-cranial effusion of far greater extent.

CASE OF OBSTRUCTION OF THE BOWELS,

SUCCESSFULLY TREATED BY THE USE OF THE STOMACH PUMP, AFTER FAILURE OF ORDINARY TREATMENT, WITH REMARKS.

By EBENEZER FLEMING, M.D., L.R.C.S.E.

H. S., Esq., æt. 59 years. Previous to present illness, had three different attacks of obstruction of the bowels, in one of which, after the desired relief, gout appeared in great toe of left foot. The attack yielded to repeated doses of calomel and opium. Is of constipated habit.

22nd November, 1865.—Bowels not having been moved for four days—a thing not unusual—he took a dose of castor oil. Next morning, the medicine not having acted, he sent for his Medical attendant, Dr. J. G. Dickson, of Newton Stewart. He prescribed a laxative pill, then eight grains of calomel, followed by castor oil, laxative saline mixture, warm bath,

and repeated injections, but these all failed. I was requested to meet Dr. Dickson in consultation on Saturday afternoon (25th). The countenance indicated suffering. Pain occurred in paroxysms. Frequent vomiting of dark bilious substance, urine in small quantity and highly ammoniacal. Tongue dry and furred; pulse 72, of good volume; abdomen much distended; considerable dulness on percussion over right iliac region; no pain on pressure. We agreed first to inject a quantity of soap and warm water, by means of the long tube attached to stomach pump. The tube, measuring a yard long, passed freely and without pain its whole length, but from the distended state of abdomen, the injected fluid caused considerable uneasiness. It was retained. A small quantity of frothy mucus was passed. No other result. The following pills were prescribed, to be used during the night:—℞ Sub. mur. hyd. gr. xij., ext. hyoscy. gr. xviij. M. et div. in pil. xii. One every three hours. Abdomen to be well fomented and rubbed with Ung. hydr. mit.

26th, 12 noon.—Dr. D. White, of Whithorn, who had attended Mr. S. in some of the former attacks, was now associated with us in the case. No vomiting since last night; abdomen more distended; other symptoms unchanged. We agreed again to pass the long tube, and throw into the colon a pint of infusion of salts and senna, with ʒss. ol. terebinthinæ. Retained, but no result. 4 p.m.—Distension of abdomen much increased, so as to impede respiration; pulse continued good. Hab. pulv. jalapæ ver., ℈ij. 6 p.m.—Repeated last injection, with addition of tinct. assafœtidæ, ʒij. The ordinary enema apparatus was on this occasion used. After an ineffectual attempt at the night chair, the pulse suddenly increased to 132, and became feeble; respirations 48; abdomen distended to its utmost limit; outline of colon distinctly perceptible. The symptoms now became more and more alarming. We thought of putting patient into a warm bath, and dashing a pitcher of cold water over the abdomen, but he became so depressed that we could not attempt it. Dr. Dickson suggested that the long tube should be passed, with the hope of drawing away flatus. At our subsequent deliberations this gave the cue to our agreeing to pass the tube into the colon, and applying the stomach-pump, to try whether it would relieve the distension. 10 p.m.—The long tube being attached to the pump, as for emptying the stomach, I again pass it its whole length without difficulty into the colon. The first result of the syringe was to bring away flatus, then semi-fluid fæces until a wash-basin was filled. Dr. White supported the tense abdomen, and he felt it distinctly subsiding under each action of the syringe. Complete relief was immediately experienced. Habent ol. ricini, ʒj. During the night the bowels were two or three times very copiously relieved, and all the severe symptoms subsided. Next day gout appeared on great toe of left foot (as on a previous attack), for which he was treated by Dr. Dickson.

A letter, dated 6th inst., from Mr. S., now residing in a distant part of the country, informs me that he is keeping well, but that he requires to take great care, and adds, "My left foot still looks gouty, and swells slightly in the evening."

Remarks.—The progress of the case corroborated our opinion that the cause of the attack was gout seizing upon some part of the bowel, causing primary contraction, but more extensive dilatation. Dr. Wood, of America, in his first volume of Practice of Medicine, refers to such cases of obstruction of the bowels, and considers them less dangerous than other forms. In this particular case, however, the symptoms became so alarming, and the ordinary treatment so inefficient, that we all felt that at any moment fatal inflammatory action might set in. In our experience or course of reading, none of us had ever seen or even heard of the stomach pump being used in this way; but it is very probable that other Practitioners have applied it similarly, although I have not been able to find a published case. Before reporting this case, I intended to have more experience of this application of the operation. Such cases, however, do not often occur in a country practice; and should similar cases be treated on this principle by other Practitioners after the failure of the ordinary routine of treatment, I should be much obliged by receiving brief reports of the result. In mechanical occlusion of the bowel, whether caused by intussusception, twist, internal hernia, tumour, gallstone, or structural change, this operation would most probably fail; but in many cases of obstruction we cannot determine the real cause during life; and other means having failed, the stomach pump might be applied as herein recommended—viz., to inject a warm fluid as a solvent or diluent, allow it to remain two or three hours, reverse action of pump, and eject—with the hope that in the worst forms of obstruction it is possible, and in the simple forms probable, that it will be successful.

Stranraer, Wigtonshire, N.B.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SPECIAL REPORT ON THE TREATMENT OF FRACTURES IN THE LONDON HOSPITALS.

Bandaging—Fractures of the Femur—Modifications of Liston's Long Splint—Treatment of Fracture of the Femur at St. Bartholomew's, the Middlesex, University College, and Charing-cross Hospitals.

Before passing to the proper subject of the present paper, we will refer to a fact of considerable practical importance which has forced itself upon our observation while we have been engaged in collecting materials for our report. We find that many Surgeons dispense as far as possible with bandages of all kinds in the early treatment of fractures. In the various handbooks on Surgery there are found a number of woodcuts representing limbs very neatly and artistically bandaged: the affected part is cunningly covered by a roller, whose successive turns exactly correspond with each other—not a wrinkle or irregularity is to be seen. One of the earliest tasks that the student of Surgery sets himself is to learn how to "bandage neatly," and it is in consequence common to see in the different Hospitals excellent specimens of this kind of workmanship. It is at least a question whether the welfare of the limb is not sometimes forgotten in the effort to please the eye of the manipulator and the bystander. "Neat bandaging" is often rather a piece of handiwork than a means nicely calculated to meet the requirements of the injured part. The great error into which a "neat bandager" is apt to fall is that of not distributing pressure evenly and to the same amount over the different parts of the surface. It is not rare to see, when a limb which has been bandaged for twenty-four hours is uncovered, a regular series of parallel lines of indentation corresponding with the edges of the roller, with a more or less œdematous condition of the intervening soft parts; or a considerable œdema of the toes and dorsum of the foot, or of the parts below the ankle. Such a condition indicates an amount of interference with the circulation which is certainly opposed to the favourable repair of an injury. We venture to offer one suggestion as to the application of a bandage—it is not advanced as new, but as important enough to justify its repetition.

The bandage should be laid upon the limb inch by inch, with that degree of tightness or firmness which it is deemed expedient to impart to it. It should not, as is frequently the case, be passed round the limb, and be then tightened, for it is by this latter plan almost impossible to secure an equal distribution of pressure. Pressure applied to a part is always a powerful agent, and in many instances is a very valuable resource; but as it is beneficial in some conditions, so it is injurious in others. As we have said, some of our most prominent Surgeons prefer to conduct the early stages of the treatment of fractures with as little pressure as possible. In our next we shall describe a method by which Mr. Paget, at St. Bartholomew's, puts up fractures of the bones of the leg, whether simple or compound, transverse or oblique, or comminuted, wholly without bandages. At the Middlesex Hospital we found that no bandages were employed in the management of fractures of the femur. The chief advantages of this method appear to be that the circulation is left wholly uninterrupted; there is no wasting of the limb, such as is caused by firm bandaging; the muscles, while they are naturally at rest, are allowed to retain their tone, so that the limb the sooner regains its usefulness when the patient begins to exercise it; and lastly, the progress of the repair of the fracture can be carefully watched, and the relative position of the fragments can be exactly known.

FRACTURES OF THE FEMUR.

The apparatus which is in almost universal use for the treatment of fractures of the femur is Liston's long splint, or

some modification of it. Mr. Wormald, at St. Bartholomew's Hospital, and some other Surgeons, still employ the "double inclined plane;" but as a very general rule, this is wholly disearded. We will first mention the various modifications of the long splint which we find in use, and then refer to some points relating to the application of the apparatus. Mr. Paget is in the habit of employing a long splint (first used, we believe, by Mr. Busk), jointed opposite the hip, so that the part between the hip and the axilla can, by means of a screw, be fixed, either in a line with the rest of the splint or at any required angle. What is gained by this arrangement is, that when union of the fracture has advaneed to a certain degree, the patient can be allowed some change of position. He can sit up, for a longer or shorter time, propped by pillows to any angle not greater than 45° with the plane of the bed. It is important to bear in mind that the body must not be raised beyond this, for in the sitting posture the relation of the fragments would be disturbed by the thrusting of the upper downwards over the lower. We have seen exeellent results obtained by this arrangement, while the patients have found great relief from the temporary alteration of position. Mr. Bloxam, Mr. Paget's House-Surgeon, has contrived a splint which has the following peculiarities: it is shorter by several inches than the Liston, reaching only a little above the crest of the ilium; it is kept securely to the side, and is prevented from passing upwards to the axilla by means of a strong abdominal belt, into the side of which, where there is a kind of pocket, open below and closed above, its upper extremity is thrust. As fixing the level of the abdominal belt is equivalent to fixing the upper end of the splint, since they move together, the perineal band is fastened by buckles to the belt, and thus is very readily altered. At the lower extremity of the splint, and about eight inches below the foot, is a strong cross-piece; through this, and corresponding with the middle line of the foot, there passes an iron screw: at that end of the screw which projects towards the foot is a hook turning on a swivel, and this catches the strapping-stirrup, by which extension is now so commonly made. From a description this splint may appear complicated, but practically it is simple enough. It is very strong and firm, without being cumbersome, and by means of the screw any required extension can be made without any disturbance of the limb.

At the Middlesex Hospital Mr. Worthington has fitted up an apparatus which deserves a special notice. An outside long splint has a strong cross-piece passing inwards eight or ten inches below the foot. Pancoast's stirrup is first applied. A cord, one end of which is tied into the stirrup, runs round a peg in the cross-bar, and then, changing its direction, turns over the lower end of the splint, and is continued upwards along its outer surface. Just above the knee it is interrupted by the insertion of a piece of india-rubber cording about eight inches long, and as thick as the little or ring finger. Now continuing its course, it passes over the top of the splint, and is looped into the perineal band (which is made not to tie, but as an ellipse), and being again reflected over the end of the splint, is fastened to its ascending portion by means of a "tent tightener." The foot and ankle are bandaged to the splint, and generally, but not always, a chest-belt fixes the splint to the side. At those parts of its course at which the extending cord changes its direction, small rollers are placed so that it runs easily and smoothly, and does not catch. No bandage or other appliance is used to fasten the limb to the splint higher than the ankle. We are afraid of prejudicing the various apparatus in the eyes of our readers by the, we fear, tedious and incomplete descriptions which we give of them. We are sorry should this really be the case. The splint now referred to is most simple, and is very readily managed; any amount of extension of the limb can be made by means of the tightener. We were surprised to see the limb left so unsupported at the seat of fracture, but we were assured that very good results were obtained by means of this arrangement. The necessary movements, as in the use of the bed-pan, were said to be accomplished without leading to any mischief. The chief peculiarity, however, of this apparatus is that it provides for *continuous* extension by the column of india-rubber which is let into the cord. We cannot but think it a defect in the common appliances that continuous extension is not provided for. Ordinarily, when the perineal band is just tightened or when the stirrup is newly bound to the lower end of the splint, no doubt extension is efficiently made; but this to a great degree ceases upon any, even a slight, movement of the patient, or as soon as the bandages have had time to "give." We have especially noticed the state of the perineal band in the different cases we have seen, and we have almost without exception found one of two conditions to prevail. When the band has just been tightened the patient has complained of uneasiness or even of pain, and when it has not been altered for twenty-four hours it has been obviously so loose that no extension was being made. In Holmes's "System of Surgery," Mr. Holthouse states (a) that while he was writing his article he could find only three instances among the fractured femurs in adults then under treatment in the London Hospitals in which there was no shortening of the limb. In two of these cases the fracture had happened only a very few days, so that the ultimate result as to shortening was uncertain, while the third case was somewhat apochryphal, as the limb was still enclosed in splints, so that "one could not be sure that the limb had been fractured."

There appears to be nothing either in the fracture or in its method of repair which renders shortening thus apparently inevitable, and the difference in its amount in different examples of the same kind of fracture and in the practice of different Surgeons certainly seems to show that it depends on the means employed to prevent it. That it is in part, at least, explained by the usual condition of the perineal band, any one, we think, may readily convince himself. By means of the india-rubber cord, however—unless something should give way, or the splint be thrown out of place—constant extension is secured. Mr. Quain at University College has for a long period made extension by a strong india-rubber band fastening the foot to the end of the splint. A very efficient and very simple way of making extension is by a weight fastened by a strong cord to the stirrup and hanging in the air at the foot of the bed. By it a known and easily regulated amount of extension is provided which must, as long as it hangs in the air, be continuous and always equal. The common objection raised to this appliance (which, we may remind our readers, was very strongly recommended by Sir B. Brodie for making extension in hip disease)—namely, that the patient slides down in bed till the weight lodges on the floor, is easily met. The occurrence is prevented by raising the foot of the bed six or eight inches by blocks of wood or some such contrivance. It is advisable in the use of the weight that there should be some kind of pulley or roller over which the cord may run, so that it is not entangled in the bedclothes. In a French bedstead a hole bored through the footboard will answer quite well, but in any case some simple means will be at hand. The weight recommends itself as a means of extension by the fact that with it no perineal band is required. To be able to dispense with the latter is always a gain, but it is especially so where the skin is irritable, or where there is, along with fracture, bruising of the groin, or when the habits of the patient make frequent washing necessary. At the Charing-cross Hospital Desault's splint is commonly used. This differs from Liston's only in having a foot-piece corresponding with the sole. At the Dreadnaught we saw a splint recommended by Mr. Busk. It is an ordinary long splint with a joint at the middle of the thigh, so that it can be adapted to the arch of the femur. It has a complimentary joint at the knee. In some Hospitals three short splints are adjusted—one in front, one behind, and one in the inside of the thigh, at the seat of fracture, the whole being fastened by straps and buckles. In several Hospitals, however, these are seldom or never used.

The following points in the application of the apparatus, whatever this may be, seem of importance. (*a*) A cross-piece of sufficient length, and projecting on either side, should always be fixed to the lower extremity of the splint. This gives great firmness to the splint, and prevents any rolling of it outwards or inwards. (*b*) The best way of making extension is undoubtedly by means of the strapping-stirrup invented by Professor Pancoast, of Philadelphia. This, as the great majority of our readers are aware, is thus applied:—A long piece of strapping, about four inches wide, is bent upon itself at its middle, and made to adhere to the inner and outer surfaces of the leg as high as the knee, a loop or "stirrup," between four and five inches deep, being left below the foot. The two ends running up the leg are fixed by means of circular strips and a lightly applied bandage. The loop is fixed to the extremity of the splint. The simplicity, safety, and efficiency of this contrivance leave nothing to be desired. If good strapping is employed—Professor Pancoast uses a material much stronger than that in ordinary use—it will remain in place for two months, or even longer, and as it dif-

(a) Holmes's "System of Surgery," vol. ii., p. 613.

fuses pressure over a large surface, it can scarcely inflict any injury on the soft parts. American Surgeons, in order to protect the malleoli from pressure caused by the sides of the stirrup, are in the habit of using what they term a "spreader." This consists of a thin piece of wood, a little longer than the foot is wide, which they place transversely in the stirrup, just below the sole, like the "set stick" in a horse's trace.

There is a difficulty, however, in keeping this "spreader" in place. Mr. Worthington, whose name has been already mentioned, places instead of this a rolled-up bandage of the requisite thickness in the stirrup. This simple means will be found to answer excellently. (*c*) The perineal band should be very carefully made. Our Transatlantic brethren use a tubular india-rubber band carefully covered with chamois leather. The elasticity which this material possesses seems to us to be a great recommendation. In the London Hospitals, however, it does not find many advocates. The band we commonly see is made of a strong piece of bandage, around which a sufficient quantity of cotton wool is carefully rolled, the whole being covered with chamois leather or gutta-percha tissue. The former covering is preferable, as the latter frequently irritates the skin. (*d*) The perineal band is often too small, and meagre, and cord-like, so that it is apt to excoriate the skin. Those which answer best are as large as the wrist, and are made by winding a long, narrow piece of cotton wool transversely round and round upon the central strip of bandage, the whole being afterwards covered with chamois leather. (*e*) It is advisable every few days to remove the band, while extension is carefully maintained by an assistant, and thoroughly to wash and dry and powder the skin in the groin. This adds very greatly to the comfort of the patient, and materially helps to keep the soft parts in a safe condition.

We have not made any reference to the treatment of particular fractures of the femur, for we have found the same method employed in all cases. From fractures of the neck of the bone (except in very feeble old persons, who are left with the limb simply supported by pillows) to fracture through the condyles, the long splint variously modified is all but universally used.

We may, however, refer our readers to a lecture lately published in our columns by Mr. Hutchinson, in which he describes the treatment of separation of the condyles in young subjects.

Medical Times and Gazette.

SATURDAY, APRIL 21.

DECLINE OF THE CATTLE PLAGUE.

The official return of the Veterinary Department for the week ending April 7 shows the number of attacks in that week as having declined to 3361, and thus it appears we may regard the disease as fairly in process of extinction. For there is no ground for the statement which has appeared in nearly all the daily papers that the downward course of the epizootic has been arrested. The attacks in the last three weeks have numbered 4704, 3956, and 3361 respectively, and the decline has therefore progressed gradually at the rate of 19 and 18 per cent. in the past fortnight, which proves that the slaughtering is less influential as a disturbing element than might reasonably have been expected.

If our readers will turn to Dr. Farr's diagram, which we printed five weeks ago, and will draw the ordinates in continuation of the "reported cases" up to the present time, they will find that the two curves—the calculated curve and the curve of fact—are going downwards so simultaneously that if one leg of a compass be made to follow one curve, the other leg will describe the other curve almost to a nicety.

The *Times* has ascribed the diminution of the weekly attacks solely to the effects of recent legislation, and this view is of course in keeping with the doctrines to which that journal has become converted, although at the outset it was their most doughty opponent. It seems incomprehensible that the champion of the cause of Medical science and skill against the rough-and-ready practice which Professor Gamgee has consistently recommended should have so completely gone over to the other side, and become the most vehement opponent of any attempt to subdue the disease by curative treatment.

Now, it appears to us that if the official returns are worth anything at all, they show incontestably that the gratifying decline of the disease is not primarily due to the interference of the Legislature, inasmuch as the tide had turned before a single head of cattle was slaughtered under the new Act.

The attacks reached their maximum elevation in the week ending February 17, and then fell 44 per cent. in the succeeding fortnight, up to which time the disease was running its natural course; whilst in the two following weeks ending March 17, when the poleaxe was in full play, the attacks diminished at the greatly reduced rate of 17 per cent.

Two opposite theories have been propounded regarding Rinderpest: one that the plague will never die out until it has killed all the animals it can reach, less a small percentage of recoveries; the converse, that the disease, like contagious diseases of human beings, is subject to a law of increase and decrease, and that as an epizootic it will, like a fire, burn itself out if no further fuel be added. We had the opportunity of conclusively establishing the truth of one or other of these positions, but in consequence of the attempts to "stamp out" the disease by summary slaughter, the natural course which it would have followed is left undetermined. The second theory is proved up to a given point, but from thence we can only reason by analogy as to what would have happened subsequently.

Objection has been taken to the doctrine, that epidemic disease is so essentially exhaustive of its own virus that irrespective of human agency it will die out like a fire unreplenished, on the ground that it savours of the Oriental idea of fatalism; in fact, it is held to imply that when epidemic disease manifests itself, either in an individual or in a community, Doctors should stand aside, and let the poison work its will unchecked.

If this were correctly put, it is perhaps needless to say that we should fight against it *à l'outrance*, as being repugnant to every principle of scientific action; and we venture, therefore, to point out wherein, as we conceive, Dr. Farr's views have been misunderstood. On such a subject we, of course, speak subject to correction, and not *ex cathedra;* but an illustration of what the doctrine means may be found in this: supposing we throw a stone into the air, the height to which it will attain will depend on the resistance of the atmosphere, and its descent will be quickened or retarded just in the degree that the force of currents or of density is augmented or diminished at different times. And whatever law may be deducible from the progress of epidemic disease amongst human beings, that law *ex necessitate* implies interference with the disease in the form of Medical treatment. It was therefore strictly applicable to Rinderpest, so long as the legitimate mode of attempting to check or modify its virulence by curative measures was permitted, the bane and antidote being both in the natural order of things. But directly such measures were suspended, and the (certainly not *Medical*) system of slaughtering all the animals attacked was substituted in

their stead, all reasoning on the applieability of any law of epidemies to sueh an abnormal state of things was at onee made impossible, and fatalism in an unmitigated form—that of admitting an element of evil to be unconquerable—was stamped with the hall-mark of Parliamentary approbation.

That the most stringent provisions of the Act have been already greatly modified in practiee is quite certain, else there would have bcen no "recoveries" in the last month, nor would there be any left under treatment, as we gather there must be at the date of last return.

DR. FARR'S LAW OF EPIDEMICS.

Nearly four months have now elapsed since Dr. Farr enunciated the proposition commented upon by us about a month ago—that the behaviour of the cattle plague during the last nine weeks in 1865 warranted the belief that Rinderpest would speedily attain the height of its severity, and then rapidly subside. The Rinderpest *is* rapidly subsiding, and we are all eongratulating ourselves that this piece of good luck is entirely owing to the measures which have been adopted by Government for the "stamping out" of the disease. This we believe fallacious, and wish to put before our readers what we conceive to be the true state of the ease. Dr. Farr states that Rinderpest offers no exception to the general rule which obtains amongst all epidemics—viz., that their zymotic poisons tend by transmission through species of the same kind to lose much of their virulence, and we have already shown that this is the case with Rinderpest virus. Now the Rinderpest attained its height about March 17, and the weekly returns showed a decrease of attacks for the week ending Feb. 24 of nearly 3000 cases, and it was not till after this time that stamping out measures were adopted. It will be remembered that during the last ecntury Rinderpest seized upon the eattle of Italy, and it has been erroneously supposed that its spread was effectually checkcd by the adoption of stamping out measures suggested by Lancisi. This is quite erroneous. The Rinderpest ran its course, rising and falling—speaking figuratively—in the form of a curve, and subsided entirely in nine months. Rinderpest has behaved in an exactly similar manner now. In March of the present year the stamping out system began to be put into full operation. Before that time the calculations of Dr. Farr and the weekly returns of the Privy Council exhibited a wonderful agreement during the increasing stage of the epidemic. On Feb. 24, just before the play of the stamping out measures—just after the attacks of Rinderpest began to fall in number—there was actually only a difference of 98 between the two totals; but just after the adoption of the stamping out system the actual number fell considerably below the caleulated attacks of Dr. Farr.

The following table will show this:—

	Calculated series.	Actual reported attacks.	Difference.
February 17 . .	10,327	13,001	
,, 24 . .	10,098	10,767	scarcely any
March 3 . .	9706	7310	2396
,, 10 . .	9171	6518	2653
,, 17 . .	8518	6261	2257
,, 24 . .	7777	4704	3073
,, 31 . .	6980	3956	3024
April 7 . .	6158	3361	2797
,, 14 . .	5340		

It will be seen that the reported attacks are very much less than the calculated attacks of Dr. Farr. But what did we say ourselves in reference to this matter? We anticipated as much in the *Medical Times and Gazette* for March 17—"If certain additional circumstances that have lately arisen in reference to the spread of cattle plague, such as stamping out measures, were considered, and a series of calculations deduced from the actual observations, embodying the latest data, that the new corresponding curve would exhibit a mueh more marked fall than that represented in the diagram."

Before, then, the adoption of stamping out measures, the Rinderpest has begun to declinc. Up to the date at which such procedures were in action there had been a marvellous agreemcnt between the prophetie proposition of Dr. Farr and the returns of actually reported attacks. Subsequently to that time there has been a marked difference, but this difference has been proportionately marked from week to week, ranging between 2590 and 3000; and if the elcmcnt of back cases were properly assignecl its influence, the chances are that the agreement would be all the more curious still.

Hence the curve formed now by the aetual returns contrasted with that representing Dr. Farr's ealculations, runs a *parallel* eurve. We know that a new and additional influence was brought to bear upon the epidemic at the time the first marked difference between Dr. Farr's totals and those of the Privy Council were observed; this has eontinued to be in operation ever sincc, whilst an exactly comparative difference has been observed week by week. As the new factor has been uniformly at work, and has produced a uniformly continuous differenee, other things remaining the same, it is only fair to suppose that the alteration from the original curve is due to the aetion of the new factor. The stamping out system, in other words, produced a sudden decrease, which we can recognise week by week in the returns of the Privy Council, when eontrasted with those of the ealculated series of Dr. Farr.

We have the best reason to think that the Rinderpest has a very natural tendeney to die out, but that this is hastened to some extent by the stamping-out system; and this is in harmony with all we know of epidemic diseases in general.

It has not unlikely occurred to some to suppose that Dr. Farr's law underrates the importance to be attached to the use of preventive and eurative measures; but this is the result of hasty eonclusion and careless thought. Dr. Farr's law expressly supposes the possible occurrence of new factors and influences. To imagine that it encourages any doctrine tending or merging towards fatalism is proof that its meaning has not been grasped. It does not imply that a disease will run a given course, whatever we may do. It signifies that there are certain circumstances that cause a diminution in the activity of every zymotic poison and others that increase the resistant power of those attacked or exposed to the risk of attack, and that these may be approximately calculated.

These are most important considerations in referenee to treatment, and indeed Dr. Farr's law really paves the way for the elearer elucidation of therapeutic data. Though the conditions upon which we base our calculations of the progress of any epidemic may alter and new agencies may be introduced, yet in all cases antiseptics can alter the character of the poisons; tonics afford increased resistant power; a patient may be removed away from the influences that court the action of any poison; and it is possible to rectify any hitches that occur to the human machinery or remove local complications. There is plenty of stern work for the Physician to do, and the natural course of the disease is but favourable to the success of the treatment he employs.

The question of diminution in the intensity of a poison produeed by its passage through the organisms of animals or human beings is one of no little general practical interest. Let us take vaccination for illustration. Some of us believe that vaccination is retrograding in quality; or, whether this be true or not, that the enemy variola is recovering some of its lost power. It may be well for us to inquire whether the present system of lymph manufacture is not faulty? Is it possible that by the long continued transmission through the human system the vaccine matter may have lost much of its efficacy, and perhaps have acquired new properties of an objectionable nature? Such questions are involved in the law enunciated by Dr. Farr, and if there be any truth in it the affirmative must be admitted; at all events, we are justified in demanding a thorough experimental inquiry.

We only claim for the theory of Dr. Farr a legitimate degree of importance, and have, therefore, attempted to point out the limits within which its application may be made, and to show that the remarkable co-relation between the predicted and actually observed occurrences is something more than the result of accident.

THE THERMOMETER IN PHTHISIS.

Mention was made in our last article of the influence sleep exerts on the appetite. If the sleep be broken, the appetite, with digestion and assimilation, are greatly impaired. Indeed, too much attention cannot be paid to this point, for from the loss of appetite patients rapidly waste, and the reparative powers of the system are greatly lessened, and thus the recovery is greatly retarded. Indeed, the loss of appetite resulting from want of sleep may completely wear out the patient, and be the chief influence causing death. It is thus of the utmost importance to secure to patients sufficient sound and refreshing sleep. This should always be accomplished when possible without the administration of medicines. The ventilation of the room should be carefully looked to, the diet must be carefully regulated, and regard must be paid to the amount of stimulants given. Often sleep is prevented by these latter being administered too late in the evening, or, on the other hand, if patients be very weak their absence may cause wakefulness, and patients previously restless not unfrequently fall into a refreshing sleep when stimulants are freely administered. All undue excitement before the usual time of sleep must be avoided. If pain prevents sleep, this must be allayed; and if the restlessness be caused by cough this should be remedied. The cough of phthisical patients not infrequently results from sore-throat. This is then red, injected, and it may be ulcerated. In such cases local applications to the throat are efficient remedies; one of the best is that recommended by Dr. Edward Smith. An eighth or tenth of a grain of morphia dissolved in a drachm of syrup or glycerine should be either painted on the throat with a soft camel's-hair brush, or, which is better, swallowed slowly. This application frequently allays the cough, and allows sleep. If the cough proceed from irritation in the chest, this may often be allayed by counter irritation under either or both clavicles. For this purpose either a mustard poultice, or a blister, or a strong solution of iodine may be applied. Inhalations, moreover, often succeed when given to allay cough: iodine or creosote inhalations are often of greater service than those of simple steam. The patient should be directed to rinse out a jug with boiling water to heat the vessel, and then to pour into it a pint or a pint and a half of boiling water; into this twenty drops of the tincture of iodine or the same quantity of creosote should be dropped. The vessel should then be covered over with a towel, and the patient must put the mouth and nose under the towel. This inhalation should be continued for five or ten minutes. If the cough be paroxysmal and violent, a mixture of laudanum with some chloric ether and tincture of lobelia inflata may often be given with advantage.

Sleep should always be obtained if possible without the use of large doses of opium, for this medicine itself lessens the appetite and often greatly interferes with the other functions of the body. The Practitioner has to decide whether greater harm will result from want of sleep or from the administration of opium. Patients exhibit great individual peculiarities in respect to the action of opium, and thus the above question can only be decided by a trial of the action of this medicine. With many patients this causes much excitement, sometimes of a pleasant, at other times of a disagreeable, kind. With many it destroys the appetite or constipates the bowels; in such cases the opium may inflict even more harm than the want of sleep. On the other hand, some patients under its use fall into a refreshing sleep, and are in no other way affected by its administration. It should be the anxious endeavour of the Physician to cure his patient with the smallest amount of medicine possible.

THE WORKHOUSE INFIRMARY MOVEMENT.

The objects of the Association for Promoting the Improvement of Workhouse Infirmaries are so good, and the conditions of some of these public institutions so unsatisfactory, that every well-wisher to the community must look, and will not look in vain, for good results from the agitation now existing on the subject. We think it no small contribution to the general good if we offer, as we have already done, a few criticisms on the "movement," in order to point out the dangers which may be incurred from injudicious and over-zealous friends, who are apt to forget that it is possible to be unjust even in a work of benevolence. We have already pointed to the forensic spirit displayed by the Archbishop of York at the public meeting of the Association, and the effects of this on the guardians of at least one important parish are well known. And we would ask whether it were worth while to begin a public movement in such a way as to wound the feelings of noblemen and gentlemen of all shades of politics and grades in society whose benevolent devotion to the sick and poor of their own parish is unquestionable?

A second act of injustice was committed—no doubt unintentionally—towards the body of gentlemen who hold the office of Medical attendant to the London parishes and workhouses. We clamour as loudly as possible for the increase of their salaries, for the elevation of their status, for relieving them from the expense and drudgery of dispensing medicine, and for conferring on them all the facilities and appliances of good Hospital organisations. Workhouse Hospital wards, well and scientifically worked by good men, publicly, as cliniques, with pupils, would be as foci of skill to the Profession of a whole district, and should be honourable objects of ambition to the best men. But it must be remembered that the gentlemen who attend the sick in workhouses are the regular Medical attendants of the middle classes, of the ratepayers themselves; and are the ratepayers to be led to believe that their own Medical attendants are not good enough for the poor, or that they are likely, as is asserted, to stoop to the sordid impulse to defraud the sick poor of necessary drugs?

There seems no doubt but that every large Workhouse Infirmary should have a resident House-Physician or Surgeon, as every Hospital should. But the superior and responsible Medical attendant should be the best man who will accept the post. Are we to understand that the future Medical officers are to be unsalaried, and that general Practitioners, who cannot afford to accept unsalaried places, are to be shut out? Is the pernicious system of unpaid Medical officers to be extended?

So also with regard to nurses. Of course, the head nurses should be skilled and paid. But is it intended that no pauper is to do any of the functions of a nurse? Supposing that pauper not to be in the house (but, as many of them are, an infirm or decrepit family servant), is she to be entrusted with no work at all?

The space in some workhouses is doubtless insufficient, but will any one be ready to throw all the blame on the guardians who knows the restrictions which the law placed on the raising of money for such purposes?

By all means let there be new Hospitals—State Hospitals worthy of the name—supported out of funds to which all classes contribute; but let us ask, why should these Hospitals be governed by a *layman?* which is said to be the proposition.

We must return to this subject shortly, in order to sift some of the statistical and other details which find their way into the newspapers, and to take care that the first ideas thrown out by impulsive benevolence may not be worked out in such a manner as to be unjust to the benevolent and hard-working part of the public, nor to the Medical Profession.

THE WEEK.

THE NEW CATTLE PLAGUE DEPARTMENT.

