This volume consists of two distinct parts; the first is a new edition of the Essay on Diseases of the Veins, which gained for its author the Jacksonian Prize for 1849; the second is composed of a series of essays, chiefly practical, on "Affections of the Rectum;" the two, at first sight, dissimilar subjects being brought into association by the interposition of a chapter on "Hæmorrhoidal Tumours."

In the essay on Diseases of the Veins, Mr. Lee traces the successive steps by which our present knowledge of phlebitis and other allied affections has been obtained. Hunter "found that when fatal consequences had supervened after bleeding, the coats of the injured vein were inflamed and thickened, and that this inflammation extended for a considerable distance along the vessels." He also described the process of suppuration in veins, and came to the conclusion that the lining membrane of veins was liable to inflammation which might lead to abscess. Ambrose Paré and others described the formation of abscesses in the liver, and tubercles (indurations) in the lungs after injury of other parts, but failed to obtain any distinct idea of the way in which these originated. Dance, Cruvelhier, and others at length established a connexion between the inflammation of a part originally injured, and the secondary abscesses observed in internal organs; but they, along with Sedillot, probably misled by the belief of Hunter that in inflammation of a vein pus is secreted directly into the current of the circulation, conceived the opinion that these secondary abscesses were produced by metastasis; that is to say, that pus, being carried along in the blood stream, and being arrested in the capillaries of distant parts, as the lungs or liver, gave rise to a capillary phlebitis, ending in abscess, wherever this arrest took place. This theory, which Mr. Lee characterises as "highly ingenious and beautiful," has not stood the test of later research. It has been proved by experiments performed by Mr. Lee himself, by Callender, and others, that the inner coat of a vein does not, as Hunter thought, suppurate after the manner of a serous membrane—that pus is never secreted into the interior of a vein so as to become mingled with the current of the blood. "No one has yet satisfactorily demonstrated the presence of an inflammation limited to the lining membrane of a vein." It is also now known that the appearance which Hunter mistook for pus in the canal of the inflamed vein is in reality produced by an aggregation of white corpuscles, which are found in phlebitis, as in several other diseases, to exist in greatly increased numbers in the blood. Foremost among those whose opinions have of late years attracted attention stands Professor Virchow. This distinguished pathologist, seizing on one of the chief features of the malady—coagulation of the blood in the affected vessel (thrombosis)—contends that the phenomena of what is termed "phlebitis" are due to this condition or to its results. He holds that the "secondary abscesses" are produced by changes which occur around fragments of the softening thrombus, which having become detached are carried along in the circulation till they are arrested in the capillaries of some remote part.

Striking and attractive, however, as this theory may be, and although it no doubt affords an explanation of what occurs in many instances, yet the generality of pathologists hesitate to accept it as the whole truth, and as an adequate explanation of all the phenomena that are observed. There can be no doubt that a great deal of the pathology of "phlebitis" centres in this *thrombosis*, or coagulation of blood in the affected vessel, but concerning its exact bearing on the origin and course of the disease much remains to be made out. As the author remarks, "phlebitis" is sometimes the cause, and sometimes the consequence, of the clot: the former when the vein has sustained any mechanical injury, the latter whenever some irritating substance has been included in the clot. We are told that three distinct varieties of "thrombosis" have been at one time or other included within the term "phlebitis."

1. A spontaneous coagulation of the blood, in the vessels, unconnected with the entrance of any extraneous material. This may take place in many cachectic states, where the circulation is weak, and where there is an absolute or relative increase of fibrin in the blood.

2. A coagulation induced by the entrance of some abnormal material into the circulation, and its action on the circulating fluid.

3. A coagulation due to irritation, injury, or any disease affecting the venous coats themselves.

The author enters into a long discussion of the effects of various noxious agents introduced into the blood, and of such collateral topics as bear upon his subject. The space at our disposal does not allow us to dwell on this part of the work.

We cannot but regret that Mr. Lee should have made no attempt—although we fully appreciate the difficulty of the task—to classify on a pathological basis the very important group of diseases which are now in such hopeless confusion under the various titles "Phlebitis," "Pyæmia," "Purulent Infection," etc. A sweeping reform of nomenclature is here most urgently called for. Much has been done to dissipate error and to bring truth to light; but, however satisfactory and complete the knowledge gained by original investigation may be, it is almost or wholly impossible, in the present state of things, that this should become available for the busy part of the Profession. It is now a matter of utter uncertainty to all who have not time to be constantly studying the literature of the subject what any particular writer means by the terms "Phlebitis" and "Pyæmia." In the present essay the author, in pages headed "Phlebitis," discusses along with this disease pyæmia, thrombosis, embolism, and septicæmia, and although doubtless by attentive study of his argument the reader can extract wherein the distinctions between these various conditions consist, yet to accomplish this will require some leisure and not a little close application. It will be a great thing gained when the terms now in use are either

altogether banished, and made to give place to a rational nomenclature, or when they have their precise significance defined in accordance with our present knowledge.

Under the heads "Varicose Veins" and "Varicocele" the author gives a number of cases in illustration of the success which attends his method of operating for the cure of these affections. The gist of this method is, as our readers will remember, the subcutaneous division of the vein in the interval between two points at which the vessel is compressed by means of a pin passing beneath it, and an india-rubber band crossing above it, and exerting the requisite pressure. This operation, of which the details are given, has been planned by the author with the object of obviating the chief source of danger after interference with veins—namely, the detachment of clot *débris*, and the consequent production of embolism.

The section on "Hæmorrhoidal Tumours" is devoted chiefly to the operations which the author prefers in those affections. For the cure of hæmorrhoids which are composed of a soft vascular substance, and which readily bleed, he very strongly recommends the application of nitric acid; while for those in which the mucous membrane has become thickened, and the subjacent parts infiltrated with lymph, he advises that the pile should be seized with a clamp and excised, and the cut surface freely treated either with the actual cautery or with nitric acid. The instruments required for this latter proceeding, and which Mr. Lee has been at great pains to perfect, are of a simple and inexpensive kind. They are fully and clearly described. The operation is intended to take the place of that by ligature, which Mr. Lee, for several cogent reasons, considers open to objection. The success of his own method which he is able to record is very satisfactory.

In the essays on "Affections of the Rectum" the author's object seems to be rather to insist on a number of practical points which he has found by experience to be important than to offer an orderly and complete monograph on any of the subjects of which he treats.

Mr. Lee writes in an easy, every-day way that is well in keeping with the clinical material which he has to convey. Indeed, the style in some parts is rather loose and inaccurate. In spite, however, of these minor drawbacks, the volume will well repay the perusal both of the pathologist and the Surgeon, for it embodies the results of long and laborious research, and of much carefully-considered practical experience.

Leprosy, Ancient and Modern; with Notes taken during recent Travel in the East. By Tilbury Fox, M.D. Lond., M.R.C.P.

This pamphlet, a reprint from the *Edinburgh Medical Journal*, contains some valuable information as to the leprosies of our own and olden times, and the various relations of the allied eruptive conditions. Dr. Fox made good use of the opportunity afforded by a recent trip through the East to study the disease, and thinks that all discrepancies and contradictions may fairly be explained away; that Moses described the *early* stages of leprosy only, under the terms berat cecha and lebena, answering to our morphæa alba and nigra, the leuce and melas of Celsus, and the Greeks states or stages that have recently been shown to antecede the development of the tubercular and anæsthetic stages. These are the forms of eruption which rendered a man unclean.

There has always been a difference of opinion as to whether the Hebrews were affected by a special form of disease, of which no trace remains now-a-days; but Dr. Fox mentions the remarkable and novel fact that in Syria there exists, and has existed for a long period, a form of eruption which is termed *barasel Israily*—literally Hebrew leprosy—regarded as distinct from the baras of the Arabs, even in the traditional record of the Mahommedans. This Dr. Fox diagnosed as nothing more or less than lepra vulgaris, the alphos of Celsus, the disease of Gehazi and Naaman, and the book of Moses, all identical, and constituting the form of leprosy which did not render a man unclean. "It is therefore unnecessary," says the author, "to suppose the existence of a disease peculiar to the Jews," of which, of course, no trace exists at the present time. Further, it is held that the results of modern research give a peculiarly prophetic aspect to the Levitical code, and fully prove its truth.

The relation of syphilis and leprosy, the influence of fishy and oily diet, and other points, are also noticed.

Our readers will not find the like information elsewhere.

Verhandlungen der Gesellschaft für Geburtschilfe in Berlin. Transactions of the Berlin Obstetrical Society, 1864.

In the transactions of the Berlin Obstetrical Society for 1864 we have a paper by Dr. Winckler, of Rostock, "On the Action of Chloroform on the Activity of Labour Pains," in their normal and abnormal conditions. He alludes to those who have preceded him in this department of research, particularly to Sachs, and to Johns, of Dublin, but objects to the observations of the former on the ground of inexactness, seeing that there was no observation before or after the administration of chloroform, but only during the period of anæsthesia. To obviate this objection, Winckler gives his observations before and after, as well as during the period when the patient was under the influence of chloroform, and attends to the various stages in each pain, giving the periods of increment, acme, and decrease. He also draws a distinction between normal and abnormal pains, selecting as instances of the latter those occurring in cases of "rigid os." Besides the pains themselves, the duration of which was estimated by the hand resting on the belly, he observed the pulse, the respiration, and the temperature of the vagina; but one source of error he appears to have overlooked when he compares pains without observing the particular stage of anæsthesia. From his observations, here given at full length, he concludes that chloroform lengthens the pauses between the pains, whether normal or abnormal, and, without much affecting the other stages of each pain, considerably shortens the period of acme. Spasmodic pains are not regulated, only rendered less painful by its use, and it appears to have little or no effect on temperature; but, on the other hand (and this has attracted some attention at home), it increases the tendency to post partum hæmorrhage.

Unfortunately, from the small number of cases cited (two normal and two abnormal), his conclusions do not carry that weight to which the accuracy of his observations would otherwise entitle them.

GENERAL CORRESPONDENCE.

CARRIAGES FOR SMALL-POX PATIENTS.

Letter from Lieut.-Colonel T. St. Leger Alcock.

[To the Editor of the Medical Times and Gazette.]

Sir,—There are now three cases of small-pox in the barracks of the regiment under my command at Hampstead. I attribute this inconvenience to the circumstance of the Small-pox Hospital being full. The first case was sent there and returned for the above reason, thus preventing the measures of disinfection which had been ordered. The consequence has been that the sister of the little boy first attacked is now ill, and a young girl of 18 of another family is sickening. As there is no Hospital carriage in the parish, the removal of infectious patients is attended with great danger to the public health.

I am, etc.,
T. St. Leger Alcock,
Lieut.-Colonel 6th Middlesex Militia.

REPORT OF THE COMMITTEE ON THE RANK, PAY, AND POSITION OF NAVAL AND MILITARY MEDICAL OFFICERS.

[To the Editor of the Medical Times and Gazette.]

Sir,—At a recent meeting of the Fellows of the College of Physicians that venerable body, after a little self laudation, are reported to have endorsed with their approval the labours of the above-named Committee. And the College of Surgeons, following suit, have also delivered themselves of an opinion couched in the most favourable terms.

With all respect for those representative bodies, and with a grateful sense of the services they have rendered to the cause of the Army and Navy Medical officers, I must demur to the conclusion they have arrived at, and express my firm conviction that the Committee's recommendations, even if fully carried out, will fail to obtain recruits for the Navy.

The "bait" of 2s. 6d. a day additional pay for the first five years is too transparent to be successful; and the staff-pay two years earlier than at present is no equivalent for the loss of time on half-pay. In point of fact, there are no beneficial recommendations whatever. The increase of pay to Assistant-Surgeons for the first five years of service was not asked for,

nor is it required. And continuous service time would be more acceptable to Surgeons than the staff-pay after eighteen instead of twenty years' service as at present. The question of rank is, and will remain, a dead letter; while the distribution of prize-money is still left to the judgment of the Board of Admiralty for the time being.

Under these circumstances, the rising generation of young Surgeons do well to pause and ponder, for until continuous service time, a more liberal promotion to the higher grades of the Profession, and retirement after twenty-five years' service with the rank and minimum half-pay of a Deputy-Inspector-General, be granted, the Medical officers of the Navy cannot be contented. And unless those in the service are contented, I feel safe in affirming that it will be hopeless to expect that others will join.

Continuous service; an increase in the Inspectorial class by the appointment of Deputy-Inspectors-General to all Hospitals and flag-ships; and the rank and minimum half-pay of a Deputy-Inspector-General to all Staff-Surgeons after twenty-five years' service who may not be fortunate enough to obtain promotion, and who may then wish to retire. These may be called the three points of the charter, and nothing less will give complete satisfaction.

London, April 21. A Retired Surgeon, R.N.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, April 10, 1866.

Dr. Alderson, F.R.S., President.

A paper, by Dr. Morehead, was read, entitled,

NOTES ON THE PATHOLOGY OF PNEUMONIA AND HEPATITIS.

1. The object of this paper is to show that the pathology of inflammation of the lungs and of the liver cannot be rightly understood unless it be kept clearly in view that in both organs there is a double system of capillary circulation; that of the bronchial and hepatic arteries being for the nutrition of tissue, and that of the pulmonary artery and of the portal vein for functional purposes, the one being of arterial blood, and the other of venous blood. The pathological question in respect to both organs is, which system of capillaries is the seat of inflammation in pneumonia and hepatitis? 2. *Pneumonia.*—It has been lately argued before the Society by Dr. Waters that the branches of the pulmonary artery which constitute the pulmonary plexus are the nutrient vessels of the air-cells and the seat of inflammation in pneumonia, because—1st, capillaries of the bronchial artery do not exist in the air-cells; 2nd, the absence of the bronchial arteries in some animals shows the capability of the pulmonary vessels for the purpose of nutrition. It is argued in the present paper that if inflammation be an altered state of the nutritive processes of the affected part, then the capillaries immediately concerned in inflammation must necessarily be those which in their normal state circulate arterial blood for purposes of nutrition; that the blood which is a factor in inflammation must always be blood which in the normal state is a factor in nutrition. It is maintained, therefore, that capillaries of the bronchial arteries are those immediately concerned in the nutrition of the air-cells, and in pneumonia, because—1st. They are the nutrient vessels of the visceral pleura, of all the tissues of the bronchial tubes, the coats of the bloodvessels, the nerves, and lymphatics, and the connecting areolar tissue of the lungs, and the seat of inflammation in visceral pleuritis and bronchitis. 2nd. It is improbable that bronchial capillaries should ever be discoverable in the air-cells, because (*a*) inflammation of the air-cells must always be followed by turgescence of the pulmonary plexus, and (*b*) artificial injection of a bronchial artery always in part fills the pulmonary plexus; hence bronchial capillaries, if existing in the air-cells, are almost certain to be veiled by the larger pulmonary plexus under the only circumstances in which it is reasonable to expect to see them. 3rd. Though admitting, as is very likely, that bronchial capillaries do not exist in the air-cells, it does not follow that the blood of the bronchial arteries is not the nutrient blood of the cells and the factor in inflammation. May not the thin walls of the cells be nourished by a process analogous to that which is effective in the cornea, articular cartilages, and lamellated osseous tissue? The capillaries of the termini of the bronchial tubes and of the interlobular areolar tissue carry the blood near enough to the air-cells to admit of their nutrition by imbibition of the plasma. 4th. The argument, from analogy, that because there are animals without bronchial arteries, there may be nutrition by the pulmonary plexus, fails because we are dealing with an animal with, not without, bronchial arteries, and because it applies with equal force to the other tissues of the lungs as well as the cells. Further reasons are also advanced, drawn from the manner of termination of the bronchial arteries and from facts of the fœtal circulation. 3. Then it is explained that though the pulmonary capillary circulation is not the immediate agent in the nutrition of the cells or in inflammation, still it plays a very essential (secondary in point of time, though not of importance) part in the pathology of pneumonia, because inflammation of the air-cells obstructs in various evident ways aëration, and this must be followed by more or less stagnation of the blood in the pulmonary capillaries, small in degree in the first stage, but complete in the second stage (hepatisation), and unless this be borne in mind we cannot understand the morbid anatomy of pneumonia; and, as is fully explained in the paper, there are questions relating to symptoms, progress, and treatment which are not intelligible without a distinct recognition of stagnation of blood in the pulmonary plexus, not as constituting inflammation of the air-cells, but as a necessary sequence of it, and a part of pneumonia. 4. The question of position of the exudations, whether into or external to the cells, is shortly noticed, and regarded as one of great simplicity, not requiring the microscope for its elucidation, but bearing in the structure of the lung the proof that the exudation must be chiefly into the cells. The analogy between pleuritis and pneumonia is noticed, in the slight anatomical difference in the tissues concerned, in the exudation being on a free surface in both—in pleuritis tending to become organised, in pneumonia to liquefy. The difference depending on the exudation in pleuritis being on the free surface of a closed sac; that of pneumonia on the free surface of sacs exposed to the air. 5. *Hepatitis.*—The question in regard to hepatitis is noticed very briefly. It is argued that the capillaries of the hepatic artery are the nutrient vessels of the liver and the factor in inflammation; but that the symptoms, pathology, and treatment of hepatitis cannot be rationally explained unless the important facts in the anatomy and physiology of the portal circulation in the liver be borne in mind.

Dr. Williams said that he had not been able fully to comprehend the meaning of the author in the elaborate and ingenious views just read; but Dr. Morehead, who was his old and valued friend, had apprised him that he was about to communicate a paper on the subject, and requested that he (Dr. Williams) would attend. He was very happy to do so, although the opinions expressed by Dr. Morehead appeared to be in opposition to those entertained by himself. It was upwards of thirty years since he (Dr. Williams) first propounded the opinion that the essential seat of pneumonia is in the great capillary plexus of the pulmonary artery and vein. This view seems to have been generally adopted by the Profession; and even during the present session they had had a paper confirmatory of it from Dr. Waters, of Liverpool. Dr. Morehead now maintained an opposite view—that the first and essential seat of Pneumonia is in the capillaries of the bronchial arteries, the congestion of the pulmonary capillaries being a secondary effect. But all the prominent features of pneumonia declare it to be, from first to last, an affection of no subordinate or diminutive set of vessels, such as those of the bronchial membrane, but of an important vascular plexus standing in close relation with the blood of the whole body; so that, as he (Dr. Williams) had remarked when Dr. Waters' paper was discussed, pneumonia might be represented to be a general or blood disease, rather than a mere local inflammation. He would not reiterate the arguments which he had used on that occasion, but would point out, as an objection to the notion of Dr. Morehead, the remarkable diversity which existed between the two diseases, pneumonia and bronchitis. For if pneumonia always originated in the same vessels that were the seat of bronchitis, there ought to be more or less of a constant tendency of the diseases to pass into each other. There could not be general or capillary bronchitis without more or less pneumonia; and pneumonia could not exist without a considerable and spreading bronchitis. Yet how different was the fact if we appealed to actual observation. Considering the proximity of their seats in the same organ, it was most striking to observe the marked difference between the two diseases, pneumonia and bronchitis. This difference has

reference to their causes, their symptoms, their physical signs, and their anatomical effects. Of course he spoke of the typical forms of the maladies; for he was ready to admit that cases occur in which the diseases may be mixed or in combination, so that we have a broncho-pneumonia, or pneumonia with bronchitis. But these cases are by no means so common as those of the pure diseases, in which their respective characters stand out boldly and distinctly as affections that cannot and ought not to be confounded. The causes of pneumonia would be found to be those acting more generally and profoundly on the bloodvessels and blood than those which excite bronchitis. The latter might result from common chill or exposure to cold; but if the cold was intense or so long continued as to deeply disturb the circulation, as in prolonged cold bathing, or if after fatigue or exhaustion from other causes, or if combined with the operation of deleterious gases, then the great pulmonary plexus would be congested, and pneumonia would be the result. Some causes of pneumonia operate through the blood itself. Thus he might cite an experiment of Magendie, that of injecting phosphorated oil into the veins, and inflammation of the lungs was produced. So febrile poisons and the poison of the rattlesnake and of some fungi, operating through the blood, at once develope inflammation in the capillaries of the lungs, which constitutes a formidable complication in the operation of these deleterious agencies. In all these and similar causes of pneumonia we recognise influences which seriously and extensively affect the blood and its circulation, and develope their operation on the great blood-purifying organ; and if we study the symptoms of pneumonia, we find the same evidence of profound and general impression on the system. The rigor is more marked and more constant than in any other inflammation, and was mentioned by Chomel and Grisolle as a symptom characteristic of pulmonary inflammation. Then follows an equally distinctive intensity of heat. How often when applying his ear to the back in examining the chest had he been struck by the feel of pungent heat in the patient's body—a heat often rising several degrees above 100° Fahr. So in sthenic cases at this period the face is flushed with the throbbing headache of fever; the skin dry; the urine scanty, dark, and without its normal saline matter, which is retained in the inflamed lung. And if to these symptoms we add a strong, frequent pulse, we have such a condition of inflammation, local and general, that it is no wonder that blood-letting should be trusted as the great remedy. He (Dr. Williams) had used it frequently in years long past, and with the best effects; but he admitted that of late years it was very rare to meet with a case in this state, and blood-letting was seldom called for. The flush soon gives place to pallor, and the pulse loses its strength and fulness, and assumes the liquid jerky character of a half-filled artery; the blood, in fact, being in great part arrested in the inflamed lung, and, therefore, not available for the general circulation. No wonder, then, that now an opposite treatment is called for, and that stimulants become the best remedy. And now, if we compare the corresponding symptoms in bronchitis, we shall find a marked difference. The rigor, if present, is less marked; the heat and flush are more transient, and less intense; the pulse, though frequent, has neither the strength of the first stage of pneumonia nor the collapsing liquidity of the second. In extensive bronchitis it becomes small and frequent as the disease advances; and instead of the pallor of pneumonia from the arrest of blood in the lung, we have the purple lividity of the surface from the blood circulating in an imperfectly arterialised state. Again, the blood-stained expectoration of pneumonia is another token of its origin in a large and blood-filled capillary plexus, beyond the mere mucous secretion of bronchitis. Then, if we come to the physical signs of the two diseases, we find further evidence of their difference, even in the commencement. In bronchitis the signs are those of bronchial obstruction, more or less complete. Rhonchi attending inspiration and expiration, first lengthening both, subsequently shortening the former and prolonging the latter, with more or less diminution of the proper vesicular murmur. In pneumonia the first sign—the crepitation—comes at once from the vesicular tissue. There may be no general or bronchial rhonchi; but at the seat of the inflammation the fine crepitation comes out sharp and close to the ear at each inspiration, and so confined to the spot in the vesicular tissue of the lung that if you remove your ear to a spot an inch or two from it you cease to hear it altogether. Like vesicular respiration, it is heard only in the spot in which it is produced; and unlike tubular respiration and rhonchi, which are commonly heard to some distance. In the second stage of pneumonia the consolidation developes the tubular sounds of breath and voice, while in advanced bronchitis there are no signs. In the naked-eye anatomical results of the two diseases we find the distinction equally marked. In bronchitis, the lung is distended with air imprisoned in the obstructed bronchi; spongy and frothy on incision; and although parts are often much congested from weakened circulation and impaired aëration, yet this condition is not sufficient to supersede the air in the cells, and there are no signs of consolidation. In pneumonia, in the first stage there is still air in the cells; but the lung feels heavy, pits on pressure, and on incision exudes abundantly frothy serum or spumous blood. The transition to the stage of hepatisation is marked by the gradual substitution of solid deposit for the air and part of the fluid previously present. Seeing, then, that bronchitis, the acknowledged affection of the bronchial arteries, so entirely differs from pneumonia in its whole course, could any further light be thrown on the subject by an appeal to microscopic anatomy? In his early attempts in this mode of investigation he (Dr. Williams) had been struck by the large size and number of blood-filled capillaries, even in the earliest stage of pulmonary inflammation; which forcibly suggested the idea that they were pulmonary, and not merely bronchial. Subsequent observers had come to the same conclusion; Dr. Waters being the most recent. Still this field was open to further investigation, which would be more conclusive than speculative reasonings on the subject. The attempt of Dr. Morehead to explain the development of pneumonia from a primary affection of the bronchial capillaries was ingenious, but far-fetched and wanting in simplicity. Why should not this very characteristic inflammation have its origin as well as its seat in the pulmonary capillaries?—which, conveying arterial blood, and backed by the force of the right ventricle, have in themselves all known capabilities of inflammation; while their intimate relation with the whole mass of blood in the body serves to explain much of those remarkable features which distinguish pneumonia from the common group of visceral inflammations.

Dr. Sibson said that he, like Dr. Williams, had some difficulty in following Dr. Morehead's paper. He gathered, however, that the author, while he considered that in pneumonia the bronchial capillaries were the primary seat of pneumonia, yet that the pulmonary capillaries were also affected with congestion and stasis, and that the air-cells were the seat of exudation. He in this respect coincided with the observations of the best recent pathologists. In a paper in the Provincial Medical Transactions for 1844 (p. 440) the speaker described the condition of the pulmonary vessels in pneumonia, from preparations in which those vessels were injected from the pulmonary veins. The pulmonary capillaries were much enlarged, irregularly swollen, and tortuous in the bronchial tubes entering the inflamed air-cells, which were filled with exudation; and it was very remarkable to notice the abruptness with which the injection stopped short at the point where stasis was established. The rapidity with which the disease usually passed through its whole stages, from the first ushering in of inflammation to the complete restoration of the function of the lung, was surprising. Active congestion, stasis, exudation into the whole of the air-cells, solidifying the affected lung, softening and conversion into pus of the exudation, its complete evacuation and the readmission of air into the cells, the removal of stasis and re-establishment of circulation in the capillaries, succeeded each other in steady progression, and in doing so occupied, on an average, only the short space of nine or ten days. The speaker owned that every time he witnessed these remarkable changes he was filled with wonder. It must be allowed that both the bronchial and pulmonary capillaries were affected in pneumonia, when it was considered that the bronchial vessels were distributed to the whole structure of the lung (bronchial tubes, connective tissue, interlobular structure, and pleura—structures which were all involved in the inflammation), and that they not only immediately adjoined, but anastomosed extensively with, the pulmonary capillaries. The existence of this anastomosis had been established by Ruysch, Haller, and Reisseisen, as well as by Guillot, Rossignol, and Adriani. The question as to whether the bronchial or the pulmonary capillaries were first affected in uncomplicated acute pneumonia, would perhaps never be brought to the test of direct observation, owing to the difficulty of obtaining the lung at the earliest stage of the disease; it would therefore probably have to be decided by a process of reasoning. In some of what might be termed the marginal pneumonias the primary vascular seat of the affection could be fixed upon. Thus it could with precision be said that the disease commenced in the pulmonary capillaries in those cases depending

on passive congestion, from obstacle to the flow of blood along the pulmonary veins, as in hypostatic pneumonia, and in pulmonary apoplexy, which differed from pneumonia, in the character of the exudation (being almost pure blood, composed of fibrin and red corpuscles, with a few white; while in pneumonia there were, in addition, numerous exudation—white—corpuscles), and in the extent and kind of limitation, but agreed with it in the seat of the exudation, its stages, and the existence in many cases of pleuritic exudation superficial to the part affected with pulmonary apoplexy. In bronchitis, a subject to which the attention of the Society had just been called by Dr. Williams, the injections described in the paper alluded to showed that the pulmonary vessels were enlarged, tortuous, varicose, and looped on the inner surface of the bronchial tubes; the bronchial capillaries, which were superficial to the pulmonary, were also undoubtedly affected.