Perhaps it would be as well, now that a new department has been formed for the transaction of business relating to the Cattle Plague, that we should suggest to Colonel Harness to amend the Weekly Return, which, it is presumed, will in future be issued under his authority, so as to render it more intelligible. As an instance of what we mean we may point out that for the last twelve weeks from 12,000 to 15,000 cases have been returned weekly as "unaccounted for." Now, either the greater part of these animals must have died or been killed, or they have recovered, for it is not reasonable to suppose that so large a number are, under present regulations, still remaining diseased. The greater probability, for many reasons, is that the major part of them have recovered, and in such case the general rate of recovery would be largely increased. Any way, they are an element of confusion as they stand now. There is another point. In the first columns of the Return are professedly given the cases "reported as having commenced" during the current week, but the detailed return for the week ending March 31 shows under that heading, 3956 attacked, and yet that there were 4139 killed, died, and recovered in the week. And we have again to reiterate that the calculated ratios which are now appended to the Returns are, for the reasons we have before adverted to, utterly useless, and, in fact, mischievous, as leading to erroneous conclusions. We trust that the head of the new Cattle Plague Department will not think it beneath him to notice suggestions which are offered on public grounds alone.

ELECTION OF MEDICAL OFFICERS TO THE NEW SURREY COUNTY HOSPITAL AT GUILDFORD.

This institution is now completed, and will be very soon opened for the reception of patients. The election of Medical Officers took place on Tuesday, the 17th, when the three gentlemen at the top of the poll were elected. The number of votes stood thus:—Mr. Henry Taylor, 174; Dr. J. R. Stedman, 162; Mr. R. Eager, 122.—Mr. F. Yate, 97; Mr. T. J. Sells, 58.

THE ALDIS TESTIMONIAL.

We are glad to learn that the project for presenting a substantial testimonial to this veteran worker in so many a good cause is now in full activity, under the direction of Dr. Synnot, of Eaton-square. Dr. Aldis's Medical brethren have subscribed liberally, thus stamping the movement with the approbation of the Profession, and testifying to the reality of his services. But now the time has come to appeal to the public. Dr. Aldis has for long years filled the office of Physician to at least three important Dispensaries. He has thus been the instrument or agent of those benevolent persons, who establish these institutions for the sake of the sick poor. But we would appeal to the noblemen and gentlemen, and to the rich manufacturers, whose contributions are represented by an annual guinea, whether they do not think it but just to give something in recognition of the long, weary, often unthanked duties of the Physician who devotes day after day to the string of miserable people who attend the Dispensary?

REGISTRATION OF SUCCESSFUL VACCINATION.

The other day, happening to saunter down Old Bond-street, we joined a small knot of *dilettanti* who were gazing into the window of a print shop. What particularly excited their admiration was a set of photographs of Mother and Child in various attitudes, which looked very much like photographs of classical pictures. In fact, one looker-on, pointing to one group, said, "This here is a Madonna by *Raffle*." On scrutinising and looking into it rather closely, however, we could not help seeing that the naked arm of the Child exhibited four very well-marked vaccination scars; hence it was evident that the photographs were not copies from "Raffle," but had been taken from some cleverly-posed sitters in the 19th century. A vaccinated arm in the 16th century was a thing not *in esse*. This little incident set us thinking what better "certificate of successful vaccination" could any one desire than this? Dr. Gibbon seems to be of the same opinion, if we may judge from the following extract from a report which he has recently presented to the District Board whose Medical Officer of Health he is. Still we do not see why every parent who registers a birth should not be required to register vaccination of the infant within four months. The worst of it is, however, that the vagrant and reckless part of the population, who are constantly shifting their quarters, could not be reached without a very well-organised police agency, and very stringent penalties:—

"The Vaccination Bill.—A Bill to consolidate and amend the Statutes relating to vaccination in England has been introduced into the House of Commons by the Government and read a second time, (says Dr. Gibbon). At the present time, when small-pox is prevalent, every one feels that it would be a great blessing if vaccination could be made universal. The provisions of this Bill are almost identical with those of former Acts on the subject, and I fear that if it becomes law it will do little to promote vaccination. It still prescribes an elaborate and costly machinery for effecting a registration of all vaccinated children. The attempt to do so has now for years proved futile, and even if a complete register could be made in every sub-district, it would be worthless; the only use it could be put to—a use, by the way, it never has been put to—would be to check the fees of the public vaccinators. The only registers of vaccination ever consulted by the Medical examiner for schools; army, navy, insurance companies, or the Medical officer of health, are the arms of the examined; where, if it has been successful, it is always found indelibly registered. Even in the case of legal proceedings, in the absence of a Medical witness, it is unnecessary, for the *onus probandi* lies upon the accused, and the Act provides that certificates of successful vaccination shall be given free of charge by the public vaccinators. If this attempt at registration were given up, the Government might make the other provisions more effective."

GAS-WORKS.(a)

The appointment of a Parliamentary Committee for the purpose of considering the proposal of the City Corporation to supply gas for public and private consumption in the City of London, and of reporting on the whole subject of gas manufacture and supply, is, we hope, the first step towards a reform of abuses of power on the part of the great gas companies which exercise an equally disastrous influence on the sanitary condition of the population of London and on the pockets of the consumers. The charges against the gas companies are that they carry on their manufactures in the midst of town populations; that they are constantly attempting to force bills through Parliament to enable them to increase their capital and extend their obnoxious works in urban districts; that they thus imperil the lives of the population, not only by the chance of accident such as the recent explosion at Nine Elms, but by charging the atmosphere with large quantities of noxious vapours and gaseous impurities; that the quality of the gas they supply is indubitably bad, and that for it they charge extravagant prices; and lastly, that their profits are so large as greatly to exceed the rate of return on their capital allowed by law—viz., 10 per cent. It is now indisputably proved that gas may be conveyed for almost indefinite distances; there is no reason, therefore, why the air of London should be rendered poisonous to animal and vegetable life by contamination with ammonia, sulphurous acid, sulphuretted hydrogen, tarry matter, soot, and carbon evolved from gas factories, or why large numbers of people should be

(a) "Gas-Works- the Evils Inseparable from their Existence in Populous Places." By Thomas Bartlett Simpson. London: William Freeman, 102, Fleet-street. 1866.

*

exposed to the risk of sudden death from the bursting of gas-holders containing a million feet of gas. The spirited opposition which has defeated the Imperial Gas Company's proposed extension of their works at Fulham and Chelsea, shows that at least the Upper House of Legislature are not prepared to sacrifice the health and comfort of a large mass of people to the greed of a powerful company. The majority of the House of Commons, also, which passed the second reading of the City Corporation Gas Bill, proves that, however influential these companies may be in that House, there are enough independent members remaining who will listen to the dictates of science and common sense, and will honestly protect the public interest and welfare. The bad quality of the gas supplied, and the extravagant prices charged, are only such as might be expected when a monopoly of manufacture is legalised. The Corporation of the City undertake to furnish gas at a maximum price of 3s. per 1000 cubic feet, or at least 25 per cent. cheaper than the metropolitan gas companies are now supplying it. The ground for their manufactory is already chosen at West Ham. For ourselves, on sanitary as well as on economic grounds, we wish success to their proposal, and we trust that the labours of the Committee on their Bill may lead to the banishment of this poisonous manufacture from our great cities, and a limitation of the powers which the great gas companies have so openly abused.

THE PURCHASE OF A PRACTICE.

The more a practice partakes of the nature of a business the more certainly and justly can it be appraised at a money value and transferred for a money consideration from hand to hand. The practices of Consulting Physicians and Surgeons are manifestly unsaleable; the income derived from them depends entirely on the reputation and Professional acquirements of their owners. A barrister could as readily sell his connexion amongst the attorneys as a leading Physician his patients. In either case were the attempt made it would be tabooed by the respective Professions, not merely as a proceeding contrary to Professional etiquette, but, to say the least, as morally a very equivocal one. On the contrary, a practice founded on a retail shop in a great thoroughfare can, as a rule, be bought or sold with thorough *bonâ fides* on the part of the vendor, and with the reasonable expectation that the purchaser will not be disappointed. Few young Professional men, however, now-a-days relish the idea of keeping a retail for drugs, and it is only the select minority who can hope to succeed in the highest lines of consulting practice. The great mass of young Professional men want practices which only partially partake of the nature of businesses, and the farther the practice recedes from the business—the more purely Professional it is—the greater will be the risk of investing money in its purchase. An introduction from the present possessor may be bought, but the opinions and predilections of his patients cannot. The purchase of a practice is therefore proverbially an uncertain venture. Yet with a very large number of men entering the Medical Profession it is a necessity. To live whilst a man makes his own practice requires the possession of a private income for a certain number of years. The young Surgeon with only a few hundreds at his disposal may easily exhaust his means whilst his practice is still unmade. The same amount of money fortunately expended in a purchase would give him work and income for life. It is for this reason that purchase has become so common. The greater number of men entering our Profession are not wealthy, although they possess sufficient if wisely expended to give them a start in life. To such we would say—Buy a practice, but be very careful how you do so. Recollect that the retention of any practice which is not partly a trade must depend entirely upon your obtaining the confidence and esteem of the patients who compose it. Human nature is truly much the same in all ranks of society; but, nevertheless the same individual will succeed admirably with one class of patients, whilst he will not be tolerated by another. We have lately seen a little pamphlet(a) on the purchase of practices, by Mr. J. Baxter Langley, in which the moral we are hinting at is well illustrated by the following story:—

"A few years ago an Edinburgh graduate, who had obtained the highest honours in the Northern Athens, settled in a good town in Cumberland, where he was personally known, and succeeded in three years in making a good practice there. Flushed with success, he came to London, and resolved to practise in the metropolis at the West End. Nothing could convince him that London was difficult to move. Other Scotchmen had succeeded, and therefore he should succeed also. The writer warned him firmly, yet delicately, that his broad Scotch brogue and terrible strabismus were likely to be impediments; but received as a reply that obstacles which destroyed small men were the opportunities of great ones. He took a partnership with an invalid in one of the best squares at the West End, and paid a large amount for it. At first the patients tolerated him as the *locum tenens* of their former attendant, but no sooner learned that he was partner than they flatly refused to see him. Ultimately, after a good deal of ill-feeling, the partners separated, and the unfortunate and accomplished Scotchman learned that Professional acquirements are not the sole condition of success in aristocratic English practice."

Mr. Langley's pamphlet is of course written from an agent's point of view; nevertheless, it contains a great deal of sound sense, exposes a good many popular fallacies, and offers capital advise both to purchasers and vendors. The notion that superannuated Practitioners are often ready to give away their practices to deserving young men is not an uncommon one. Here is Mr. Langley's experience on the subject:—

"Among the prevalent fallacies perhaps the most common is, that an old gentleman who has a good practice in a very eligible locality is very anxious to find an amiable and intellectual young man upon whom to bestow a partnership without premium. The amiable (and I may add innocent) young man who is looking for this benevolent myth always urges that he is prepared to do a large share of the work, etc., etc, but he forgets that the 'old gentleman' can readily obtain a good premium for such a partnership, and will make arrangements for the lessening of his own labour, so far as his patients will permit. No Profession is so liberal or charitable as ours, but it is rather too much to suppose that our senior Practitioners will forget the interests of their own families for the benefit of some young aspirant to Æsculapian fame, who, having taken a few prizes at College, thinks that the world is now at his feet. People will not usually give away that which they can readily sell for a considerable amount. In fact, the old gentleman in declining health sighing for a junior partner without a premium is a myth."

Bills accepted by firms trading on the principles of "Disinterested Benevolence," or "Professional Feeling," would not find much favour in the money market; and if buying and selling practices be a recognised commercial proceeding, the more strictly both buyers and sellers treat it so the better. It is on this ground that Mr. Langley argues that the services of a respectable trustworthy agent, who thoroughly understands the business, should be invariably sought by Professional men who wish to buy or to sell.

ROYAL INSTITUTION.

The Friday evening discourse last week at the Royal Institution was by Professor Emil du Bois Reymond, on the "Rate of Transmission of Sensation and Volition along the Nervous Structures." A very large audience assembled to listen to the remarks of the learned Professor, which were interspersed with a series of elegant experiments in illustration of the propositions enunciated.

The Professor began with some general observations on the use of the nervous system in bringing us into relation with

(a) "A Few Words of Advice on the Buying and Selling of Medical Practices." By J. Baxter Langley. Published by the author, 50, Lincoln's-inn-fields.

the external world, and rendering us capable of appreciating the manifold physical phenomena which go on around us. He likened the nerves to telegraph wires, for without any apparent external effect which was appreciable to our senses, a something was transmitted along them in obedience to certain stimuli, the transmitting cords being, however, like the wires, necessarily entire. The Professor then showed that the effect of the application of stimuli to nerves in connexion with muscle, was contraction of the latter. This was shown by a charming experiment,—one end of the muscle of a frog, in connexion with its nerve, was made a fixed point; to the other was attached a thread running over a pulley, and suspended from the thread was a little pail full of shot and a moveable disc. When the muscle was made to contract, the disc described the sweep of a half circle, and the little pailful of shot was raised. The next step consisted in showing that the analogy between the telegraph wires and the nerves as transmitting agencies was not a perfect one. A nerve was connected with two electrodes, and its muscle with a disc moveable by the shortening or contraction of the muscle as before; at one part a string was placed ready for tying; on sending a current through the nerve, contraction ensued and the disc moved; the ligature was then tightened, and the bruised part of the nerve was found to be incapable of transmitting the excited nerve force and no contraction ensued. The inference drawn was this,—that a certain something travelled along the nerve; if it were only electricity it would have skipped over the ligature.

The Professor then turned to the question of the velocity with which this *nervous agent* travelled from brain to muscle or, *vice versâ*, from the outer surface to the brain itself. In the ordinary occurrence in which volition and sensation are concerned, we do not, for instance, appreciate any delay between the reception and the perception of a sensation. In the exercise too of the faculties of the special senses, the same holds good. We fancy we see and hear, as it were, instantaneously, coincidentally with the impression made by any given object, but this is probably an error. Experiments with heat and light have shown that there is a difference, but it is such as we do not generally notice; a delay of about one-tenth of a second is the least degree of time that we can appreciate.

There is a delay in the transit of nervous impressions, though we are not usually aware of it. Only fifteen years ago, Professor du Bois Reymond observed, Müller in his lectures was wont to declare that we should never be able to make out the rate of transmission, because we had so small a compass to deal with, and that in the human body we could not get space for the purpose. The lecturer proceeded to show that the rate of transmission through different lengths of nerve was really appreciable by artificial means. He contrived an apparatus by which the exact commencement and ending of the time and the current were registered. He fixed the end of a muscle, and from the other supported a lever by a table at such a height that the muscle itself just supported the lever without being put upon the stretch. The nerve was then put in connexion with a secondary coil. If the muscle contracted it would act on the lever, and this being lifted breaks the current by the first action of the muscle. The whole was connected with a galvanometer, and when the current was excited it was deflected slightly. A weight was then attached to the lever, so that a greater contraction—in other words, more time—was required for the muscle to contract so as to lift the lever sufficiently, and the deflection of the needle, in consequence of the long-continued current, was greater than in the previous experiment. The next point was to show that a stimulus applied to two different parts of the nerve more or less distant from the muscle was appreciable on account of the comparative difference in the distance which was necessarily travelled over in the two cases. Professor Reymond used a myographion, which registered a certain curve corresponding to the muscle in action, and he stimulated the nerve near and at a greater distance from the muscle. He got two different curves, which showed the variation in the speed of transmission due to the varying length of nerve through which the stimulus travelled. The following rates are taken from a table exhibited:—

	Millimetres in one second.
Electricity	464,000,000
Light	300,000,000
Sound in iron	3,485
,, water	1,435
,, air	332
Cannon-ball	552
Wind	1—20
Eagle's flight	35
Greyhound or racehorse	25
Nervous agents	26—30
In throwing a stone 24 in. high	21·9
Muscular contraction	·8=1·2
Arterial wave	9·25

From this table it appears that a man can move his foot, an eagle can fly, a greyhound or racehorse run, as fast as the nerve action travels. The lecturer observed that it takes about a second before the penetrating harpoon which strikes the tail of the whale is felt, and another second before the mandate from the brain arrives at the creature's tail with orders to upset the boat. The velocity in man can be measured. Schelske has shown that the velocity in a living man is not greater than that of the nervous agent in the frog, about 80 feet per second. More than this, the time that thought and other mental operations take to travel has been measured. By means of certain specially constructed apparatus, a certain signal can be produced to indicate the occurrence of sensations. For example, a sensation is felt: this is answered by the production of a signal. Now, it is very curious that if the answer required be known beforehand, the time occupied in the transmission is shorter than when the answer is unknown. The following table shows this. For example, the same signal is given, but in one case the face is touched, and you know it will be; in another the foot is touched, and you are not aware of it beforehand.

Time required for answered signal, as given by the sense of touch—

	Second.
Place of body known	·204
,, unknown	·272
Eye—colour known	·201
,, unknown	·355
Ear—sound known	·215
,, unknown	·307

The lecture concluded with a reference again to the fact that the transmission of nervous influences was not like that of the electric fluid through a telegraph wire, chiefly because as in the first experiment a ligatured nerve ceases to transmit, and secondly, on account of the difference in the rates of transmission of the two kinds of influence, as shown by experiment—the one, nerve force, about 26 millimètres a second; electricity, 464,000,000 in a second.

FROM ABROAD.—THE FRENCH MEDICAL CONGRESS—SINGULAR PROPERTIES OF ACETATE OF SODA—CHOLERA RECOMPENSES IN FRANCE.

The French Medical Congress, which held such successful meetings at Rouen and Lyon, is this year to meet at Strasburgh, on Monday, August 27, and the six following days. It will be managed by the Medical officers of the Strasburgh Society of Medicine, having M. Herrgott as President and M. Hecht as Secretary, to whom, 42, des Grandes-Arcades, communications are to be addressed. The Practitioners inhabiting the Departments of the Bas-Rhin and Haut-Rhin become members by subscribing 10 francs each, but all other French and foreign Practitioners, on application, are admitted without contributions. The Committee has determined that the

following subjects shall be brought before the Congress for discussion:—1. On the mode of propagation in cholera, and on the suitable measures of public and personal hygiene; 2. The treatment of constitutional syphilis; 3. Ovariotomy and the extirpation of fibrous tumours of the uterus; 4. Histology and its relations to pathology and clinical observation; 5. Anæsthesia in Surgery. Any member of the Congress who may wish to address a verbal or written communication either on any of the above questions or on some other subject, is requested to forward to the Secretary a resumé thereof at least a week before the opening of the Congress. The Committee reserves to itself the power of deciding whether any other subjects shall be introduced than those specified above, and the order of their sequence. The last day will be reserved for communications not contained in the programme, and twenty minutes will be the maximum time allowed for reading each of these.

Professor Jeannel, of Bordeaux, at the last meeting of the Académie des Sciences, presented a note illustrative of the "History of Acetate of Soda," in which some curious physical and allotropic properties of this substance are detailed. We have not yet had an opportunity of seeing the paper, but M. Legrand, in the *Union Méd.* for April 14, gives a brief account of some of its contents. From this it appears that crystallised acetate of soda melts in its water of crystallisation at a temperature of + 58 Centigrade, and when it is exposed to cold, after being dissolved, it crystallises at this temperature, which remains stationary during the whole time that the crystallisation continues, so that acetate of soda in crystallising presents a fixed point at 58° C., just as water, in the crystallised state, presents in melting a fixed point at 0° C. Dissolved acetate of soda which is exposed to cold but secluded from the air, either in a vessel that is corked or one that is simply covered over, does not crystallise; but what is in the highest degree surprising is that, while cooling thus protected from the air without crystallising, it retains in a latent condition the greatest portion of the caloric which it had absorbed when entering into a state of solution. This caloric reappears and is disengaged when the crystallisation of the salt is induced by simply exposing the solution to the air on uncorking or uncovering the vessel which contains it.

This singular property leads to a curious result. The temperature of 60° C. is easily obtainable from the sun's rays concentrated under a glass frame, and therefore the solar heat suffices for the solution of acetate of soda. But if this solution be effected in a corked or covered vessel, it will retain the greater portion of the caloric absorbed, and will restore this when convenient on the vessel being opened. And the quantity of calorie so absorbed is considerable, for 1 kilogramme of the acetate melted and cooled down to 0° C. will disengage, on removing the crystalline condition, sufficient caloric to melt 360 grammes of ice or raise 360 grammes of water from 0° C. to 79° C.

"In fine, here is a means of magazining solar heat. What will come of it in practice? Will human industry be able some time hence to store up for winter a provision of caloric which has been collected during summer? Why not? The observations of M. Jeannel are, as it were, the first steps on this seemingly fantastic path."

M. Behic, Minister of Agriculture, Commerce, and Public Works, has just published the Report he has addressed to the Emperor concerning the recompenses recommended to be decreed to persons who have exhibited exemplary devotion in the late epidemic of cholera. Besides several bestowals of the Cross of the Legion of Honour, there is a whole shower of medals — gold, silver, and bronze, between 400 and 500 in number. In fact, so numerous are the occasions on which a French Practitioner may reckon to be in receipt of medals, for even very ordinary proceedings, that we suppose a *boite a medailles* must form a necessary part of his outfit. They are decreed to industrious vaccinators, mineral-water inspectors, reporters of epidemics, and numerous other Practitioners in such profusion that one would have thought that long ere this their distinctive value must have undergone a deterioration that rendered them well nigh worthless. That Medical students should derive some satisfaction from such distinctions at the onset of their career is intelligible enough; but we must confess feeling a little astonished at finding that no less than twenty-five Paris Hospital Physicians considered themselves honoured in receiving silver medals for the performance of what after all is one of the ordinary duties of the Medical career. Certainly our own Government is chary enough in the recognition of services, but we think that it indicates a more healthy state of affairs to leave the appreciation of these to the public and the Profession rather than submit them to so puerile a system of recompense which prevails not only in France, but generally on the Continent. However, if medals they must have, we have no doubt that our *confrères* on this occasion deserved them, for there seems to have been no lack of devotion and no sparing of exertion. The mechanism by which the respective merits were judged of, and impartiality in the distribution of the favours secured, we are ignorant of; but it is evident that there must be ample room for the exercise of official patronage and favouritism.

PARLIAMENTARY.—SURGEONS IN THE GUARDS—THE COMMITTEES ON THE CONTAGIOUS DISEASES AND CITY CORPORATION GAS BILLS—THE EMPLOYMENT OF CHILDREN IN MANUFACTURES AND AGRICULTURE.

On Friday, April 13, in the House of Commons,

Captain Vivian asked the Secretary for War whether he would object to lay upon the table of the House a copy of the Warrant of 1860, under which the system of promotion of the Assistant-Surgeons of the Brigade of Foot Guards had been altered, and whether a copy of such warrant had been forwarded to officers commanding those regiments.

The Marquis of Hartington said the hon. baronet the member for Fifeshire had given notice of his intention to move for the documents bearing upon the subject in question, and until then he should abstain from making any remarks upon the matter.

On the motion of Lord C. Paget, it was ordered that Lord Hotham be discharged from further attendance on the Select Committee on the Contagious Diseases Bill, and that Sir C. Russell be added to the committee.

Mr. Otway suggested that one of the members of some of the towns affected by the Bill should be appointed on the committee.

Lord C. Paget acceded to the suggestion, and hoped the hon. gentleman would give a notice to that effect.

Mr. Crawford moved the Select Committee on the London (City) Corporation Gas Bill:—Mr. H. Russell, Mr. Dutton, Mr. Woods, Colonel North, Mr. Morrison, Mr. Westropp, and Mr. Waldegrave-Leslie, be appointed.

On the motion that Mr. Waldegrave-Leslie form one of the committee,

Mr. Ayrton said, as his hon. friend objected to serve, he begged to give notice that he would propose to substitute the name of the hon. member for Finsbury (Alderman Lusk).

The name of Mr. Waldegrave-Leslie was then omitted.

In the House of Lords, on Tuesday,

Lord Shaftesbury referred to the disclosures contained in the report of the Commissioners upon the employment of children in particular trades and manufactures, and asked whether the Government intended to carry out the recommendations of the Commissioners.

Lord Russell said the subject was under consideration.

In the House of Commons,

Mr. Fawcett asked the Secretary of State for the Home Department when the Government would introduce their promised measure for the extension of the Factory Acts, and whether the Government had considered the desirability of regulating the employment and education of children who are employed in agriculture.

Sir G. Grey said, in reply to the first question, that it was not possible to fix a day for the introduction of the Bill. The last report of the Factory Commissioners applied to a variety of trades, and it would require some time as well as much consideration to deal with the various details connected with

the subject. The process of investigating them with a view to legislation was, however, being carried on with all due despatch. The Government, he might add, had framed no plan on the subject of his hon. friend's second question.

THE COMMITTEE ON LEPROSY.

The forthcoming report of the Leprosy Committee of the Royal College of Physicians will be a valuable addition to Medical literature, if we may judge by the "Memorandum" already issued containing the first batch of replies, received in answer to the interrogatories proposed and circulated by the Committee.

We must be prepared for a little more delay than was at first anticipated, as we understand that the mass of written evidence received since the issue of the first "Memorandum" is very large indeed, and to arrange and criticise carefully the various details must be a matter of very considerable labour. The Memorandum to which we now refer contains an abstract of the replies to questions received from New Brunswick, Bermuda, Bahamas, Jamaica, Tortola, St. Kitts, Nevis, Montserrat, Antigua, Dominica, St. Lucia, St. Vincent, Barbadoes, Grenada, Tobago, Trinidad, Cape of Good Hope, Sierra Leone, Tangiers, Tunis, Tripoli, Bengazi, Cairo, Jerusalem, Beyrout, Cyprus, Damascus, Aleppo, Rhodes, Smyrna, and parts around; Crete, Ionian Islands, Salonica, Bucharest, Dardanelles, Constantinople; the Indian Presidencies, Ceylon, Mauritius, China and Japan, Australia and Norway.

We noticed in reading through the abstract, a very great uniformity in the opinions expressed in regard to the leading features in the history of the disease, and a general agreement in the more important points in the course and pathology of elephantiasis. Leprosy is known to be dependent upon some condition associated with bad food and bad hygiene, and it is universally, without exception, admitted to be hereditary—to exhibit two forms, the anæsthetic and the tuberculous—to be more prevalent in males than females—to be developed most frequently between the ages of about 6 and 20—to be incurable when once established, and to be generally, if not always, non-contagious. It is more frequent amongst the blacks and coloured races, as a rule, but it may arise in those whites who have sojourned in leprous districts for any length of time. It is regarded by the reporters, with one exception, to be quite independent of syphilis.

But there are many special circumstances worthy of note, and first of all the transplantation of elephantiasis is well illustrated by the report received from New Brunswick and Australia. It appears to have been carried to the former place by a French emigrant from St. Malo, in Normandy, and still remains as a heirloom in the descendants alone of the original leper. Dr. McCrea states that in Australia it is only known amongst the Chinese, who imported it from their own country.

Secondly, as to the earliest stages of disease. It will be remembered that Dr. Vandyke Carter has strongly contended for the necessity of describing the early stage as an *eruptive* one. The eruption partakes of the character of erythema, out of which are developed whitish, sometimes darkish coloured anæsthetic spots. This is described as a "fine red rash" by Dr. Benson (New Brunswick): "as erythematous patches of bright red colour," so that the patient looks as though overheated by exercise, by Dr. Hinson (Bermuda). At St. Kitts and Nevis, the same is noticed, and the disease is called in the latter place "Red Leprosy." Governor Hamilton observes that in Antigua there are reddish blotches somewhat resembling urticaria, but they are permanent, and in addition anæsthetic patches like *pityriasis vesicolor*. Dr. Carrington, of Barbadoes, describes the eruption as of a pinky-rose hue; Dr. Young notices this also; Dr. Aguart (Grenada), "red irregular patches;" Drs. Murray, Anderson, and Saturnin state that the eruption is noticeable in Trinidad, and Dr. Tygaldos in the Ionian Islands. Dr. Carter, of course, describes it as seen frequently in India, and Dr. Hobson, in China, as consisting chiefly of "red spots;" but the Chinese have a white spot and a red spot leprosy, which are recognised as early stages of the more fully developed elephantiasis. From all sides, then, there comes abundant testimony to the fact that leprosy is marked at its outset by an erythema. This is often mistaken for syphilis. A case of this kind is mentioned by Dr. Tilbury Fox in the *Edinburgh Medical Journal* for March, 1866. Dr. Hinson, of Bermuda, says it is "often mistaken for syphilis;" Dr. Stevenson, of Barbadoes, that it produces similarity to syphilis.

As to the connection of syphilis with leprosy. There is a general and almost unanimous agreement amongst the reporters that these two diseases have no connection with each other in nature. Mr. Bradshaw, of Sierra Leone, is an exception, and observes that it is a result of syphilis. In Arabia it was known long before syphilis was introduced there. A resemblance may be produced between the tubercular stage of either disease, but the history soon clears up all doubt. It is astonishing to note how frequently observers call attention to the use of bad fish and rancid oil as a chief article in the diet of those countries in which leprosy is common. We gather from the contents of the Memorandum that leprosy has no topographical connection with malarious districts, that it prevails in spots that have no right to the title "malarial." Dr. Bowerbank notices that "there is no connexion between malarial districts and leprosy," and Dr. Abercrombie (Cape) testifies to the same fact. But all writers agree that leprosy is most abundant along and near the sea coasts, or at any rate in spots where fish-eating habits are a characteristic feature. This fish is often putrid, pickled, or salted. If fish be not taken, sour milk or rancid oil enters largely into the diet of people in leprous districts. Drs. Bayard, Gordon, and Nicholson (New Brunswick) give as part of the cause the use of decomposing and offensive fish diet. The same is noticed in Bahamas by Drs. Chapman and Sweeting; in Jamaica, in St. Lucia, where bad salt fish is the most general animal food, Dr. Gardiner; and at St. Vincent's (Dr. Smith). In Scio, leprosy is extremely rare amongst the Turkish peasants, who practise frequent ablutions, use more animal food, and little, if any salted fish; but their Greek neighbours are largely affected. Dr. Hjorth says, in speaking of Crete, the food of the peasant consists of "a large quantity of bad salt fish, barley bread, and of an enormous quantity of olive oil, often rancid, which they will drink like water;" and he calls attention to the analogy between the oily diet of the Norwegian and that of the Cretan. Dr. Tygaldos also remarks upon the bad bread and bad olive oil consumed by the people of the Ionian Islands. On the Malabar Coast, "rice and shell-fish are the staple articles of food," (Dr. Innes). A fish diet is frequent in China and Japan, (Dr. Dickson). In Trinidad, "tainted fish" is used (Dr. Saturnin). At Barbadoes, the Cape, Cairo, Beyrout, the same fish-eating habit prevails, whilst bad olives, rank oil, salt and putrid fish, and bad bread, are relished in such places as Smyrna, Scio, and Mytellene. There would seem to be good ground, then, for believing that the consumption of putrid fish and rancid vegetable oily matter in abundance has something to do with the causation of elephantiasis. Observers differ somewhat as to the contagiousness of leprosy. The Chinese believe it to be eminently contagious, and evidence to this same effect has been furnished by Dr. Reynaud (Mauritius), who states that "a wife got leprosy from contact with the dressings of her leprous husband." Dr. Aguart (Grenada), Mr. Rogers, Dr. Stevenson, Dr. Goding (Barbadoes), and Dr. Checkley (St. Vincent), also relate cases which seem to indicate that the discharge from leprous ulcerated surfaces, may be the means of communicating the disease; but it is open to question whether even in these cases there may not be hereditary predisposition which is developed coincidently with the influence of the supposed cause. The *majority* of observers, however, agree that while intermarriage favours its propagation, the disease is not, as a rule, in any degree contagious, and therefore we find that in a large number of districts lepers are allowed to be at large without any special restriction, except that which is self-imposed or inseparable from poverty and vagrancy.

It is very curious that whilst in Cairo and Jamaica the Jews are specially affected, they should be peculiarly exempt in Syria. In Cairo the lighter coloured races appear, contrary to the general rule, to be more affected than the darker Arab race. No cases of leprosy are reported in Monastir, Bosnia, Bucharest, Varna, Dardanelles, or Brussa. A good deal of mystery has always surrounded the so-called "Bouton-d'Alep." Dr. Mongeri (formerly of Crete) states that it is the same as the "Bouton-de-Crete," a form of the ordinary tubercular leprosy.

We should have been glad if the Committee had included

questions that would have lead to the distinction of the pellagrous form of leprosy. We cannot help thinking that many of the cases used as the basis of records are those of pellagra, and it is of some importance to separate (in determining causation) pellagra from true elephantiasis.

With regard to treatment, the recommendations are expressed in general terms. Nothing appears to be of any very great benefit when the disease is once developed. "Rare cases of spontaneous cure in a very early stage of the disease are said to have occurred by the removal to a climate quite different from that where the disease originated (Scio), as Wallachia, Moldavia, Russia. A man, 28 years of age, son of a leprous mother, and having four brothers younger than himself, all leprous, left this island on the earliest appearance of the disease for Constantinople, where he lived four years. Last spring he returned apparently quite well; but, being obliged to return to work in the fields, within three months he became quite leprous." The chief thing to be aimed at is non-intermarriage with lepers, the allowance of the most nutritious food, and the adoption of good hygienic states. Medicinally, arsenic internally and iodine externally seem to be the chief remedies.