Dr. Salter wished, in the first place, to correct an erroneous impression to which, from some remarks that had fallen, the paper seemed to have given rise—viz., that the author meant in any way to confuse bronchitis and pneumonia, or to imply any connexion between them. What the author evidently meant was, not that in pneumonia there was any bronchial inflammation, but that true pneumonia, having the recognised symptoms, signs, seat, and morbid anatomy of pneumonia, might nevertheless be due to derangement, not of the pulmonary, but of the bronchial vessels. The anatomical question involved in the paper was a very interesting one—namely, the fact of communication between the two independent circulations—bronchial and pulmonary. The purpose served by these two coexistent circulations in the lungs (the nutrition of the lung-tissues with arterial blood and the carrying off of venous blood without its going to the left side of the heart) is such as to imply that there should be no communication between them. Such a communication, however, undoubtedly existed. But it had been shown by Rossignol and Adriani that the communication was such as not to involve a mixture of the bloods. Thus the bronchial arteries could be injected from the pulmonary veins, and the pulmonary veins from the bronchial arteries, in both cases the blood being arterial; but the bronchial vessels cannot be filled from the pulmonary arteries—that is, venous blood cannot get into the bronchial circulation. These observers had also shown that the mucous membrane of the smallest bronchiæ was also supplied from the pulmonary artery; and there was one circumstance, otherwise difficult of explanation, that this distribution satisfactorily explained—the fact, namely, that the production of slight asphyxial congestion by the shutting off of air, as for instance in asthma, was always attended with the exudation and discharge of little pellets of bronchial mucus. The circulation in which engorgement was produced by shutting off of the air being the pulmonary, and not the bronchial, it would be difficult to understand how it should give rise to mucous exudation unless the pulmonary vessels had to a certain extent a bronchial distribution. But such being the case, the phenomenon was perfectly intelligible. He (Dr. Salter) thought that the author's definition of the inevitable seat of inflammation, based on the word "nutrition," gave to that word too narrow a signification. When inflammation is said to be a disturbance of nutrition, the word nutrition is taken in its widest sense, as standing for all those vital or other processes of which the capillaries are the seat. In relation to the arterial condition of the blood, there was not really that difference between pulmonary capillaries and other capillaries which had been supposed. No doubt the blood delivered to the pulmonary capillaries was venous, but it immediately became in them arterial, and in that state left them, so that while in the systemic capillaries it passed from arterial to venous, in the pulmonary it passed from venous to arterial, and was probably as much arterial in the latter as in the former; so that as far as the arterial character of the blood went, the pulmonary capillaries might as well be the seat of inflammation as any other.

Alleged Starvation in Shoreditch Workhouse.—An inquest was held on Friday, April 20, in Hoxton, on the death of an infant, named Griffiths, whose death was alleged to have resulted from neglect in the Shoreditch Workhouse. It was stated that the father and his family were received into the Workhouse, and that after their admission the mother was not supplied with food necessary for her condition, and that she was so weak as to faint when she attempted to suckle her child. The jury returned a verdict to the effect that the food ordered by the Medical officer for the mother was insufficient.

OBITUARY.

E. J. SEYMOUR, M.D.

There are many, both within and without the Profession, who will mourn with deep regret the death of Dr. Seymour, which took place at his house, in Charles-street, Berkeley-square, on Monday, the 16th, after a short, but very suffering illness. Dr. Seymour was one of the Profession who had long enjoyed the confidence of the public, but especially of the more aristocratic part of society. He was educated at Cambridge, and, after an early marriage, removed to Italy, where he practised successfully, chiefly at Florence. On returning to England, he soon fell into extensive practice, and was elected Physician to St. George's Hospital. He was considered one of the most distinguished of the staff of that Hospital. In the school he was remarkable for his facility in communicating knowledge, and was much looked up to by the student, to whom he was ever a kind and considerate friend. Dr. Seymour held the office of Commissioner of Lunacy, in consequence of which he paid considerable attention to the subject, and in his later years was much consulted in mental disorders.

BOOKS RECEIVED.

Life and Death in our Mines. By Jabez Hogg, F.L.S. Pamphlet. From the *Intellectual Observer* of February, 1866. Pp. 16.

*** An able and interesting exposition of the diffusion of gases, the history of safety lamps, and Mr. Ansell's fire-damp and gas indicator.

A Tariff of Medical Fees for Bridgewater and its Neighbourhood. Pamphlet. Bridgewater: A. Graham. 1865.

*** An attempt, and we hope a successful one, to enable the patient to pay his Doctor for skill and time, not for bottles of physic.

The Dictionary of Chemistry. Part xxxiii. Longmans.

*** Contains nearly 200 pages, and is occupied chiefly with an account of phosphorus and its compounds.

The Pocket Formulary and Synopsis of the British and Foreign Pharmacopœias, comprising Standard and Approved Formulæ for the Preparations and Compounds employed in Medical Practice. By Henry Beasley. Eighth Edition, including the Formulæ of the British Pharmacopœia. Pp. 583. London: Churchill and Sons. 1866.

*** This excellent manual should be in the possession of every Practitioner who has not an abnormal memory. It is convenient in size, clearly printed, and closely packed with information.

On a New Method of Applying Remedial Agents to the Cavity of the Tympanum. By Edward Bishop, M.D., M.R.C.S.E., Surgeon to the Metropolitan Infirmary for Diseases of the Ear, Sackville-street, London. London: Churchill and Sons. Pp. 19. 1866.

*** The author's object in these papers is "to bring before the Profession a mode of applying remedial agents directly to the seat of lesion in those cases where disease exists in the middle ear or in the passage leading to it." He proposes to do this by means of tepid pulverised water, and describes an ingenious instrument for the purpose. Dr. Bishop has already found its use satisfactory, and the patency of the Eustachian tube may be secured by forced expiration, by which air is driven into the middle ear—Valsalva's experiment, which "every schoolboy knows."

MEDICAL NEWS.

University of Aberdeen.—At the late Medical Graduation term, the following candidates received promotion to

THE DEGREE OF M.D.

Frederick Page Atkinson, M.B., C.M. (hon.), Kew, Surrey
Anthony Charles Colborne, M.B., C.M. (highest honours), London
John Smith Fowler, M.B. (hon.), C.M., Aberdeen
Alex. Riddoch Gray, M.B., C.M., Aberdeen
Alexander Ogston, M.B., C.M. (highest honours), Aberdeen
Charles Edward Saunders, M.B. (hon.), C.M., Cuckfield, Sussex
James Dear Smith, M.B., C.M., Mayo
Francis Smith, M.B., C.M., Boston, Lincolnshire
Wm. Heath Strange, M.B., C.M., London.

And the following candidates, after the usual Examinations, received Degrees in Medicine and Surgery:—

THE DEGREE OF M.B.

Wm. Scott Aitken, Greenock
Edwin Atherstone, M.R.C.S., Cape of Good Hope
John Attygalle, M.R.C.S., Ceylon
Richard Carter, M.R.C.S., and L.S.A., Newbury, Berkshire
George Edgelow, M.R.C.S., and M.R.C.P., Teignmouth, S. Devon
Alfred John Freeman, M.R.C.S., Southsea, Hants
John Murray Gibbes, M.R.C.S., Sidmouth, Devon
Wm. Robert Gordon, Banffshire
Benjamin Graham, M.A., Morayshire
Robert Grant, M.A., Banffshire
Alfred Swaine Lethbridge, Devonshire
Richard John Lupton, M.R.C.S., L.S.A., L.R.C.P., Bradford
George Maconachie, Forgue
Patrick Manson, Aberdeen
Wm. M'Donald, Cromdale, Morayshire.

Lewis Wayne Morgan, M.R.C.S., L.S.A., Pontypridd, Glamorganshire
David Nicholson, Aberdeen
Henry Rayner, M.R.C.S., and L.S.A., Hythe, Kent
Robert William Tibbits, M.R.C.S., L.S.A., Bristol
Charles Meymott Tidy, M.R.C.S., L.S.A., Hackney
Frederick John Wadd, London
James Williamson, Aberdeen.

THE DEGREE OF C.M.

Wm. Scott Aitken	George Maconachie
Edwin Atherstone	Patrick Manson
George Edgelow	Wm. M'Donald
John Murray Gibbes	Lewis Wayne Morgan
Wm. Robt. Gordon	David Nicholson
Benjamin Graham	Henry Rayner
Robert Grant	Chas. Meymott Tidy
Alfred S. Lethbridge	Fred. John Wadd
Richard John Lupton	James Williamson.

Of the above-mentioned candidates,

Wm. Scott Aitken | Henry Rayner
Chas. Meymott Tidy

received their Degrees in Medicine and Surgery, with highest Academical Honours;

George Edgelow | David Nicholson
James Williamson

received their Degrees in Medicine, with Academical Honours.

At the same time,

Alexander Dyce Davidson and
John Thomas Hughes

were certified as having passed all the Examinations, and are entitled to receive Degrees on their attaining the necessary age.

And the following were declared to have passed part of their Examinations:—

Charles Adam	Charles Maclean
John Arthur	Alexander M'Arthur
James Cameron	Donald M'Ewen
Joseph Carbery	Robert M'Pherson
James Allan Coutts	Douglas Moir
Matthew Dickson	William Muil
J. K. V. O. D'Uminy	Arthur H. Nowell
Alex. G. Dunean	James Allan Philip
Charles Edward Hoeken	Francis W. Smith
Francis W. Jaekson	Arthur Stephen
Sydney Johnson	David Tulloch
Hugh Johnstone	Francis A. Van Der Smagt
Joseph F. Keith	Alexander Wilson.

The next Professional Examination for Degrees in Medicine commences on Saturday, July 28, 1866.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The lowing gentlemen having undergone the necessary Examinations for the Diploma were admitted Members of the College at a meeting of the Court of Examiners on the 24th inst., viz.—

Messrs. Henry Warlow, L.S.A., Haverfordwest; John Williams, Fishguard, Pembrokeshire; Edward Lodewyk Crowther, Hobart Town; George Spearman, Plymouth; Arthur Matthews, Salehurst, Sussex; Henry Kirwan King, Camberwell; Edward Matthews Owens, L.S.A., Sutton, Surrey; Frederick William Fowke, Byfield, Northamptonshire; and Henry Maynard, Durham, Students of Guy's Hospital. Richard Bond Moore, Wolverhampton; David Hawley Burn Anderson, Edinburgh; Henry Aubrey Husband, L.S.A., Jamaica; William Square, Plymouth; Joseph Goodall, Walworth; and William Barnet Burn, Limehouse, of St. Bartholomew's Hospital. Hugh Ferguson, Haverstock-hill; John Hornsey Casson, Ironvill, Derbyshire; and Arthur Griffith Evans, Nasberth, Pembrokeshire, of the Middlesex Hospital; Frederic Morell Mackenzie, Tiverton, Devon; and William Edwin Ditchett, Lout, Lincolnshire, of the London Hospital. James Webb Booth, L.S.A., Huddersfield; and Thomas Baron, Ulceley, Lincolnshire, of St. Thomas's Hospital. George Henry Snape, Liverpool; and Eli Crew, Tithbury, Gloucestershire, of King's College. Samuel Shapland White, Barnstaple, N. Devon, of the Charing-cross Hospital.

The following gentlemen were admitted Members on the 25th inst., viz:—

Edward James Leverton, Truro, Cornwall; Mowbray Jackson, Bowbrickhill, Bucks; Lestock Holland Reid, Toronto, Canada West; Frederic Harry Haynes, Evesham, Worcestershire; and Herbert Chrippes Upton, Petworth, Sussex, students of St. Bartholomew's Hospital. George Vivian Poore, Andover; John Mildred Creed, Melbourne, Australia; and Thomas Bailey, L.S.A., Gough-street North, of University College. Frederic Stewart Colquhoun, Tiverton, Devon; Thomas Horder, Salisbury; and Waren Tay, Worcester, of the London Hospital. Henry Morris, Petworth, Sussex; and Arthur Goodwin, Chesterfield, of Guy's Hospital. William Bennett Rule, Maida-hill; and Alfred John Leggatt, Lowndes-square, of St. George's Hospital. Frederick Stoeks, Wakefield; and George Lucas, Burwell, Cambridgeshire, of St. Thomas's Hospital. James Forbes Sargent, Bentinck-terrace, Regent's-park, of St. Mary's Hospital. Edward Ireland, Kendal, Westmoreland, of King's College. Frederick Baldock Farley, Cretingham, Suffolk, of the Middlesex Hospital; and William Edmond Richardson, of Leeds.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 19, 1866:—

Charles George Langdon, St. Bartholomew's Hospital; James Robinson, Ulverstone, Lancashire; Samuel Woodcock, Glossop, Derbyshire; James Tily, Walkern, Herts; Thos. Prince Fothergill, Bedale, Yorkshire.

The following gentlemen also on the same day passed their First Examination:—

John Greaves Wiseman, Guy's Hospital; Edward Noble Edwards, Guy's Hospital; Ernest Thomson R. Evans, St. Bartholomew's Hospital; Owen Tudor Gronow, St. Mary's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ARMISTEAD, J. W., M.R.C.S.E., has been appointed Assistant-Medical Officer to the Leeds Public Dispensary.

CLEMENTS, G., M.R.C.S.E., has been appointed Senior House-Surgeon to the Royal Infirmary, Manchester.

DOUDNEY, E., has been appointed Assistant-House-Surgeon to the Kent and Canterbury Hospital.

HICKMAN, WILLIAM, M.B., F.R.C.S., has been appointed Surgeon for out-patients at the Samaritan Free Hospital.

SANSOM, A. ERNEST, M.B., has been appointed Honorary Medical Officer to the Booksellers' Provident Institution.

WATSON, SPENCER, F.R.C.S.E., has been appointed Assistant-Surgeon to the Central London Ophthalmic Hospital.

BIRTHS.

BAINES.—On April 22, at 11, Cranley-place, Onslow-gardens, the wife of Matthew Baines, M.D., of a son.

BIDDLE.—On April 18, at Yately, Hants, the wife of T. J. Biddle, Staff Assistant-Surgeon, of a daughter.

COWAN.—On April 6, at Achentoshan, the wife of J. B. Cowan, M.B., of a son.

DUKA.—On April 18, at 37, Coleshill-street, Eaton-square, the wife of T. Duka, M.D., Surgeon Bengal Army, of a son.

ELLISTON.—On April 16, at Ipswich, the wife of W. A. Elliston, M.D., of a daughter.

FELCE.—On April 6, at Launceston, the wife of S. Felce, L.R.C.P. Edin., of a son.

GREIG.—On April 12, at 4, Sunnyside, Saudgate, Kent, the wife of Dr. Greig, Royal Artillery, of a daughter.

MARSHALL.—On April 23, at Holly House, Mortlake, the wife of W. Marshall, M.D., of a son.

WALLIS.—On April 17, at Mullingar, the wife of W. Wallis, Staff Surgeon 12th Depôt Battalion, of a son.

MARRIAGES.

ALDERSON—WILLETT.—On April 19, at St. Matthew's, Brixton, F. H. Alderson, M.R.C.S., to Eliza, eldest daughter of F. Willett, Esq., Derwent-villa, Brixton-road.

CALLON—CARTWRIGHT.—On April 18, at Wolverhampton, W. J. Callon, M.D., to Beatrice Teresa, fourth daughter of J. Cartwright, Esq., of Wolverhampton.

RICKARD—LEGH.—On April 19, at Lewisham, Dr. H. Rickard, R.N., to Catharine Emma, third daughter of E. Legh, Esq., The Limes, Lewisham.

WADE—PICKERING.—On April 21, at Henley-on-Thames, Seaton Wade, Surgeon H.M.S. *Asia*, to Mary Esther, third daughter of the late W. B. Pickering, Esq., of Wilton House, Denton.

DEATHS.

ELLIOTT, ARCHIBALD, Surgeon R.N., at Belle Vue House, Exeter, on April 17.

HENSMAN, THOMAS, M.R.C.S.E., L.A.S., at 26, Canning-street, Liverpool, on the 27th ult., aged 55.

JOHNSTONE, J. M., M.D., at Larkhall-place, Bath, on April 18.

LAITY, JOHN, M.R.C.S., at Marazion, Cornwall, on April 8, aged 39.

MACBETH, WILLIAM, Surgeon Her Majesty's 105th Regiment, at Fort William, on February 11.

WEST, THOMAS, M.D., at Newnham House, near Daventry, Northamptonshire, on April 21, aged 70.

YULE, JOHN ALEXANDER, at sea, on board the *Euxine*, on his passage home from China, on April 10.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Isle of Thanet Union.—Mr. G. P. Phillips has resigned the Minster District; area 15,797; population 3479; salary £25 per annum. Also the Workhouse; salary £120 per annum.

Ongar Union.—Mr. James Shilleto has resigned the Workhouse; salary £40 per annum.

Weymouth Union.—Mr. W. P. Brodribb has resigned the Portland District; area 3555; population 8468; salary £35 per annum.

Worksop Union.—The Blyth District is vacant; area 7072; population 1660; salary £20 per annum.

APPOINTMENTS.

Barnsley Union.—Peter D. Muir, M.D. University of Edinburgh, to the Wombwell District.

Bradford (Yorks) Union.—John Foster, M.R.C.S.E., L.S.A., to the Horton East District.

Camberwell Parish.—Edward Pinder, L.R.C.P. Edin., M.R.C.S. Edin., L.S.A., to the Camberwell District. John C. Roberts, L.R.C.P. Edin., M.R.C.S.E., to the South Peckham District.

Chailey Union.—Lewis Smythe, Graduate in Medicine University of Glasg., F. and M.R.C.S. Eng., L.S.A., to the Fifth District.

Chertsey Union.—George John Scaly, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Weybridge District.
Cockermouth Union.—William P. Murphy, M.R.C.S. Ire., L.S.A., to the Second Cockermouth District.
Kington Union.—William Langston, M.R.C.S.E., L.S.A., to the Pembridge District.
Newport (Monmouth) Union.—William James, M.R.C.S.E., L.S.A., to the Western District and the Workhouse.
St. Austell Union.—Samuel Mason, L.F.P. and S. Glasg., M.R.C.S.E., L.S.A., to the St. Blasey District.
Weobley Union.—William H. Kerbrey, M.R.C.S.E., L.S.A., to the Dilwyn District.

Recognition of Medical Services by the French Government.—The *Moniteur* contains a list of 300 medals granted by his Majesty to those of the Medical Profession who proved during the late visitation of cholera their zeal and devotedness in the care of the sick.

The British Museum.—The accounts of the British Museum have been laid before Parliament as usual. Professor Owen reports the acquisition of 30,402 specimens in the departments of natural history; room has been made for the exhibition of a selection from them, but the bulk have been stored for exhibition and scientific applications when the required space may be obtained. Mr. Gray reports the acquisition of specimens which serve to show the changes that take place in the gradual development of the growth of species of animals, while some illustrate the slight differences which exist between allied species that belong to closely connected localities, thus exhibiting to students the variations that occur under these circumstances, which is a question of much interest and much discussion at present.

Eye Wards at St. Bartholomew's Hospital, Chatham, with Out-Patient Department for the Special Treatment of Eye Cases.—We understand that the trustees of St. Bartholomew's Hospital have determined upon establishing an Ophthalmic Hospital in connection with that institution, and that Mr. Woolcott, the oculist, founder and late Surgeon of the Kent County Ophthalmic Hospital at Maidstone, has been solicited to act as the Consulting-Surgeon. The workmen employed in Her Majesty's dockyards at Chatham and Sheerness will receive this intelligence with welcome, as accidents to the eye of a serious nature and of very frequent occurrence, have happened since the building of iron-clad ships in the dockyard.

Cholera on Board an Emigrant Ship.—Letters from Halifax state that cholera broke out among the German emigrants on board the *England* during her passage from Liverpool. She left the Mersey on the 28th of March and Queenstown on the 29th, and she had then over 1000 passengers, of whom 400 were Germans, on board. On the fifth day after leaving Queenstown cholera appeared among the steerage passengers, and raged with great virulence despite the efforts of two doctors, who were fortunately on board. By the time the *England* put into Halifax the deaths were 46; and in two days after her arrival they had increased to 140. On the 11th of April, when letters left, there were 25 deaths per day. The whole of the deaths were among the steerage passengers and the crew; among the latter there were five deaths. The authorities at Halifax took prompt measures to alleviate the condition of the sufferers, and at the same time to prevent the spread of the disease. The Admiral sent down the hulk *Pyramus* as Hospital ship, and the governor 80 tents, in which the healthy survivors were encamped on Macnab's Island.

Discovery of a Mammoth.—At the last sitting of the Academy of Sciences a letter was received from M. de Baer, of St. Petersburg, announcing that a mammoth, still covered with its skin and hair, had been discovered in the frozen soil of Arctic Siberia. This discovery had been made in 1864 by a Samoyede in the environs of Taz Bay, the eastern branch of the Gulf of Obi. The news only reached St. Petersburg towards the end of 1865; but as the bodies of large animals will keep a long while in those regions, if they are not completely uncovered, and as this mammoth was still enclosed in the frozen soil, the Academy of St. Petersburg has, with the aid of the Russian Government, sent M. Schmidt, a distinguished palæontologist, to examine the animal and its position in the locality. It is hoped M. Schmidt will arrive before the decomposition is too far advanced, and that a correct notion may be obtained of the outer appearance of the animal, and also, from the contents of the stomach, of its natural food. The pre-historical figure of the mammoth drawn on a piece of ivory, found in a cavern of Périgord by M. Lartet, will then admit of verification.

The Great Prize in Electricity.—The French Government has issued an invitation to the *savants* of all nations to compete for the prize of 50,000 frs. which will be decreed five years hence to the author who shall have discovered the means of rendering Volta's pile economically applicable to manufactures as a source of heat, to illumination, to chemistry, mechanics, or practical Medicine. The *concours* will remain open for five years, dating from April 18, 1866.

Blistering in Chronic Gonorrhœa.—M. Tarneau, a French Army Surgeon, states that he has employed this means with success in two cases, one dating two years and the other six. Of six cases of 50 days' duration, four were cured; and of eleven cases, which had reached from the thirtieth to the thirty-fifth day, the application of the blister was successful in nine, it requiring to be applied a second time in one of these. The blister, two centimetres in width, is applied along the course of the urethra, and in none of the cases has it been attended with other than slight inconveniences, ischuria or strangury never having occurred. The means seems to be more efficacious in proportion to the length of time the affection has lasted, and is well worthy of notice.—*Recueil de Med. Mil.*, March.

The Mortality at Hong-Kong.—Colonel Sargent has suggested to the Committee now examining into the causes of last year's mortality at Hong-Kong, the employment of floating barracks for the troops on that station. He proposes that the obsolete men-of-war now lying in ordinary at our naval stations should be utilised for the purpose. On the subject of his proposal a contributor to the *Times* writes:—"Imagine a large and crowded city (Hong-Kong), hemmed in between a harbour and a steep mountain, with sea vapours, land vapours, and town vapours steaming up all day, left in the shade for an hour or two before sunset every evening. It is the very arrangement for malaria on the largest possible scale. The rich merchants, and all who can afford it, drive round the mountain and spend the evening and the night on the sunny side. We presume that our soldiers cannot do this, and that it would not be possible to perch them up over the town, though even that would not take them out of the deadly shadow. But whatever the dilemma, the difficulties, and the cost, we cannot afford to lose a regiment there once in three years. It appears from Colonel Sargent's letter that even the best barracks that can be built are not safe under the circumstances. So there is really much to be said for his suggestion of floating barracks, and we hope it will be well considered."

Hydrophobia.—A girl residing at Neuville-les-Dames, France, has just died from hydrophobia. She had never been bitten by any dog, but had often played with one which was killed three weeks since in a rabid state, and had allowed the animal to lick her face when she had a small sore on her lip. —*Guardian.*

The following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked.			2. Result of reported Cases from the Commencement of the disease.				
	Week ending April 14.	Week ending April 7.	Week ending March 31.	Attacked.	Killed.	Died.	Recovered.	Unaccounted for.
1. Metropolitan Police District	23	63	92	7946	3478	3523	346	599
2. South Eastern Co.	4	6	8	5060	1618	2786	446	210
3. South Midland Co.	344	396	526	18204	6394	9895	1548	367
4. Eastern Counties	127	126	217	10611	4672	4771	767	401

Note.—43 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Cambridge, 1; Cornwall, 1; Cumberland, 3; Lancaster, 1; Lincoln, 5; Middlesex (extra Metropolitan), 2; Northampton, 1; Oxford, 1; Stafford, 2; Worcester, 2; Yorkshire, 5; "The Metropolis," 1; and Scotland, 18. These Inspectors returned 780 cases last week.