The pathology of the disease is meagre in the extreme. We cannot help thinking that very much good might result from the appointment of some Commission to investigate this aspect of leprosy in its endemic haunts. We want also some very precise knowledge as to the influence of topography, malarial poison, diet, contagion, in addition to information as to the minute microscopic changes in the tissues of lepers. At present we are only at the threshold of such an inquiry. The labours of the Leprosy Committee will no doubt define the more important doubts and differences which await solution—in fact, supply us with the average beliefs of Medical men, and we think this may fairly be supplemented by special research.

REVIEWS.

Lehrbuch der Psychischen Krankheiten. Von Dr. Max Leidesdorf, Docent der Psychiatrie an der Wiener Hochschule, etc.

Text-book of Mental Diseases. By Dr. Max Leidesdorf, Teacher of Psychiatry in the High School, Vienna. Enke, Erlangen. 338 pp.

This work has already appeared in a somewhat different form and under a different title, having been originally published in 1860, and then called "Pathologie und Therapie der Psychischen Krankheiten" (Pathology and Therapeutics of Mental Diseases). In this shape it met with decided success, and a new edition having been called for, the book now appears enlarged in form and under a new title. Although Dr. Leidesdorf is the responsible author of the whole work, still men eminent in particular departments have lent their aid in revising certain portions of it, and while thus giving it a somewhat encyclopædic character, have also given it additional weight as an exposition of the most recent views entertained on the Continent in connexion with psychological Medicine. Thus the part treating of the anatomy of the brain has been revised and illustrated by Dr. Meynert, a *Docent* in the High School, Vienna. Stricker, and the well-known Brücke, have superintended the production of that division which relates to cerebral physiology; while Schott, for some years principal assistant to Rokitansky, and himself no mean authority on the subject, has revised the chapter on the pathology of mental diseases.

We shall try to give some idea, however inadequate, of the contents of the work, taking each chapter in regular sequence, although the space at our disposal does not admit of any very lengthy report.

The work begins with an historical sketch of the development of psychiatry in the four great historical periods, which Dr. Leidesdorf designates the primitive, the antique or artistic, the dialectic, and the scientific. The first of these extends from the Creation to the time of Hippocrates; the second, from the days of Hippocrates downwards to about the time of the Christian era; the third, from the third to the fifteenth centuries; and the last, from the revival of learning to the present time. The author directs his attention principally to the last of these, in which, like every other department of science, Medicine has made its principal advances, while psychiatry may almost be said to have taken its rise with it. The progress of this department of Medicine has been most marked in France, Germany, and England, and to its history in these countries Dr. Leidesdorf chiefly draws attention, noticing in an especial manner the researches of Prichard, Morison, Haslam, Winslow, Conolly, and others of our countrymen.

As an introduction to the more practical part of the work, we have next a short outline of the anatomy of the brain, illustrated by figures from sketches by Dr. Meynert, and comprehending the latest researches of Leuret, Gratiolet, Lockhart Clarke, Huschke, and Schroeder van der Kolk. Following this is an outline of cerebral physiology, where notice is taken of the most recent advances in our knowledge of the subject, and the investigations of Kussmaul and Tenner, of Schroeder van der Kolk and others, as to the states of the brain causing convulsions, etc., discussed at some length. Some account is also given of Pflüger's researches as to the propagation of nervous energy, du Bois Reymond's on the electrical condition of the nerves, Schiff's on the functions of the various parts of the brain, along with many other points which we cannot here refer to. As a natural sequel to such a chapter, we have next a sketch of psychology, treated, however, chiefly in its somatic relations, which, in turn, leads to a discussion of the more elementary mental derangements, including an appreciation of the value of mental depression, hallucination, illusion, hyperæsthesia, anæsthesia, etc., as diagnostics and prognostics. Next in order comes a chapter on the etiology of mental disease, and an estimation of the relative values of its various causes, both predisposing and exciting. Among the former special importance is attached to hereditary taint, example, period of life (from 30 to 40 being the most critical time), etc. The author divides the exciting causes of insanity into somatic and psychical; of the former class some are directly referable to the brain or its coverings, as meningitis, encephalitis, new formations, parasites (for an account of which with reference to insanity we are indebted to Professor Griesinger, of Zurich), apoplexy and its consequences, embolism, choking of the cerebral arteries by pigment in intermittent fevers, concussion of the brain, injuries to the head, protracted epilepsy and chorea, exostoses, or caries of the bones of the skull, sunstroke, hyperæmia or anæmia of the brain and its membranes, influence of narcotics, etc. Embolism, one of the most common of these, may, in turn, arise from endocarditis, deficiency of the aortic valves, or aneurism of the aorta, and usually gives rise to loss of consciousness, hemiplegia, and loss of speech. This subject, which is discussed at considerable length, is further illustrated by the citation of a few cases selected from those published by Oppolzer and Gerhardt. Among other causes of mental derangement, not so directly referable to the brain, are pneumonia, spermatorrhœa, pregnancy, delivery, puerperal fever, lactation, acute rheumatism, intermittent fever, secondary syphilis, and the exanthemata. Among the psychical causes the most important places are assigned to love or jealousy in women, and ambition in men.

Having discussed the causes and symptoms of insanity, Dr. Leidesdorf next proceeds to classify the various mental disorders, and in so doing avoids the clumsy and artificial arrangements adopted by many German writers, as Neumann and others. Following the example of Reil, Pinel, and Esquirol, he selects the nature of the aberrations themselves as the basis on which to found his groups. These divisions are three in number, the first characterised by *depression*, the second by *exaltation*, and the third by *weakness*. The two first, marked by disturbance of thought and perception, of a depressed or elevated nature, are sometimes termed the *primary*, and are characterised by their comparative curability; the third, known also as the *secondary* class, is hopeless as to curability, while the delusions are usually more equable in their character than in either of the others.

The first group, or that characterised by depression, consists of two members—viz., Hypochondriasis and Melancholia—the former being the milder form of the two, in which the attention of the patient is entirely centred in himself, and his hallucinations are connected with his own person. If to these, insanity of a depressing kind be superadded, we have melancholy, which Leidesdorf divides into melancholia religiosa, dæmonomania, melancholia metamorphosis, and melancholia cum stupore.

The next division is devoted to diseases of exaltation, or mania properly so called, divided into two forms—*Tobsucht* (acute mania), characterised chiefly by muscular excitation, increased mental activity with delusions, etc.; and *Wahnsinn*,

a chronic condition of the former, where the excitement is more protracted and the delusions more permanent, ending in complete loss of identity on the part of the patient.

The author next proceeds to consider the forms of insanity characterised by permanent weakness of mind, corresponding somewhat to our fatuity or dementia, as the congenital forms (idiocy and imbecility), are not here discussed. The first of these conditions does not appear to have any exact representative in our classifications. It is called *Verrücktheit*, literally derangement or craziness, and is described as being usually developed from acute mania (*Tobsucht*) or melancholia. The delusions apparent in this form of insanity are uniform in character, but the whole appearance of the patient is changed, even though a considerable degree of intelligence may remain during the earlier portion of its course. It ultimately ends in the next variety known as *Blödsinn*, or idiocy, this being only seen in advanced life (primary) or as a result of one of the disorders already mentioned (secondary), when it corresponds more exactly to our dementia. Both of these kinds of insanity are accompanied by lesions of the cerebral organs, and are reckoned incurable. To a particular form of this Blödsinn, corresponding to our general paralysis, the author devotes a valuable chapter, giving the latest results of the Continental pathologists. The part of the book devoted to the description of mental disease closes with a chapter on the relations of epilepsy and mental alienation. As a remedy for the former affection, the author recommends atropine.

A valuable section of the volume is given up to the pathology of insanity, where the morbid conditions which usually accompany it are described in order, beginning with those dependent on the bones of the head, then those on the membranes, and finally those connected with the brain itself. Some of the causes less known in this country are, thickening of the epithelial coat of the dura mater or arachnoid, various kinds of ulcers of the same, thrombosis of the cerebral sinuses, etc.

In his last division, our author gives an outline of insanity in its Medico-legal relations, with extracts from the various German codes with regard to it, but as this subject is already known to most of our readers through the New Sydenham Society's translation of Casper, we shall draw our notice to a close. The volume ends with some very characteristic plates of individuals labouring under the various forms of insanity.

Contrasting this volume with the best of our general treatises on insanity—Bucknill and Tuke's "Psychological Medicine"—we must say that the German work is a worthy rival, so thorough is it, and so comprehensive—indeed, we could not well conceive a greater boon to the Medical public than a translation of such a work as that just noticed, with the practical remarks of a man of standing, approximating and contrasting the German and British systems of psychiatry.

Balneologische Notizen über die Kurmittel des Bades Reinerz, in Schlesien. Von Dr. Hermann Beigel. Enke, Erlangen.

Balneological Notes on the Curative Effects of the Reinerz Baths, in Silesia. By Dr. H. Beigel.

By a treatise on the curative effects of the medicinal waters of Reinerz, in Silesia, Dr. Beigel has added another to the already overgrown balneological literature of the Continent. As usual, he commences with the site, its beauties, and advantages in the shape of temperature, etc.; as usual, also, he gives lithographs of the bath-house and of the neighbourhood, sketches of the various plans and means of treatment, analyses of the waters, and, finally, a number of cases supposed to have been benefited by the treatment usually adopted. This treatment may conveniently be put under two heads—water, internally and externally, and whey. One of the baths, supposed to be particularly useful in cases of scrofula, rheumatism, etc., contains a small quantity of iodine, as iodide of sodium, but whether their fame will ever be sufficient to tempt English visitors is rather doubtful. With regard to the value of such books as this we have also our doubts; at all events, we are of opinion that what is here detailed in about two hundred pages would, in all probability, have been condensed into five-and-twenty by an Englishman. In such works there is always a one-sidedness which is not at all to be desired in a book intended for guiding a Medical man in the disposal of his patients: they may, in fact, be said to be written for two motives—self-glorification and patient hunting, and these in about equal proportions, the preponderance slightly inclining to the latter. To such an extent has the plague of balneological literature spread on the Continent that a satire on it appeared in Frankfort in 1861, entitled "The Salzloch Spa: its Iodine-Bromine-Iron- and Salt-containing Sulphur Springs, and the Tannic Acid-Animal-Air-Baths; with a Defence of the Game of Hazard. By Dr. Polycarpus Stranger-Catcher (Gastfänger)." With regard to Dr. Beigel, what he has done he has certainly done well; we only wish he had written on something else.

Compendiöses Wörterbuch der Speciellen Arznei-Verordnungslehre bearbeitet. Von Dr. Karl Philipp Falck, Prof. Med. an Marburg. Enke, Erlangen.

A Compendious Dictionary of Medicinal Formulæ. By K. P. Falck, Professor of Medicine at Marburg.

A very different book from that just noticed is "The Dictionary of Medicinal Formulæ," by Professor Falck, of Marburg, which might almost be called a treatise on the Materia Medica, arranged according to their pharmaceutical preparations. The most valuable point in connexion with it is that it gives at one view the officinal preparations of all the German Pharmacopœias, as well as the best modes of exhibition, the properties and doses of substances not contained in any Pharmacopœia, though employed in medicine. As examples of these might be cited curara, guaco, such preparations of mercury as the santonate, the preparations of manganese, phenol, fusel oil, picrotoxine, etc., etc. In some cases we have specimens of prescriptions; thus, under the head of Phosphorus three are given to indicate the various ways in which it may be exhibited. Again, where the components of preparations having the same names differ in the different Pharmacopœias, the ingredients of each are given in the form of a table: while in an appendix a series of tables are given, showing the differences between the 6th and 7th editions of the Prussian Pharmacopœia and of these from the other German State Codices. The volume terminates with a double index, the one in Latin the other in German.

The doses are given throughout according to the Nurnberg Medical weight, which is the same (with reference to the grain, at least) as our apothecaries' weight.

This is a book we can most cordially recommend to those who are in the way of reading German Medical works, and who are doubtless sometimes puzzled by the prescriptions contained in them; nor will it be by any means a useless addition to the library of any Medical man who wishes to make himself acquainted with the state of therapeutical science in Germany.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, March 6.

Dr. Peacock, President.

The President exhibited to the Society a specimen of

ABSCESS IN THE RIGHT HEMISPHERE OF THE BRAIN.

The specimen was removed from a boy aged 4, who was a patient of his at St. Thomas's Hospital. The boy was admitted in April, and then was reported to have been ill three months. He had been first seized by convulsions, and on recovery was found to be paralysed on the left side. On admission he was very intelligent for a child of the age, but the left arm and leg were completely powerless. There was ptosis of the right eyelid, both pupils were dilated, and the right was entirely insensible to light, the left nearly so; he was apparently blind of the right eye. When asked what was the matter with him, he uniformly placed his hand on the right temple, and said "pain," "pain." Some time after he had been in the Hospital the ptosis disappeared, but both pupils were dilated and insensible, and the vision of the right eye was apparently abolished, and that of the left imperfect. He was again taken with convulsions, and died very shortly after in July. On dissection an abscess containing fully eight ounces of greenish yellow pus was found in the right middle cerebral lobe, extending close to the convolutions. This was surrounded by indurated tissue, and there were compound granular corpuseles also in the right corpus striatum and thalamus. There was also some sub-arachnoid effusion, and lymph on the surface of the right hemisphere. The left side of the brain and the other organs of the body were free from disease. The President remarked that the great interest of the case arose from the fact

that, though the abseess was evidently of old date, the ehild was peeuliarly intelligent up to a very short time before his death.

Mr. Holmes then gave partieulars of a ease which in some respeets resembled that narrated hy the President. A boy was under his eare for disease of the hip. Excision was performed. The boy had convulsive attaeks, but recovered. Subsequently, however, amputation was necessary for inflammation of the femur. From this also he recovered, hut died at length, after a severe attack of convulsions, from abscesses of the brain, one in the cerebrum and the other in the cerebellum. The origin of the abscesses was not known. It might be suggested that they were pyæmie, but there had been no pyæmic symptoms.

Dr. Hughlings Jackson said the specimen exhibited by the President was one of interest in reference to the question of the seat of damage to the nervous system, when speech was lost,—a question now much discussed in France. It was worthy of remark that in the President's ease, the child could talk, although there was a large abscess in the right hemisphere. Dr. Jaekson asked Mr. Holmes as to the side of the brain affected in his patient's case.

Mr. Holmes was under the impression that the right hemisphere was the one diseased.

Mr. Holmes read, for Mr. Hickman, the following aecount of a speeimen of

CYSTIC DISEASE OF BOTH OVARIES.

This specimen was removed from a patient who eame under my notice at the Western General Dispensary on account of an umbilical hernia, and who died of exhaustion from vomiting, coupled with fatty degeneration of the heart. The subject of it was a large, fat woman, aged 64, and the ovarian disease had not been suspeeted during life, all her abnormal symptoms having been attributed to the hernia; but it appeared that for several years past she had suffered from pain and weight—greatly increased by walking or riding—at the lower part of the abdomen, had had constant attacks of sickness, and had been unable to make water except in a standing position. She had borne several children, the last at the age of 41; the menses became very irregular after this, and eeased at the age of 52. The tumours were freely moveable, and at the post-mortem lay one behind the other, the large one oecupying the front in the centre of the pelvis, and looking exactly like a distended bladder: this one had one long, firm adhesion to the back part of the pelvis. The walls of the eyst were excessively thin, so that the mere manipulation in drawing the tumours to one side caused some of them to burst, allowing a quantity of reddish serous fluid to escape. The tumour of the right ovary was about the size of a duck's egg, that of the left, before being injured, was as large as the egg of an ostrich, showing two stages of eystic disease.

Dr. Greenhow exhibited a specimen of

COLLIER'S LUNG,

for which he was indebted to the kindness of Dr. Philipson, of Newcastle-on-Tyne. It was taken from the body of a pitman, aged 30 years, who had not died of pulmonary disease, but in consequence of injuries received in the mine. The lungs were free from consolidation and from any trace of tubercle, but they were very dark in colour, almost black, and under the microscope black pigment was found deposited in and around the cell-walls. A portion of the lung incinerated and afterwards boiled in strong nitrie and hydrochloric acids left a considerable residue, which was found to consist of silica, partly in an amorphous state, partly in crystalline fragments, which polarised light. On analysing the acid liquor in which the ash had been boiled a considerable traee of alumina was discovered.

Dr. Greenhow also exhibited a speeimen of

POTTER'S LUNG,

which had been forwarded to him by Mr. W. Dunnett Spanton, of the North Staffordshire Infirmary. It was taken from the body of a man, aged 35, who had worked as a potter all his life, and had died with symptoms of phthisis. On section cavities were found in the upper lobe of the lung, and the pulmonary tissue was consolidated and contained many small, hard, perfectly black nodules, which near the apex were intermixed with granular matter resembling tubercle. There was likewise much black pigment deposited in patches throughout the crepitant portions of the lung. Under the microscope the cell-walls showed deposits of black pigment, and the field was here and there traversed by what looked like semi-transparent fibrous bands. The eells in the eonsolidated portions of the lung were oceupied by opaque, yellow granular matter mixed with irregular nuclei. A portion of lung ineinerated left an ash partly soluble in boiling nitric and hydrochloric acids, the insoluble residue eonsisting of amorphous silica. The acid liquor was found to contain a large amount of alumina. These specimens were further illustrations of a subject which he (Dr. Greenhow) had already on two former occasions brought under the notice of the Society. There could be no doubt that in both cases pulmonary irritation had been excited by the inhalation of dust, and that in the potter's case true phthisis was superadded to the results of that irritation.

Dr. Moxon suggested that it was not quite certain whether the presence of the foreign bodies in the lungs was cause or effect. Healthy lungs, he said, would be able to get rid of a large quantity of foreign matter, but if there were a bronchitis it might be impossible. All chronic lung disease, he remarked, was attended with deposition of pigment.

The President said that in a speeimen of very dark lung which he had exhibited to the Society, obtained from a Cornish miner, the black material was found by Dr. Bernays to be carbonaceous, not an animal pigment. He inquired of Dr. Greenhow whether there had been any coal found in the lung in the first ease he had exhibited to the Society, as well as silieeous and aluminious matter.

In reply to these and several other speakers, Dr. Greenhow said that he had no doubt as to the inhalation of dust being the direct cause of the pulmonary disease to which colliers, grinders, potters, and other operatives in dusty employments were liable. The disease was in the first instance bronchitis, to whieh, at a later period, consolidation of the lungs was often superadded. Doubtless the bronchial irritation caused by the mechanical irritants produced a change in the bronehial membrane, impairing the function of the ciliated epithelium, and thus favouring the further passage of the irritating particles into the smaller tubes. As regarded the black colouring matter, he had no doubt that in some cases it consisted partly of matter received from without by inhalation; but, as the lungs were found black in cases in which the dust inhaled was not of that eolour, he could not doubt its being also frequently a deposit formed within the body. He might say that he had on many occasions boiled portions of black lung in strong hydrochlorie or nitric acid without producing any effect on the colouring matter, which was evidently carbonaceous.

Mr. Spooner showed casts of specimens illustrative of the

CATTLE PLAGUE.

The casts were numerous, and were all from decided cases of cattle plague. They were made by Mr. Tuson, and represented the mucous membrane of the mouth, the trachea, the rumen, omasum, fourth stomach, large and small intestines, etc. In the course of his remarks Mr. Spooner said that Mr. Worms' treatment of the disease had turned out to be a eomplete failure.

The President said that some time ago he had requested Mr. Spooner to show these specimens, and he felt sure the Society would feel thankful to Mr. Spooner for having done so.

Mr. Spencer Watson showed a specimen from a

CASE OF STRANGULATED OBTURATOR HERNIA.

The patient was a woman, of 76 years of age, who had all the symptoms of strangulated hernia without any signs to indicate the precise seat of the hernia. She had an old inguinal hernia on the left side, which eould be easily reduced, and the only part at which there was the slightest unusual fulness which eould have pointed out the true nature of the case was at the upper part of Scarpa's triangle on the right side; this fulness, however, seemed to be due to enlarged glands in that locality. The hernia was a small one occupying the left obturator eanal, the bowel being ulcerated on the mucous surface, but the peritoneum remaining entire.

Mr. Spencer Watson also showed specimens from a

CASE OF ALVEOLAR DISEASE OF BOTH OVARIES.

A widow lady, 49 years of age, had symptoms of abdominal tumour for some months, and accompanied by frequent vomiting. The diagnosis was not made during life, though several different opinions were formed. The nature of the tumour was of the alveolar variety, eonsisting of numerous cysts varying in size from that of an orange to that of a pin's head, and very closely packed together. The microscopic appearances resembled closely those observed in a similar case exhibited by Dr. Julius Pollock to the Society. There were no adhesions in front of the tumours, which, however, were adherent to each other and to the deeper structures.

Mr. Pick showed a specimen of

RUPTURE OF THE POPLITEAL ARTERY.

As this case excited much interest, we give a full report of it.

The patient, aged 25, was admitted into St. George's Hospital with the history that on the 21st of December of last year he was engaged in raising a heavy truck by means of a crow-bar, when the bar slipped and struck him a violent blow on the front of the right thigh. This was followed by a sudden and intense pain in the back of the knee joint, which lasted some minutes and caused him to feel very faint. The pain then passed off, and he resumed his work, that of a navigator. He continued at work for a week in spite of pain and some slight swelling of the limb, and on the 27th of December he walked several miles, from Edgeware to Barnet. Whilst walking the pain in the knee became very severe, and considerable swelling of the limb came on; so much so, in fact, that he was unable to get home again, and was obliged to be conveyed there. From this time he was confined to his bed, and was seen by a Medical man, Dr, Wotherstone, of Stanmore, who states that the limb was then much swollen, but without discolouration, and that there was pulsation in the tibial artery. He was ordered bran poultices. The swelling continued to increase till the middle of January, after which it remained stationary. A day or two before admission into Hospital, however, a soft fluctuating spot was felt in the ham, and was punctured and discharged some broken down blood-clots. When admitted on February 1 he was in a state of extreme collapse and delirious; so much so, indeed, that no history could be obtained from him. The pulse was 144, very weak, and he was covered with a cold, clammy sweat. The left leg was enormously swollen to a short distance above the knee. The skin was quite cold, tense, and white; there was not the slightest appearance of discolouration about it, except on the heel, where there was a large bleb, filled with bloody serum. No pulsation could be felt in the tibial; but this might have been due to the swelling. There was forcible pulsation in the femoral in the groin. In the popliteal space there was a small opening, from which fluid blood was oozing. An incision was made into the leg, and it was found to be one mass of coagulated blood. The thigh was, therefore, amputated by the double flap method. On making an incision into the leg after the operation, the whole of the back of it was found to be occupied by a mass of coagulated blood, weighing over two pounds; this was diffused throughout the tissues, and was in no way encysted or circumscribed. In the centre the clot was broken down, and commencing to suppurate. The blood was found to come from a rupture in the popliteal artery, opposite the knee-joint; the rupture was not quite complete, the two ends being still united by a small portion of the anterior wall of the vessel. The coats around the rupture were much thickened, and there was no plugging of the orifice. The popliteal vein was uninjured, but the walls of this vein, as well as those of the anterior and posterior tibial were much thickened, and they contained clots adherent to the lining membrane. The tissues on the front of the leg were infiltrated with a gelatinous serum. The knee-joint was uninjured. After the operation the patient rallied for a time; symptoms of pyæmia then set in, and he died from this disease on the nineteenth day after the operation. The interest in connexion with this case is the fact that the lesion should have existed such a length of time—six weeks—without any appearance of gangrene; this, no doubt, was due to the fact, as has been shown by Mr. Poland, in the fourth volume of "Guy's Hospital Reports," that the rupture was not quite complete. In a case which occurred under the care of Mr. Cæsar Hawkins in 1858, the rupture, though not complete, was followed by gangrene on the fifth day. Another point of interest in connexion with the case is to determine the exact time at which the rupture took place. It seems most probable that at the time of the accident the coats of the vessel were only injured, perhaps the internal and middle ruptured, and that the complete laceration and effusion of blood was the result of walking, with an injured vessel, so many miles on December 27.

Mr. Holmes remarked that the case was interesting in several points. In the first place, with regard to the very long period during which gangrene was delayed, and which had been referred by Mr. Pick, with much probability, to the fact of the laceration having been incomplete at first. In the second place, the case was of interest with reference to practice. Ought the limb to have been amputated at the outset? The Medical man who had had charge of the case originally was, as he understood, threatened with an action at law because he had not pointed out the nature of the injury at once, and recommended or performed amputation. But in the cases of this injury which Mr. Holmes had seen at St. George's Hospital, it appeared to him that they had done better by delaying amputation until gangrene was unmistakeably declared, while as to diagnosis he had seen cases in which the diagnosis was impossible, in consequence probably of the laceration being, as in this instance, only partial. Thus, in a case under Mr. Cæsar Hawkins's care some years ago, Mr. Hawkins was confident that he could feel the pulsation of the anterior tibial, and a good deal of doubt at first existed as to the nature of the injury.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, March 7, 1866.

Dr. Barnes, President.

The following gentlemen were elected Fellows of the Society: Drs. G. B. Brodie, John Easton, C. B. Fox; Messrs. N. Avent, R. Blagden, J. H. Bryant, Thomas Dane, W. Dewsnap, R. A. Elliott, John Loane, W. Soper, H. Winterbottom. Professor Retro Laggati, (of Milan), and Dr. Theodore Hugerberger (of St. Petersburg), were elected Honorary Fellows.

Dr. Tyler Smith showed a new Vaginal Speculum made for him by Messrs. Weiss. He considered it much more convenient than any other known to him. It was made in the form of a double duck-bill, the ends being in close apposition. The nuisance of having a plug for the sake of introduction was done away with.

The President stated that he had had a rod made after the fashion of the uterine sound for the purpose of Cauterising the Cervix Uteri in the manner described by him at the last meeting.

Mr. Baker Brown, jun., exhibited a little boy, ten weeks old, born with Amputated Arms and Legs, but perfect in other respects. On one of the thigh stumps there was an appearance of toes, and on each of the stumps of the upper extremities was a distinct nipple.

Dr. Madge showed a specimen of Fibrous Tumour of the Uterus. It measured fifteen inches in circumference, and weighed nearly two pounds. It had a pedicle, which was attached to the posterior wall of the uterus.

Dr. Barnes exhibited a specimen of an Encysted Fœtus, which had been removed at the patient's death, forty-three years after its escape into the abdominal cavity. He also showed a Mummified Fœtus, which had been expelled after the birth of a full-grown child.

Dr. Braxton Hicks exhibited a specimen of the Echinococcus, which had been discharged from the vagina.

Dr. Walker, of Peterborough, read the history of a case of Ruptured Vagina during Labour.

Mr. Baker Brown read a paper on the

USE OF THE ACTUAL CAUTERY IN OVARIOTOMY.

The author observed that on February 1, 1865, he placed before the Society his first case of completed ovariotomy in which the pedicle was divided by the actual cautery. Since then he had published ten or eleven more in the *Lancet*; and now he wished to relate his last eleven cases. and make some remarks on the use of the actual cautery. In the eleven cases the operation was completed, and all recovered. Mr. Baker Brown found that, in a few of the cases, the cautery was not sufficient alone, he having to ligature several vessels in the adhesions; and in case 6, the artery, which was bleeding, was from a very fat mesentery, and the superabundance of fat prevented the seared edge from puckering. He considered it highly necessary to have a properly-made clamp; also, it was advisable that the iron should not be too hot, a simple red heat being best, so as not to hurry the process of separation, but to bruise the pedicle by cutting it off slowly, and afterwards care must be taken not to disturb the stump. On one occasion, the author being anxious to see if the vessels were safe (after the cautery), gently rubbed the edges with a towel, when the crust was broken, and a small vessel bled. Of twenty-three cases of completed ovariotomy, the author had lost but two. He thought it must appear evident that this success had arisen from the use of the actual cautery.

Mr. Brown then presented a cyst and pieces of omentum from a patient operated on the day before, which showed that

the whole omentum was so fat that the cautery would not act safely on the adhesions. In such cases it was better not to attempt its use. The pedicle itself was safely removed by the cautery clamp.

Dr. Routh read a paper on

A CASE OF FIBRO-CYSTIC DISEASE OF THE UTERUS WHICH WAS MISTAKEN FOR OVARIAN DISEASE.

It occurred in a woman aged twenty. There were two large abdominal fluctuating tumours united by a large solid mass. These were diagnosed as multilocular ovarian disease by Dr. Savage, Dr. Greenhalgh, Sir W. Fergusson, and Dr. Routh. All advised operation except Dr. Greenhalgh, who recommended delay. She was operated upon on November 16, 1865. There were no adhesions of any consequence. The tumour was freely moveable on the right side. On the left, it was bound down by the usual ligaments, and had become very dense and unyielding. Extirpation was thus impossible. Portions of the omentum were removed by actual cautery. The larger right cyst was punctured, and emptied of a quantity of pus, and the abdominal wound brought together. The patient scarcely rallied, was constantly sick, and died, after evidence of internal bleeding, in thirty-four hours.

The post-mortem examination revealed that all the cysts were full of blood, vessels having giving way in them, probably through the vomiting. The actually cauterised surfaces were quite shrivelled, and free from even an appearance of blood. The whole fundus of the uterus was fibro-cystic.

The importance of this case was brought out in the error of diagnosis. All the usual symptoms of fibroid disease were absent—namely, early fibroid hardness of tumour; absence of flooding; increased length of uterine cavity; absence of tubular souffle; and previous exploratory puncture would have only given exit to pus. Secondly, owing to numerous vascular trabeculæ in the tumour, death might at any time have resulted from simple puncture with the trocar. Thirdly, it proved the great efficacy of the actual cautery, even in a case of constant sickness following operation.

Mr. Spencer Wells said he fully admitted that in some rare cases it was very difficult, perhaps impossible, to arrive at an exact or positive diagnosis as to the nature of an abdominal tumour; but he contended that in the great majority of cases —in at least nine out of ten—it was quite possible to arrive as near the truth in this as in any other department of Surgery. He admitted most fully that men of great experience, after carefully examining a case, would sometimes find it impossible, even with the help of an exploratory incision, to make a positive and complete diagnosis. In such a case as that narrated by Dr. Routh, the exact nature of a tumour might be doubtful even after its removal. But such cases were few and far between, and by no means opposed to the rule that in a large majority of cases of ovarian and uterine disease a very accurate diagnosis might be made. With regard to the use of the cautery in ovariotomy, the cases brought forward certainly proved that we had been taught an additional and successful mode of dealing with the pedicle. But they also convinced him that it should be an exceptional and not a general method. The number of cases in which ligatures had been also required, the accounts of the melting and flaming fat, the care required as to the precise temperature of the irons, the slowness of the searing, the effects of disturbing the eschar, and the very frequent suppuration in the abdominal wall were very unsatisfactory. And the argument that because out of twenty-three cases only two had died, therefore this success was due to the use of the cautery was clearly untenable; for it was a curious fact that of the last twenty-two cases of ovariotomy in which he (Mr. Wells) had been able to secure the pedicle by a clamp, only two had died, and one of these lived twelve days and died of cancer of the peritoneum, which was not detected before the operation.

Time not admitting of further discussion or reply from the authors of the papers, the meeting adjourned.

WESTERN MEDICAL AND SURGICAL SOCIETY.

Friday, February 2.

Mr. Charles Hunter showed to the Society a boy subject to severe periodic attacks of

NEURALGIA OF THE SPINE, UNDER TREATMENT BY THE ATROPINE INJECTION.

William K., aged 7 years, had a severe convulsion fit after whooping-cough four years ago. The fit was followed by insensibility for many days, and hemiplegia of the right side has existed from that time. The boy now walks lame with the right foot; the right hand remains clenched. Since the fit the boy has hardly been free from neuralgia (epileptiform?) of a peculiar nature, and for four years he has been almost constantly under treatment of different kinds without beneficial results. The neuralgic attacks last from three to seven days, during which time he gets very little sleep; it is then absent usually about two, or at the most three, weeks. The attack consists of paroxysms of two degrees of severity. The milder, which are very numerous, last but a short time, and are partially relieved by patting the boy on the back, for which treatment the boy usually runs to any one near; the severe paroxysms are in number ten or twelve a day, which the boy usually treats himself, by hitting himself over the eighth dorsal vertebra with a ninepin. This "dulls the pain of the paroxysm." There is no tenderness of the spine to be felt. The pupils are always dilated before an attack comes on. On November 29 one-sixtieth of a grain of atropine was injected over the spine, an attack having begun some hours previously. 30th.—The progress of the attack and all further paroxysms were arrested. December 16.—Another attack began, six severe paroxysms having occurred before the puncture could be used. The fortieth of a grain was injected: complete arrest of spasms for twelve hours. A return began; a repetition of the injection then arrested all paroxysms until January 12, 1866, when a third attack threatened; it was arrested by a single injection of atropine in the arm. February 3.—Altogether five attacks have thus been arrested up to this date; a single injection, with one exception, sufficed every time. The boy usually slept after the injection, and never had the "intoxication atropique" to any extent. The case is still under observation.

Mr. Hunter then exhibited a specimen of

CANCER OF THE PHARYNX.

The patient, a healthy-looking, well-nourished woman, aged 33 when she died, did not live more than seven months from the first appearance of the disease. For three or four months the symptoms were chiefly those of a cold in the throat and windpipe, slight huskiness of voice, clear white expectoration, soreness of different parts of the throat, slight dysphagia. Gradually the dysphagia became the prominent symptom, and she died with all the symptoms and results of stricture of the œsophagus. For the last few months she was fed chiefly by beef-tea and milk enemata. The disease did not involve the œsophagus, but greatly contracted the lower part of the pharynx, with a villous growth, which ulcerated on the right side of the larynx, opened into it by a minute orifice, and produced an abscess which traversed among the condensed tissues of the neck, and opened externally just before she died.

Mr. H. P. Bannister exhibited two tape-worms from the peritoneum of a rabbit. No worms were found, after careful examination in the intestines.

Mr. Vasey showed a lower jaw-bone in which the wisdom teeth were situated in the sigmoid notch of the rami.

Dr. Martyn showed two good-sized pieces of glass which had travelled under the scalp from a wound of the forehead.

Collegial Prizes.—The Council of the Royal College of Surgeons of England has just awarded one of the Jacksonian Prizes of twenty guineas to Mr. William Paul Swain, of Devonport, a Member of the College, for his essay on "The diseased conditions of the knee-joint which require amputation of the limb, and of those conditions which are favourable for excision of the joint, with an explanation of the relative advantages of both operations as far as can be ascertained by cases properly authenticated." Mr. Swain was a pupil of King's College. For the other Jacksonian prize on the relative value of the various modes of treatment of popliteal aneurism, it does not appear there were any competitors. The following are the subjects for the Jacksonian prizes of the present year—viz., "Ovariotomy: pathology and diagnosis of cases suitable for this operation, with the best method of performing it, and the results of recorded cases;" and on "Fractures into joints: their modes of union, with the treatment and result."

At the London Quarter Sessions on Saturday a report of a committee was adopted, increasing the salary of the City coroner to £885 a year.

OBITUARY.

BENJAMIN GUY BABINGTON, M.D., F.R.S.

We gave last week a very short and imperfect sketch of the life and work of Dr. Hodgkin, who made his Professional reputation at Guy's Hospital and Medical School. We now have to give a notice of another celebrity of the same school, Dr. B. G. Babington, who, though several years Dr. Hodgkin's senior, died in London just at the time that we received the tidings of Dr. Hodgkin's lamented death at Jaffa.

Dr. Benjamin Guy Babington was the son of a very well known and popular Physician, whose statue stands in St. Paul's Cathedral. Descended from a good old Irish family, Dr. William Babington was one of the most successful London Physicians of his day, and filled a very prominent and active place among his brethren, though we are not aware that he found time to much enrich the literature of the Profession. He was one of the first Vice-Presidents of the Medico-Chirurgical Society on its formation in 1805, and President in 1817-18. A paper of his, read before the Society in 1807, will be found in the first volume of the *Transactions*. He was Physician to Guy's Hospital, and lectured there on Chemistry, and on the Practice of Medicine. He died of influenza in 1833, and a very eloquent eulogy on him, by Dr. Bright, is printed in vol. xii. of the *Medical Gazette*. Dr. Bright, while paying homage to his excellent judgment, extensive information, and love of science, dwells with affectionate insistence on his warm and admirable qualities of heart; and any friend of B. G. Babington's who may read that eulogy will recognise in the father's character many of those gifts and qualities which they most loved and admired in the son.

Benjamin Guy Babington was born in 1794, and was educated at the Charterhouse. We have seen it stated that he began public life in the Navy, and was present at Copenhagen and Walcheren, but if so he soon gave up that career and entered Haileybury College, where, after going through the usual two years' curriculum, he proceeded, in 1812, to the Madras Presidency, as a member of the Indian Company's Civil Service. After seven years' residence in India, ill-health compelled his return home, and abandoning the Indian service, he adopted his father's Profession, entered at Pembroke College, Cambridge, and took his M.B. degree in 1825. In 1830, he proceeded to the full degree of M.D., and in the year following was elected a Fellow of the London College of Physicians. Early in his Medical career he obtained the appointment of Physician to the Deaf and Dumb Asylum; and for many years he, like his father, lived in the City; but about 1840, we believe, he moved westward, to George-street, Hanover-square, where he died. He naturally selected Guy's as his London Medical School, and when a vacancy in the Medical staff of that Hospital was made by Dr. Cholmeley's death in 1837, he contested the appointment with Dr. Hodgkin. His Cambridge degree, and, we may fairly suppose, the influence of his father's name and memory, added to the reputation he had already made as an accomplished Physician and hard worker, enabled him to triumph over the strong claims of his opponent, and he was appointed Assistant-Physician. We say "the strong claims of his opponent," for Dr. Hodgkin had by many years of untiring labour at Guy's made himself an European reputation as the best pathologist in England. The splendid Museum at Guy's was his creation almost, and the catalogue of it, which he published, together with his work on the Serous Membranes, had made him known and admired far and wide. He was much chagrined by his failure to obtain Hospital promotion, and though we have heard that an offer was made to appoint him Assistant-Physician at the same time as, but below, Dr. Babington, he declined the proposal, and resigned his post as Lecturer and Pathologist; and ceasing from that time to take the same interest as formerly in pathology, he was known of late years rather as a warm and large-hearted philanthropist than as a Physician.

To return to Dr. B. G. Babington. In 1840 he became full Physician to Guy's, having Drs. Bright and Addison for colleagues. As a clinical teacher he was very painstaking, and was popular with the students, but he was not successful as a lecturer, and after assisting Dr. Addison for a short time he gave up lecturing, and in 1854 altogether retired from the Hospital.

His earliest writings were on animal chemistry, in which subject he made original observations and experiments. He was not, like his colleagues, Drs. Bright and Addison, so fortunate as to be the first to point out a special pathological condition which should afterwards bear his name, but he created the felicitous phrase "the liquor sanguinis," as signifying the blood after the separation of the red corpuscles, and that ought to keep green his memory so long as physiology, pathology, or organic chemistry are taught. The expression occurs first in a paper by him on "Some considerations with respect to the Blood, founded on one or two very simple Experiments on that Fluid;" it is published in vol. 16 of the Medico-Chirurgical Transactions, 1830. He also wrote the essay on "Morbid Conditions of the Blood," in vol. 1 of Todd's "Cyclopædia." His more purely Professional writings are to be found in the first series of the Guy's Hospital Reports, and two of these—the articles on epilepsy and on chorea—specially deserve mention as excellent practical papers, well worthy of study. Dr. Babington then—twenty-five years ago—wrote as strongly of the power and value of arsenic over chorea as Dr. Begbie very recently has; but his appreciation of the power of the medicine for good—and he says "I believe this the most powerful remedy of all"—was more tempered by his recognition of its power for mischief.

Possessing a good knowledge of several languages, Dr. Babington excelled as a German scholar, and we owe to him the elegant translation of Hecker's "Epidemics of the Middle Ages," which was published by the Sydenham Society; he edited also their issue of Feuchtersleben's "Medical Psychology." He was a great admirer and a successful cultivator of the "fine arts," and was the friend of many eminent musicians, painters, and sculptors. Tall, well formed, and muscular, he was framed to excel in physical exercises, and many stories are told of his skill and prowess with the gloves.

We have already said that he inherited some of the best qualities of mind, heart, and temper of his father, and we cannot in any way better show this than by quoting the following notes on him for which we are indebted to a Physician who knew him long and well, and is himself one of the most eminent of the present "Guy's men:"—"Personally," he says, "Dr. Babington was universally beloved, for a more amiable and genial temper than he possessed could not be imagined. He was overflowing with fun and good humour, and his benevolence was carried to a fault. He was an excellent 'clubbable' man, and had the most enduring friendships, and his cheerfulness, gaiety, and even sprightliness were so great that even up to the time of his death he was never regarded as an old man. He was highly accomplished, and had indeed a remarkable facility of manipulation—there was scarcely any operation with the hands which he could not accomplish. It was, therefore, rather the art than the science of his Profession which he cultivated; and not only could he write an elegant prescription, but he was always ready with the most remarkable and clever devices for the good of his patients. He was one of the first who put into practice the 'boot' for drawing the blood from the body; he had a new mode of making issues by the actual cautery; he invented a curved stethoscope, and was a great adept in using mirrors for examining the throat; one made especially for the larynx was the first laryngoscope. He invented a chamber utensil by which the urine could be separately collected, and many other ingenious contrivances too numerous to mention. The writer remembers that the first patient he ever saw bled was operated on by Dr. Babington; none of the pupils around him had ever bled, whereupon the Doctor said he would do it himself; and as he wished to open a vein in the left arm, the operation was done with the left hand, the Doctor being ambidexter. But every accomplishment of this kind must sink into insignificance compared with his goodness of heart. In common with his father, he had the most generous spirit. Every poor person received his commiseration. Like his father, he gave an immense amount of gratuitous advice, not at his own house ostentatiously, but by kind visits to the needy. Like his father, he would remit fees did he discover he had been impoverishing his patient. Although so large and unknown an amount of unrewarded advice is given by our Profession, yet Dr. Babington's virtues in this respect were so remarkable that they formed a striking trait in his character; and his friends could no doubt show that he has failed to enrich himself by his benevolence, and too often, perhaps, through the niggardness of those whom he benefited. In this selfish world he deserves a memorial, though it were for nothing else than his kindness of heart."

We will only add that Dr. Babington was mainly instrumental in founding the Epidemiological Society in 1850, and was President of it till very recently. During the last year he employed all his spare time upon the subjects under notice by the Venereal Commission, of which he was a most active and efficient member. He mastered all the modern literature on the subject, and was engaged at the time of his death in framing an analysis of the mass of evidence given before the Commission. For a long time he had been troubled by a urinary complaint, and for some months had been losing flesh. About a fortnight before his death he was taken worse, with rigors and other symptoms denoting suppuration in the kidneys; and this was the immediate cause of his death.

DR. JOSEPH POULTER MACKESY, OF WATERFORD.

We deeply regret to announce the sudden death of the above-named gentleman, son of Dr. Thomas Lewis Mackesy, so well known as taking a leading part in every movement having for its object the dignity and advancement of the Profession in Ireland. Dr. J. P. Mackesy passed the Irish College of Surgeons in 1838, and was admitted a Fellow of that body in 1844. He graduated as Bachelor of Medicine in 1839, and was also a Master of Arts in the University of Dublin. He very soon acquired extensive practice in his native city (Waterford), and at the time of his lamented decease occupied a high position in his Profession. The *Waterford Conservative* gives the following account of the melancholy event: —"It is impossible to describe the painful sensation that was felt on Tuesday in Waterford by every one who heard of the almost sudden death of Dr. J. P. Mackesy. There could not have been any death more unexpected, as he was in the prime of life and apparently in the enjoyment of the most robust health. Late on Monday evening he felt an uneasiness in the region of the heart, and, notwithstanding the skill of his Medical attendants, he became worse until he expired on Tuesday, shortly before three o'clock in the afternoon, having been for some time insensible. He had been for several years in a leading position in his Profession, and was highly esteemed by all who knew him. He has left a widow and two sons."

NEW INVENTIONS.

MEDICATED PESSARIES AND SUPPOSITORIES.

A paper was read at the last meeting of the Pharmaceutical Society, by Mr. Brady, of Newcastle-on-Tyne, on the subject of "Medicated Pessaries and Suppositories," of some considerable economic interest to the Profession. The author strongly urged the necessity of some *recognised standard of weight* for suppositories and pessaries. In regard to pessaries, there is, perhaps, little difficulty to be overcome, since in all the papers which have been published about them, with formulæ for their preparation, *two drachms* had been very properly adopted as a suitable size. With suppositories the case is far different. The two Pharmacopœial formulæ are not alike, and suppositories containing the same medicinal ingredient might be found of any size from 10 to 30 grains. This is a matter of very great annoyance to the chemist. That suppositories should be neatly dispensed, it is necessary that they be cast in moulds, and if an *uniform* size were recognised, there would be no more liability to misunderstanding or annoyance than in dispensing pills or mixtures. At present, while suppositories are very difficult to make nicely, there is no standard for them. The author suggested *fifteen grains* as the standard weight for suppositories. It is not too large for such things as morphia, and just large enough for the exhibition of tannin and other bulky substances. *As the Profession are beginning to use these suppositories largely, it is essential that some uniform plan be adopted.* The chemist is anxious that attention should be called to the matter, and, as we have said, it is suggested by Mr. Brady that *fifteen grains* be the standard. Messrs. Maw and Sons have taken great pains in the manufacture of a fifteen-grain mould. The author condemned the Pharmacopœial formulæ, especially their base, and recommended theobroma oil, either by itself or with an admixture of 5 to 10 per cent. of lard, which might be previously used to take up the morphia or other medicinal agent.

THE LONDON SICK POOR.

On Saturday afternoon a large body of noblemen and gentlemen attended at the Poor-law Board, Whitehall, as a deputation from the meeting which was held a few weeks since at Willis's Rooms with respect to the condition of the sick poor in Workhouse Infirmaries. Among those in the deputation were the Archbishop of York, the Earl of Shaftesbury, the Earl of Airlie, Earl Carnarvon, Earl Grosvenor, M.P., Mr. Ernest Hart, Dr. Anstie, Dr. Carr, Dr. Rogers, Dr. Dobell, Dr. R. Fowler, Dr. Ogle, and Dr. Stallard.

The deputation was received by the Right Hon. C. P. Villiers, M.P., President of the Poor-law Board.

The deputation having been introduced as from the Association for the Improvement of the Condition of the Sick in the Metropolitan Workhouse Infirmaries, Lord Carnarvon proceeded to call the President's attention to the large and influential meeting held at Willis's Rooms a few weeks since, and to the resolutions then carried. The first was:—

"That the present management of the sick poor in the metropolitan Workhouse Infirmaries is highly unsatisfactory; that the buildings are inadequate and unhealthy, the Medical attendance insufficient, the nursing merely nominal, and the general administration radically defective."

The noble lord observed that there was not a single sentence in all the resolutions passed at this meeting which was not distinctly borne out by facts, and nothing whatever was stated at that meeting by those who represented the Association for the Improvement of the Condition of the Sick Poor in Workhouses which could be said in the least to approach exaggeration. The facts were perfectly clear, and it must be obvious to all who had looked into the matter that the terms of the first resolution were fully borne out by the facts, for the Medical attendance was insufficient, the buildings were proved to be unhealthy, and the staff of nurses was nothing like proportionate to the wants of those who were in these places. There was no hope of improvement being effected in the workhouse Infirmaries by those who had the administration in their hands, and the gentlemen who had their interest awakened in this matter now came before the right hon. gentleman to appeal to him, as President of the Poor-law Board, and as representing her Majesty's Government, to deal with a state of things disgraceful at once to society and to the administration of the law. It was not for the deputation to suggest the measure of reform which should be applied to these existing evils; but he felt bound to say that no system would be satisfactory which did not include the separation of the sick poor from the able-bodied paupers, and the placing of the sick under a distinct management. Those who knew the buildings at present used as workhouse Infirmaries, most of which had been erected for a totally different purpose, were quite hopeless of any effective improvement being carried out in these buildings. The gentlemen around challenged inquiry into the condition of those Infirmaries, and they trusted that the inquiry being conducted by the Poor-law Board would be a full and free one, for then it would prove the necessity for a change being made, and the Poor-law Board would feel bound to consider principles and and rules signed by some most eminent Medical gentlemen connected with Hospitals as to the primary rules with regard to space in and the government of any Infirmaries instituted under the Poor-law Board;—Dr. Thomas Watson, President of the College of Physicians; Dr. George Burrows, President of the General Medical Council; Dr. James Clarke, Dr. Wm. Jenner, Dr. Edward Sieveking, Sir William Fergusson, and Mr. James Paget. The principles and rules laid down by these authorities he would lay before the Poor-law Board. They were:—"The sick poor should be separated from the able-bodied paupers, and their treatment should be placed under a distinct management. In lieu of sick wards annexed to each workhouse, consolidated Infirmaries should be provided, where the following rules of Hospital management should be adopted under skilled supervision. They are those generally accepted in this and other European countries. 1. The buildings should be specially devised for the purpose, of suitable construction, and on healthy sites. The rules laid down by the Barrack and Hospital Commission may be consulted with advantage on this subject. 2. Not less than 1000 (and for particular classes of cases 1200 to 1500) cubic feet of air should be allowed to each patient. 3. The nursing should be conducted entirely by a paid staff, and there should not be less than one day nurse, one night nurse, and one assistant nurse for each fifty

patients. 4. There should be resident Medical officers in the proportion of not less than one for each 250 patients. 5. The Medical officers should not have any pecuniary interest whatever in the medicines supplied, nor should they be charged with the duty of dispensing them. 6. A judicious classification of patients should be strictly observed, the epileptic and imbecile, the acutely sick, and the aged and infirm, being treated in separate wards. 7. The aged and infirm, the chronically sick, and the convalescent should be provided with day rooms separate from the dormitories." The noble Lord concluded by urging that these should be the bases upon which any reform in workhouse administration should be conducted.

The meeting having been addressed by the Archbishop of York, Dr. Rogers, Mr. Paget, the Earl of Shaftesbury, Mr. Ernest Hart, and Mr. J. S. Storr,

The PRESIDENT, in reply, said the deputation would see that he was unable to give any definite reply to the propositions which they had laid before him. Lord Carnarvon had appealed to him as a member of the Government and as President of the Poor Law Board, but, looking at the nature of the case, and the extent of the evils which the Association had brought under review, and the very comprehensive character of the changes proposed, he could not state what the Government might think it right to do, or what would be practicable. But, certainly, as President of that Board, he could say that he felt, and he was sure the public must feel, deeply indebted to this Association for the inquiries which had been instituted, and for the effective manner in which the results of those inquiries had been made known in the effort to reform the system of which they complained. By bringing such matters forcibly before the public, and enlisting its sympathies in the cause, the best chance was afforded of ultimately giving effect to their views. Many of the things which the Association had observed had not taken him by surprise, for cases had often, too often, arisen in these houses and come before the Board showing that the Hospital arrangements of the houses were still very defective, and, indeed, he was not indisposed in consequence to agree substantially with the terms of the resolution passed at the meeting. As far as he understood the subject—for to understand fully almost required a Professional knowledge—he believed the resolution to be true, and saying this it was hardly necessary to add that it was a state of things which ought not in his opinion to continue, and in which great change was required. Referring to the statements which had been made with respect to the inquiry instituted by the Board, he assured the deputation that it had been instituted for the purpose of placing the Board in the official possession of facts with regard to London Workhouse Infirmaries, so as to be prepared to lay them fully before the Government and the Legislature if opportunity should offer. The fact that the inquiry was being carried out by Dr. Smith, who was eminent in his Profession, and by Mr. H. B. Farnall, the well-known Poor-law Inspector for the metropolis, was a guarantee that the inquiry would be full and impartial. An inquiry had certainly been made, but it was, in one sense, private in its character—he alluded to that instituted by the proprietors of the *Lancet*. He begged to say that he had never questioned the capacity or the good faith of the gentlemen who had made that inquiry, and he had yet to learn that there had been any overstatement in the cases they had apparently established. He feared, however, that the difficulty in this case was not so much in getting at the truth as in giving effect to the remedy suggested. He was certainly not prepared to dispute the conclusions to which the deputation had arrived, and the remedy proposed was, he understood, that there should be six separate Hospitals for the sick at present lodged in the metropolitan Workhouse Infirmaries. The meeting must not lose sight of the fact that such a scheme involved a great change in the principle upon which the poor were now maintained in this country. That charge was now local, and the administration of the law was in the hands of those who contributed locally to the fund out of which the poor were relieved, whereas this scheme would treat the sick poor as belonging to the whole metropolis, and the expenses of raising the buildings and maintaining the Hospitals would be charged on the whole property of the metropolis. He did not say it would be wrong on that account, or that the system of local management for the purposes of the poor had been faultless; but the system was one of which the community was extremely tenacious, and there would be considerable difficulty in suspending it even in this city, where the adoption of a more general system would appear to be so reasonable, and if it were clearly proved that a change was essential for the proper treatment of the sick poor he did not say that it might not become even popular, especially if it were proved that the defects under the present system were irremediable. There had always been a difficulty as to the hands in which the administration of the Poor-law should be placed, and the great dread of the Legislature had been that there would be a lax and wasteful expenditure, injurious to property, and tending to the promotion of pauperism, if the administration was not in the hands of those directly interested in the economy of the funds, and the guardians were chosen for this purpose. Some guardians, he acknowledged, performed their duties with judgment and humanity; but as the chief duty which they had to perform was what was termed "to keep down the expenditure," it was somewhat of a chance when guardians were found possessing all the qualities required for a wise administration of the law. The right hon. gentleman proceeded to deal with the other facts of the case, and said he thought that if the House of Commons could be prevailed upon to alter the present system of rating in the metropolis, it would do so for the sick poor, and have a general rate, as in the case of the casual poor. He concluded, amid loud cheers, that, though he could not pledge the Government in the matter, he could assure the deputation that nothing should be wanting on his part in recommending the propositions for favourable consideration.

The deputation thanked the President, and withdrew.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on Monday, April 16, 1866, the following gentlemen having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Thomas Thornely Brooke, Stockport; George Carr Dunn, 17, Stanley-gardens, W.; Henry James Ellery, St. Stephen's by Saltash, Cornwall: John Cooper Garman, Wednesbury, Staffordshire; Richard Samuel Purnell Griffiths, 11, Dudley-place, Harrow-road, W.; George Augustus Hicks, Torquay; William Hoffmeister, M.D., Heidelberg, Cowes, Isle of Wight; Jordan Roche Lynch, 12, Horbury terrace, Notting-hill, W.; George Monlas Slaughter, Fort Pitt, Chatham; Thomas Wise, Castletown, Isle of Man.

At the same meeting the following were reported by the Examiners to have passed their Primary Examination:—

Robert Vacy Ash, St. Mary's Hospital; George William Barroll, St. George's Hospital; George Earp Burton, Liverpool; Edward Noble Edwards and William Betts Giles, Guy's Hospital; Thomas George Palmer Hallett, University College; Richard Clement Lucas, Guy's Hospital; Wm. Gordon Maddox, University College; John Aaron James Timmins, St. Bartholomew's Hospital; John Greaves Wiseman, Guy's Hospital.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.—The under-mentioned gentleman passed his Examination in the Science and Practice of Medicine, and received certificate to practise on Thursday, April 12, 1866:—

Harry Burrill Glaister, Southwell, Notts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 17th inst, and when eligible will be admitted to the Pass Examination:—

Messrs. Lancelot Newton, W. T. Thurston, Charles Wade, E. R. Evans, W. W. Saul, J. M. Kirkman, and H. T. Butlin, Students of St. Bartholomew's Hospital; Edward Colson, J. A. Sharp, Benjamin Walker. T. J. Burroughs, J. R. Morgan, and Henry Gould, of Guy's Hospital; J. F. P. McConnell and Leonard Smith, of St. George's Hospital; Joseph Gabe and G. E. Norton, of the Middlesex Hospital; William Little and H. E. Juler, of St. Mary's Hospital; Joshua Duke and A. C. Air, of St. Thomas's Hospital; R. L. Sheffield, of the London Hospital; Rowland Heathcote, of Manchester; Henry Bland, of King's College; J. R. Fielding, of Leeds; J. B. Ryley, of Dublin; and Samuel Pidwell, of University College.

The following passed on the 18th inst., namely:—

Messrs. B. W. Chapman, Clifford Crewe, J. F. Goodhart, J. F. Codrington, and P. T. Scott, Students of Guy's Hospital; G. A. Woods, Peter Ryder, J. E. Burton, and Alfred Trubshaw, of Liverpool; J. R. Lazenby, Charles Aldridge, and Charles Richardson, of Leeds; T. H. Pinder, J. T. Fox, and A. O. McKellar, of Manchester; Edward Young, George Amsden, and Walter Hart, of King's College; Alfred Pern. C. W. Milne, and Frederick Pollard, of St. Thomas's Hospital; Reginald Bayley and F. B. Besly, of the Charing-cross Hospital; J. W. Blandford and Robert Laing, of Newcastle; Samuel Alford and E. W. Minter, of University College; W. H. Wood, of St. Mary's Hospital; Joseph Massingham, of the London Hospital; Arthur Atkinson, of Hull; Henry Case, of the Middlesex Hospital, and T. H. Hickman, of St. Bartholomew's Hospital.

The following passed on the 19th inst:—

Fred Wallace, Albert Williams, John Webb, George Mason, T. C. H. Spencer, Alfred Ashby, J. R. Hughes, and W. R. Cortis, students of Guy's Hospital: Joseph Wharton, Thomas Fawsitt, J. G. Blackley, F. M. Pierce, Thomas Greenhalgh, and W. H. Middleton, of Manchester; W. A. Hunt, Fletcher Beach, W. J. G. Bedford, and R. H. Prior, of King's College; John Orton, J. H. Humphrys, T. P. Davies, and James Brown, of Birmingham; William Swan, B.A. Oxon, W. W. G. Stables, and W. D. Butcher, of St. Bartholomew's Hospital: M. W. W. Chorley and J. T. Gobat, of Leeds; Richard Hughes, of Liverpool: R. L. Roberts, of University College; and Alexander Fox, of the London Hospital.

It is stated that out of the 108 candidates who offered themselves for examination, nineteen failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their studies for three months.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 12, 1866:—

John Lorimer, Carlton-hill, St. John's-wood; Thomas Bailey, 4, Gough-street North; Thomas Bell Hay, 43, Caledonian-road, N.

The following gentleman also on the same day passed his First Examination:—

J. A. J. Timmins, St. Bartholomew's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

GODFREY, FRANK, L.R.C.P, L.R.C.S., L.M. Edin., has been appointed Assistant-Surgeon to Her Majesty's Convict Prison Hospital, Gibraltar.

HECKMAN, W., M.D., has been appointed Surgeon for Out Patients to the Samaritan Free Hospital for Women and Children, Edward-street, Portman-square.

JUNKER, F. E., M.D., has been appointed a Physician for Out Patients to the Samaritan Free Hospital for Women and Children, Edward-street, Portman-square.

KARKEETH, P. Q., M.R.C.S.E., has been appointed House-Surgeon to the General Infirmary, Chester.

TAYLOR, J., M.R.C.S.E., has been appointed Assistant House-Surgeon to the General Infirmary, Chester.

BIRTHS.

DAVIDSON.—On April 7, at 8, Devonshire-place, Wandsworth-road, the wife of C. M. Davidson, M.R.C.S.E., L.S.A., of a son.

HARVEY.—On April 15, at 5, Avenue-villas, Belsize-park, N.W., the wife of F. Harvey, Staff Surgeon R.N., of a son.

HICKMAN.—On April 11, at 1, Dorset-square, the wife of W. Hickman, M.B., F.R.C.S., of a son.

LANGFORD.—On April 14, at Knackersknowle, Devon, the wife of E. C. Langford, M.R.C.S.E., of a son.

MASON.—On April 14, at Woolwich, the wife of R. Mason, F.R.C.S., of a daughter.

NOYES.—On April 14, at Lee, Kent, the wife of H. G. Noyes, M.D., M.R.C.P. Lond., of a son.

ROSE.—On February 22, at King William's Town, Cape of Good Hope, the wife of H. J. Rose, Staff Assistant-Surgeon, prematurely, of a daughter.

SHEPPARD.—On April 7, at Ashford, Kent, the wife of William Sheppard, M.R.C.S.E., of a daughter.

WATTS.—On April 13, at 23, Westbourne-park-terrace, the wife of A. J. Watts, L.R.C.P. Edin., of a daughter.

WILMOT.—On April 2, at Merrion-square North, Dublin, the wife of S. G. Wilmot, M.D., of a daughter.

MARRIAGES.

CROSBY—PLATT.—On April 12, at St. Mary's, Oldham, William Crosby, M.R.C.S., to Elizabeth, daughter of the late H. Platt, Esq.

WILSON—WOTHERSPOON.—On April 11, at 124, Blythswood-terrace, Glasgow W. A. Wilson, M.D., C.M., to Jeannie Erskine, daughter of John Wotherspoon, Esq.

WINTLE—MACKINLAY.—On April 12, at St. Barnabas, West Kensington, R. P. Wintle, M.R.C.S.E., to Catherine, youngest daughter of the late John Mackinlay, M.R.C.S.

DEATHS.

BOGG, JOHN, M.R.C.S., at Louth, Lincolnshire, on April 15, aged 66.

BRAITHWAITE, W., M.R.C.S., at Stoke Damerel, on April 9, aged 43.

CLARKE, E. S., M.D., M.R.I.A., at Richmond-hill, Dublin, on April 3.

HARRISON, G., F.R.C.S., of 65, Grosvenor-street, on April 12, aged 60.

HODGES, F. S., M.R.C.S., at 84, Brompton-road, April 12, aged 43.

MAY, W. H., M.R.C.S., at St. Martin's, Leicester, on April 9.

PARSONS, W. A., M.R.C.S., at Leamington, on April 4, aged 65.

SCOTT, W., M.D., at Greenwich, on April 12, aged 41.

SEYMOUR, E. J., M.D., F.R.C.P. Lond., at 13, Charles-street, Berkeley-square, on April 16, aged 70.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Wolverhampton Union.—The Second District is vacant; area 807; population 12,800; salary £54 8s. per annum.

APPOINTMENTS.

Alnwick Union.—George W. Turnbull, M.D. Edin., L.R.C.S. Edin., to the Warkworth District.

Liverpool Parish.—Edward Adam, M.R.C.S.E., L.K. and Q. Coll. Ire., to the Fifth District; Samuel John B. Caldwell, M.R.C.S.E., L.R.C.P. Edin., to the Sixth District.

Plymouth Incorporation.—Josiah Oake Adams, M.R.C.S.E., L.S.A., to the Third District.

Redruth Union.—Thomas S. Reed, M.R.C.S.E., L.S.A., to the Workhouse.

St. Saviour's Union.—Henry John Thorp, L.R.C.P. Edin., M.R.C.S.E., L.S.A., to the St. Saviour's District.

Sleaford Union.—George John Blasson, M.R.C.S.E., L.S.A., to the Heckington District.

Sunderland Union.—Charles N. Foote, M.R.C.S.E., L.S.A., M.D. St. And., as Assistant Medical Officer for the Workhouse.

West Derby Union.—James V. Worthington, L.R.C.P. Edin., L.R.C.S. Edin., L.S.A., to the Garston District.

CHRIST'S HOSPITAL.—The salaries paid to Medical officers in London, and to the Surgeon and Apothecary at Hereford, amounted to £745.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on the 10th inst., Sir E. Hilditch, Inspector-General, in the chair, the sum of £70 was distributed among the various claimants.

THE PUBLIC MEDICAL SERVICES.—The Profession, and especially the Military and Naval officers, will be glad to learn that the Lords Commissioners of the Admiralty have just received a copy of the following resolution passed unanimously at a meeting of the Council of the Royal College of Surgeons of England on the 13th inst.—viz., Resolved, "That the Council, in acknowledging the receipt from the Secretary to the Admiralty of the Report of the Committee appointed to inquire into the whole question of the rank, pay, and position of the Medical officers of the Army and Navy, beg to express to the Lords Commissioners of the Admiralty, the Secretary of State for War, and His Royal Highness Commanding-in-Chief their cordial concurrence in the recommendations contained in that Report, and their belief that those recommendations, if fully carried out, will obviate the objections at present felt to entering the Medical Service of the Army and Navy. That the Council further desire to express their opinion that the adoption of these recommendations will induce a better educated class of Medical candidates to seek admission into these services than hitherto, and will thereby tend to promote the health and efficiency of Her Majesty's Military and Naval forces." It remains to be seen whether these recommendations will be carried out by the heads of the respective departments of the public Medical services.

UNIVERSITY COLLEGE HOSPITAL.—The annual dinner of the North London or University College Hospital was held on Wednesday evening at Willis's Rooms, when the Duke of Cambridge presided over a large assembly. After the usual loyal and patriotic toasts had been duly honoured, his Royal Highness remarked, in proposing the toast of the evening, that the annual expenditure incurred in maintaining the Hospital was £6500; but the subscriptions did not amount to more than £1000 a year, and, although the Physicians and Surgeons made a donation to the charity of the fees they received from the students who walked the Hospital, yet a deficit was left of nearly £4000, to meet which the public was appealed to. He regretted that the response to this appeal did not permit of the maintenance of a sufficiently large permanent staff, nor could the Committee receive into the Hospital as many patients as their wards would permit. Nevertheless, the Hospital had done great good. 1396 in-patients and 10,415 out-patients were attended to during the past year; relief was given in 1446 ophthalmic cases, and nearly 12,000 casualties were attended to. His Royal Highness also observed that he had recently inspected the Hospital, and could bear personal testimony to the excellent way in which it was conducted. He especially referred to the nursing arrangements, which were conducted by the sisters of All Saints' Home. In doing so he extolled those ladies for their self-denial, and expressed his conviction that the good they did, not only in connection with the physical, but also the mental ailments of the patients, was incalculable. In proposing the toast of the Army and Navy the noble duke assured his hearers that the most cordial feeling existed on the part of the army to the Medical Profession, and

he trusted that a reciprocal feeling would be exhibited in the shape of a large number of efficient candidates for the post of Army Surgeons. It was announced in the course of the evening that a legaey of £2000 had been left to the institution by the late Mr. Goldsmid. The subscriptions amounted to £1500.