Cinchona Cultivation in India.—From a report sent in to Government by Mr. McIvor, the superintendent of

Government cinchona plantations on the Neilgherries, we learn that the number of plants planted out during the month of January remains the same as in last month—viz., 244,871. The increase by propagation is 42,894, being 11,082 under the average of the last six months, making the total number of plants at the end of the month 984,143. The average growth of eleven plants of *Cinchona Succirubra* planted out by his Excellency the Governor and other gentlemen at Neddivuttum on August 30, 1862, during the month is $\frac{8}{11}$th of an inch, or $\frac{6}{11}$th of an inch under the growth of last month. One of the two plants cut down on March 20, 1863, for the bark submitted to Mr. Howard for analysis, has made strong shoots of $82\frac{1}{2}$ inches in height, giving the growth of half an inch during the month. The twelve plants of *Cinchona Officinalis* (a shrubby species), on the Dodabetta plantation, gives an average growth of $2\frac{3}{4}$ inches, or $\frac{1}{4}$ of an inch under that of last month. The total number of plants issued to the public during the month is eight, making the total distributed 83,684. —*Homeward Mail.*

EVERY aspirant to Surgical honours is sure to be told early in his course by some kind friend or other that to be a good Surgeon a man must have a lion's heart and a lady's hand. Well—he looks down at a hand of anything but feminine proportion, and looks back to his sensations at the first operation he witnessed; and he is apt to conclude that he has chosen the wrong path in life. By-and-by, he finds that by constant practice in the use of instruments his fingers have acquired a new delicacy and flexibility; and he finds too, that as the source of the lion's courage lies in consciousness of strength, so the moral courage and firmness typified by the lion's heart may come to him as sure results of better knowledge and training, and self-reliance. Uncertainty and ignorance can hardly produce anything but cowardice or rashness; true courage is associated with judgment and reflection.—*Introductory Address at St. Thomas's Hospital, October* 2, 1865, *by William M. Ord, M.B. Lond.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Smyth's interesting case shall be inserted, if possible.

Dr. Fearnside, Preston.—We shall be very glad to be favoured with Dr. Fearnside's other papers.

Dr. Grindlay.—Mr. Clement, F.R.C.S., and Dr. Brady, are both Members of Parliament. Dr. Michell has not been a Member for some years.

E. B.—A capital and complete account of the alleged preservative virtues of belladonna against scarlatina is to be found in the *British and Foreign Medico-Chirurgical Review* for June, 1855.

A Provincial Fellow.—The annual dinner of the Fellows takes place on the day of election, at the Albion Tavern. Mr. Wormald, the President of the College, will take the chair on the next occasion. Write to Mr. Hulme, of Gower-street, the Honorary Secretary.

To Correspondents.—We are requested by the Secretary of the Anthropological Society to correct a misstatement contained in a paragraph on Mr. Laing's discoveries in the mounds at Caithness, which we inserted last week from the *Pall-mall Gazette.* It was at the Anthropological, and not at the Ethnological Society, as asserted by our contemporary, that doubt was first thrown on the accuracy of Mr. Laing's deductions. The Anthropological Society were the first to circulate Mr. Laing's statements, which they published. They were also the first to call in question his conclusions.

A Surgeon, Liverpool.—The late Dr. Scott, of Southsea, and Messrs. Cock and Arnott performed the operation of Œsophagotomy; the first two gentlemen with success.

A Successful Student.—The admirable dissections to which you allude and on which you were examined, were prepared by Dr. Pettigrew, the Assistant Conservator of the Museum.

Christ's Hospital.—Perhaps the following are the lines to which you refer:

"Jerusalem's curse is not fulfilled in me,
For here a Stone upon a Stone you see."

A Young Member.—Generally speaking, it is not wise to sign a document without first reading it. The following is the declaration to which you have bound yourself:—"I, John Jones, of Timbuctoo, do solemnly and sincerely declare that, while a member of the Royal College of Surgeons of England, I will observe the byelaws thereof; that I will obey every lawful summons issued by order of the Council of the said College, having no reasonable excuse to the contrary: that I will demean myself honourably in the practice of my Profession, and to the utmost of my power maintain the dignity and welfare of the College." The document is signed in the presence of a College official, and preserved amongst the archives of the Institution

Wm. Farrer, Esq.—The gentleman alluded to by Sidney Smith left behind him £100,000, with the following laconic account of how he had acquired the fortune by different diseases:—"Aurum catharticum, £20,000; aurum diureticum, £10,000; aurum podagrosum, £30,000; aurum apoplecticum, £20,000; and aurum senile et nervosum, £20,000."

We observe that a new edition of Mr. Cecil Austin's "Cattle Diseases Prevention Act, 1866," has lately been published by Nicholls, of Frederick-street.

Vaccination Bill.—Copy of a letter addressed to the Vice-President of the Privy Council by the Board of Works, Holborn District:—

"Sanitary Department, Little Gray's-inn-lane, E.C.,
April 13, 1866.

"The Right Honourable H. A. Bruce, Esq., M.P.

"Sir,—I am directed by the Board of Works for the Holborn District to submit for your consideration the expediency of expunging from the Vaccination Bill now before Parliament that portion which enacts a compulsory registration of all successful vaccinations.

"This registration, necessarily incomplete, has now been carried out for twelve years without, as far as this Board has been able to learn, ever having been applied to any useful purpose, whether public or private. It entails additional labour and trouble on the parent and vaccinator, and expense upon the ratepayers.

"The great objection to it is that it acts as a discouragement to vaccination, not only by the trouble it gives, but because the poor and uneducated have an aversion to be registered for any purpose. For this reason, as this Board has twice represented to the Home Secretary, a large percentage of the births in this district go unregistered.

"The Board considers such registration to be unnecessary—

"1st. Because, as far as the public vaccinators are concerned, a complete return of all operations, whether successful or unsuccessful, is made week by week to the Board of Guardians.

"2nd. Because, as a matter of fact, such register in this district has never been referred to. The Board are informed that Medical examiners of recruits for the army, navy, militia, public and charity schools, insurance companies, etc., never search any other register for evidence of vaccination than the arm of the examined, where, if successful, it is always indelibly registered.

"There are grounds also for believing that it is unnecessary for carrying out compulsory vaccination and other purposes of State hygiene.

"The Board are of opinion that one certificate, either of successful vaccination or of insusceptibility of the operation, should in every case be given by the vaccinator to the parent or guardian of the child.

"I am directed to furnish you with any further information in my possession that you may desire to have on this very important subject.

"I am, Sir, your most obedient servant,
"SEPTIMUS GIBBON, M.D., Medical Officer of Health."

REGISTRATION OF VACCINATION.

The following is part of a letter from Mr. Felce, read by Dr. Richardson at the late Vaccination Meeting:—

"A more adequate remuneration to the public vaccinator would do much to improve the present unsatisfactory state of affairs; but so long as the cases of successful vaccination are only partially registered, any Vaccination Act must prove a failure. We all know how efficiently the registration of births and deaths is carried out, and I would, therefore, append to this more closely than is now done a system of registration of vaccination. Whenever the birth of a child is registered let a notice be given to the parent or guardian that he or she must, within a certain time, register the vaccination of the said child with the same functionary who has registered its birth; in short, make the production within a given period of a certificate from a registered Practitioner compulsory, not the actual operation. This would simplify the whole matter, and instead of the present cumbrous, complex, and, therefore, inefficient machinery, we might have an Act simple in its details, and ensuring a correctly-kept register, which could always be open to proper officials, whose duty it should be to prosecute and enforce a penalty in all cases neglecting to comply with the regulation, and this, I take it, would soon be but rarely necessary, for I believe that the 'registration of vaccination' would soon cease to be considered more of a hardship than the compulsory 'registration of a birth, death, or marriage.'"

ICE IN CHOLERA.

A correspondent of the *Englishman* gives an account of the successful treatment of a case of cholera, apparently in an advanced stage, by the application of ice to the spine, as recommended by Dr. Chapman. The writer says:—"On Sunday, the 25th February, about 10·30 a.m., my servants requested me to go and see a man who they said was dying of cholera, and to give him some medicine. I proceeded to the place, where I found a man lying on the ground in the greatest agony, with the usual symptoms of cholera,—vomiting, etc.; he was much emaciated, and to me appeared to be rapidly sinking. I had no medicine in the house. I ordered one of my servants to go round among the neighbours and try and get some medicine, but in this I was unsuccessful. I recollected, however, having read in the *Times* a letter in which the writer advocated the use of a bag of ice down the spine. Feeling that if I did no good, I could, under the circumstances of the case, do no harm, I made up my mind to try whether ice would do any good. I now proceed to give you an account of what I did, and as to what the results were. 10.30 a.m., the man, a Mussulman, a hackery-wallah, arrived with his own and other hackeries from Calcutta. He had been for two or more hours purging and vomiting violently; voice scarcely audible; pulse imperceptible; hands, arms, legs, and feet quite cold. He was throwing his legs about and twisting his body in great agony; he complained much of thirst. I gave him water with a little carbonate of soda in it. He appeared to be sinking fast. 11 a.m., I procured some ice from a neighbour. Having no gutta percha bag, I took the leg of a pair of flannel trousers and made a long bag to reach from between the shoulder-blades to the bottom of the spine, of a width of three inches; into this I put broken ice and applied it on the spine. After I had applied the ice, the purging and vomiting ceased, and by 11.20 the spasms were much diminished. 11.30.—The patient was much easier. On questioning him, he said in a very low voice that he felt easier. A little before 12, I found that his pulse was perceptibly stronger, and that his arms and legs, which were previously as cold as stones, began to be slightly warm. The flannel in which the ice was put was now saturated with water, and as the cold was to be a dry, not a wet cold, one of my natives suggested the use of a

bottle, on which I got a preserved fruit bottle, into which I put the ice, and had the bottle held against the spine. 12.30.—No more vomiting, etc.; the arms and legs getting warmer. No pain, very great thirst; I let the man drink as much as he liked. From this time until 1.30 p.m., I kept the bottle of ice on his back; when finding that his hands, arms, legs, and body were becoming hot as if he had a fever, I removed the bottle of ice, and as I was about to leave my house for tiffin with a neighbour, I told my khansamah if fever came on, to put in the place of the ice bottle a bottle of hot water. 4.30.—I returned to the man. He was fast asleep, and a more deadly object I never saw. At 5.30 he awoke and asked for food. I gave him some thick conjee with sugar and brandy. 7.30 a.m., Monday, the 26th.—The man is sitting up; convalescent, but weak. He wants to take his bullocks and hackery away. The above are the facts of the case."—*Homeward Mail.*

Mercurial Fumigation.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Is there really any such great superiority in mercurial fumigation over inunction? To me the former appears a very laborious and tedious method of inducing the specific action of mercury. Why cannot the Surgeons of such Hospitals as the Lock be a little more logical? Would it not be a very easy matter to select, we will say fifty cases, as nearly as possible of the same type of disease, and treat half by inunction and half by fumigation, and then compare the results? I am young at present in the Profession, and from having been kept "at my books" till I was twenty-three, I was inclined, when I then commenced Medical studies, to attend too much to book work. I have since found out, by my short term of practice, how much more easy and efficacious it is to gain knowledge by experiment, or, which is the same thing, by experience. What splendid opportunities of knowledge have Hospital Practitioners!

I am, &c.,

M.B.Aug.

The Purity of the Atmosphere.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you permit me, through your columns, to inquire whether any of your readers has ever repeated, or heard of having been repeated by others, and with what results, the experiments for determining, by means of a standard solution of permanganate of potash, the amount of organic or oxidisable impurities present in various atmospheres, which, on the sole authority of Dr. Angus Smith, have been so generally accepted as reliable, and so frequently quoted by writers on sanitary subjects?

I am, &c.,

London, April 24. Air-Test.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·844 in. The barometrical reading decreased from 30·13 in. on Sunday to 29·62 in. on Thursday.

The general direction of the wind was S.W. and W.S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 47·8°.

APPOINTMENTS FOR THE WEEK.

April 28. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. G. Scharf, Esq., "On National Portraits."

30. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

Medical Society of London, 8 p.m. Clinical Discussion. Cases by the President, Dr. Leared, Dr. Tilbury Fox, and Mr. Walter J. Coulson.

May 1. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Pathological Society, 8 p.m. Meeting.

Royal Institution, 2 p.m. Annual Meeting.

2. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Hunterian Society (Council, 7½ p.m.), 8 p.m. Dr. R. Bennett, "On Certain Derangements of the Nervous System occasioned by Shock, especially in Reference to Railway Accidents."

Obstetrical Society of London (Special Council, 7½ p.m.), 8 p.m. Dr. Thomas Radford, "Cases of Lacerations of the Uterus, with Remarks." Mr. Robert Ellis, "Anæsthesia by Mixed Vapours."

3. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Mr. Berkeley Hill, "On a Case of Empyemia, with Fistulous Openings, Cured by Repeated Evacuations of the Pus." Mr. Haynes Walton, "On Detachments of the Retina, their Causes and Treatment, with Specimens."

Royal Institution, 3 p.m. Professor Huxley, "On the Methods and Results of Ethnology."

4. Friday.

Operations. Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Meeting.

Royal Institution, 8 p.m. Professor Abel, F.R.S., "On Substitutes for Gunpowder."