Beneficence.—The funds of some of our metropolitan Hospitals will be seasonably augmented under the wills of the following gentlemen, viz.:—Captain John Moore, R.N., C.B., who has bequeathed to St. George's, the London, and Royal Free Hospitals, £500 each; John Palmer, stock-broker, of Maida-hill, has left £100 to St. Mary's Hospital, Paddington; Mr. John Goodwin Marner, the well-known coach-builder, of Oxford-street, has bequeathed £3000 to the Convalescent Hospital at Weybridge-heath, towards building a new wing to that institution, and £50 each to such fifty charitable institutions as his executors may select. The executors of the late Duke of Northumberland, finding that his grace had not drawn his pension for some years as an Admiral in the Royal Navy, made application for the amount, and handed over the sum to the present Duke, who has generously bestowed the whole amount in charity, giving to the *Dreadnought* Seaman's Hospital Ship, off Deptford, the sum of £2000, and the remaining £5000 to other charities connected with the mercantile marine.

Successful Action for Damages against one of the "Anatomical Museum" Fraternity. — Young *v.* Hamilton—(Bail Court, before Mr. Justice Mellor and a common jury).—Mr. Ribton and Mr. Besley were for the plaintiff. The defendant did not appear, either in person or by counsel. The action was brought to recover compensation for impaired health, in consequence of the defendant falsely representing that he was a regular Doctor, and thereby inducing the plaintiff to employ him as a Medical man. In the other counts it was alleged that the defendant had carelessly and negligently treated the plaintiff, and had guaranteed to cure him of a disorder under which he suffered. The plaintiff, an agricultural labourer, who had saved a little money, visited an anatomical museum in Oxford-street, and was persuaded by the defendant, who described himself in a "Guide to Health" as "John Hamilton, M.D., Doctor of Medicine and Surgery, Lecturer on Physiology, Accoucheur, and author of the 'Botanic Essay and Family Physician,'" to submit to his treatment. He paid at first £5 5s. and then £6 6s., and the defendant, stating that he had underestimated the case, and should have charged any one but a poor man between £40 and £100, wanted to obtain a further sum of £9. The plaintiff then went to Mr. O'Donohue, a regular Practitioner, in the Westminster-bridge-road, and some two months elapsed before the ill-effects of the defendant's treatment could be eradicated. The poor fellow had been salivated, and rendered incapable of earning his livelihood by his daily labour for the space of several months, besides having to pay £10 for the necessary Medical aid which his state of health required. The jury found a verdict for the plaintiff—damages £60.

Sussex and Brighton Medico-Chirurgical Society, and the Proposed Vaccination Bill of 1866.—At a special meeting of this Society, held on April 11, 1866, it was resolved that:—1. This Society decidedly approves of compulsory vaccination. 2. This Society would urge that, in consideration of the knowledge and care required of the Medical man in practising vaccination in the safest and most efficient manner, and of the amount of his time which must be consumed in filling up and signing so many certificates and returns, the fees of eighteenpence and two shillings and sixpence respectively proposed in Clause 5, should be increased to two shillings and sixpence and three shillings and sixpence. 3. This Society would urge that the Bill should provide for every Medical Practitioner (when not acting as a public vaccinator) being entitled to charge a fee to any parent or other person for every certificate that he may be required to give. (See Clauses 17 to 19, 22, and 28.) 4. This Society would recommend that Clause 31 should be made more stringent by rendering it imperative that every parish, or Union, should provide a special and proper vehicle for the removal of the infected, which vehicle should also be obtainable on hire by any private individual for the like purpose. 5. That a copy of these resolutions, signed by the President, be forwarded by the Honorary Secretaries of the Society to Mr. Bruce and Mr. Baring (the promoters of the Bill), and to the members of the borough and of the county, accompanied with a request that they will all give them their gracious and best consideration and support.—Signed, on behalf of the Society (containing eighty-five members), by G. F. Hodgson, President. Brighton, April 11, 1866.

King and Queen's College of Physicians in Ireland.—On Friday, the 5th inst., at the quarterly meeting of the President and Fellows, Dr. Wynne Foot was duly elected a Fellow. Dr. Foot is well known to the Profession as a frequent contributor to its Medical literature. He was one of the Commission recently sent to England by the Irish Government to investigate and report on the Cattle Plague. He is Assistant Reader in Anatomy in the University of Dublin, where he graduated B.A. and M.B. in 1862 and M.D. in 1865. He was admitted a Licentiate of the College of Physicians in 1862. Licences to practice Medicine were granted to the following gentlemen during the months of January, February, and March, 1866:—Wm. Walsh, F.R.C.S.I. 1865, L.R.C.S.I. 1860, Kilmuckridge; David Moore, M.R.C.S. Eng. 1859, House-Surgeon, Belfast Hospital; Patrick Walter Tuite, L.R.C.S.I. 1865, Dublin; Patrick Brady, L.R.C.S.I. 1865, county Cavan; Joseph Irwin Welsh, L.R.C.S.I. 1865, county Donegal; Samuel Henry Banks, L R.C.S.I. 1865, Wicklow; Charles Fryer, Lancashire; Stephen McDermott, L.R.C.S.I. 1865, Roscommon; John Fagan, L.R.C.S.I. 1865; Edward Aloysius Stephenson, L.R.C.S.I. 1865, Kilkenny; James Stirling, L.R.C.S.I. 1866, county Kilkenny; William Longworth Watkins, L.R.C.S.I. 1866, Dublin; Edward William Adrian, M.R.C.S. Eng., county Dublin. To the following gentlemen Midwifery Diplomas were granted during the same term:—Rowan Purdon, L.K.Q.C.P. 1864, Tralee; David Moore, L.K.Q.C.P.I., Belfast; P. F. McGlorin, M.D., Queen's Univ. 1863, county Mayo; J. Urwin Welsh, L.K.Q.C.P. 1866, Ballyshannon; John Fagan, L.K.Q.C.P., L.R.C.S.I., 1865; Edward Aloysius Stephenson, L.K.Q.C.P., L.R.C.S.I, 1865, county Kilkenny; James Stirling, L.K.Q.C.P., L.R.C.S.I. 1866, county Kilkenny; William L. Watkins, L.K.Q.C.P., L.R.C.S.I. 1866, Dublin.

Verdict of Manslaughter against an Amateur Prescriber.—Mr. Taylor, coroner, resumed an inquiry on Tuesday, at the Coopers' Arms Inn, Wakefield, relative to the death of Mr. Joseph Newsom, innkeeper, who had been poisoned under unusually distressing circumstances. Mr. Newsom for some weeks past had been suffering from a bad cold, which caused him very restless and sleepless nights. On Saturday night he was talking to the company at his bar about the trouble his illness gave him, and a young man named Rigg went away, saying that he would get him something that would do him good. He shortly afterwards returned with a bottle containing about six ounces of a light-coloured watery fluid, and told Newsome to take half that night, and half the next morning. Newsome followed the instructions given, became very drowsy, wandered very much during the night, and was so dangerously ill next morning that Mr. Kemp, Surgeon, was sent for. The Doctor, however, arrived too late to be of any service, the deceased shortly afterwards undergoing every symptom of death from the effects of a narcotic poison. A chemist and druggist named Dennison stated that Rigg came into his shop on Saturday, and asked for five or eight grains of quinine and six or eight drachms of opium. Witness told Rigg that half a drachm was a full dose under ordinary circumstances, but in such cases as delirium tremens a Medical man might administer more. Rigg said the person for whom he wanted the medicine was labouring under some such complaint, and the witness added two and a-half drachms of laudanum to the quinine, and filled the bottle up with water. At Rigg's request he put a label on the bottle, giving directions for three tablespoonfuls, or about a quarter of the contents, to be taken every three hours. When Rigg returned to the publichouse the bottle had no label upon it, and instead of following the directions of the druggist, and giving Newsome a fourth of the bottle's contents, he told him to drink off half. As regarded the statement of Rigg that the person for whom he intended the potion was suffering from delirium tremens, it was proved that Mr. Newsom had had nothing but tea and coffee on Saturday, and had not tasted three glasses of malt liquor or spirits for a month. The jury returned a verdict of "Manslaughter" against Rigg, but the Coroner admitted him to bail.

Workhouse Infirmaries.—At a meeting of the guardians of St. George's, Hanover-square, held on Wednesday, the appointment of Mr. H. B. Farnall, C.B., together

with Dr. Smith, to visit and report upon the state of the metropolitan workhouse Infirmaries, was discussed at great length. On the motion of Major Lyon, seconded by Mr. Westerton, it was unanimously resolved that the clerk should write to the President of the Poor-law Board, stating that, while the guardians of St. George's, Hanover-square, cordially concurred in the advisability of the proposed inspection, and had every confidence in Dr. Smith, they at the same time begged to protest most earnestly against the appointment of Mr. Farnall on the Commission. Mr. Farnall had, in the most emphatic manner, already condemned the mode in which the London guardians and their officers administered Poor-law relief; he had denounced the treatment of sick paupers, both indoor and outdoor, and he had further stigmatised the guardians as being of a low *status*. Having, therefore, come to a foregone conclusion on the matter, Mr. Farnall was not, in their opinion, the man that should be selected for the duty, nor did the guardians consider he would approach the subject in the impartial spirit that was absolutely necessary for the elucidation of the truth. The guardians of St. George's, therefore, trusted the Poor-law Board would substitute an unbiassed gentleman to accompany Dr. Smith in his visits. One of the guardians here said, that in order to ascertain how far Mr. Farnall was supported by the Poor-law Board in his sweeping condemnation of the metropolitan guardians, he would rise in his place in the House of Commons and put a pointed question to the President of the Poor-law Board on the subject. He would also ask his colleagues, who were vestrymen and guardians of the parish, and who also had seats in Parliament, numbering about a dozen, to support him in endeavouring to ascertain further whether Mr. Farnall's private statements made by him to the Association for the Improvement of Workhouse Infirmaries, and which were printed and circulated, met with the sanction of the Poor-law Board. This announcement gave every satisfaction, and the guardians separated with the expressed determination that their character as guardians of St. George's, Hanover-square, should not be trifled with by any person, be he archbishop or Poor-law Commissioners.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked.			2. Result of reported Cases from the Commencement of the disease.

Note.—62 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Buckingham, 1; Cambridge, 3; Chester, 1; Hertford, 1; Huntingdon, 2; Lancaster, 5; Lincoln, 6; Norfolk, 3; Northampton, 3; Northumberland 1; Salop, 1; Stafford, 1; Suffolk, 1; Surrey, 1; Yorkshire, 15; Metropolitan District, 7; Flint, 2; and Scotland, 8. These Inspectors returned 594 cases last week.

TREATMENT OF FEVER BY ALCOHOL.—I have, however, ascertained that 534 cases were treated with wine or spirits during some part of their illness, and out of this number 138 died. On the other hand, 491 were treated without any alcoholic stimulants, with only 9 deaths. From the much higher rate of mortality amongst the former than amongst the latter, I would caution any one against drawing the conclusion that the greater relative number of deaths was at all influenced by the administration of the stimulants. All the inference that I think may be deduced from those numbers is, that a large proportion, say fully one-half, of the cases of typhus in the present epidemic, may be advantageously treated without any alcoholic stimulants. Doubtless a considerable number of those who got wine or spirits would have recovered without a drop of either, but I am satisfied that, in many of them, the risk of a fatal issue would have been much increased, and the patients would have had a much more tedious convalescence. Of 245 patients below 15 years of age, only twenty-nine had any alcoholic stimulants, and several even of that small number had only very small quantities, and for only a few days. The state of the cardiac and radial pulses, as pointed out by Dr. Stokes, is the best guide for the administration of alcohol; and, as I before mentioned, the time for giving and the quantity required must be regulated by it in each individual case.—"*Observations on the Present Epidemic of Typhus,*" *by Robert Perry, M.D., Physician to the Royal Infirmary, Glasgow.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

J.L., M.D.—It is an impudent assumption of the title.

Mr. H. Gardiner.—One drop of Condy's solution of permanganate of potass to a gallon of water, then stir with a stick.

L.R.C.P. London.—1st. Yes, but not if you practise pharmacy. 2nd. Doubtful. 3rd. Not M.D.

A Student.—Registration at the College twice annually; at the Hall three times.

A Metropolitan Student.—The examination takes place this day. The questions can be obtained on application to the Secretary.

Mr. Latham.—You will find nearly perfect skeletons of those extinct birds the dodo and the great auk in the British and Hunterian Museums.

A Member will see in another page that the award has been made. The subjects for the Jacksonian prize for 1867 will be announced shortly. Write to the Secretary.

Dr. Montgomery, York.—You cannot consult a better work on the subject of your inquiries than Atkinson's "Medical Bibliography." It is an admirable work, which the author only lived to carry to letter B, calling it his A B. performance. The dedication is as quaint as the notice of Albinus,—viz., "To all idle Medical students in Great Britain, Sit," and here follows a drawing of the "*sacrum.*"

Prehistoric Remains.—A great deal of interest was excited last year by the discovery of certain "prehistoric remains," human bones, flint implements, and so forth, by Mr. Laing, in mounds at Caithness. The learned interpretations of Professor Huxley and Professor Owen were sought and obtained. The peculiar construction of the mounds was elaborately described by Mr. Laing, the adult skeleton was pronounced to have ape-like peculiarities, and the jawbone of an infant which was submitted to Professor Owen was said to have certain marks which were painfully indicative of the cannibalistic habits of our prehistoric progenitors. The Ethnological and Anthropological Societies had rival discussions, and a great deal of erudite dissertation and debate took place which is preserved in print. At the last meeting of the former society it was broadly stated by several persons who had since examined these mounds that not any of them contain any traces of prehistoric age. The harbour mound is composed almost entirely of limpets, and the churchyard mound of periwinkle shells. The harbour mound contained a pair of weaver's shears, and was itself the ruins of a common corn kiln of the country. The stone implements were said to be chips such as may be collected by the barrowful. The Birkle Hills, instead of being places of worship and sacrifice, were thought to be natural hillocks of blown sand, which had served as the rendezvous of country folks on occasion of wrecks. The ape-like skeleton is declared to be the remains of a Danish seaman, and the jawbone of the child which afforded indications of cannibalism to have been borrowed from a neighbouring churchyard. Coins are said to have been found among these "prehistoric" remains belonging, not to the age of the great auk, but to the reign of William III. The controversy of the authenticity of the Abbeville jawbone will probably fade before the battle over these mounds at Keiss. Science will grieve and orthodoxy will rejoice at these widely differing interpretations.—*Pall-mall Gazette.*

POOR LAW MEDICAL REFORM AND VACCINATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me, through the medium of your columns, to say a few words on the subject of the Vaccination Bill, which most of your readers are now aware has been referred to a Select Committee of the House of Commons. A Member of Parliament in writing to me on the subject said, "By this morning's papers you will see the fate of the Vaccination Bill, which had not a single friend in the House." Yet this very Bill had passed a second reading without a single word being said against it, proving most incontestably that the check given to a Minister of the Crown is due to our Profession, and in no small degree to our Association, which, so far as I know, was the only body that sent a pamphlet on the subject to each Member of Parliament. I have written to the Select Committee requesting to be allowed to give evidence, and I trust other gentlemen will do likewise.

I am, &c., RICHARD GRIFFIN.

Condy's Fluid.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The deep regret which is universally felt at the death of Dr. Hodgkin can hardly but be increased by the circumstance that, as stated in your last number, the cause of that lamentable event was apparently a preventible one. There is little doubt in my mind that if Dr. Hodgkin had been fully aware of the importance of the permanganate water test, as first practically introduced by me, and of my plan of freeing water from organic contaminations, he might have avoided the danger to which he seems to have fallen a victim. But even those who have not yet made acquaintance with Condy's Fluid as a disinfectant and general domestic purifier, would be greatly advantaged by being informed that Condy's Fluid is the most readily available source of the permanganates, because it is infinitely easier to be met with than the pure chemical salt, which, though now in the Pharmacopœia, is still kept by comparatively few chemists in this country, and perhaps by hardly any in India and the Colonies.

Independently, however, of these reasons, I have no hesitation in saying that those who consider they are doing good by commending the sanitary properties of the alkaline permanganates, are bound in all fairness to bear in mind what is due to the individual who not only discovered them, but, at the time when those salts were most expensive and inaccessible, ran the risk of undertaking their manufacture on the large scale, and thereby putting them within the reach of the public.

I will take this opportunity of calling attention to the important fact that the permanganates, in extremely small quantity, not only completely free water from organic impurities, but also from the metal lead, by converting that substance into peroxide, which is its most insoluble form. An account of the experiment by which this is proved and others relating to the purification of water, will be found in my published treatise on "Air and Water."

In conclusion, I would beg to observe that the extremely favourable results obtained from the internal administration of Condy's Fluid in Asiatic cholera, as shown in one of the tables of the rates of mortality of various treatments given by Dr. Howard B. Montgomery, in the letter of his which you published on the 10th of March last, are no doubt due to the chemically antidotal properties of the permanganates to effete and foul organic substances of every kind, and seem to me for this reason particularly deserving of the attention of the Profession.

I am, &c.,

Battersea, April 10. H. B. Condy.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·710 in. The barometrical reading increased from 29·17 in. on Wednesday to 29·96 in. at the end of the week.

The general direction of the wind was S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 42·4°.

APPOINTMENTS FOR THE WEEK.

April 21. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. G. Scharf, Esq., "On National Portraits."

23. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

24. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Ethnological Society of London, 8 p.m. John Thrupp, Esq., "On the British Superstitions relating to the Hare, the Goose, and the Fowl." Thomas Wright, Esq., "On the Intercourse of the Romans with Ireland."

Royal Medical and Chirurgical Society, 8½ p.m. Dr. John Harley, "On Hydatid Disease of the Liver." Also, if time, Papers by Mr. Toynbee or Mr. Durham.

Royal Institution, 3 p.m. Rev. Chas. Kingsley, "On Science and Superstition."

25. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

26. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Rev. Chas. Kingsley, "On Science and Superstition."

27. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. The Very Rev. the Dean of Westminster, "On Westminster Abbey."

ORIGINAL LECTURES.

ON

MECHANICAL DISEASES AND THE SECONDARY CHEMICAL DISEASES THEY PRODUCE.

By H. BENCE JONES, M.D., F.R.S.

Part V.—Lecture XII.

In my previous lectures I have shown you that chemical diseases are the parents of mechanical diseases, and I have frequently had occasion to point out how a secondary mechanical complaint sets up a more serious tertiary chemical disease than the primary chemical wrong, of which renal or biliary calculus are two most striking examples. I shall now endeavour once more to bring before you the compound or mechanico-chemical or chemico-mechanical nature of the actions in disease by taking an illustration or two from a vast number of instances which, in the subdivision of labour, fall under the care of the Surgeon instead of the Physician.

If I were a Surgeon, I could give you a long course of lectures on mechanical diseases and the secondary chemical diseases which they produce, and on mechanical treatment and on the consequent beneficial alterations thereby produced in the chemical actions going on in the body.

The purest portion of pure Surgery consists in the treatment of mechanical accidents and the increased or diminished chemical actions produced by the mechanical wrong. How important the relationship of the chemical to the mechanical effects is, may be seen in the fact that Surgical accidents would, speaking generally, be free from danger, if it were not for the secondary chemical actions which necessarily come out of them and often rise to fatal diseases.

I might take my illustrations from fractures of the bones or from rupture of the tendons, vessels, or membranes; or from dislocations, as of the joints or viscera, as in hernia; or from wounds, as of the skin, vessels, muscles, or nerves.

By any of these different mechanical accidents, I might show you the danger of secondary chemical disease, and if it were desirable to extend this long list of mechanical disturbances, I might take parturition, with all its accidents and consequences, to prove the origin of chemical from mechanical complaints.

You must not suppose that in this lecture I take my illustrations from Surgery and Midwifery, because Medicine will furnish me with no examples sufficiently striking to be brought before you; on the contrary, in Medicine also mechanical complaints abound—Medical accidents, if I may so call them, among which I may mention obstructions, hæmorrhages, ruptures of valves connected with the heart, causing dilatation and hypertrophy; dilatation of the veins; emphysema of the lungs, and many other diseases. In addition to the Surgical accidents, I shall bring before you one or two of these sudden or slow Medical accidents to prove to you the connexion of mechanical with chemical disease, or, if you please, of Surgery with Medicine.

From the immense variety and amount of mechanical diseases to which he ministers, and from the greater use he makes of mechanical remedies, the Surgeon may be regarded as the mechanical Physician; but in consequence of the secondary chemical diseases that are set up, he requires the same knowledge of chemical remedies as the Physician who, in the treatment of disease, can use comparatively no mechanical remedies whatever, except rest. This comparative limitation to one class of remedies enables the Physician to become more skilled in their use against the innumerable multitude of chemical diseases that he is called upon to treat.

My first illustration of the production of chemical disease by previous mechanical action will be taken from a compound fracture of the leg,—in other words, fracture of the bone, with laceration of the muscles, blood-vessels, and skin at the same time. When the same amount of injury is done to the bone, muscles, and blood-vessels, the skin remaining unhurt, the accident is, comparatively speaking, slight. Hence the amount of mechanical injury cannot be the cause of the seriousness of the compound fracture, for a broken skin could not in itself make the difference of danger between a simple and a compound fracture. The difference really consists in the secondary chemical diseases which are set up in the two accidents. In the simple fracture, when perfect rest is possible, moderate peroxidation and pertrophic action only occur, and generally no formation of pus takes place. In the compound fracture the admission of the air to the injured parts is sure to determine excessive local peroxidation, and pus is much more likely to be formed, and this suppuration from the position of the wound, and from the access by the air of infusorial germs, or from the peculiar condition of the albumen, rapidly sets up decomposition. A state of general peroxidation is readily produced in the system, and not unfrequently the pus enters the blood, and becomes itself a species of ferment, modifies the peroxidation in the system, and, when it lodges mechanically (embolically) in different organs, it there becomes the nucleus and cause of a local modified peroxidation, which gives rise to secondary abscesses wherever the lodgment is effected. Hence increased oxidation and altered nutrition is the chemical complaints produced by this mechanical accident.

The first and most necessary part of the Surgeon's treatment is to put the fracture in that position in which no fresh mechanical disturbance can take place; then, by chemical means, lotions, and diet, he lessens or increases the chemical action, and day by day he carefully removes the foul matter, which is apt to become a chemical poison, and then not only interferes with the healing process, but, if absorbed, poisons the whole system.

If the general peroxidation is excessive, and if the drain of matter endangers life, the Surgeon is obliged to use mechanical instead of chemical treatment, he removes the limb with the knife. Thus a clean surface is gained instead of a foul one, and chemical and mechanical irritation is removed, and moderate oxidation and nutrition soon close the wound.

My second illustration of the production of chemical disease by a mechanical action will be taken from dislocations. A dislocation is a mechanical misplacement, as, for example, of the bones; but it may also occur in the viscera, as with the uterus or the bowels. In this last instance it constitutes hernia.

In all severe dislocations of the joints the mechanical injury that is done to the parts around the joint causes more anxiety to the Surgeon than the misplacement of the bones. The capsule, the ligaments, the vessels in the neighbourhood, may be so injured that violent inflammation may be set up; in other words, great alteration of the chemical actions of oxidation and nutrition around the joint may occur. The motion may be completely lost either by the formation of pus within the joint, or it may be only more or less hindered by the effusion of lymph in the surrounding textures.

When the dislocation accidentally remains unreduced the mechanical pressure may cause so much inflammation that the displaced bone may become so fixed that no motion may be possible.

When the Surgeon is called to remedy the accident, he applies mechanical force in the opposite direction to that force that caused the dislocation. He counteracts the displacing force, the tension of the muscles and the contraction of the tendons, and then, by rest and by remedies, cold lotions, salines, and aperients and diet, he tries to prevent the occurrence of increased chemical action.

He saves the joint, and ultimately the use of the limb is restored. Whilst if the dislocation has been neglected, he counteracts a very small part of the original mechanical injury and of the results of the chemical actions set up around the displaced bone by means of constant and long-continued mechanical motion of the limb, whereby a greater or a less amount of motion by means of a false joint is obtained.

But you will see better in a case of hernia how chemical actions arise from mechanical injuries and how they add to the distress and danger which the accident occasions.

Usually constant mechanical pressure with a truss prevents any accident to the bowel, but when from a mechanical cough or from a jar displacement occurs, then mechanical pressure must be used by the patient or by the Surgeon to return the bowel and to prevent the occurrence of any secondary chemical wrong action. When the hernia cannot be reduced, the mechanical strangulation immediately begins to affect the progress of the chemical actions in the part.

The entrance and escape of the supply of blood to the bowel may be so stopped that no oxygen may go in and no carbonic acid may come out. The action of the oxygen on the fuel may be so diminished that the chemical conditions necessary for producing mortification may occur, and to prevent the death of the intestine the Surgeon, as soon as he finds that the pressure cannot be otherwise removed, mechanically divides the

stricture. Then if the operation has not been too long delayed the circulation is restored and healthy chemical actions again take place, unless the chemical changes that have occurred in the bowel during the extreme pressure preclude all healthy action.

When the mechanical work of the Surgeon is done, he then by perfect rest to the body and rest to the bowel, by the least amount of pressure of the general and local circulation, by diet, by lotions, and by medicines, endeavours to stop the increased chemical action, which under the name either of peritonitis or of diffuse cellular inflammation is so apt to deprive him of the credit of his handicraft, and his patient of his life.

In every one of the mechanical injuries which may be brought to the Surgeon, this relationship of the chemical disease to the mechanical accident is always in his mind. In some slight accidents, or in some parts of the body, the mechanical injury may hardly visibly alter the healthy chemical actions of oxidation and nutrition; but a disturbance always takes place; and in some parts of the body, from the nature of the textures or from the mode in which the nutriment and oxygen are supplied, and the products of change and disintegration are removed, a very slight mechanical cause may give rise to a very great chemical effect.

Of all wounds, why are scalp wounds the most serious? Not surely because of the nature of the mechanical injuries themselves, but on account of the secondary chemical results which from the anatomical structure of the parts are more apt to occur in these than in most other kinds of wounds.

The two chemical consequences of scalp wounds generally are diffuse inflammation (peroxidation and altered nutrition) consequent on the looseness of the structure of the cellular tissue of the scalp; and necrosis or chemical death of the bone, which occurs when the periosteum which supplies the bone with food and oxygen is torn away by the mechanical injury.

As soon as the peroxidation begins in one spot of the cellular tissue it rapidly sets up similar action in the adjoining healthy texture, and causes the healthy oxidation going on in it to rise in degree until it becomes capable of increasing the oxidation in the neighbouring cells and structures, and so the inflammation spreads, and altered actions of nutrition occur. These altered chemical actions might extend through the whole cellular tissue of the scalp if the Surgeon did not mechanically divide the tense skin, which relieves the pressure and the circulation, and allows the products of the inflammation to escape freely from the inflamed part.

So, also, when more or less of the surface of the bone is mechanically deprived of its nutriment, the part so injured immediately begins to go through changes of anoxidation and atrophy; whilst around the obstruction increased circulation is set up, and increased chemical action, which would slowly end in the removal of the dead and sometimes decomposed bone. The Surgeon, by the removal of the dead bone, mechanically does what nature would do chemically, and by so doing he rapidly puts an end to a state of chemistry which, when left to its course, ends not unfrequently by the absorption of pus, in a general poisoning of the system, and a stoppage of all the actions which constitute life.

In another very large class of diseases—those, namely, which follow child-birth, the same relationship between mechanical injury and altered chemical action may be shown to obtain.

The removal of the child from the uterus may be regarded as a mechanical accident, an operation performed by nature; and violent mechanical injuries are often inflicted on the mother and child in the process of parturition. Thus by pressure, for example, rupture of blood vessels and other textures between the uterus and placenta invariably occur, and accidentally other ruptures take place. Thus rupture of the perineum not unfrequently happens, and rupture of the bladder or even of the uterus itself more rarely occurs. The rupture of the vessels connecting the uterus and the placenta, and a tranverse rupture of the uterus, cause oftentimes such hæmorrhage that an acute state of anæmia is rapidly produced; and the actions of oxidation and nutrition so suddenly decrease in consequence of the deficiency of the supply of oxygenated blood to the nerves and muscles that they cease to act, and death rapidly ensues. When the rupture of the uterus is longitudinal, there is less hæmorrhage, and in some rare cases a less fatal result ensues.

Rupture of the perineum is slight or serious according to the degree of the mechanical accident. In slight cases healthy increased chemical action soon closes the wound, and little or no inconvenience is produced. In more extensive ruptures more serious wrong chemical actions arise, mortification, inflammation, and passage of the fæces into the inflamed false opening keeping up constant irritation. These evil effects may last through life unless by skilful mechanical treatment the Surgeon can enable nature to close the opening which the mechanical force originally produced.

Among the diseases which have been classed together under the term puerperal fever you will find not only the best illustrations of the relationship of chemical to mechanical diseases, but also the best possible example of the close connexion that exists between the actions that constitute fever and those that constitute inflammation.

At the time of child birth the whole of the chemical and mechanical actions going on in the body are suddenly disturbed. The whole oxidation and nutrition that was going on in and through the uterus is suddenly checked. An entirely new set of chemical and nutritive actions are beginning to be set up in the mammary glands. Each structure of which the uterus is made up is undergoing more or less altered action. The peritoneum has been stretched to the uttermost, and then is suddenly squeezed up. The muscular structure of the uterus has suddenly been called into the most intense action, and then suddenly has its violent action stopped, and its substance gradually dwindles, by oxidation and altered nutrition, away. The mucous membrane is not only bruised, but is torn, and has to be repaired and absorbed. Even the blood vessels of the uterus are torn, and have to be closed and gradually to undergo that change of texture which reduces them to a small fraction of the size to which a short time previously they had attained. Without any inoculable products of inflammation being brought to the uterus by the accoucheur or nurse inflammation may be set up by spontaneous development from cold, from unhealthiness, from physical or mental distress. The inflammation may be most intense in one or in all of the uterine structures, and according to the different textures involved different names have been given to the resulting chemical disease.

If the inflammation is most intense in the peritoneum, the disease is called puerperal peritonitis. If in the veins, it is called puerperal phlebitis, and cases of inflammation of the absorbents have probably been included in this designation. When the symptoms are less manifest in the peritoneum and veins, the inflammation then is in the mucous and muscular structure, and when less distinctly localised, it is designated as puerperal fever, which in all cases is a spontaneous or inoculated inflammation of one or many of the textures of the womb just after delivery, when all the forces in the body are in a state of very great disturbance.

The effects of pressure upon the child in parturition are in the highest degree mechanical and dangerous. It may be mechanically strangled, or suffocated, or crushed; it may be so wedged in that it must either be removed in pieces, or the mother must be opened to get it out. No stronger proof of the energy and extent of the chemical actions of oxidation and nutrition that go on within us can be given than that they should be able to continue in action during the violent mechanical accident to which we are exposed at the end of the ninth month of our existence.

The pure Surgeon considers that all these accidents of parturition do not belong to his handicraft, and the division of labour has almost taken them from the pure Physician, and has given them to a separate class. But the amount of skill that is required to obviate and to remedy these mechanical accidents, and the amount of judgment and knowledge that the skilful treatment of the secondary chemical diseases requires, shows that no distinction can be drawn in the relative requirements of those who practise any one of the three branches of our Profession. All should possess the same chemical and mechanical knowledge, while the handicraft can be neglected by the Physician alone, who, to compensate for this loss of power, should possess the greatest insight into the chemical and mechanical forces that are in action in health and in disease. Even in the treatment of Medical accidents no handicraft is of use to the Physician. Whether these accidents are sudden or slow, generally speaking, no mechanical treatment can touch the cause of the evil. The Physician may palliate or cure by mechanical and chemical remedies the secondary chemical diseases that may be set up; but no direct mechanical treatment of the original injury is possible, except that which can be obtained by rest.

(To be continued.)

THE CHOLERA IN FRANCE.—The *Armorique* of St. Brieuc states that the cholera is raging at St. Trephine.

ORIGINAL COMMUNICATIONS.

REPORTS AND LECTURES ON ORIGINAL RESEARCHES IN SCIENTIFIC PRACTICAL MEDICINE.

By BENJ. W. RICHARDSON, M.A., M.D., F.R.C.P.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

II.– ON SOME NEW COMPOUNDS OF ETHER.

III.—STYPTIC OR HÆMOSTATIC ETHER.

My researches on the production of local anæsthesia by means of ether spray have led me to invent a few new compounds of ether which cannot, I think, but prove useful in practice, and to which I would direct the attention of the readers of the *Medical Times and Gazette*.

Hæmostatic Ethers.

In observing the influence of the cold produced by the dispersion of absolute ether during operations, nothing has struck me more than the effect of the cold in immediately stopping the flow of blood. For a time, cold alone, when carried to its fullest degree, prevents all venous and capillary hæmorrhage, and even the hæmorrhage from small arterial trunks. After a time, however, as reaction returns, and the vessels relax under the influence of heat derived from the renewed circulation, there is bleeding, which, if a wound be closed too quickly, is a cause of after trouble. The observation of the immediate effects of cold led me to think that if they could be supplemented by a styptic which would spray evenly with ether, and which would take up the constringing action when the vessels commenced to relax, an important desideratum in both Medical and Surgical practice would be supplied.

Xylo-Styptic Ether Spray.

With this object before me, I requested Mr. Robbins to make for me a solution consisting of absolute ether, having a boiling point of 92° Fah., charged to saturation at a low temperature with tannin, and afterwards treated with xyloidine, a little short of saturation. The compound, made with much care, came out well. It ran easily through the spray tube without blocking; it produced good local anæsthesia, and it possessed an agreeable odour.

In order to test to the extreme the effects of this preparation as a styptic, I took sheep's blood, removed all the fibrine previous to coagulation by whipping, and then let the blood remain exposed to the air for two days to ensure partial decomposition. In this way the blood was rendered nearly as fluid as port wine, and in the most unfavourable condition for being transformed into clot. A few drachms of this blood were now placed in a saucer, the saucer having been warmed to the temperature of the body. The spray of the styptic ether was then directed upon the blood from a full-sized spray tube, and in five seconds the whole mass of blood was so thoroughly solidified that the saucer could be turned upside down without any escape of fluid. The blood, which had previously presented the odour of putrefaction, was also deodorised, and remains quite inodorous at this date—ten days after the experiment. The blood sets in a firm leathery consistence, covered on its upper surface with a fine whitish layer, with a bright vermilion colour beneath.

These are the effects of the styptic ether on blood, the spontaneous coaguability of which has been lost, and I had the pleasure of showing these effects at the College of Physicians on Friday last during a lecture on heat and cold in the treatment of disease; but these effects are trifling when compared with what takes place on blood newly drawn, and which contains fibrine. In this case the process of coagulation under the influence of the spray is the work, I had almost said, of a second.

When this spray is directed on an open bleeding living surface, the primary effects are those produced by the cold—namely, the condensation and whitening of the tissues. If blood be flowing, it solidifies, and when the parts relax, new blood that may ooze up enters the solid blood as though it were a sponge, quickly solidifying by coagulation and stopping further flow.

The applicability of this process for the arrest of hæmorrhage will occur to the mind of every Practitioner. The substances used in the compound are innocuous, and the combined influence of the cold and the styptic are immediate, and so decisive that I can scarcely imagine any hæmorrhage they would not control. I have not had an opportunity of testing the point, but I have no doubt from the influence of the styptic on the decomposing albumen of defibrinated blood that even in those cases of hæmorrhage where the blood is preternaturally fluid, the styptic spray would arrest the hæmorrhage entirely. Where the blood contains fibrine in a natural condition, I cannot imagine a case in which the fluid would not prevent exudation.

The essential elements of this process are three in number:

1. The immediate constringent effects of cold on the blood-vessels.
2. The chemical action of the solution on the fibrine and albumen of the blood.
3. The extreme mechanical fineness of distribution of the fluid on the bleeding surface.

The styptic ether can not only be applied to open wounds on the skin, but to hæmorrhage after the extraction of teeth, and, by means of a uterine tube, to hæmorrhage arising from cancerous disease of the uterus or other cause. It might also be applied to the rectum in cases of hæmorrhage from piles.

The apparatus required for this styptic ether is mechanically the same as for ordinary ether—that is to say, my spray tube with Dr. Clarke's hand bellows. The tube, however, requires to be made of different metal from that ordinarily in use for local anæsthesia; and I have therefore instructed Messrs. Krohne and Sesemann to construct a special tube for the purpose.

Ferro-Styptic Ether.

I have tried other experiments with the persalts of iron, which are more or less soluble in ether, especially the perchloride, and these one and all produced, as a styptic ether, rapid coagulation of blood. Solutions of iron salts in ether are not, however, more effective than the ether I have already described; and as they destroy the tube rapidly, act upon clothing injuriously, and do not so thoroughly deodorise, I do not think they are in the main so practical.

The styptic ether, containing xyloidine and tannin, will keep ready for use any length of time, as there is nothing in it to undergo decomposition; and as very small quantities of it are required, it will become, I trust, of standard service to the Medical Practitioner. It would be of great use also to Surgeons on board ship, and particularly to Army Surgeons. In case of warfare it would be exceedingly useful on the battle field, as under the instruction of the Surgeon it could be used by an orderly, so as to prevent hæmorrhage instantaneously in the case of flesh wounds. It would also form a useful addition to the Medical cabinet of travellers, who by necessity are removed from the direct succour afforded by Medical art.

I have invented some other ether compounds—namely, a caustic ether, an iodised ethereal oil, and an ozonised ether, to which I will refer in a future number.

ON THE OCCURRENCE OF AMPHORIC RESPIRATION IN PLEURISY AND PLEURO-PNEUMONIA.

By H. FEARNSIDE, M.B. LOND.,
Member of the Royal College of Physicians of London.

The not unfrequent occurrence of amphoric respiration in the course of pleurisy and pleuro-pneumonia has scarcely, I think, received from English Physicians and writers on auscultation the amount of attention which it deserves; for, as cases which have come under my own observation have proved to me, its want of recognition may lead to errors both in diagnosis and practice.

The doctrine formerly held respecting amphoric respiration was that it is heard (most generally) in broncho-pleural fistula, and in some examples of large pulmonary cavern.

Chomel, in his "Traité de Pathologie Générale" (1842), mentioned that gurgling was sometimes heard in chronic pleurisy, and supposed that it was owing to the presence of a pulmonary cavern, separated by a thin layer of tissue from the pleuritic effusion.

MM. Rilliet and Barthez ("Traité des Maladies des Enfans," vol. i., p. 152) stated that when a pleuritic effusion is superadded to pneumonia, most frequently the bronchial souffle augments in intensity, and sometimes assumes a true cavernous

timbre; whilst, if mucus be present in the bronchial tubes, and be disturbed by the passage of air, a sound resembling gurgling is produced, and at the same time the voice is pectoriloquous, and thus the idea of the existence of a cavern naturally arises. These observers subsequently reported instances of pleurisy (*Archiv. Gén. de Médeeine*, 1853) from which they concluded that where there was no union of pneumonia with pleurisy, nor any communication of the bronchial tubes with the pleural sac, nor any large pulmonary cavern, these signs may exist, and that for days, weeks, or even months, a bronchial souffle may be heard, which by its intensity and timbre simulates cavernous and even amphoric respiration.

MM. Béhier, Trousseau, and Gallard have also narrated cases of simple pleurisy in which these phenomena have been present.

To M. Landouzy, of Rheims, however, belongs the merit of specially studying this subject, and of deducing useful rules for practice.

The eases, of which an abstract follows, afforded good examples of the signs in question, and as such I beg to place them before the readers of the *Medical Times and Gazette*.

Case 1.—Some months ago I was requested to visit a young woman who had been ill for several weeks with symptoms of fever of an intermittent type. The patient (a domestic servant) was descended from healthy parents, and although not robust, had generally possessed good health. Her illness was not, in the first instance, attended by any notable signs of pulmonary disease, but, after the lapse of about three weeks, she began to complain of pain in her left side, and shortness of breath. She also became troubled with a cough, which in the course of ten days was accompanied by a considerable amount of muco-purulent expectoration. She had much evening fever and night perspiration; her strength rapidly declined, and her weakness was still further increased by occasional attacks of diarrhœa and by her inability to take food. Signs were noticed which were thought to indicate the formation of a large cavity in the lung. In this condition, she was supposed to be the subject of acute phthisis, and at this stage of the complaint she fell under my notice. On examining her chest, the following signs were observed:—The movements of the left side were much less free, and the lower intercostal spaees were less marked than those of the right side. On measurement immediately below the mammæ, the circumference of the left side was the same as that of the right. On percussion over the left side, the sound was universally more or less dull, except under the clavicle and near the sternum, where it was tympanitic. From this point to the fourth rib it was less dull than below, where the dulness was absolute both before and behind. Vocal fremitus over the lower half of the left side was absent. On auscultation under the left clavicle the respiration was tubular; over the third and fourth ribs moist crackling sounds were heard; below this there were no respiratory sounds; behind, over the left upper scapular region, the sound was bronchial, which increased in intensity and acuteness of tone as the ear descended over the lower part of the scapula, until near its inferior angle, where it passed into pure amphoric respiration, which was heard both in inspiration and expiration. Occasionally, over the same part a liquid sound, not distinguishable from that of gurgling, was audible, and the voice was not œgophonic, but pectoriloquous; below, as in front, no respiratory sounds were heard. On the right side the stroke sound was clear, and the respiration puerile. The heart was displaced, and its impulse felt behind the sternum; the pulse was weak and quick; the respiration short and frequent. The tongue was unnaturally red, the stomach irritable, and the bowels relaxed.

Treatment and Subsequent Progress of the Case.—To correct the morbid state of the gastro-intestinal mucous membrane, bismuth and hydrocyanic acid were prescribed, and were speedily found useful. Alteratives and alkalies (iodide of potassium, with bicarbonate of potash) were then given, and the lower half of the affected side of the chest was freely painted from time to time with a strong solution of iodine. A diet, simple, but as nutritious as the stomach would bear, was allowed, and under these means she gradually improved. The respiration over the lower scapular region remained amphoric for about three weeks; it then became tubular, and did not altogether lose this character so long as the patient remained under observation. The vocal resonance subsided, and became bronchophonic; the expectoration diminished, and at the end of three months ceased. At this date the patient considered that her health was re-established; there was evidence, however, that there remained a considerable amount of condensation in the lower half of the left lung, and the circumference of the left side had contracted by about an inch.

Case 2.—During the last summer my opinion was asked respecting a young lady, 14 years of age, who had been more or less out of health for some months. She did not inherit any predisposition to tuberculous disease, but had lost several relatives from cancer. Her health, however, had been much impaired some years before by a severe attack of scarlatina. The catamenia had appeared a year previously, but had been suspended for a considerable time. In the summer of the preceding year, Miss A. had been sent to a school in one of the midland counties, where the subjects of study were more numerous and required closer application, and where also the diet was less abundant and supporting than she had been accustomed to when at home. Her health remained as good as usual until about Christmas, when she took cold, and was confined to bed for a short period. A slight cough remained; and about the middle of March she expectorated about two tablepoonsfuls of blood. At this date she was again confined to bed for a few days, and discontinued her studies for about a fortnight. Her cough recurred from time to time, but did not attract much notice until May, when she began to complain of pain in her left side and shoulder, and her increasing debility and emaciation led to her being sent home. She was then considered to be the subject of consumption, and was advised to take cod liver oil. I visited her in the early part of July, and made the following observations:—She was much emaciated, had a small, quick pulse, a good deal of evening fever, and some night perspiration. The motions of the left side of the chest were much impaired, and there was great dulness on percussion over its whole extent—more complete, however, below than above. Vocal fremitus was feeble, but still perceptible. The respiration was bronchial under the left clavicle; and in the lower and outer portion of this region there was a sound which no auscultator would have hesitated to pronounce cavernous; here also gurgling was heard from time to time. Behind, the breath sound was strongly tubular over the upper scapular region, and amphoric over the lower, where the vocal resonance was that of pectoriloquy. Below, the respiratory sounds were all but inaudible. The heart's sounds, impulse, and position were normal. On the right side there was no dulness on percussion, but the breath sounds were masked by sonorous rhonchus. She had a troublesome cough, and expectorated in twenty-four hours from two to three ounces of uniform brownish yellow muco-purulent matter. It is unnessary to give the details of the treatment, which varied from time to time as circumstances indicated. Suffice it to say that counter-irritation over the affected side was freely practised by means of iodine. Sedatives were given to allay the cough, and, as soon as possible, alteratives and tonics were prescribed; from the first, also, as liberal and supporting a diet was recommended as her digestive organs would tolerate. Under this plan she soon began to improve in health; her cough and expectoration rapidly subsided, and at the end of seven weeks both had ceased. The respiration over the lower scapular region lost its amphoric character in about a month; but it remained tubular, with a gradually diminishing intensity, for nearly three months. The cavernous sound, anteriorly and superiorly, became weaker and more distant; but at the end of five months it was still recognisable on deep or quickened breathing. At the same date the stroke sound over the lower half of the left side was still duller, and the respiratory murmur feebler than natural. She presented, however, all the external indications of good health, having become ruddy and plump.

Comments.—In each of these patients there was a combination of pleuritic effusion with pulmonary condensation. In the first, the affection of the lung was probably simple inflammation; in the second, it is more reasonable to suppose that some tuberculous deposit had taken place, which had even resulted in the formation of a small cavity in the upper and outer portion of the lung. The chief interest of the cases and that for which they have been narrated, relates to the occurrence in both of amphoric respiration over the lower scapular region. In considering the causes and mode of production of this sound, the possibility of the existence of broncho-pleural fistula may be dismissed at once, as there were absolutely no other signs of it. The previous history of the cases, the seat of the lesion, the rapid subsidence of the cough, the cessation of the expectoration, and the subsequent progress of the patients are incompatible with the supposition that it could be referred to the existence of a large pulmonary cavern. Hence

it can only be ascribed to a peculiar condition of the lung produced by the pressure of the effused fluid—probably aided also by interstitial deposit. Béhier, Rilliet, and Barthez think that in such cases amphoric respiration is only the reverberation of the tracheal murmur transmitted by an indurated lung, and it is so far in harmony with this view that it is especially in those points towards which the lung is pressed back that the sound is heard.

Preston.

CASE OF

FRACTURE AND DISPLACEMENT FORWARDS OF THE BODY OF THE FIRST LUMBAR VERTEBRA,

WITH PHOTOGRAPH.

By Assistant-Surgeon J. MUNDAY, H.M. 21st Hussars.

No. 326, P. R. R., aged 26, 21st Hussars, a healthy young man, of stout build, middle height, and very active habits, was mounted in the Barrack-square, at Umballa, on the morning of September 25, 1865, prior to going out to field drill with the regiment, when his horse became restive, reared up in the ranks, and fell back on him, the weight of the horse coming with full force on him and crushing him to the ground, the hilt of his sword intervening between his back and loins. He was not rendered insensible by the fall, but screamed out in great agony for some time, and when raised from the ground to be put into the dhooly, for conveyance to Hospital, it was found that both legs were completely paralysed.

He was seen almost immediately after his admission to Hospital by reporter, who found him in great suffering and quite unable to move in bed without assistance, the most severe pain being referred to the lower part of his back and loins, commencing from about the ninth dorsal, and extending down as far as the sacrum. In about the middle of this space he said it was that he received the injury, from the hilt of his sword coming under him when the horse fell back. There was much tumefaction, tenderness, and heat all along the lower part of the spine, but no fracture could be detected at the time; there was total loss of motion and sensibility in both lower extremities, but from about the upper third of the thigh towards the abdomen sensation partly remained. He was at once placed in a warm bath for half an hour, with some relief to the pain, and afterwards laid on a water-bed face downwards, and his back and loins fomented with hot water containing some tincture of opium. At bedtime a draught containing muriate of morphia was given, and the hot stupes ordered to be continued throughout the night should sleep not supervene.

26th.—Has scarcely slept at all last night, but is in no actual pain so long as he is lying face downwards on the water-bed and is not moved, any change of position being attended with sharp pain between the tenth dorsal and second lumbar vertebræ, in which situation a fracture of the spine is more than suspected. Pulse 80, and firm; has not made water since admission. A catheter was introduced, and some twenty-three ounces of ammoniacal urine drawn off. Thirty-six leeches applied to the back, followed by hot fomentations, and a morphia draught ordered at bedtime.

27th.—Slept for about two hours during the night; bowels torpid; pulse good; is anxious for food. Catheter introduced; twenty-six ounces and a half of urine similar to that of yesterday drawn off. A large warm water enema thrown up. *Vespere.*—There is still extreme pain and tenderness on pressure over the entire back and loins. Twenty-four leeches applied to the back; hot fomentations continued; haustus morphiæ at bedtime.

28th.—Slept a little during the night; feels more comfortable; pulse 86; tongue clean; bowels as yet have not been moved. A castor-oil enema administered. Twenty-one ounces of urine drawn off.

29th.—Feels comfortable unless when moved; bowels as yet unaffected. Eighteen ounces of urine drawn off. Repeat enema.

30th.—In the same state. Fifteen ounces of highly ammoniacal urine drawn off.

October 1.—This morning, at 1 a.m., was seized with sharp rigors, which lasted more than an hour, followed by severe pain in the pubic region and distension over the bladder. A catheter was passed, and about an ounce of dark-coloured and offensive smelling urine drawn off. An enema of warm water and oil was thrown up, which brought away some fæculent matter, the first passed since admission to Hospital. Thirty-six leeches were applied over the lower part of the abdomen, and the whole belly well fomented. On being again seen at the usual hour of the morning visit he was found still in severe pain over the pubic and right and left iliac regions, and the whole surface of the belly was hot and tender to the touch; tongue furred; pulse small and quick. Ordered an anodyne draught at once, and to take calomel gr. iij., opium gr. j., in a pill every three hours. Abdomen to be frequently fomented. 12 noon.—Abdomen tympanitic; pulse small, feeble, and quick; complains of shortness of breath; features greatly changed and sunken since the morning; has vomited some bilious matter. Haustus effervescens, c. spt. æth. sulph., omni horâ. 3 p.m.—Pulse almost imperceptible at the wrist; arms and chest cold and clammy. To have an ounce of brandy, with some soda-water, every hour, and strong beef-tea at intervals. His stomach continued very irritable, and his pulse weak and thready. Towards evening the pain in his abdomen entirely ceased, the upper extremities being cold and clammy; belly tumid and hot. An ounce and a-half of turbid urine was drawn off, and hot turpentine stupes were continued to the abdomen, brandy and beef-tea being given at intervals. He slowly sank, and became unconscious towards midnight, and died at 1·30 a.m., October 2, eight days after receipt of the injury.

Autopsy Six Hours After.—Rigor mortis not fully established; body well nourished. Head not opened. Thorax: Old adhesions of the pleura throughout the lower half of the chest; some congestion of the lungs at their bases, although otherwise healthy; heart of normal size, valves healthy; the pericardium contained about eight drachms of straw-coloured serum. Abdomen: This cavity was distended with air. About two pints of bloody serum was found, in which the intestines (which were matted together) floated; the peritoneum was thickened from the effects of recent inflammation; externally the sigmoid flexure of the colon presented a patch of livid discolouration, extending downwards for some five or six inches, and a corresponding appearance for the same extent internally, but no ulceration was apparent; bladder quite empty, its mucous membrane pale; liver large and somewhat congested; kidneys enlarged. Dorsal Region: On dividing the integuments over the seat of the injury, an immense mass of congested tissue appeared extending from about the three last dorsal vertebræ down to the sacrum, and about three inches broad on each side of the spinal column, from which a quantity of dark venous fluid oozed. On raising the muscles in this situation and exposing the back of the spinal column, fracture and dislocation forwards of the first lumbar vertebra were discovered. The transverse process and pedicle of this vertebra were also broken off, and the jagged edges were found compressing firmly the first lumbar nerve as it emerged through the "intervertebral foramen." The transverse process of the second lumbar vertebra was also splintered off. On taking out that portion of the spine comprising the eleventh and twelfth dorsal and first four lumbar vertebræ, and making a careful dissection, the extent of the fracture was more fully seen, and the specimen subsequently photographed. This fracture extended diagonally from right to left from below upwards, through the pedicle and superior articulating process of the first lumbar vertebra, and across the body of this bone in its upper third—in fact, it seemed as if the head of this vertebra had been knocked off, with the interarticular cartilage adhering to the upper fragment. The theca vertebralis was congested and thickened for about an inch and a-half above and below the seat of injury, and here the nerve fibres were crushed, and a few of them torn across from violence inflicted by the sharp edges of the bone. A photograph of the fractured spine is enclosed, which gives an excellent view of the extensive injury.

Umballa.

THE library of the late T. J. Pettigrew, Esq., which comprises several early printed works, some on vellum, ancient MSS., and missals, and valuable works on archæology, is about to be sold by Messrs. Sotheby.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

THE LONDON HOSPITAL.

REMARKS ON A RARE FORM OF INDURATED CHANCRE IN THE MALE.

(Case under the care of Mr. MAUNDER.)

A VERY large majority of indurated chancres which are presented to the notice of the Surgeon have the physical characters of the kind termed "Hunterian," the induration giving to the sense of touch the idea of a foreign body—such as a split pea or hemispherical piece of cartilage let or sunk into the tissues. I here allude to this induration only in order to compare it with a corresponding physical sign, which was well marked in a case of indurated chancre (*chancre parcheminée, en surface*) of Ricord, recently under my care, among the out-patients of the London Hospital. The subject of it was a young man about 20 years of age, and the ulcer, which was seated on the integument of the penis, behind the level of the corona, and on the left side of the organ, had existed about month. It was of the shape and size of an ipecacuanha lozenge, and had the appearance of being seated upon the surface of the organ, just as a lozenge or coin would appear if similarly situated. In the left groin some four or five lymphatic glands were enlarged, indurated, but painless (constituting an adenopathy), quite separate, and the adjacent tissues were normal; the surface of the sore was granulated, and secreting pus freely, On taking it between the finger and thumb in the direction of its long axis it yielded (bent up), and the induration was not recognised, but when gently compressed in its short diameter the induration was at once appreciated by all who examined the case.

So rarely has this form of induration come under my observation that I deem it to be worthy of record. I pointed out to my dressers and others that had not the specific induration been observed the sore would probably have passed for one of the soft variety, and urged the necessity for physical examination by the finger and thumb in all case of chancre; and specially directed their attention, when a doubt existed concerning the nature of a chancre, to the condition of the lymphatic glands associated with the region in which the chancre is seated. In the case before us, had a doubt existed concerning the variety of sore, whether indurated and infecting or soft and non-infecting, the condition of the glands in the corresponding groin would at once have determined the question in favour of the former variety.

In order to prove the correctness of the diagnosis, and to press upon my class the peculiar characters of this form of indurated chancre, I withheld specific treatment so as to avoid the possibility of checking the natural evolution of symptoms, and in the course of a few weeks a delicate rose rash and sore throat (mucous tubercles on the tonsils) were manifested.

The few examples of *chancre parcheminée* that I have seen have been seated on the integument of the penis.

NATIONAL HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

CLINICAL REMARKS ON CASES OF TEMPORARY LOSS OF SPEECH AND OF POWER OF EXPRESSION (EPILEPTIC APHEMIA? APHRASIA? APHASIA?), AND ON EPILEPSIES.

(Under the care of Dr. HUGHLINGS JACKSON.)

JUST as a patient may lose sight for a time, so a patient may lose speech for a time. To this sudden and temporary loss of speech Dr. Jackson had given the name of Epileptic Aphemia. Aphemia is the term introduced by M. Broca as a name for the loss or defect of *articulate* language. Dr. Jackson thinks this term is rarely applicable to the defect or loss of speech which occurs with hemiplegia (nearly always of the right side) from disease of the [left] hemisphere, as there are generally other troubles besides inability to talk. But in one of the cases of sudden and temporary loss of speech that he had seen the patient had been able to express himself in writing quite well. The term aphemia might, therefore, be correctly applied to cases like this in which only *articulate* language appears to have been lost. Dr. Jackson, however, thought it undesirable to use such terms as aphemia or aphasia. Besides, M. Broca has recently introduced a new term—aphrasia. Dr. Jackson wished, however, to be understood as saying this respectfully, for under such names a vast amount of most excellent work had been done, as any one might easily learn by reading Trousseau's most charming and exhaustive lecture on aphasia, recently translated by Dr. Bazire. With students, however, there might be a fear that in any particular case they would think it chiefly desirable to know whether the mental defect should be called aphemia, aphrasia, aphasia, alalia, aphthenxis, etc., and thus pay too little attention to it as an individual departure from healthy language or healthy mind. It is probable that the so-called faculty of language "resides" wherever mind resides, and that language is but an outward form of thought. An intelligent student will not infrequently say of a case that he does not know what it is, when in reality he knows much about it, but does not know the name it would generally go by. He is in a better frame of mind than the one who quickly applies terms to cover up generalities. Dr. Jackson said it was good for students—in the wide sense of the word—to study even such common diseases as scarlet fever as if they had never seen or heard of the disease before. It was, he urged, especially desirable that we should not blunt our appetite for knowledge in investigating cases of defects of expression by the too free use of technicalities. The books to read to make us feel the importance of single cases of loss of speech as flaws of mind were those of Max Müller, Herbert Spencer, J. S. Mill, etc.

Moreover, in cases of sudden and temporary loss of speech it is by no means clear even what the relations of the superficial phenomena really are, and probably the defects differ in different cases. For a like reason Dr. Jackson had suggested, in the cases of permanent defect of speech, the use of the loose general term Expression, as this would force on us a description of what really happens, and especially prevent us from dwelling with exaggeration on defects of expression by articulate sounds. However, Dr. Jackson had, he confessed, made little progress in his investigations as to the general power of expression in cases of sudden and temporary failure of power of speech. In some of these cases he had asked the patients' friends to procure specimens of writing when the loss of speech came on, but nothing had come of his requests. He is, therefore, particularly anxious to learn from those who may have intelligent patients (who are subject to occasional loss of power to talk) under their constant observation, if these patients lose power to express themselves by writing and by signs when they lose speech.

Now, as regards the adjective "epileptic." This is used to call attention to the circumstances under which the defect often occurs, and is not meant to be a definition of what its real nature is. Indeed, Dr. Jackson thinks the term "epilepsy," whilst it may pass as a rude mark for certain groups of outward symptoms, should be used also as a definition of our ignorance. For instance, calling these sudden and temporary failures of speech "epileptic" is simply affirming that they occur with epileptiform seizures, or under similar circumstances as epileptic seizures do; and it is also affirming that the real nature of the changes in the nervous tissue in these cases is not known. It puts them in a larger group—not lazily to dispose of them, but to widen the basis for their study. Indeed, Dr. Jackson suggests that the word "epilepsy" should be degraded, and be used to imply the condition of nerve tissue in sudden and temporary loss of its function, whether that be loss of sight, loss of consciousness, or "running down of tension" in those parts which govern muscles. For it is not unlikely that the condition of nerve tissue is the same or similar (although this is not taken for granted) when a patient loses sight for, as he says, half a minute, or has temporary loss of consciousness, or becomes unable to talk for a short time, or has spasm of the hand, or of the side of the face, or of the leg, or of all three on one side. Probably, too, in cases in which a man all at once passes into a violent rage from no apparent cause, or into a state somewhat like somnambulism, in which he may walk a mile or two, or walk into a canal, or in which he takes off his boots in church, or undresses himself in the streets, there is epilepsy—using the word in the new sense—

of some parts of the hemisphere. Yet it is clear that the part of the nervous system affected must be different in each instance. In some we may, Dr. Jackson thinks, plausibly infer its position. A patient may have several of the above-mentioned symptoms at once, one after another; and here probably the temporary condition of nerve tissue is similar, but the tract affected is wider. Dr. Jackson has spoken of sudden and temporary failures of sight as "epilepsy of the retinæ" (possibly of other parts of the optic nervous system), thus suggesting that the retinal nerve tissue is, in attacks of temporary blindness, in the same condition as the hemisphere in *its* blindness—loss of consciousness. The use of the term "epilepsy of the retinæ," however, has not passed without criticism: and Dr. Jackson says he has several times been jocosely asked if the retinæ are subject to convulsions. Strictly speaking, it is as incorrect to use the terms "epilepsy of the retinæ" as it is to speak of apoplexy of the retinæ or pulmonary apoplexy.

No one knows what the condition of nerve tissue is in any of the temporary seizures alluded to, nor even in what are called "genuine" attacks of epilepsy, and the word epilepsy, therefore, as Dr. Jackson here uses it, must, in our thoughts of cases, hold some such place as x or y in an algebraical problem. There are speculations more or less valuable on the condition of the nervous tissue in epilepsy and in epileptiform seizures, and the one which seems to be most explanatory is that which refers the temporary phenomena to disorders of circulation.

As we cannot have a large basis for a rational treatment, unless we have a knowledge of the state of tissues in disease, our ignorance in this particular instance is unfortunate. Dr. Jackson believes, adopting the views of his colleague, Dr. Radcliffe, that nervous tissue is below and not above par in the paroxysm. How it happens that the arteries begin suddenly to contract, if they do, or why the state of tension suddenly begins to run down, it is not possible to say. It is possible that there are waves of periodicity in the system, in which certain enfeebled regions do not, as it were, come to time. Indeed, in such instances of definite periodicity as ague fits, the periodicity must be in the system.

Using the word epilepsy as herein defined, Dr. Jackson thinks it will be possible to show, at least in some instances, that the epilepsy is of nerve tissue in particular arterial regions. The whereabouts of the changes might be studied distinctly from their nature, although not separately. It may first be asked, do the symptoms of the epileptiform attack point to disorder of that part of the motor tract which is supplied by the middle cerebral artery?

The above remarks were suggested by the case of a boy who had had an attack of convulsions of the right arm and leg and right side of the face, with inability to talk, although consciousness was not obviously affected. Now, as paralysis of the right side of the face, of the right arm and leg, with permanent loss of speech, are sometimes due to plugging of the middle cerebral artery, it may be well, Dr. Jackson thinks, to inquire whether the temporary symptoms in the above case were not due to some temporary cause (possibly spasm of the blood vessels) in the range, or beginning in part of the range of the left middle cerebral artery. In the boy's case there was no information as to whether the chest or abdominal walls had been fixed or not; probably they had been. In another case of unilateral convulsions affecting the left side in which Dr. Jackson had witnessed the seizure, the chest and abdominal walls had been fixed, thus tending to demonstrate, as Dr. Jackson believes, the truth of the hypothesis recently brought forward by Dr. Broadbent to explain the escape of the muscles of the trunk (or, more in the terms of Dr. Broadbent's hypothesis, the muscles acting bilaterally) in hemiplegia from disease of the corpus striatum. Dr. Jackson ventures to use the expression "tend to demonstrate," as in the case mentioned (recorded Royal London Ophthalmic Hospital Reports, January, 1866, "Defects of Sight in Disease of the Nervous System," case xvi.) disease was found after death in the region of the middle cerebral artery. If the above explanation of unilateral epileptiform seizures holds good, *mutatis mutandis*, it will, Dr. Jackson believes, account for the symptoms of chorea.

In some cases of loss of speech with hemiplegia for a few days, the cause may be cerebral hæmorrhage. In one such case Dr. Jackson found after death, several months after recovery from these temporary symptoms, a small clot affecting the hinder part of the corpus striatum and the hemisphere outside it.

GUY'S HOSPITAL.

A CASE OF OBSTRUCTION OF THE BOWELS SUCCESSFULLY TREATED BY OPIUM—CLINICAL REMARKS.

(Under the care of Dr. BARLOW.)

This week we take the opportunity of bringing forward a very instructive case of obstruction of the bowel. Dr. Barlow delivered an excellent clinical lecture on the case. We below record some of his remarks. It is hardly necessary for us to mention that some years ago, in the Guy's Hospital Reports," Dr. Barlow called attention to certain symptoms of this disease, and in so doing clearly showed that it was possible to make a diagnosis much more correct as to the seat of the obstruction than had previously been believed to be practicable. Dr. Barlow's remarks will show that his more recent experience has still further confirmed his previous conclusions.

We are indebted to Mr. Fred. E. Manby for the particulars of this case:—

William S., aged 15, a "street boy," admitted October 24, 1865. States that four days ago he was suddenly seized with griping pains in the abdomen. A Medical gentleman was sent for, who prescribed a dose of castor oil, which was taken, but no action of the bowels followed. He suffered greatly from nausea and sickness. The day before admission he had another dose of castor oil, but his bowels were not relieved by it. He appears to have passed the usual quantity of urine. His sickness increased, and he could not "keep anything down long."

On Admission.—His face was blue and livid, skin feels cold, and he complained of slight cramps in his legs; his pulse very feeble, about 90. He was frequently seized with spasmodic pains in his abdomen. On being put into bed, and on examining the abdomen, it was found to be very tense, and percussion gave a somewhat dull sound over the situation of the cæcum. He passed, soon after admission, about half a pint of light-coloured urine, the specific gravity of which was 1020, acid reaction, and contained no albumen. He had had an enema, but it produced no effect. Dr. Barlow saw him the same afternoon, and was struck with the resemblance of his physiognomy to that of a patient suffering with cholera. His cheeks were flushed, an anxious look, with shrunken, drawn features, sunken eyes, and pinched nose. He ordered a warm bath, and a soap enema while in the bath. The enema retained, but no fæces passed. He was put to bed, wrapped in blankets, and a grain of opium given. Soon after this he expressed himself as feeling rather easier. Just before taking his bath he vomited a quantity of yellowish, sour-smelling matter. 7 p.m.—Much the same; no better; he has passed a little urine; has had another enema, but with no more success than the first. Has not vomited since he had the bath; pulse 108: face flushed; slight headache; pain in the abdomen increased by pressure, but the abdomen seems less tense than it was a few hours ago. 9 p.m.—Had another grain of opium by the mouth. Four ounces of urine were drawn off. Passed a gum elastic catheter into the intestines to the extent of fifteen or sixteen inches, and it was particularly noticed that it did not double on itself; no flatus escaped. Ordered hot fomentations, with opium, to be applied during the night.

25th.—This morning the nurse tells me he slept at intervals during the night. Passed about two pints of urine during the night; was rather sick; had great pain in the abdomen, also in his back. His bowels had not been relieved. To continue the fomentation; pulse 108, small; tongue very dry. 11 a.m.—Has been very sick: vomited yellowish, sour-looking matter with a feculent odour; no relief to the pain. Ordered pil. saponis co., gr. v., 4 tis horis. Passed the long tube of the stomach-pump about eight inches up the lower bowel, then injected nearly a pint of warm water. On withdrawing the tube he passed the injection with some small flakes of feculent looking matter and mucus; also voided two or three ounces of urine. 6.30.—Has not been sick since the enema. He is lying now on his left side, and expresses himself as feeling more comfortable; pulse 112, very small and feeble; tongue very dry. 7.30 p.m.—Again introduced the enema tube and injected about a pint and a-half of warm water, and withdrew half the quantity by reversing the action of the syringe. This had a feculent odour, but not discoloured; still very sick.