EXPECTED OPERATIONS.

St. Peter's Hospital for Stone and Urinary Diseases—The following Operations will be performed on Tuesday at three o'clock:—

By Mr. Armstrong Todd—For Recto-vesical Fistula.

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

(Continued from page 411.)

Detachments of Part of the Lower Epiphysis of Humerus or Fractures of Condyles—Detachment of Lower Epiphyses of Humerus—Case of Union in Malposition: Restoration of Free Motion in Six Months—Detachment of Lower Epiphysis of Humerus treated as a Dislocation: State of Things Two Months Afterwards.

I HAVE already mentioned an example of a compound injury in which the line of fracture passed almost exactly through the epiphysal line by which the three separate points of ossification at the lower end of the humerus are joined to the shaft. Detachments of the whole or of a part of this lower epiphysis of the humerus are very frequent in practice. The common accident known as fracture of the internal condyle is, when it occurs in children, as it most often does, usually a detachment of the inner epiphysis. I have a few notes to make respecting this accident. It is to be recognised by the circumstance that the inner condyle appears deficient, does not project sufficiently, and on further examination you find that there is a little portion of bone displaced in front of the inner part of the joint, and that this is moveable. In adults the displacement is rarely so great as in children, and in them crepitus can often be produced, whilst in the latter this sign is usually wanting. I believe that the displacement, if there be any, is always forwards and towards the middle line, so that the breadth of the bone is diminished. It is, of course, caused by the muscles attached to the condyle (the pronators and flexors), which have no antagonist behind. A month or two after the accident you almost invariably find a solid lump of bone fixed in front of the joint, and somewhat impeding its motions. At the end of six months this inconvenient projection has much diminished in size; indeed, if the patient be a child, the bone may have become so moulded that all trace of the injury excepting a slight loss of width in the condyle has disappeared. Now, looking at the character of the displacement, what ought to be the position of the arm in which this fracture ought to be treated? Usually, I believe, an angular splint is employed, but clearly a state of extreme flexion would be that most likely to restore the detached condyle to its place. The forearm should be pronated and the elbow bent to the utmost. In this position the offending muscles would become useful as pads by which the fragment would be pushed back towards its proper position. The position described may be obtained either by fastening (with plaster) the patient's forearm in such a position that he could apply the palm of his hand to the side of his neck (same side), or that his palm would lie flat on the upper part of his sternum. The latter is the more comfortable, but the less effectual.

Detachment of Lower Epiphyses of Humerus.—We will pass now to that class of cases in which the detachment involves the whole of the lower epiphysis. I think I have seen about half a dozen recent examples of this form of injury, and at least twice as many old ones in which advice was sought in consequence of the awkward deformity which often follows it. It is by no means a frequent accident, and I have never had an opportunity for dissecting a specimen, nor have I ever seen a specimen in a museum. Yet the symptoms in recent cases are so marked that there can be little room for mistake. This group of cases presents three very interesting points for our investigation:—1. The symptoms produced; 2. The treatment which ought to be adopted; and 3. The results to be expected.

The symptoms of a transverse detachment of the lower end of the humerus at the epiphysal line are like those of a dislocation at the elbow backwards. There is conspicuous deformity; the end of the elbow projects backwards; the tendon of the triceps is prominent and curved; the forearm looks shortened. You make your diagnosis by ascertaining the relation of the tips of the condyles (external and internal) to the olecranon and head of radius respectively. Bear in mind that this epiphysis is very short, and that the lower fragment will be scarcely high enough to reach the upper edge of the greater sigmoid notch. Still, however, the symptom which I have pointed out, the relative position of the internal condyle and olecranon will be a definite one. In addition to this sign, you will find that there is very free mobility; that the elbow can be easily pushed a full inch further backwards; and that when it is so the lower corners of the upper fragment project in front, and the inner one even threatens to perforate. By first reducing the deformity by extension, you may usually elicit some kind of crepitus. In addition to the displacement of the lower fragment backwards, I believe it is usually somewhat rotated; and in the cases which I have seen the rotation has always been inwards, so as to leave the inner extremity of the lower fragment prominent beneath the skin. I have never seen an instance of displacement forwards. Three times I have examined the relation of parts after this accident immediately after the injury, and before any swelling had occurred to conceal them. In one of these, a boy of 10 fell from a horse just in front of the Hospital, and was carried straight into the receiving-room, where I chanced to be at the time. As the deformity was very characteristic, we took him over to the College, and the stereoscopic photograph which I now show you was taken within twenty minutes of the accident. So rapid, however, was the swelling, that the points had already been much masked. You can still, however, by the exercise of a little faith recognise in the photograph the prominences of the inner and outer angles of the upper fragment as they project forwards and press against the skin. The projection of the olecranon backwards is very evident. It looks, indeed, like an ill-marked dislocation backwards. When I first saw the arm there was a deep rounded hollow or dimple in front just over the tendon of the biceps, caused probably by adhesions of the skin to the deep fascia below. This was obliterated very quickly by swelling. Three-quarters of an hour after the accident all the points of bone were buried in the effusion which had occurred; yet the injury had been by indirect violence, and there was no contusion of the parts nor any extravasation of blood. No doubt the rapidity and extent of the swelling were in part to be explained by the fact that in this injury the synovial membrane of the joint is torn.

The two other cases to which I have referred presented symptoms so precisely similar to the above that I need not describe them. One of them occurred only about a month ago, and I was able then to demonstrate its features to you.

In attempting to reduce the displacement in these cases you will find that the action of the triceps upon the olecranon, dragging the forearm and lower fragment of the humerus together backwards is the chief hindrance. Thus, what French Surgeons call a *movement en totalité* is effected, leaving the lower end of the shaft of the humerus prominent in front. Your first idea as to position would probably be to relax the offending muscle by extending the arm. No worse practice could possibly be adopted. Remember that in all positions of the forearm the relations of the ulna to the lower or epiphysal fragment will remain the same, or nearly so, this fragment being maintained by the muscles arising from the tips of the condyles in a position of flexion—*i.e.*, at right angles with the axis of the ulna. Now, if you put the elbow straight it follows that the lower and upper fragments must be at right angles to each other, and as there will probably be some shortening, the broken surface of the lower fragment (*i.e.*, its upper surface) will be in apposition with the posterior surface of the lower end of the shaft. Should union occur in this position, the patient will be unable to flex his arm beyond a very limited extent. I think, then, that in these accidents we ought to flex the elbow as much as the patient can bear, and keep it so, avoiding by all means any approach to the straight position. This rule applies to fractures just above the elbow, and to detachments of the epiphysis (see page 410). It applies with especial force to fractures, for in the case of separation of epiphyses, as the patients are young, there is always much more to be hoped in the way of subsequent moulding of the growing bone, even if it may in the first instance have united in bad position.

That the arguments used are more than mere theory the frequent results of practice fully prove. We every now and then meet with examples of injury near to the elbow in young persons, after which permanent inability to flex the elbow, with a simulation of some of the symptoms of an unreduced

dislocation backwards, has resulted. The inability to flex is always the chief inconvenience, and it may, I think, be certainly obviated by keeping the limb bent in the first instance. I fully admit that it is difficult, if not impossible, to effect accurate coaptation of the fragments. There is almost certain to be some overlapping, but still the bent position is the best one.

Every one must have seen instances in proof of the assertion that the growing bones of children, although united with much displacement, will gradually become so moulded that their natural form is restored. I will quote but one example out of several which I have seen, in which very disagreeable deformity at the elbow, resulting from these injuries, was subsequently almost wholly remedied.

Case of Union in Malposition—Restoration of Free Motion in Six Months.

In October, 1863, Mr. Rea Corbet, of Stanford-le-Hope, brought to the Hospital for Mr. Curling's opinion a boy, aged 11, who had sustained an injury to his elbow seven weeks before. It had been treated (not by Mr. Corbet) in a position between extension and a right angle, and was now almost straight, and with but little motion. Different opinions had been given as to the nature of the accident. Mr. Curling kindly asked me to examine the case, and I think we quite agreed that it was in all probability an instance of union in bad position, after detachment of the epiphysis. The symptoms were well characterised. It was agreed not to employ forcible extension, but to use an angular splint and passive motion, and trust to time for a re-modelling of the deformed extremity of the bone. Six months later Mr. Corbet reported that the motions of the joint were almost perfect.

I have already remarked that this accident simulates at first sight a dislocation backwards, and no doubt a certain number of cases are treated as such. Of this the following case appears to be a definite example. Possibly if the mistake were more frequently made, and the cases all treated as dislocations ought to be, and usually are, in the flexed position, the average results would be at least as good as they now are. Splints are by no means essential, and often inconvenient.

Detachment of Lower Epiphysis of Humerus treated as a Dislocation.— State of things two months afterwards. — In August, 1862, a young gentleman, 8 years old, was brought to me from the country, his parents being anxious respecting a certain amount of deformity and stiffness which remained after a so-called "dislocation of the elbow." The accident had occurred two months before, and the Surgeon under whose care the boy had been had considered it a dislocation merely. It had been "reduced" and kept bandaged, in a sling, but without splints.

The joint was now wholly free from swelling, and the outlines of the bones could be easily felt. A certain degree of deformity was evident to the eye, the outer condyle projecting too much. The irregular margin of the detached epiphysis at this part was easily felt. The lower extremity of the shaft was a little too forward, and there had also been some lateral displacement of it inwards. There was a certain amount of thickening at the place of union, but not very great. Supination and pronation were perfect, but extension and flexion, although possible through a considerable range, were not nearly normal.

It is interesting as an instance of union in good position obtained without the use of splints.

(To be continued.)

Pathological Society of Dublin.—The concluding meeting of this Society for the session took place on Saturday the 21st ult., when the gold medal for an essay on diseases of the kidneys was awarded to Mr. Gerald Yeo. The President, Dr. M'Dowel, in presenting the medal to Mr. Yeo, complimented him very highly on the great ability displayed in his essay, which, he said, evinced not only extensive knowledge of the literature of the subject, but the results of diligent and accurate clinical study.

The late Mrs. Carlyle.—This lady was the daughter of Dr. Welsh, of Haddington, who practised Medicine in that town up to the year of his death, 1819. At her funeral, one of the pall-bearers was her late father's partner, Dr. Thomas Howden. She lies by the side of her father in the centre of the ruined choir of the old cathedral of Haddington, known as the *Lucerna Loudoniensis*, or Lamp of Lothian.

THE PHYSICAL AND CHEMICAL CHANGES IN LIVING BEINGS FROM A MEDICAL AND PHYSIOLOGICAL POINT OF VIEW.

By Dr. LIONEL BEALE, F.R.S.,

Fellow of the Royal College of Physicians, Professor of Physiology and of General and Morbid Anatomy in King's College, London, and Physician to King's College Hospital.

On Oxidation.

Oxygen is often spoken of as being a life-giving substance and necessary to *life*, and this view is generally entertained without question, for when one of the higher animals is deprived of oxygen its death results almost instantly. But are there not living beings which not only live in the absence of oxygen, but are destroyed by its presence (Pasteur)? Do not many living things live, at least, for a long time deprived of oxygen? And can it be affirmed that all the matter that lives in a man or a higher animal is dependent for its life upon a supply of oxygen? How, then, can oxygen be a life-giving substance or necessary to life in all cases, or how can life be the result of the action of oxygen? Before affirming that oxygen is a life giver and that life is the result of oxidation, ought we not to try to ascertain what effect oxygen really does exert upon living matter and living beings?

Let us consider how oxygen acts upon the simple anatomical element or cell, which consists of germinal or *living* matter and *lifeless* or formed material.

First, as regards the influence of oxygen upon mere cell growth and multiplication. It is a well-known fact that cell growth proceeds most rapidly in parts which, so far from being most freely supplied with blood rich in oxygen, derive their nutrition from blood which is of a dark colour, charged with carbonic acid, and which circulates very slowly. Consider the state of things in a pneumonic lung when cell multiplication is taking place with marvellous rapidity. What millions of masses of living matter are produced in the air cells of the lung in the course of a few hours, and this notwithstanding the blood is almost at a standstill or quite stagnant. Little, indeed, must be the proportion of oxygen transmitted to these rapidly growing cells under the conditions present. Or look at what is going on in a common boil or in an abscess. How rapidly cell multiplication is proceeding. The living matter of the tissue increases to a great extent. It divides and sub-divides rapidly. Much of the old tissue is taken up and converted into living matter, and yet is it not obvious that the oxygenating process must be terribly reduced or altogether at a standstill? Or look at the rapidly growing cancer, with its small supply of arterial blood. Or take an ordinary gland like the liver, which consists almost entirely of cells which grow and multiply, and appropriate materials of blood which has already been deprived of much of its oxygen. Or notice the rapid cell multiplication which takes place at an early period of development, before vessels are formed, and when but little oxygen can penetrate into the substance of the developing mass, compared with the amount introduced at a later period. Even during the remainder of the intra-uterine life how little oxygen is introduced into the blood of the fœtal vessels compared to the quantity that might be introduced if this gas were required in considerable proportion for the development of the tissues. Or remark the rapid growth of vegetable textures associated with the absence of any arrangement for the absorption and free distribution of oxygen.