26th.—Dozed during the night; was very sick; passed his

urine freely. His abdomen is very tense and painful. The restlessness so marked during the whole of his illness is very great this morning. Pulse 130; tongue dry. 11.30.—Passed a small quantity of slate-coloured liquid fæces with mucus into the bed; had great pain during defæcation. Still very sick; the vomited matter is quite stercoraceous now. Dr. Barlow ordered at 1.30, calomelanos, gr.ss.; opii, gr.j., 3 tis hôris; and brandy, ʒiss. In the course of the afternoon he was very sick and passed his urine. Twice to-day he has passed a small quantity of matter from the bowel similar to what has just been mentioned. Was also very sick. 12 p.m. —Had passed a large motion. Vomiting much less. Is in less pain. Tongue very dry. Pulse 120.

27th.—Early this morning he again passed a large quantity of fæces like the last. Vomiting has quite abated. Taken a little beef-tea and milk. He expresses himself as feeling much relieved. His abdomen is not so tense. Dr. Barlow called attention to the ease with which the intestines might be seen contracting. The patient is evidently much better. No vomiting; pulse 120; tongue dry and brown. To continue the pill every four hours. In the afternoon he passed another large motion.

28th.—Has passed a restless night. Bowels have not been relieved since last night. Abdomen very tense. He is very restless. Tongue dry and parched; pulse 110; urine normal. Takes a little milk and rice in it.

29th.—Much about the same. Pulv. opii, gr.j., 3 tis hôris.

30th.—No further relief to the bowels. Abdomen very tense. Complains of griping pains. Pulse 120; tongue dry. To have a soap enema this evening. ℞. Pil saponis, gr.iv.; calomelanos, gr.ss. in pil, 4 tis hôris. The enema was followed by a copious evacuation of scybalous slate-coloured fæces. Urine not quite so plentiful and rather darker.

31st.—Passed a moderately good night and feels better this morning. Abdomen not quite so tense. ℞. Pil saponis co., gr. iv.; ext. aloes aquos, gr. ½; ext. nux vomicæ, gr. ¼, 4 tis hôris.

November 1.—Much the same. Pulse 100, small, soft, and compressible. Repeat pill. Enema saponis, which was followed by a copious evacuation, liquid and clay coloured.

2nd.—Expresses himself as feeling much better. Pulse 98; tongue still dry. Craves for something to eat. Had some fish to-day. Passed two large motions during the day.

3rd.—Says that he passed a pretty good night. Bowels again relieved this morning. Is now sitting up in bed.

6th.—Greatly improved. Abdomen quite soft. In no pain. Bowels have acted freely.

10th.—Left the Hospital quite recovered.

The boy ascribed his illness to having eaten large quantities of grapes with husks and stones just previous to his attack.

In this case we have the usual clinical history of a case of obstruction of the bowel. This boy was suddenly seized with griping pain in the abdomen, and in consequence it was thought advisable to give him a dose of castor oil. The medicine did not operate; nausea and vomiting came on, and the pain increased. Another dose of castor oil was taken without any relief to the bowels. The pain continued. His bowels had then not been open for four days. On the fourth day he was admitted into the Hospital. Dr. Barlow then proceeded to call attention to the different symptoms; and after speaking of the obstinate constipation, he remarked—"The symptoms to which I more especially wish to call your attention are, the pain in the abdomen, the nausea and vomiting, the quantity of urine passed, the degree of abdominal distension, the degree of prostration and of collapse, and, lastly, to call attention to the boy's physiognomy. The first thing the patient felt of his illness was a griping pain in his abdomen. The degree of pain in cases of obstruction of the bowels varies very much. It varies according to the nature of the obstruction, and according to the severity of the peritonitis, and, above all, according to what part of the intestine is obstructed. If the upper portion of the small intestine be the seat of obstruction, then the pain is usually very great, comes on very early —in fact, is one of the earliest symptoms. It is just the opposite when the lower portion of the large intestine is obstructed. And the reason why the pain comes on earlier, and is more severe when the small intestine is obstructed, and less so when the large intestine is obstructed, is probably to be found in the greater sensibility of the upper portion of the small intestine. Nausea and vomiting were early symptoms in the case." Dr. Barlow further remarked—"When the obstruction is in the duodenum, jejunum, or ileum, the vomiting is usually found to be one of the first symptoms, and it is usually found to be urgent from the beginning of the attack. The pain and the vomiting are often the first indications. In contrast with this, we may have the signs of obstruction; constipation that cannot be overcome; more or less pain in the abdomen; great distension of the abdomen; and these going on for three or four days, or even two or three weeks, and yet there may be little or no vomiting. The vomiting may not come on until some days, even a week, after the constipation. When, however, such is the case, it will be found that it is the large intestine that is affected, and especially the descending colon or rectum. It does, however, happen at times that the vomiting comes on early, even when the ascending colon is obstructed; or when the transverse or descending colon is obstructed." This, Dr. Barlow thinks, is owing to some concomitant circumstance, as the pressure of the tumour of the distended bowel or the administration of purgative medicines. Dr. Barlow then remarked, "I would, therefore, observe, if you find that the vomiting has come on early, it is strong evidence, but not positive evidence, that the obstruction is in the small intestine or cæcum; if, however, the vomiting has not appeared until some days after, there is positive evidence that there is obstruction, then it will usually be found to be the colon or rectum that is affected.

I now come to speak of the quantity of urine secreted. In this case you may notice that the urine was not very scanty. In some cases, however, it is so. When the obstruction is in the duodenum or in the jejunum, the quantty of urine secreted is very small, and may even be suppressed for two, three, or more days. When, however, the obstruction is low down the intestine (and I believe it to be so in this case), the quantity of urine is not much diminished. In the case of a boy who was under my care some years ago with all the signs of obstruction, no urine was secreted (the catheter showed it was not retained) for six days. The autopsy showed the obstruction to be in the jejunum. Also in a case under the care of Dr. Hughes the urine was almost suppressed. The post-mortem examination showed the obstruction to be high up in the small intestine. Dr. Munk once mentioned to me a case of obstruction of the bowel, in which the urine was suppressed, and in consequence the patient was considered by the Medical gentleman in attendance to be suffering from 'ischuria renalis.' There is a case recorded by Dr. Lever (see *Guy's Hospital Reports*, vol. ii., year 1844, p. 414) of narrowing of the upper part of the small intestine, in which the secretion of urine was very much diminished. Still more recently, in 1861, in a case of a patient of my colleague, Dr. Rees, suffering from obstruction of the bowel, the pain and vomiting were the first symptoms. The urine was almost suppressed, and after death the autopsy showed the obstruction was situated five feet from the duodenum. (See *Post-Mortem Record of Guy's Hospital* for the year 1861, No. 179.) Now, these cases clearly show that we are liable to get suppression of the urine when the upper portion of the small intestine is obstructed. But, you will ask, do we always have suppression of, or very scanty, urine in such cases? My experience is that we nearly, if not always, do. If, however, my explanation of this phenomena be correct, I can readily imagine that the urine may in some cases be much more scanty than in others." Dr. Barlow then proceeded to explain why the urine is suppressed or greatly diminished in obstruction of the upper portion of the small intestine, and said: "Without entering into the physiology of the secretion of the urine, I would remark, in order that there may be a proper quantity of urine secreted, it is essential that a sufficient quantity of water be taken into the alimentary canal, and thence find its way through the vena porta, right side of the heart and the lungs, into arterial and systemic circulation, to hold in solution urea and other urinary constituents. It is absolutely necessary that such constituents should be held in solution in order that they may be eliminated by the kidneys. Moreover, these bodies while held in solution seem to act as diuretics, and they stimulate the kidneys to a due performance of their functions. If, therefore, a sufficient quantity of water, for the purpose above mentioned, cannot find its way into the systemic circulation, then the urine is diminished in quantity or even suppressed. Now, this may occur in consequence of the fluids being rejected from the stomach before they can be absorbed by the excessive vomiting, or from the bowel by excessive purging. Now, I have already stated the vomiting is usually very urgent from the beginning, when the upper portion of the small intestine is affected. In such cases, as we might expect, the fluids are rejected before they can be absorbed, and the urine in consequence is scanty or suppressed.

Further, if the duodenum is obstructed, the fluids are exposed over a comparatively small portion of the absorbing intestinal mucous surface, and exposed over a much greater surface when the cæcum is the seat of obstruction: therefore, in the latter case much more likely to reach the arterial system than in the former. Experience has shown, when the duodenum was affected the urine was suppressed, and when the intestine in the neighbourhood of the cæcum was affected, the urine was often diminished in quantity, but not suppressed. You will thus see that I consider the quantity of urine secreted in such cases depends very much on the urgency of the vomiting and on the seat of the obstruction, but especially on the vomiting. In other diseases, also, the fluids may be rejected, not by the stomach, but by the intestine itself, before the water can be absorbed, for instance, by the excessive purging in cholera, and in which disease, as in cases of obstructed duodenum or jejunum, the urine is exceedingly scanty, or even suppressed. In order to illustrate what I have just stated, I will mention the following brief particulars of cases, in which there was severe vomiting, and, in conseuence, scanty urine :—

Wm. H., aged 36, admitted into Job Ward February 22, 1854. Said nothing had passed his bowels since February 14—that is, for six days. Sickness and vomiting had appeared on February 15—that is, five days before admission. On admission, he vomited everything he took; excessive thirst; the urine scanty. On the 23rd, the vomiting had ceased; the pain had diminished. On the 24th, the urine was more copious, the pain had almost disappeared, and the bowels moved. He was treated by opium and enema of soap and water.

Another case was that of John D., aged thirty-three, admitted June 8, 1860, under the care of my colleague, Dr. Wilks. On admission, said he had had intense pain in his belly, and nothing through his bowels since June 5. Vomiting very troublesome. Passes very little water. On admission, was in intense pain, coming on in paroxysms. Has vomited fecal matter. 9th.—He has not passed any water to-day. 10th.—Vomiting not so troublesome. Vomited very little, and has been able to take some beef-tea. He has passed about a pint of urine to-day. This patient was treated with opium, and did remarkably well.

Other cases might be brought forward to show, as the two last-named cases do show, that when the vomiting was excessive, the urine was scanty; and as the vomiting abated and fluids were retained in the stomach, by degrees the urine became more plentiful. We may here mention, in confirmation of Dr. Barlow's views, the case of a patient of Dr. Gull's, who died a few weeks ago, in the Clinical Ward, of chronic ulcer of the stomach and constriction at the pyloric extremity of the stomach. This patient of Dr. Gull's suffered with excessive vomiting, and did so up to the day of her death. Forty-eight hours before she died, she passed no urine, and at the post-mortem examination the bladder was examined, and found to be quite empty. Dr. Barlow further observed, "I would therefore on this point mention, should the small intestine, or any portion of the intestinal tract be obstructed, and there be excessive vomiting, that the urine may be diminished in quantity. Therefore if irritating medicines are administered and vomiting excited, no matter which of the intestines is obstructed, the urine may be diminished in quantity; but when there is suppression of urine, I should always look for, and experience would lead me to expect, that the obstruction would be found high up in the small intestine."

Sanatorium near Dublin.—The managers of St. Vincent's Hospital, Stephen's-green, have purchased the splendid residence known as Lyndon Castle, Blackrock, for the purpose of converting it into a sanatorium to which they will send the convalescent patients to enjoy the benefit of country air, sea-bathing, etc., previous to returning to their homes. This is the first sanatorium ever established in Ireland.

The Cattle Plague in Cheshire.—The number of animals attacked by the Cattle Plague in Cheshire had attained on April 7 the total of 50,954, or nearly one-fourth the whole number of attacks in England, Wales, and Scotland. Even now the disease lingers in the county, the number of attacks in the week ending April 7 having been 971. There appears little reason to doubt that the spread of the disease was facilitated in Cheshire by the indisposition of the inhabitants to slaughter their sick animals. Thus, to April 7 no fewer than 31,813 had been permitted to die from Rinderpest in the county, while the whole number killed to the same date was only 9,063.

SATURDAY, APRIL 28.

ASSERTED INCREASE OF INFANTICIDE.

In the report which Dr. Lankester has just issued on the inquests held by him as Coroner for the Central District of Middlesex during the year ending July 31, 1865, the subject of infanticide occupies a prominent position. Dr. Lankester appears still to hold the opinion that crime is on the increase to a very considerable extent, as is evidenced by the verdicts of "wilful murder" returned, in 1862-3 of 53, in 1863-4 of 56, and in 1864-5 of 61 newly born children; moreover, he maintains that the verdicts of Coroners' Courts cannot be regarded as the true indication of the amount of destruction of newly-born infant life, and he avows his belief that child murder is in excess of the highest rate of inquests in any part of the country.

Now, with all respect for Dr. Lankester's opinion, we venture to suggest the possibility of mischief arising from the manner in which he has at various times expressed himself upon this subject. We know him to be one of the most able and zealous of public officers, and we are concerned, therefore, lest he should set afloat ideas of an exaggerated character about an evil which is, and necessarily must be, very limited in its operation. One does not like to take up a foreign newspaper and see it written therein, professedly on Dr. Lankester's authority, that England is "a nation of infanticides;" and great as may be the benefits of a cheap press, it is somewhat irritating to find that materials for sensation "leaders" in the most ultra-accusatory strain should all be pointed with reference to the Coroner for Middlesex, tending to prove that infanticide is terribly and alarmingly on the increase. Unmindful of the worldly wisdom which lies at the root of the French proverb referring to the washing of dirty linen, scarcely a week passes without some portion of the daily press—chiefly price one penny—"improving the occasion" in this respect. Every inquest which is now held on the body of a child, as to the cause of whose death there can be the faintest shadow of doubt, goes into the newspapers as "child murder" in capital letters—in some instances when the finding of the jury directly removes the case from any such category.

No doubt the judicial investigations relative to the hag Winsor startled many by disclosing that such crimes can be and actually are committed at the present day with certain probabilities in favour of their non-detection. But there has been nothing whatever that can justly be called proof of any such increase in the number of actual infanticides as to give warrant for the lamentations which have been so loudly expressed. The plain truth about the matter was summed up in a few words by Lord Stanley when speaking at Birmingham last autumn on this very subject, that "it is just one of those periodical panics to which all who have watched the course of public opinion in this country know we are liable."

*

Not long ago we had an astounding piece of intelligence from the Abbé Cesare Contini, who was sent over here by the Papal Government to collect statistics of infanticide, and who afterwards published a statement to the effect that "13,000 children perish in England annually, *des mains de leur parents*." This estimate rests, we are informed, upon a statement of Dr. Lankester that, as Coroner for Middlesex, he holds annually from upwards of 70 to 80 inquests on bodies of children found exposed in the streets and elsewhere, and that judging from the advanced state of decomposition in which many of them are found it is probable that an equal number escape observation. M. Contini turned then to our judicial statistics for 1863, and found that 6506 inquests were held by the Coroners of England on bodies of children under seven years of age, and he then complacently inferred that, on Dr. Lankester's own reasoning, 6506 cases were lost sight of, consequently that 13,000 children are murdered annually by one or other of their parents. It was a great deal too bad of Dr. Lankester to lay such a trap for unwary travellers through the domain of figures; and it must be no small source of satisfaction to those whose undoing has been wrought by his specious theory that he is in a measure "hoist on his own petard," for he has publicly committed himself on more than one occasion to an "estimate" that over 4000 children become the victims of infanticide in a year in England—a number which is about as trustworthy as M. Contini's 13,000. Does Dr. Lankester mean seriously to say that because in his district of about one million of population 80 inquests are held and 80 cases are unrecognised, therefore in the remaining two millions of population in London the same proportion of inquests and undetected cases to the population obtains?—in short, that nearly 500 children are murdered in London in a year? And even if this were not an entirely erroneous assumption as regards London, it would be the veriest *reductio ad absurdum* to apply such a mode of reasoning to the country towns and rural districts. Yet Dr. Lankester has gravely asserted that the facilities for infanticide are actually greater in the country than in London; that "the opportunities for throwing murdered newly-born children into ponds, and of burying them before the crime is discovered, are much greater in the country than in London." If there were no premonitory evidence of pregnancy all this might be possible, but everybody who has had experience of country life knows how unlikely it is for such an event as the birth of a child to take place without its being patent to, and canvassed by, all the gossips of the neighbourhood. It is in London, above all places, where people live for years without knowing their next-door neighbour, that infanticide can be most readily and safely committed; and Dr. Lankester's district, comprising as it does the termini of three great lines of railway, is peculiarly situated in that particular, insomuch that inquests are not uncommonly held by him on bodies of children which have been conveyed by rail from other parts into his district. Indeed, we believe that about 90 per cent. of the inquests on young children in London are held by Dr. Lankester alone.

But we have yet another bone to pick with Dr. Lankester, for following up the hypothetical 150 infanticides yielded by his district he makes a calculation that "one out of every 30 women met in the streets of London has at one time or another during her life 'put away' her child," and as he has complained of being misunderstood, we will give him the full benefit of his own explanation:—

"It is not probable that the 150 women in his district will commit the crime of infanticide a second time; and, therefore, it is fair to suppose that the 150 a-year are new mothers. The average age of these women is about 20 years, and the expectancy at that age is 40 years; if you multiply 150 by 40 you will have the number of women living in my district who have made away with their children. There are 360,000 adult women in London; so that, according to my calculation, there are 12,000 women, or one in 30, who have murdered their children."

We quote the above from a report of some observations addressed by Dr. Lankester to the Statistical Society in December last.

Now, it appears to us that it would be an extremely difficult matter to prove either one of these hypotheses; first, that women who have committed the crime with impunity once will be unlikely to do it again; secondly, that the expectation of life of women in London of the class amongst whom the crime is at all common is as high as the average expectation of women of all classes, wealthy as well as poor, and living in all sorts of localities, healthy as well as unhealthy; thirdly, that conclusions drawn from Dr. Lankester's district are equally applicable to the whole metropolis.

We believe that the negative of these three positions is much more in accordance with absolute fact, and we therefore think it unwise that statements so open to question should be publicly advanced by one who presumedly speaks with authority.

We take leave here of Dr. Lankester, with the assurance that our criticism is intended only to remind him of the necessity of the greatest exactitude in whatever he may utter in public whilst discharging the duties of his office. For his active and zealous efforts to put a stop to crime of whatever nature we have nothing but commendation.

It is satisfactory to know that our official statistics give no support to the notion that we are going backwards in the scale of morality. At any rate, our chief statist, Dr. Farr, has very recently proclaimed himself "on the side of the angels"—to borrow Mr. Disraeli's phrase—and has asserted his belief that infanticide is not at the present day the cause, in any country, of any considerable number of deaths. Moreover, he calculates from positive facts that, with the exception of the Scandinavian race, the mortality of young children is less in England than in any Continental state. We all know that the loss of infant life in our densely-populated cities and towns is excessive, but the miserably defective sanitary conditions under which the poorer classes in those places struggle through their brief term of existence makes it superfluous to seek in violent death for a solution of the question why their little ones die so fast. One thing seems clearly established, that we need not go beyond the first year of age to get at the measure of child murder. Every day, every hour of life, makes the crime more difficult of accomplishment, both as regards secrecy and the amount of vital energy to be destroyed. An infant just born has but the feeblest hold on life, a breath would almost suffice to extinguish the flickering lamp; but three months hence its presence will have asserted itself, and every day increases the number of witnesses to the fact of its existence. If, then, we take the number of children of less than one year of age returned to the Registrar-General under the head of "Murder and Manslaughter" during the six years 1858-63, in England, it will be found that the deaths from that cause are less in proportion to the population in the last three years than in the first trienniad of the period. In London the increase in the number of infant murders does not, we believe, keep pace with the increase of the infant population. And with regard to a favourite mode of argument adopted by those who contend that infanticide is rapidly increasing, namely, that the coroners' inquests do not give anything like the full measure of infant murder, that "thousands of infants are murdered by suffocation or overlaying in bed—or, perhaps, as Mrs. Gamp has it, "shut up unbeknownst"—while "thousands are killed by the slower process of opiates, neglect, and other easily devised means of getting rid of children who are in the way," the sufficient answer is that all this is the wildest conjecture, unsupported by proof, the onus of supplying which rests with the propounders of the theory.

A careful and discriminating inquiry into the causes of death of young children will do more to reveal the secret of their high mortality than any amount of "estimates" and

conjectures. That 200 children should be murdered in their first year is a sad and terrible thing enough; but 200 is an infinitesimal part of the 100,000 deaths of young children from all causes; and if all the 1500 deaths by accident or negligence be added to the 200 murders, it is evident we are yet only dealing with "a drop in a bucket." Where violence slays its hundreds, ignorance, "poverty, hunger, and dirt" slay their tens of thousands. It is in the fever-stricken "Providence-places," in the foul back slums and courts, shut out from the pure air of heaven, that the demon of infanticide holds sway. But he works neither with the knife nor the thumb on the throat; secresy is not necessary to his operations, which are patent to all who have eyes to see and noses to detect the noxious elements in the midst of which he works; and his most potent auxiliaries, those who should be arraigned for this most alarming, because infinitely the most wide-spread system of child murder, are the landlords who grow rich on the money which they wring from the miserable occupants of hovels unfit for human habitation, and the parish authorities who have no higher conception of their duties than the snubbing of an energetic health officer or the endless squabbles arising out of their own self-conceit and ignorance.

An outcry against one particular wrong is apt to direct the public mind too much to its exclusive consideration, and the terrorists who proclaim aloud that infanticide is making such rapid strides are possibly doing more mischief than they themselves are aware of; for it has been well said of another form of crime that "nothing is more clearly established than that such crimes are too often committed from imitation. A single paragraph or some particular but apt expression, may be, as to the mode in which the deed was done, seizes the imagination, and the disposition to repeat the act in a moment of morbid excitement proves irresistible." The persistent efforts which Dr. Lankester and others are making to put a stop to infanticide deserve every support, but sensation "leaders" and "penny-a-liner" paragraphs cast a shadow of suspicion and distrust over everything to which they relate.

PURIFICATION OF WATER.

According to the recently published report of the commissioners concerning the pollution of the Thames, there are on the banks of the main stream and its tributaries 1001 cities, boroughs, towns, hamlets, and parishes above the pumping-station at Hampton. Besides the refuse matters from tanneries, paper-mills, etc., the river water before it is supplied to us receives the sewage from hundreds of thousands of people, together with dead dogs and other abominations thrown into it. Now if we could feel assured that these matters were thoroughly destroyed by natural causes before the water reaches us, the fact of its having received such impurities would not be so objectionable. But we cannot feel thus assured, so that the organic matters found in the Thames water must, to say the least, excite our suspicion.

For the benefit, therefore, of those who, like ourselves, dislike to drink water with a certain percentage of yellowish, heavy-smelling "oxidisable organic matters," made up of sewage, infusion of dead dogs, and other such things, we call their attention to the means of ready and simple purification of water which are within their reach.

Water may be purified by the *black oxide of iron*, which, as Mr. Thomas Spencer, of Euston-square, has discovered, frees water from very nearly all its organic impurities. He was led to this discovery by studying the natural purification of water during its percolation of the soil. He found that sands which contained the black or magnetic oxide of iron purified the water which was filtered through them, and that sands which did not contain this substance had no appreciable effect.

Magnetic or black oxide of iron as obtained for medicinal purposes is unsuited for use, not only on pecuniary grounds, but because of its finely-divided state. By heating native carbonate of iron, or spathose iron ore, magnetic oxide is obtained in a suitable condition, but not cheaply enough for application on the large scale. Mr. Spencer obtains it by heating together hæmatite, or red oxide of iron ore, with sawdust. The oxide as made by his process contains a small percentage of carbon. The use of this carbon is, he states, to render the substance harder and less brittle.

In the state in which it is used it is in the form of coarse black grains, which are strongly attracted by a magnet. Its commercial name is "magnetic carbide."

Now, if ordinary river water, even the more impure kinds of it, are made to percolate a layer of magnetic carbide some inches thick, it is not only filtered, as it would be by passing through a similar layer of gravel or sand, but *it is deprived of much of its soluble organic impurities*. According to Mr. Spencer, water containing several grains of organic matter by filtering through a sufficient layer of magnetic carbide loses nearly the whole of it, containing, after its filtration, only about half-a-grain or less of organic matter. The effects of passing the water supplied by the London companies through a domestic filter containing a layer of this substance is certainly very striking. In a few minutes the water passes through the filter, and when compared with some of the water which has not been purified in this way a great difference is observed. Not only is it remarkably bright, but it is found to have lost its previous yellowish colour, and to be free from taste or smell of any kind. But more than this, if a few drops of solution of permanganate of potash are added to the water, the pink colour thus given to the water will be found to be unchanged when the water, which has not been purified by this process, will have wholly destroyed the colour of permanganate of potash similarly employed. We have found (our experiments were made upon the Grand Junction Company's supply) that water purified in a few minutes by Mr. Spencer's magnetic carbide will preserve the faintest tint given to it of permanganate solution, if preserved from the atmosphere in scrupulously clean vessels.

Lastly, the crowning property of the black oxide of iron, or magnetic carbide of Mr. Spencer, is that it suffers no perceptible diminution in its power by time and use. In the waterworks at Southport, in Lancashire, it has been in use for seven years without showing any diminution in power, and in domestic filters in use for the same period the same is stated to be the case, although the purifiers have not once been cleansed or refitted. With a filter which Mr. Spencer stated had been thus in use the effects upon water were as striking as in one newly fitted.

Mr. Spencer has put forth a theory of this remarkable and valuable property of the magnetic oxide of iron. He regards this property to be due to the conversion of ordinary oxygen into *ozone* by the magnetic carbide. Granting the production of ozone, the rapid disappearance of oxidisable organic matter is only what we should expect from its known properties. Mr. Spencer says its purifying property is "due to its power of attracting oxygen to its surface," which then "becomes changed into ozone—or, at least, a body having its properties." He regards ozone as "oxygen polarised," and considers that oxygen when attracted by the magnetic substance becomes polarised, just as a needle is polarised when attracted by a powerful magnet. The question, however, may be raised as to whether there is such a thing as self-existent *polarised oxygen*, with little chance of a definite answer being received. That the magnetic carbide does ozonise oxygen, Mr. Spencer considers to be established by the facts that air passed through a layer of it turns tincture of guaiacum paper blue, as would ozone, that the carbide itself turns the tincture blue, and that water filtered through the oxide into a solution of starch and iodide of potassium rendered it faintly blue. May not, we suggest, the oxide, which must not be crystalline, but in the amorphous state, have a common principle of action with

spongy platinum and charcoal, and other non-magnetic porous bodies? But whatever be the theory of its action, its effects in removing oxidisable and other organic matter from water are undoubted.

Another way in which water may be purified, probably well known to most of our readers, is that of Mr. Condy. The solutions of permanganate of potash and other bases when added to water soon oxidise organic matters, sulphuretted hydrogen, and other oxidisable bodies which may undesirably be present in water. The quantity necessary for the purpose is so exceedingly small that the alkali introduced into the water is of no importance, while the manganese is converted into hydrated peroxide of manganese, which gradually settles down or may be removed by filtration. The permanganate should be added to the water in as large a quantity as the water can deprive of its pink colour on standing for two or three hours after it has been added.

By one of these ways, by using Mr. Spencer's purifying filter or by adding a little of Mr. Condy's solution of a permanganate and subsequently passing the water through a common filter, those who appreciate the hygienic importance and the luxury of pure drinking water can easily supply themselves with it, albeit the water may have to come from the Thames or other stream similarly polluted.

THE WEEK.

MERCY TO RATEPAYERS.

We see with satisfaction a notice in the *Times* that it is proposed by the Metropolitan Board of Works—(we believe that the real originator of the scheme was Major Lyon)—that the *owners* of property shall in future bear their share in the cost of permanent improvements of the metropolis. Hitherto that burden has rested on the shoulders of the *occupiers—i.e.*, the *ratepayers*, who are assessed upon their rental for improvements in which they have a very passing interest, whilst the value of the property they occupy is increased for all time. Medical men are *par excellence* householders and ratepayers, and ought to have an eye to any changes which affect the burdens they bear in that capacity.

THE NEW CATTLE PLAGUE DEPARTMENT.

We learn that Colonel Harness has obtained the assistance of Mr. William Clode, of the Registrar-General's Office, in organising the new department under the Privy Council for business connected with the cattle plague. This appointment is highly satisfactory, as Major Graham's office is one of the best training schools for public servants to be met with under the Crown. In addition to the conduct of the business of his own department proper, the elaborate and extensive arrangements connected with the taking of the Census have for many years been entirely in the hands of Major Graham and his assistants; and as Mr. Clode has held responsible positions during both of the last of these operations, and also subsequently, we augur well for the efficiency of any staff whose formation and drilling into working shape are placed under his supervision.

THE SUPPOSED CASES OF POISONING AT THE CARDIFF WORKHOUSE.

We regret to state that the Medical Officer at the Cardiff Workhouse, Mr. Henry Edwards, has been subjected to a charge of having caused the deaths of two men, Francis Buckley and Evan Frank, who died on the night after taking some medicine which had been prescribed for them by Mr. Edwards. Our readers, however, will be glad to learn that the scientific evidence given by Dr. W. B. Herapath in the case has completely exculpated Mr. Edwards. The inquiry was held in the Cardiff police-court before the local magistrates. The post-mortem examinations showed that the deceased men had died from congestion of the lungs and brain. No poison, metallic or vegetable, was detected in their bodies, and analysis showed that the medicine administered by Mr. Edwards was a harmless mixture containing iodide of potassium and carbonate of potash in small doses. In the case of one of the men, Francis Buckley, who was old and weak, a large mass of unmasticated undigested food was found in the stomach, and probably might have contributed to depress the vital powers and induce the fatal result. No such cause, however, could be alleged in the other case, and the Medical witnesses were unable to account for the cerebral congestion which proved fatal. The case, indeed, seems to have been one of simple congestive apoplexy. The charge against Mr. Edwards was at once dismissed by the Bench, and we heartily congratulate that gentleman on the result.

CHOLERA.

Cholera has appeared in Rotterdam and its vicinity, as well on the French coast. Its occurrence in the former locality has been notified to the authorities at the various outports of the United Kingdom in the following official letter:—

"Privy Council Office, April 23, 1866.

"Sir,—I am directed by the Lord President of the Council to request you will call the attention of the authorities at to the communications which, by his Lordship's instructions, were addressed to you from this Office in August, 1859, and subsequently in July, 1865, soon after the cholera had broken out in Egypt and in Turkey.

"The progress which the disease has made in Europe since the date of the last-named letter, and the fact that, from information received to-day, cases of Asiatic cholera have occurred at Rotterdam and its vicinity, have again called attention to the importance of not neglecting any means of arresting the progress of the disease, if it should be introduced into the United Kingdom; and I am, therefore, directed to reiterate the precautionary suggestions contained in the above-mentioned letters, and to repeat the expression of a hope that means will be provided for the reception and Medical treatment of any poor seamen or other persons who may, on their arrival in this country, be found to be suffering from cholera.

"I am, Sir, your obedient servant,

"The Worshipful the Mayor. "Arthur Helps."

OVARIOTOMY UNDER DR. RICHARDSON'S METHOD OF LOCAL ANÆSTHESIA.

Some weeks ago we reported a case of ovariotomy in which Mr. Spencer Wells operated after local insensibility had been produced by Dr. Richardson's method. We have now to report another successful case of a similar kind. In this instance Dr. Thorburn, of Manchester, produced the local anæsthesia while Mr. Braddon operated. Dr. Thorburn used a triple jet, and although some little longer time than is usual occurred before the skin was insensible, the anæsthesia was made perfect, and the long incision was carried out without any pain. It turned out, on removing the cyst, that the adhesions to the intestines were very firm and extensive, so that the operation was tedious and difficult. But wherever the knife had to go the ether spray was directed, and from the first to the last the pain experienced and expressed was almost *nil*. The patient being unusually feeble, chloroform was considered undesirable, so that the substitution of the local anæsthetic, which presented all the advantages of chloroform without any of its dangers, was most fortunate. We may add that the new anæsthetic method has also been successfully used by Dr. Thorburn for the operation of femoral hernia. The patient made a good recovery.

DR. GREENHALGH'S CASE OF CÆSARIAN SECTION.

Dr. Greenhalgh's patient, on whom Cæsarian section was recently performed under the new method of local anæsthesia, returned to her home in Essex on Saturday last. In the whole course of her recovery she suffered from not one

untoward symptom; indeed, it seemed as though the natural tenour of her life was at no moment disturbed. The wound healed by the first intention; there was at no time any inflammatory indication; the appetite and sleep remained good; and the circulation quiet. Once in the course of her convalescence she was startled, but the effect was not lasting. On the twenty-first day after the operation she went to church, walking there herself, and she bore her long journey home well, but was considerably affected on rejoining her children. The wound in the abdomen has healed so neatly that the position of the sutures could hardly be defined. As yet Dr. Greenhalgh has deemed it prudent not to subject the patient to examination to determine the condition of the tumour in the uterine passages that prevented the possibility of natural birth; but there are no general symptoms indicative of its progress. On the contrary, the general health has improved since the delivery by operation. As we have already said, this case ranks amongst the most important in history, and marks a distinctly progressive step in our science and art.

ST. GEORGE'S HOSPITAL.