I might adduce many other examples demonstrating the same fact, that rapid cell growth and multiplication may occur under conditions actually unfavourable to the introduction of a large supply of oxygen. In truth, in those cases in which *vital* processes are taking place with the greatest activity, we find a small, not a large, supply of oxygen. By the *greatest activity of the vital processes* I mean to imply simply that a greater quantity of lifeless matter becomes living matter in a given time. Many Physicians and some physiologists, however, maintain, oddly enough, that the highest state of vital activity is when little change of this kind takes place, and they seem to think that the tissues of a man exhibit a greater degree of vital activity than those of a child or of a fœtus; and the normal, slow-changing tissues, a higher degree of vital activity than the rapidly-growing cancer. In fact, they make slow change, not rapid change, synonymous with a high degree of vital activity. An old organism must, therefore,

exhibit a higher degree of vitality than a young one, and according to this view the old, hard, dead, and, perhaps, slowly-decaying cell-wall, than the new, soft matter within which is undergoing the most active change.

Oxygen, then, cannot be a life-giving substance. It is not a stimulus to life, nor does it combine with matter that is alive, neither is it an *excitant* of vital phenomena. Vital phenomena are manifested although little oxygen is present, and certain living beings may increase—pass through the various phases of their existence—without any oxygen at all. Oxygen is not a substance actively concerned in supporting life. It performs a very secondary part. It seems to be mainly concerned in facilitating the removal of the products resulting from death. As we shall see, it plays a highly important part in the changes of the higher organisms, but not as a direct supporter of life. It converts the substances resulting from death into materials that can be rapidly removed, so that there may be no impediment to the access of the inanimate pabulum to the living matter. Oxygen promotes the removal of old material, that new material may be readily transmitted to the living matter, and so supply the place of that which dies. Oxygen acts upon dead, not upon living matter. It is the dead material upon the outer part of cells that become oxidised, not the germinal matter within.

The quantity of oxygen is therefore a measure *not of the vital activity*, but of the *decay taking place*. The quantity of oxygen required is a measure of the work resulting from the chemical change in lifeless tissue, but has little or nothing directly to do with the development and building up of new tissue to supply the place of that which is removed. The dead red blood corpuscles are oxidised, not the living white ones. The white ones grow and multiply most rapidly, to a less extent in the rapidly moving and highly oxygenated arterial blood, than in those places where the rate of flow is not active, as in the portal venous blood, and wherever the circulation is slow and the blood almost stationary.

On the contrary, the free supply of oxygen often causes germinal matter which is growing abnormally fast to increase more slowly. It actually *reduces the rate of vital changes*, and in doing so promotes the return of an organism in which the vital changes have been abnormally active, to the healthy condition in which these changes are far more slowly carried on. The most perfect state of health is not that in which vital change is most active,—or the state of things when an abscess is being formed would be a higher condition of health than when the textures are in their normal condition. Have we not found by experience that in such states of system as the scrofulous, which are characterised by the too abundant growth and multiplication of germinal matter, and the too rapid formation of a soft, and not lasting, imperfectly-formed tissue, oxidation is the real remedy to check this *morbid increased vital activity?* Nay, is it not probable that cod-liver oil, and other remedies found useful in this large and important class of diseases, facilitates the process of oxidation by supplying carbon and hydrogen, which may combine with some of the nitrogen of the too-abundantly formed nitrogenous constituents, and thus aid in the formation of a greater amount of readily oxidisable compounds than was possible before, and in this way prevent the too rapid development of evanescent tissue, which must soon run into decay, and the too free multiplication of cells which interferes with the more slow process of the formation of normal and more lasting tissue?

(To be continued.)

THE COMING SUMMER.—The hot weather set in so intensely last week that most of us no doubt anticipate a lovely but oppressive summer. Dr. Hjaltalin predicts for us rather the contrary. He observes that in his own country the mean temperature has been five degrees below the usual mean of winter; this must almost necessarily be followed by a tremendous northern icedrift, the effect of which will be felt by England amongst other countries. The Atlantic will receive the drifting ice blocks, which will melt, and be the occasion of much rain and hail, accompanied by a fall in the mean heat of the coming summer.

A CASE OF SPONTANEOUS TETANUS AT NEWTON, IN DEVONSHIRE.—A lad of about 12 years of age, the son of Captain Wakeham, has just died from lockjaw, which came on spontaneously. This is a very unusual circumstance, as tetanus is almost always the result of some injury. The lad was attended by Dr. Gillard and Dr. Deake.—*Western Mercury.*

ORIGINAL COMMUNICATIONS.

THE COLLAPSE OF CHOLERA COMPARED AND CONTRASTED WITH OTHER FORMS OF COLLAPSE.

By GEORGE JOHNSON, M.D., F.R.C.P.,
Physician to King's College Hospital, Professor of Medicine in King's College.

THERE are certain morbid phenomena which, occurring in different cases, appear on a superficial view to be identical or very similar, but which are found on more minute examination and analysis to be essentially different in their nature and origin. For instance, that collection of symptoms which we designate *coma* may sometimes be caused by a narcotic poison in the blood. In another case coma may be a result of general plethora and congestion or inflammation of the brain, while in yet another case it may be a consequence of anæmia and a defective blood supply to the brain; and again, in a fourth class of cases, direct pressure on the brain by a piece of broken bone or by a clot of blood may be the cause of coma. In each of these classes of cases it is manifest that the success of treatment depends upon the recognition of the cause of the coma. The treatment which would be curative in one form of coma might be fatally mischievous in another.

The causes of *collapse* are as various and as opposite as the causes of coma, and the practical importance of a correct pathological interpretation of each class of cases can scarcely be over-estimated.

1. Collapse may be the result of loss of blood or of such blood constituents as are drained away by excessive purging.

2. It may be a result of what is commonly called "nervous shock." The sources of nervous shock are very various; as examples I may mention great terror or other painful mental emotion, violent mechanical injury, such as the crushing of a limb, a blow on the epigastrium, the agonising abdominal pain that immediately follows perforation of the stomach or bowel and the consequent escape of the contents into the cavity of the peritoneum, the pain and peritonitis consequent on strangulated hernia, etc.

3. Collapse may result from the operation of certain poisons which paralyse the heart, as, for instance, the upas Antiar poison of Java.

4. Lastly, we have the collapse of cholera.

I purpose now to indicate the main points of agreement and of difference between these various forms of collapse. There is one point of agreement between them all, one condition which is common to them all, and it is this: the circulation of the blood is so retarded or enfeebled that there is a defective blood supply to the various tissues and organs of the body. The cause of this defective circulation is different in each class of cases.

1. When collapse is a result of hæmorrhage or of excessive purging there is an absolute deficiency of blood in the vessels, and with this there is probably some weakness of the heart consequent upon a defective blood supply to its nutrient vessels.

2. When collapse is a result simply of nervous shock there is no deficiency of blood in the vessels, but there is a defective movement of blood, occasioned by an enfeebled condition of the muscular walls of the heart, consequent on the influence of shock transmitted through the nerves of that organ.

3. Again, when collapse is a result of the paralysing influence of a poison on the heart, the enfeebled and defective blood current is a consequence of the diminished contractile power in the heart's walls.

4. Lastly, we have choleraic collapse, in which again there is a defective circulation of blood; but before I describe the cause of this it may be well to point to certain facts which appear to indicate an essential difference between this form of collapse and the other three classes of cases. In all cases of collapse there is more or less coldness of the surface of the body, while the pulse is reduced in volume and in force; but whereas in all other forms of collapse there is great *pallor* of the surface in consequence of a defective supply of blood to the minute vessels, in the collapse of cholera the surface is more or less *blue* in consequence of defective respiration and an accumulation of blood in the veins. This appearance of the body during life is found to correspond with a very

remarkable anatomical condition discoverable after death, and always found after death which has occurred during the stage of choleraic collapse. The left cavities of the heart are found to be nearly or quite empty, while the right cavities, the venæ cavæ, and the pulmonary artery are filled and even distended with blood. If this were all, there would be nothing to distinguish the post-mortem appearances in choleraic collapse from those which are found in many cases of pulmonary disease, or in cases of ordinary asphyxia; but a yet more remarkable condition remains to be noticed, and it is this,—the tissue of the lung is more or less pale, dry, and anæmic. In consequence of the small quantity of blood in the minute vessels, the collapse of the lung when the chest is opened is so complete that nearly all the air is expelled from the cells, so that the lungs are non-crepitant, and appear almost like those of fœtus, while the weight of the two lungs has been found to be on an average as much as seventeen ounces less than the average weight of healthy lungs (Parkes on "Cholera," p. 13). Here we have a combination of appearances such as is found after death from no other form of disease,—appearances which show in the most unmistakeable manner that during the stage of collapse the great bulk of the blood which is sent from the right side of the heart is arrested in the branches of the pulmonary artery before it has reached the capillaries of the lung: and in this most remarkable condition of the lung and heart we have the explanation of the impeded circulation and the defective blood current during the collapse stage of cholera. The defective blood current in cholera is not mainly a consequence of loss of blood or of blood constituents, as in cases of hæmorrhage or excessive purging, neither is it due to diminished contractile power of the heart consequent on nervous shock or the paralysing operation of a poison, but it is a direct result of a partial arrest of blood in the pulmonary vessels, and a corresponding small supply to the left cavities of the heart and the arteries.(a) We have conclusive proof that the flood-gates have been closed at a particular point of the blood-stream in the fact that there is an accumulation of blood behind the point of obstruction, and a deficiency in those parts of the circulatory system which lie beyond the impediment. It is scarcely necessary to remark that no such anatomical evidence of an abrupt arrest of blood is found after death from the other forms of collapse to which allusion has before been made—namely, collapse from hæmorrhage or excessive purging(b), from nervous shock, or from poisons which tend to paralyse the heart. Can we explain this remarkable arrest of blood in the collapse stage of cholera? I believe that we can. We know that the admixture of certain foreign bodies with the blood will cause an arrest in the lungs and sudden death. Thus the accidental admission of atmospheric air into the veins during the performance of Surgical operations in the axilla or root of the neck has occasionally been followed by speedy collapse and sudden death. The mixture of blood with a large quantity of air is retarded and arrested in the pulmonary vessels. Mr. Erichsen found, by experiments performed on a dog recently killed, that blood mixed with air required nearly twice the pressure to drive it through the pulmonary vessels that would suffice to drive unmixed blood through the lung. (*Edinburgh Medical and Surgical Journal*, vol. lxi.) Again, Blake and others have found that solutions of certain salts, when injected into the veins of a dog, speedily destroy life by arresting the blood in the minute vessels of the lungs. A solution of sulphate of soda or of nitrate of silver acts in this manner; and after death the left cavities of the heart are found nearly or quite empty, while the right cavities and the pulmonary artery are distended. (Blake's experiments are recorded in the *Edinburgh Medical and Surgical Journal*, vols. liii., liv., and lvi.) These experiments show that certain irritants introduced into the veins cause an arrest of blood in the lungs similar to that which has been proved to occur in cholera. Now, there is a large amount of evidence to show that the phenomena of cholera are the result of the presence of a morbid poison in the blood—indeed, the existence of a morbid poison as the essential cause of the disease is very generally admitted. There is evidence, too, that this poison acts as a strong irritant upon the muscular tissues, both voluntary and involuntary, in the very painful cramps and spasms which affect the limbs and the intestines. The most probable explanation of the arrest of blood in the lungs during the collapse of cholera is, that the morbid blood acts as an irritant upon the muscular walls of the minute pulmonary arteries, causing them to contract upon their contents, so as to retard and even to arrest the flow of blood through the lungs.(c)

Let us here carefully distinguish between fact and theory. The arrest of blood is a demonstrated anatomical fact. It is a fact, too, that this arrest occurs, not in the capillaries, but in the minute arteries. It is a fact that these arteries have muscular walls, and that they have the power of contracting under the influence of various stimuli. It is a fact that the contraction of a minute artery retards and lessens and even arrests the stream of blood. It appears to me, then, that short of an actual demonstration, which is here impossible, the various facts to which reference has been made, afford as complete a proof as can be given that the immediate cause of the arrest of blood in the lungs is the contraction of the minute arteries upon their morbid contents. But it may be asked, and has been asked, why does the arrest occur in the pulmonary arteries only?—why not in the systemic arteries also? In answer to this it is to be observed that the two sets of vessels have very different endowments in accordance with their different functions. The pulmonary artery readily transmits black venous blood, while the systemic arteries offer great resistance to the passage of black blood. This is abundantly proved, not only by Dr. John Reid's well-known experiments, but also by the daily observation of cases of cardiac and pulmonary disease. Then Blake found that certain inorganic salts injected into the veins of dogs are retarded in one set of vessels, and not in the other. We have, therefore, no difficulty in conceiving that a morbid poison, such as that of cholera, might cause a great impediment in the pulmonary vessels, and little, if any, in the systemic vessels. I am not prepared to say that there is no direct impediment in the systemic vessels during choleraic collapse; but that the obstruction is chiefly in the pulmonary vessels is manifest both from the symptoms during life and from the appearances after death.