The sad occurrence which took place at St. George's Hospital last week—the sudden death of Sir Frederick Roe—recals to mind an event which happened under similar circumstances many years ago in the same institution, and with which the Profession at large are familiar—the death of Hunter. In both instances there had been for some little time more or less difference of opinion in regard to the internal economy of the Hospital. On October 16, 1793, Hunter, speaking in reference to the point at issue, was interrupted in his remarks, and, says his biographer, "he immediately ceased speaking, retired from the table, and, struggling to suppress the tumult of his passion, hurried into the adjoining room, which he had scarcely reached when, with a deep groan, he fell lifeless into the arms of Dr. Robertson, one of the Physicians of the Hospital, who chanced to be present." Recently, a committee appointed to inquire into the matter recommended an alteration in the system of nursing at St. George's Hospital, and party spirit seems to have run high amongst the governors at large, if we may judge by the large attendance in the Board-room on Friday week. It was suggested that nurses should be provided from St. Peter's Home, Brompton. Amongst those who were opposed to such a change was Sir Frederick Roe. At the special meeting called to consider the matter, Mr. Abel Smith moved a resolution deprecating the introduction of any religious discussion, and pointed out that the sole object was to get good nursing for the Hospital. A first amendment, upon which a very long discussion took place, was one which affirmed that it was not advisable to introduce the system of nursing which the committee had proposed. It was upon this question that a good deal of difference of opinion existed, and about which no small amount of excitement was rife amongst the governors. Now the governors of an Hospital, in all matters that relate to the Medical care of the Hospital, are necessarily wont to be guided by the opinions of the Medical staff, but in the present instance the staff does not seem to have been specially consulted. Sir Frederick Roe, as we have said, was in favour of the continuance—or, at furthest, the improvement—of the old system of nursing, and it appears that Dr. Wilson had just made a temperate speech when Sir Frederick was specially called upon, and amid the confusion was perhaps more excited than usual. He had been, we understand, suffering for some time from symptoms that threatened apoplexy, and after he had spoken shortly he expressed himself as not feeling very well and retired. It seems that he went to the out-patients' room, and Mr. Holmes happening to be passing heard some one say, "Is there nobody there?" and found Sir Frederick sitting up, but very faint. Dr. Wilson was summoned, Mr. Henry Lee also, who had previously attended him, arrived almost immediately afterwards. All the means of restoration adopted, however, failed, but we are informed that the pulse could be felt beating after the respiration had entirely ceased. The question before the meeting was virtually shelved for the present by the adoption of a resolution to the effect, that it was expedient that the system of nursing should be improved, and that a committee of ladies be formed to assist in carrying out this object.

We are of opinion that whatever system of nursing be adopted, the control or authority in all that relates to the care of the patients of any Hospital, should be placed in the hands of the Medical officers. It would be against the interests of the patients were there two conflicting authorities in the wards. Clearly a nurse whose heart is in her work, and who is possessed of high intelligence, is far preferable to the ignorant woman who does as little as she can for her wage, and looks upon her duties as so much disagreeable daily task. It has been brought against the novel systems of nursing, that the religious convictions of patients are acted upon, and that the "Sisters" are ever aiming at preparing them for death instead of restoring them to health. We very much doubt whether this statement has any basis in fact; but, even were it true, it is not worth much as an objection. If the patients are better cared for under one than another system, by all means adopt it, only have no divided authority.

It is right to add that the system of nursing Hospitals by sisterhoods, or by societies of trained nurses, has been now extensively tried. University College Hospital is nursed by the All Saints' Sisterhood, King's College by the Sisters of St. John's House, St. Thomas's by the Nightingale Nurses, and the Great Northern by the North London Deaconesses' Institution. We believe that in every instance in which the plan has been adopted it has answered the most sanguine expectations. We can state from our personal observation that both Medical staff and patients have derived the greatest advantages from the substitution of a a force of educated and trained gentlewomen and subordinates for the Gamp and Prig race of former days. After all, the thing wanted in every Hospital is an efficient and humane set of nurses, under Medical control, not above it. Whether they shall be religious, or dressed in a quasi-conventual uniform is a question of minor importance.

THE GUARDS MEDICAL SERVICE.

Readers of the debates in Parliament must have noticed that within the last few weeks the Secretary for War has had a number of questions put to him in reference to a change which is said to be about to be introduced in the system of promotion of Medical officers in the Guards. That system has been hitherto strictly regimental; it is now proposed to substitute promotion by seniority in the brigade. The effect which will be produced by this innovation on the prospects of many of the Medical officers will be understood from the following paragraph, which we extract from a leading article in a recent number of the *Daily News*:—

"For our readers to understand the full force of the hardship which is thus intended to be inflicted upon many deserving officers a few words of explanation are desirable. The brigade of Guards consists of three regiments—the Grenadiers, numbering three battalions; the Coldstreams and Scots Fusiliers two each; in all, seven battalions. Each battalion is provided with a Surgeon, and, in times of peace, one Assistant-Surgeon. In the Crimean war, however, additional Assistant-Surgeons were appointed, and since that period some of those commissioned during the emergency have been absorbed into the strength of the regiment. So that at the present time there are four Assistant-Surgeons to the three battalions of Grenadiers, and three each to the other two regiments of the brigade—the Coldstreams and the Fusiliers. The Surgeon-Major of the first battalion in each regiment is the regimental Surgeon. Besides the duties connected with his own battalion, he superintends the Medical administration of the regiment generally. This post is a very desirable one. Its occupant is not subjected

to the changes of quarters to which the other Medical officers have necessarily to submit. He remains at head-quarters when the regiment is despatched to various parts of the kingdom, the Surgeon of the second battalion taking charge of the first under these circumstances. A married man so placed can make arrangements which will ensure him an amount of comfort impossible to be attained by an officer subject, at short notice, to be ordered away from home. The acquisition of this post, therefore, is very reasonably an object of desire on the part of those who may one day succeed to it. According to the regimental system, it is filled, when a vacancy occurs, by the battalion Surgeon next in rank in the regiment. In the proposed alteration of the scheme of promotion no change is to be made in this respect. On the other hand, by the existing method, the post of battalion Surgeon, when vacant, is filled by the senior Assistant-Surgeon in the regiment. It is here that the intended change will apply. When a vacancy occurs in the grade of battalion Surgeon, it will be filled up by the senior Assistant-Surgeon, not in the regiment, but in the brigade. So that an officer who has been able, with considerable certainty, to calculate upon his succession to the higher posts, suddenly finds his prospects of promotion deferred, and, in some instances, hopelessly baffled, by an arrangement which introduces between him and the post to which he aspires officers from other regiments of the Guards, who were previously completely out of the question. The result, supposing the scheme to be carried into effect, will be to exclude many gentlemen from the prospect of ever holding a higher position than that of battalion Surgeon. This change will be attended with no corresponding saving of expense to the country, or advantage to the service. It will simply introduce discontent where unanimity has hitherto prevailed. Moreover, by the frequent changes induced, it will go far to destroy a spirit of emulation between the Medical officers of the several regiments, which has not been without its effect in stimulating activity and Professional zeal."

It is now sought to defend the bad faith which the Government are keeping with these officers by quoting the authority of a warrant which is stated to have been in existence since 1860, but which, it is said, has only recently been acted upon. The warrant, however, has never been made public; nobody appears to have been aware of its existence, and it certainly was not in force in 1863, when a gentleman, who although the junior battalion Surgeon in the brigade was senior battalion Surgeon in the Coldstreams, was promoted to the vacant post of Surgeon-Major in his own regiment. The whole thing looks like an attempt on the part of the authorities to perpetrate a job at the expense of a number of officers who are to be deprived of rank and position, in the full expectation of which they entered and remained in the service. It is openly stated that the Duke of Cambridge is principally responsible for the measure. The mysterious warrant of 1860 is, however, to be laid before the House of Commons, but whatever its purport may be, we hope that public opinion expressed through members of that House will interfere to prevent the threatened injustice. We can have no objection to promotion in brigade if it be found best adapted to the exigencies of the service, but the change should not be retrospective; no alteration ought to affect the prospects of those officers who have been appointed under a different system.

FROM ABROAD.—THE BRUSSELS CERCLE MÉDICAL—THE FRENCH MEDICAL BENEVOLENT SOCIETY—MEDICAL ADVERTISING IN AMERICA.

THE idea of establishing a Medical Club in London has often suggested itself, and we believe has even been attempted to be realised. That it has failed in becoming so has probably resulted from the attempt having been ill-directed and too ambitious. It is obvious that advantage would arise from bringing members of the Profession together in a less formal and more social manner than is done by their meeting at the learned societies, which so many of their number do not care to attend; and if this were managed economically and discreetly, we think that it might prove successful, and would often also prove of great assistance for the discussion and consideration of the various matters interesting to our body, which can now only be accomplished through hiring rooms at public taverns, or other disagreeable expedients. But if, misled by a name, any attempt were made to imitate the costly, luxurious, and indolent institutions, known as the clubs, it would be found utterly unfitted to the wants of our hard-working, domesticated, and not over-rich Profession. We have been led to these remarks by a report recently published of the great success which has attended the "*Cercle Médical*" of Brussels, an institution at present unique of its kind in Europe. Why it should remain so, it is difficult to understand; although, certainly, in the matter of clubs, congresses, leagues, and the like, the Belgians seem to have a remarkable aptitude. However this may be, the founders of the Brussels Club have had in view "the creation of a place for agreeable meetings, where all the Practitioners of the capital may daily assemble, drawing nearer the ties of confraternity, until at last those asperities disappear which often impede the exercise of their Profession. Moreover, the Brussels *Cercle* opens its doors wide to foreign Practitioners, offering them a cordial hospitality, and presenting an attentive and well-disposed auditory to any of them who may have anything to impart as the result of any special investigation they may have been engaged in, or of any discovery they may have made of what is likely to be of utility to science or mankind. At first, the institution met with obstacles, many prejudices having to be destroyed before its success could be assured. These the founders of the institution have had the satisfaction of overcoming, so that it is now in a most prosperous state, the Profession having thoroughly comprehended at last that in it they may find not only the elements of distraction and pleasure, but also the most certain guarantee of their rights and dignities." Surely something analogous might be done in London, where, of course, on account of its vast size, two or more of such institutions would be requisite, which yet might easily be harmoniously combined in their working.

The French Medical Benevolent Society has just held its annual meeting, under its President, M. Rayer. The report represents it as being in a very flourishing condition. It consists now of ninety-six local societies, distributed over seventy-seven departments, and the proposal is under consideration of admitting individual members in those departments in which they are not numerous enough to constitute local societies, which at present cannot be done. The total number of members now amounts to 6209, being an increase of 197 over that of last year, notwithstanding the great loss (130) incurred through death during that year. On January 1, 1866, the Society was in possession of 427,277 francs, being an increase of 40,220 francs during 1865. No less than 12,103 francs have accrued from donations and legacies. Not only was a considerable sum (17,107 francs) expended in pecuniary assistance during the year, but the various local societies interfered most actively in the protection of the rights and interests of the Profession, aiding its members, with the power derived from co-operation, in resisting oppression or obtaining legal redress and prosecuting illegal Practitioners, so that 41 convictions were obtained. One abuse they have as yet been unable to control —viz., the usurpation of Medical practice by the religious sisterhoods. This has gone on to such an extent in some parts of Brittany that Medical Practitioners in despair have abandoned the localities, their number having in some of these diminished within the last ten years by 50 per cent. As might be expected, numerous accidents are the result of such an abuse, but thus far it remains unchecked. Besides its own proper business, the Society last year took under its auspices the raising subscriptions for a statue of Laennec, which now amounts to 50,000 francs.

Professional advertising in the American Medical journals differs somewhat from that which is allowable amongst our-

selves. We select a few specimens from recent numbers of the *Boston Medical Journal* :—

"Dr. Heaton, 2, Exeter-place, Boston, continues to devote special attention to the radical cure of hernia or rupture in all its forms, including not only reducible hernia, but those cases heretofore considered irreducible. He also attends to the cure of varicocele, hydrocele, strictures, hæmorrhoids, fistula, etc."

"To Physicians and Surgeons who wish to purchase one of the best locations in N.W. Ohio, I have to say that I have such a one for sale. A well-qualified Physician, whose health and inclination will permit the effort, may, by purchasing this situation, enter at once and continue upon a lucrative business increasing yearly. A detail of the advantages, present and prospective, would extend this notice beyond proper limits. Suffice it to say, our village is one of the most important points on the N. Ind. Railroad, a good business place, and growing. My property is excellent, and my practice will compare favourably with that of any Physician in this section of the State. My price for property and business, including office, furniture, medicines, horse, harness, saddle, sleigh, and rolling stock, with hay, grain, etc., is $4000.—E. P. Willard."

"Notice to Physicians.—Stand for Sale.—A desirable stand, situated only quarter of a mile from railroad station, and 10 miles from Providence R. T., in the midst of flourishing manufacturing villages, schools, churches, etc. Horses, carriages, medicines, and Medical books to be included in the sale, if desirable.—Address, M. G., Fiskville Post-office."

"G. B. Windship, M.D., Park-street, Boston.—Special attention to dyspepsia, pulmonary disease, and general debility. Also, advice and practical instruction in reference to physical development. Regular office hours daily from 10 to 12½, 3 to 6½ and 8 to 9 p.m."

"Dr. Rupparer, late of Boston, Fifth Avenue Hotel, New York, gives special attention to the treatment of diseases of the nervous system, and diseases of the throat and larynx."

"Dr. Harkett Derby, No. 6, Beacon-street, gives his exclusive attention to diseases of the eye. Office hours from 9 to 11, and from 3 to 4½."

PARLIAMENTARY. — THE CATTLE, ETC., CONTAGIOUS DISEASES BILL — THE CHOLERA — OYSTER FISHERIES — THE STRAND UNION WORKHOUSE — EXPERIMENTS ON THE TREATMENT OF THE CATTLE PLAGUE — THE EXHAUSTION OF THE COAL FIELDS—PUBLIC HEALTH ACTS — THE SMOKE NUISANCE — THE WITHDRAWAL OF WATER FROM THE THAMES — POOR-LAW EXPENDITURE.

In the House of Lords on Thursday, April 19,

The Cattle, etc., Contagious Diseases Bill passed through Committee, was reported without amendments to the House, and, the Standing Orders having been suspended, was read a third time and passed.

In the House of Commons,

Sir J. C. Jervoise asked the Vice-President of the Committee of Council on Education whether the attention of the Medical officer of the Privy Council had been directed to a statement in the *Morning Star* of October 25, 1865, that the Emperor and Empress of the French had visited the cholera Hospitals in Paris, and that M. Gustave Girard had made experiments in demonstration of the non-infectious nature of the cholera.

Mr. Bruce said that the Medical Officer of the Privy Council was cognisant of the conduct of the illustrious personages in question, whose courage and humanity on that occasion had excited such general admiration. He was also aware of the daring experiments made by M. Girard, who had placed upon his own tongue the moisture from the brow and the fur from the tongue of a man who had died of cholera. But in the first place, such an experiment only proved the insusceptibilty to that disease of M. Girard, and by no means proved that the experiment might be tried with equal safety by other persons. Even if held conclusive on that point, it did not in the slightest measure invalidate the position taken by the Medical Officer of the Privy Council with respect to the infectiousness of the disease. The hon. baronet had, moreover, overlooked the fact that, as the French Government was at present strongly advocating quarantine precautions against cholera in the East, it might be presumed that their Medical advisers entertained the same opinion as the Medical adviser of the English Government on the subject of M. Girard's experiments.

On Friday, April 20, in the House of Lords,

Lord Clanricarde called attention to the depressed condition of the oyster fisheries, and inquired whether the Government intended to act upon the recommendations of the Fisheries Commission, and especially whether any negotiations had been entered into with France for reciprocal advantages to the fishermen of both countries.

Lord Stanley of Alderley said that negotiations had been entered into with the French Government, but the subject was still open. A Bill relating to the oyster fisheries was prepared, and would speedily be laid before Parliament.

Lord Townshend then called attention to some imputed defects in the arrangements and management of the Strand Union Workhouse.

Lord Granville, in reply, stated that no complaints had been made to the Poor-law Board by the Medical officers of the Workhouse in question, but recently some improvements had been introduced.

In reply to the Duke of Buckingham,

Lord Granville stated that although permission had been granted to the Cattle Plague Commissioners to treat experimentally infected cattle, yet it was thought unadvisable, except upon very strong grounds, to grant such permission to individuals.

In the House of Commons, in reply to an inquiry by Mr. Liddell,

Sir G. Grey said the attention of the Government, in common with most other persons, had been directed to the alleged rapid exhaustion of our coal-fields, and the statements made by many persons with regard to the probable time when they may be exhausted. But the Government was not in possession of any accurate information on the subject. He was not aware that any person was in possession of any information which may be called certain and accurate, but the Geological Survey Department had furnished a good deal of information on the subject, and upon this information he believed some of the statements which had been made were founded. The Government did not see that any advantage would be derived from any other parties independent of the Geological Survey Department being intrusted with the inquiry.

Lord R. Montagu asked the Vice-President of the Committee of Council whether the Government had any intention to introduce a Bill to amend the Public Health Acts, and whether it would contain any clauses which dealt with the pollution of rivers, in accordance with the recent report of the Commissioners.

Mr. Bruce said that it was the intention of the Government to introduce a Bill for amending the Public Health Acts very shortly. It would not deal with the pollution of rivers. The Commissioners only presented their Report on the Thames Valley a few days ago. The more difficult inquiry into the waters of the manufacturing districts of Yorkshire and Lancashire was not completed, and till it was completed no general measure on the subject would be satisfactorily considered.

Sir R. Peel asked the Secretary of State for the Home Department a question with reference to the pledge given by him before the Easter recess as to the introduction of a Bill on the subject of the nuisance resulting from the smoke of furnaces in towns and country districts.

Sir G. Grey: I have addressed a circular letter to some of the largest towns in the kingdom with reference to the subject which my right hon. friend brought before the House. The result of the answers which I have received is that in every one of those towns in different parts of the country there is power on the part of the local authorities to prevent the nuisance arising from the smoke of furnaces, but there is great diversity in the mode in which the law is enforced. [Sir R. Peel: "What law?"] The law requiring the consumption of smoke or preventing nuisances arising from smoke. I shall lay on the table a copy of that circular letter, and I may add that a Bill is in preparation by my right hon. friend the Vice-President of the Council, one of the objects of which will be to provide some summary mode of proceeding by which in the matter of the nuisance of smoke and other nuisances local authorities may be compelled to do their duty.

On Monday, April 23, in the House of Lords,

The Earl of Carnarvon called attention to the statement of the noble Earl the President of the Council in reference to the Strand Union Workhouse. He said that the sick wards of the workhouse were very small, and that the air was contaminated by a large carpet-beating establishment which had been sanctioned in the immediate vicinity. He understood that complaints had been made over and over again by the Medical Officer of the workhouse to the Board of Guardians, and he believed that communications had passed on the sub-

ject between the Guardians and the Poor-law Board. The noble Earl had stated that 300 cubic feet of air was the allowance for each person required by the Poor-law Board. But this was the allowance required for each person in the dormitories; in the sick wards the minimum was 500 cubic feet for each patient. This allowance he believed to be far below the mark. The Military Hospital Commission laid down that 1200 cubic feet was the least that should be allowed, and the eminent Medical men who signed a memorandum, which the noble Earl might have received on the subject of workhouses, stated that in their opinion not less than 1000 cubic feet of air was necessary.

Earl Granville explained. The Medical Officers had never made any representation to the Poor-law Board on the subject in question, but the communication to which he had referred had come from the Board of Guardians. As to the number of cubic feet, his answer was given with regard to the casual wards. It would be satisfactory to the noble Earl to hear that a short time ago the Medical Inspector of the Poor-law Board and the architect were desired to make a round of the workhouses in order to make an inspection and report upon this subject.

In the House of Commons, in reply to Mr. Liddell,

Sir G. Grey stated that the Geological Survey Department had collected a large amount of information relative to the exhaustion of the coal fields. If the papers were laid before Parliament in their present shape, he feared they would not be intelligible; but he would communicate with the department, and with their assistance he thought there would be no difficulty in extracting a considerable amount of information connected with the subject, which he would lay on the table of the House.

On Tuesday, in the House of Lords,

Lord Redesdale, in moving to refer the West Middlesex Water Bill to a committee of the whole House, called attention to the increasing quantities of water annually withdrawn from the Thames by water companies, and suggested that new districts should be required to obtain their supplies from other sources.

After some discussion Lord Redesdale's motion was adopted.

In the House of Commons,

Mr. Knight moved the following resolution:—"That, in the opinion of this House, it is expedient that all items of Poor-law expenditure throughout the United Kingdom, not being in-maintenance or out-relief, or otherwise under the immediate control and direction of boards of guardians or parish officers, should become a national charge," which was seconded by Mr. Warner.

The Chancellor of the Exchequer professed himself opposed to all such transfers, except on very strong grounds of public policy. He pointed out that the country had adapted itself to the present incidences of these burdens, that local taxes were raised with greater facility and greater general agreement than Imperial taxes, and that the change would greatly add to the proportion of taxation borne by the working classes.

The motion was then withdrawn.

THE TYRANNY OF LECTURES.

(From a Correspondent.)

The other day, after a ten years' absence, we stood at the gate of our old school, and saw our former teachers—good, easy, prosperous men—pass with the stereotyped smile of recognition on their good-natured faces. There was a time when, as we looked on them, "forsitan et nostrum nomen miscebitur istis" sounded in our ears; on this occasion it was a sadder and more apathetic envy. We also saw an old fellow-student just returned from abroad. The set we had belonged to was a pretty numerous one, composed of men who, out of sheer vanity, worked intensely, but secretly, at all sorts of untimeous hours, affecting to devote themselves entirely to pleasure, while they loved to astonish their neighbours, who wondered at talent which, apparently independent of all habits of industry, could so easily carry away everything in the shape of a prize from the conscientious plodders of their year. It was of the members of this set we talked, as old friends do on meeting, merrily enough, until the frequent repetition of "he's dead," "*he's* dead too," made us look and feel rather serious. After musing a little, as if to recall another name, our friend said, "Except ourselves and ——, they're *all* dead," adding, "Don't you think now we were all too fast then?" Alas, we had been! Somewhere in the country, this white-faced man with a cough, and ourselves carrying a stick more for use than ornament, were the surviving representatives of "*our set.*" A chair in the students'-room was not an unwelcome rest, and as the youths clustered and talked together, we gathered from their discourse that things were not so much altered as we had been led to believe; to be sure, the comfortable reading-room was there for them instead of the cold seatless lobby of former days, and they seemed better cared for; but three more of our men had been plucked last night, and we all discussed the calamity. There was none of the old bitterness against individual examiners—that was happily of the past; indeed, the only decided expression was one of sympathy with the unfortunate trio, who were described as very hard working men, and regret that they had either not gone to a "grinder" at all or not soon enough. Typical cases were quoted of men who had been saved from impending pluck by some weeks' trituration by one whose name seemed a household word, and had been even in our time; one of our set, however, would have sooner left the Profession than be his pupil, except, perhaps, at some midnight hour. Other stars of even greater magnitude were mentioned, but what surprised us most was to hear the opinions of the regular teachers quoted, and what grinding class they recommended their own pupils to attend. Even before the boasted reforms in education were carried out, grinding was looked on as one of the vices clean-minded men speak not of. Occasionally, indeed, some timid working man would find himself being cured of diffidence in a grinder's class, but the latter rather resembled a regiment of *forçats* than a legitimate body of students of Medicine. It used to be said that a man was only forced to grind when he had neglected his classes, but what ignorant prejudice all that was. The grinders had discovered the way to teach, and only acted as middle-men between the lecturer, "always genteel," and the examiner, too often a bully. Now, it would seem that the lecture system—in other words, trying to teach many men, utterly different to each other in mental power, of different ages and acquirements, the same thing in the same words at the same moment of time—is found less efficient than ever, as the number of grinders or tutors has increased and the lecturers send their own pupils to be ground;—their own young who with "yellow beaks the precious food eschew" as they administer it in their class-rooms before they trust them to those

"—— of all men best
Their Æsculapian skill to test."

It may be said, this is only an extension of the tutorial system: of course it is; but it should be more openly substituted for lectures, because if the latter do not teach, why waste precious time attending them? The answer to that invariably is, "lectures guide the reading." But *when* is a man to read? at night? Yes, at night; he cannot do so in the day time, because he is then trotting out and in of lecture-rooms like a rabbit in a warren. Then he may read in the morning. No, he cannot, as his first lecture is at 9 a.m. Even were he sufficiently awake, look at his white cheeks, his dull eyes, and—on the strength of being an old teacher—ask him a few questions;—just a few,—which he'll answer like a kindly, honest fellow as he is,—will suffice to prove to you that, so far as his last night's reading went, he has been *losing a bit of his old age* in reading a dry book from which he has collected a few confused statements and misinterpreted inferences, about some organ or tissue which he has never seen, except in a big diagram painted on a wall by one who never saw it either. Was such reading guided by a lecturer? or, if this combination really teaches, why does the guide leave the student at a grinder's door?

Medical students are not too rich, and by no means fools; their studies include subjects which to them, in common with all other men, must be intensely interesting; is it likely that many of them would pay unnecessary fees, or neglect matters which not only excite, but satisfy curiosity, unless both appetites were spoilt in some mysterious manner? Wherever there is attraction, there is probably repulsion existing somewhere else; the only substitute for the former is compulsion. Now, when we see that students, at expense of scanty funds and leisure, are attracted to tutorial classes, it is but reasonable to infer that there is something repulsive to their common-sense in lecture classes—an inference not by any means contradicted by compulsion in the shape of a marker at the door. To arrive at some cause for all this, we have recently visited several lecture-rooms, and been much struck by the difference in the behaviour and bearing generally of both lecturers and pupils. We will only instance two. In one room the class was small, and the lecturer, who was listened to as gentlemen do listen to each other, gave a lucid account of a difficult piece of anatomy, never repeating himself, never interlarding irrelevant stories. In the fifty-five minutes he had told and shown to his students everything really known on the subject. He did not take up time in telling what was *not*, and only alluded to what *might* be, as suggestive of subjects worthy of his pupils' private and independent research—that was the way he guided *their* reading. In the second case, the attendance was more numerous, but there were fewer *students*. A marker at the door did all the majority desired, namely, registered their presence. Before the lecturer entered, they sang in concert—not old student songs, but slang melodies—and during his lecture they talked aloud, made offensive observations, pinched a kitten and made it squall, blew out the microscope lamps, went into fits of unmeaning laughter, and prevented my hearing a lecture which I have reason to believe was invaluable. The lecturer got through his performance, and seemed to take it all as a matter of course. He once, indeed, said he was sure that only one or two *mauvais sujèts* were creating the disturbance, which he must have been aware was but a pleasing fiction. It may be said, here was attraction in plenty—all the fault lay with the students. Yes, but the subject could only be practically made attractive to a few, so any mad wag present had those in his power who were crammed into the lecture-room against their will; and even if attentive, could merely have heard long statements which they would have to corroborate by their text-books at night. In sections most of that turbulent mob of giggling boys would be found not only intelligent and eager students, but considerate and agreeable companions, who individually would defend their teacher's honour and views to the death. But if during hours which ought to be spent in necessary rest and relaxation they are painfully gathering up the fragments lost in such an hurly-burly as the one we had the honour to assist at, their animal spirits will inevitably burst forth when they are obliged to spend what is to them practically an idle hour. Now, whose fault is it, and what has it to do with "lost old age?" It is the fault of the lecture system, which drives some to idle habits, but more to habits of working at times when their minds and bodies require rest or demand stimulants to enable them to work without rest. Lectures to large classes are now old-world absurdities. They were all very well when now and then a man would return, say from Leyden, with all the anatomical knowledge of the country side in his own individual head, and all the illustrative specimens in his private packing cases, but now that teachers and books abound, it is high time to begin teaching in a rational manner. Is the femur so hard to learn that it requires the assistance of two men and a boy—in other words, a lecturer, a demonstrator, and a private tutor—before a man of ordinary parts can "take it in?"

Every unnecessary hour spent in teaching and learning is so much time robbed from science and from the working lives of both teacher and student. It is true that our science creeps slowly and laboriously on, but that is the very reason why time and labour should be economised. The new emigrant does not, on his arrival, sit down and listen to long stories of how his predecessors made the clearing, so far as it is gone, or the gossip of the settlement; he goes rapidly to where *they* left off, and begins felling the remaining trees as quick as he can. If economy of time be an object, then learning the same thing from several different people, when one would do, must be unwise; but students have to appear at least to do so now. If the day be for work, let work be done—good, honest, remunerative labour, which whistling or yawning in a lecture-room is not. If the night be for rest, let the student sleep the pleasant, healthful slumber of the working man. Let his teaching be tutorial in those subjects involving detail, such as general and minute anatomy and practical chemistry; then let the lecturers on practice give the prepared minds a fine polish and the stored knowledge a definite application. Let the lecturer on Surgery show how to apply mechanics to anatomy and the laws which govern the repair of tissue; the Physician, logic, acoustics, and practical chemistry to his department; each lecturer grinding, with experienced hands, the laboriously inlaid minds to a smooth and convenient surface in which, not only will the colours harmonise, but the pieces won't tumble out just as you expect the company of the honourable Board of Examiners at Tea (do they still give tea?) in Lincoln's-inn-fields.

If rationally taught, student life would be better and happier. Manhood would be more active and useful; while the period of rest, when the more pressing cares of life need no longer harrass—call it old age, or what you will—would be more certainly reached than it is under the existing system.

THE HORSE GUARDS AND THE SURGEONS OF THE GUARDS.

(From a Correspondent.)

Promotion in the Guards has been regulated on the strict regimental system from time immemorial. About the time of the Crimean war some young men from the London Hospitals entered these regiments upon the clear understanding, of course, that they were to be promoted in that way. They have been grievously disappointed, for the Duke of Cambridge has recently endeavoured to break through the old system and establish one of promotion by brigade seniority instead. This was so unjust and detrimental to the interest of several Medical Officers that the matter has been brought before the House of Commons. The reply of the Marquis of Hartington was so very unsatisfactory that it will again be brought before the House as soon as the debate on the Reform Bill and the Budget have been disposed of.

The reason assigned by the Marquis of Hartington is not a little curious. In reply to Mr. O'Beirne, he said that up to the time of the Warrant of 1858 the system of promotion in the Guards was undoubtedly a regimental system; but in that year a Warrant was issued which conferred several advantages on the Medical Department, and that Warrant recommended that the mode of promotion, as a general rule, for the rank of Asistant-Surgeons should be in future by seniority in the service. In 1860 the question arose, in regard to the Surgeons of the Household Cavalry, whether the provisions of the Warrant would apply to that branch of the Service, and it was decided by Her Majesty, on the recommendation of the Commander-in-Chief to the Secretary of State for War, that in the Household Cavalry and in the Guards also, in consideration of the Surgeons having accepted the Warrant, they should enjoy the advantages it conferred upon them. Of course, the Medical officers accepted the Warrant of 1858. How could they have done otherwise than accept what was intended for, and imposed upon, the whole Army Medical Service? An Assistant-Surgeon in the Guards could easily enough see the difference between seven shillings

and sixpence and ten shillings, but he never supposed that for the extra half-crown he was tacitly submitting to the imposition of a new rule of promotion, so detrimental to his interests and so utterly opposed to the spirit and custom of the regiment in which he was engaged. The Guards have always been separate and distinct, and to suppose that the terms of the Medical Warrant of 1858 applied to them is absurd. If seniority were the rule of promotion, then an Assistant-Surgeon of the Guards, if senior in service, should be promoted to the rank of Regimental or Staff Surgeon in the general service, and no one would oppose this more than the present Director-General. The authorities evidently felt the unfair nature of the proceeding, and in 1860 the Commander-in-Chief—who is always so very solicitous for the well-being and happiness of any member of the Army Medical Department—recommended her Majesty to establish the brigade, instead of the regimental, system of promotion.

For six years, then, has this decision been held in abeyance, ready to be discharged at the head of an unsuspecting Medical officer on the first favourable occasion. When the proprietor of an orchard indulges in the luxury of man-traps and spring guns, he generally gives a clear intimation to the public of his practice; the warning, indeed, often proves an effectual safeguard without the reality. The Horse Guards have a very different way of doing business. They keep their guns loaded and ready to discharge at the head of any member of the Medical Department; but, like wary sportsmen, they maintain a strict silence about those weapons until they are required. Not a little dismay has been caused by the recent discharge from one of these—a sudden death to the hopes of one at least of the Senior Assistant-Surgeons of the Guards. The Director-General of the Army Medical Department occupies the position where, in the judgment of his subordinates, one might expect to find him. He is beside H.R.H., consenting and concurring in the measure, of course!

Really, the authorities appear to be bent on disgusting their Medical officers, and in maintaining the unpopularity of the public services. I do not believe that this ill-advised measure can stand. It is said that the hope of better things in the Army has had the effect of bringing forward a larger number of well-informed men at the last examination. This has evidently been owing entirely to the publication of the recommendations of the Committee. The Profession must await with some anxiety and foreboding an announcement that those recommendations are to be carried out, for on several occasions candidates have been obtained by spreading rumours that something was to be done for the Department, which something, however, still remains undone.

REVIEWS.

On Diseases of the Veins, and Hæmorrhoidal Tumours. By Henry Lee, F.R.C.S., Surgeon to St. George's Hospital; Hon. Fell. King's Col., London; formerly Surgeon to King's College Hospital; Corresponding Fellow of the Medical Society of Florence, etc. London: John Churchill and Sons.