The theory of the arrest of blood in the lungs by arterial spasm receives strong support from the remarkable temporary effect of the hot saline injections into the veins. Since the year 1832 it has been well known that all the symptoms of choleraic collapse may be removed in the course of a few minutes by this operation. Unfortunately the *modus operandi* of the proceeding was misinterpreted. The relief was supposed to be mainly due to the addition of liquid to the blood, and so it was believed to establish the truth of the theory that collapse is a result of loss of water. Now it is as nearly certain as anything of this kind can be, that the liquid of the injection acts chiefly as a vehicle of *heat;* that the heat relaxes the spasm of the minute pulmonary vessels; the blood then moves freely onwards to the left side of the heart and into the systemic arteries, the circulation is restored, and thus the state of collapse is for the time removed. Dr. Mackintosh, who injected no fewer than 156 patients, stated that "the good effects of the injection were rapid in proportion to the heat of the solution," and the temperature of the injection which he employed varied from 106° to 120°; while Dr. Parkes (*op. cit.*, p. 219), who injected only a tepid solution, appears to have obtained much less striking results than Dr. Mackintosh got from his hot injections. It appears, therefore, in the highest degree probable that the real action of the saline injections is that which I have suggested. That the symptoms of collapse should for a time be so completely removed by this simple proceeding affords proof conclusive, if such proof were needed, that choleraic collapse is not the result of "nervous shock," as some pathologists have imagined. It is not to be supposed that in any form of collapse from nervous shock the injection of a hot liquid into the blood

(a) It seems not unlikely that during the stage of collapse the contractile power of the heart must be somewhat diminished in consequence of the small stream of blood which reaches its muscular tissue through the coronary arteries, so long as the arrest in the lungs continues.

(b) In giving the above explanation of the collapse of cholera, we do not shut our eyes to the fact that excessive purging may alone cause feebleness of pulse, coldness of the surface, and other symptoms of exhaustion, which may even be fatal; but these symptoms, as we have shown, are essentially different from those which are characteristic of choleraic collapse.

(c) Dr. John Paterson, in a recent number of the *Medical Times and Gazette* (April 14), objects to the theory of a blood poison as the essential cause of cholera; that it is inconsistent with the perfect integrity of the cerebral functions which is so commonly observed in cholera. I would remind Dr. Paterson that there are many undoubted morbid poisons which have no direct action on the brain, and that most morbid poisons, although they enter the blood, appear to have special affinities for certain tissues and organs, while they leave others intact. Thus the poison of measles specially affects the skin and the mucous membrane of the air passages; that of scarlatina, the skin, the fauces, and the kidneys; that of cholera, the mucous membrane of the stomach and intestines, the muscles, which are painfully cramped; and, lastly, in severe cases, the pulmonary blood-vessels, which are perilously contracted.

would immediately restore the power of the heart and effect that wonderful improvement in the patient's condition which had so often resulted from this operation in the collapse of cholera.

And here it may be well to remark, that the essential difference between choleraic collapse and all other forms of collapse is shown most convincingly in the different and even opposite effects of the same treatment in the different classes of cases. Thus alcoholic stimulants, while they are beneficial in all other forms of collapse, usually aggravate the symptoms of choleraic collapse, and the probable reason is, that in ordinary cases of collapse, the alcohol passing freely through the lungs stimulates the left ventricle, and thus assists the circulation, while in the collapse of cholera it is arrested in the lungs and adds to the distension of the right cavities of the heart.

Venesection, again, which would be fatally exhausting in other forms of collapse, when practised during the collapse of cholera, has in numberless instances been attended with great and immediate relief—the pulse increasing in power and volume while the blood has been flowing from the veins: the only rational explanation of this result being, that by lessening the over-distension of the right cavities of the heart, it increases their contractile power.(d) Without doubt the main reason why the practice of venesection in the treatment of cholera has of late been so entirely discontinued is, that such a practice is seen to be utterly inconsistent with the commonly received theory that the collapse of cholera is the result of excessive purging. It is not uncommon to meet with believers in this theory of collapse who will absolutely deny the possibility of any sufferer from cholera ever having been benefited by venesection. Yet the writings of the earlier Indian Practitioners abound in the most striking illustrations of immediate and permanent relief from this treatment. Here is the testimony of one of the ablest of these men ("Treatise on Cholera Asphyxia, or Epidemic Cholera," by G. H. Bell, 1831):—"In no situation has the Physician more reason to be proud of his art than when, in the course of a few minutes, a patient, from the agonies of cholera and from the pains of death, is placed in safety, and not only restored to sensation of health, but to one of positive bliss. A very common expression on such an occasion is, 'Oh, sir, I am in heaven.' The effect of blood-letting would, indeed, sometimes appear almost miraculous. A patient will be brought in on a cot, unable to move a limb, and, but that he can speak and breathe, having the character, both to touch and sight, of a corpse; yet will he, by free venesection alone, be rendered, in the course of half an hour, able to walk home with his friends." There is only one mode in which those who advocate the theory of collapse from loss of blood-constituents can consistently deal with such evidence as this—they can only take refuge in incredulity. This they do; but the facts remain, and refuse to be ignored.

Opium, which is especially useful in many cases of collapse from nervous shock, has a deadly influence upon cases of choleraic collapse. It prevents or retards the natural cure by vomiting and purging, it favours the accumulation of the morbid poison in the blood, and thus adds to the fatal obstruction of the pulmonary circulation.

In conclusion, I have only to observe that all the most striking symptoms of choleraic collapse receive their explanation from the arrest of blood in the lungs, and the consequent small supply to the systemic arteries. So simple and complete is the explanation thus afforded of the chief physical and chemical phenomena of the disease, and the influence of various modes of treatment, that it can scarcely be doubted that in this anatomical fact—this arrest of blood in the minute branches of the pulmonary artery—we have the true key to the pathology of cholera.

(d) One of Blake's experiments affords very interesting confirmation of this doctrine (*Edin. Med. and Surg. Journ.*, vol. lvi., p. 120). He had ascertained by repeated experiments that a solution of a salt of soda injected into the vein of a dog caused death in a few seconds—usually in less than a minute—by arresting the circulation through the lungs, and he had found that when the distended and motionless right cavities of the heart were punctured immediately after death, the escape of a portion of their contents usually led to a renewal of the heart's contractions. He, therefore, performed the following experiment, with a view to ascertain the influence which venesection might have in prolonging life in these circumstances:—"The animal (a dog) was prepared by exposing the two jugular veins. A solution, containing three drachms of nitrate of soda, was injected into the venous system—a quantity more than sufficient to arrest the passage of the blood through the lungs. A few seconds after the injection, violent opisthotonos came on. This was instantly relieved by dividing both the external jugular veins—congestion in the brain being thus prevented. The animal lost a great deal of blood, but notwithstanding this it survived the experiment two hours. The respiration continued regular; there were no convulsions: in fact, the animal seemed to be suffering only from loss of blood, the presence of so large quantity of soda in the blood being, apparently, in no way injurious, except by its action on the lungs. At the end of two hours, the animal died asphyxiated, owing to the air cells becoming filled with frothy serum."

THE CASE OF CHOLERA IMPORTED FROM ROTTERDAM TO BRISTOL.

By DAVID DAVIES, M.R.C.S., &c.

Henry T., aged 20, seaman, a native of Bristol, sailed from Java last December, arrived at Rotterdam on April 14; left that place for London by steamer early on Sunday morning, April 22; arrived in London at 8½ a.m. on Monday, the 23rd, and immediately left London by train for Bristol. He was quite well when he left London. About 11 a.m., when in the train, he was taken with violent diarrhœa and vomiting, but the latter symptom was not prominent. A lady in the same compartment gave him some brandy. He reached his friends' house about 4 p.m.; he came under my notice about 5 p.m.; his symptoms then were extreme prostration; a small, thready, quick pulse; cold extremities; forehead and face covered with a cold, clammy perspiration; violent pain from spasmodic contractions of the abdominal, gastrocnemii, and other muscles. The eyes were sunken; the intellect collected and perfect, with an air of indifference about the serious nature of his illness. The evacuations had been of the rice water character, but when I saw him the fluids of the body were nearly drained. He had not been drinking to excess—had not taken more than a glass of porter and a glass of brandy and water. I pronounced the case at once to be one of Asiatic cholera. His treatment was warm applications to the feet and abdomen, rice water gruel freely in small quantities, and the following draught immediately, and to be repeated according to circumstances:—℞. Æther sulph., ♏xx.; spt. ammon. arom., ʒj.; tr. cardamom., co., ʒj.; tr. opii, ♏x.; mist. camph. ad., ʒjss. This with the warm applications, relieved the spasms of the muscles, and it was not administered more than three times. He was apparently better; the attendants exhausted with their attention to him fell asleep, and when they awoke he was dead, having been ill about eighteen hours. His death must have occurred a little after 4 o'clock on Tuesday morning. I believe the diarrhœa stopped from the exhaustion of the supply of fluid in the body. The belly was collapsed, and the intestines evidently with hardly any fluid or air in them. When I first saw him there was but a slight oozing of watery fluid from the rectum. If any remarks should be made by any one against the treatment pursued, I beg to state at once I am not going to defend it, as I have yet to learn the treatment of "cholera in a state of collapse."

Being diffident in applying the term "Asiatic" to an isolated case without being supported by another, I laid the history of the case before a very able pathologist and high authority on epidemic diseases, Dr. William Budd, who visited the house and examined the corpse with me. He unhesitatingly expressed his opinion that it was a case of "Asiatic" cholera. At this time I was not aware there was any cholera at Rotterdam. On the 24th I wrote to apprise the Registrar-General of the case, who communicated it to the Privy Council. On the 25th His Worship the Mayor of this city received a communication from the Privy Council, apprising him of the existence of cholera at Rotterdam. This was dated April 23, so my letter must have crossed that communication in the post.

The following were the means adopted for preventing the spread of the disease:—The linen soaked with the discharges was buried; the closet, which has a good eject, washed down and flushed, and afterwards disinfected with a quantity of chloride of lime; the house permeated with free chlorine gas. The body was put in a coffin, covered with sawdust, and screwed down. I am sorry it was not buried until Thursday, the 26th ult. The inmates of the house were requested to be careful in their diet, but to live rather more generously than usual. As the house is isolated and nearly surrounded with water, I am sanguine there will be no offspring from this case.

This was not a Bristol case, but evidently one imported here from Rotterdam to die shortly after its arrival. So it must not be considered as in the least reflecting on our sanitary condition.

This morning (April 29) I visited the Rotterdam steamboat the *Balmoral*, which reached here last evening. I was told

by one of the men that the disease prevails extensively at Rotterdam; that vessels in the harbour pump water from the river for drinking purposes. I am not acquainted with Rotterdam; but if the above statement be correct, it is no wonder that sailors visiting that port should contract the disease.

I shall add a few words about the treatment of the premonitory stage of cholera. In 1849 I saw some hundreds of cases of cholera and choleraic diarrhœa. I have no theory to oppose, support, or to offer. My experience was this: In collapsed cholera under any treatment two-thirds of the patients will die, and one-third will recover. I have seen administered large and small doses of calomel, etc., with the same result; but I consider choleraic diarrhœa as amenable to treatment as the ordinary summer diarrhœa of this country with astringents, opiates, etc. Every case of choleraic diarrhœa in 1849 in which I administered castor oil or any other purgative died. My rule at last was, when a person was subject to choleraic atmosphere, to keep the bowels quiet at any other risk. When cholera had broken out in the workhouse of this city at Stapleton in 1849, I volunteered with Mr. Stock and Mr. Joseph Williams to enter the house and attend the patients. On the first day after our arrival 21 corpses were taken out of the house; on the third day my much lamented colleague and that brave man, Joseph Williams, fell a victim to the disease. The epidemic was running rapidly through the house, containing about 800 paupers, and was gaining upon us until we hit on the happy expedient of having all the inmates drawn up in a line three times a day—viz., 10 a.m., 2 p.m., and 5 p.m. Those who had been twice to the closet before 10 had a dose of chalk mixture with ten drops of laudanum; at 2 another dose if necessary, and the same at 5 p.m. In this way we soon got the disease under. I found that either from apathy or ignorance the inmates would not inform us of diarrhœa until too late unless they were closely questioned and the closets watched. Should any remarks be made adverse to this view, I have neither time nor inclination to dispute about it. Let every one examine for himself and form his own opinion.

With regard to the sanitary state of this city, I consider that on the whole we are well prepared to meet the anticipated epidemic. Our main drainage is good and efficient. Under the Board of Health, with the assistance of four very able Nuisance Inspectors, the Medical Inspector has done all in his power to remedy the evils in our courts and alleys. The Board of Health have been trying to do away with all privies in common, and they do not allow, where practicable, more than two houses to use the same privy. They have paved at the public expense — or the landlords', where possible — hundreds of courts and lanes; they have required all privies to have good ejects, to be well cemented, and of certain dimensions. I send you a copy of their requirements, drawn up by their surveyor. They have endeavoured to remove all pigs and other nuisances out of the city.

I do not mean to say that they have fully succeeded, or that the sanitary condition is as good as could be desired. They have to combat at one time the filthy habits of many of the poor, the poverty of many of the landlords, who are but a step above paupers, and above all the evils connected with the geographical arrangements of an ancient city, once a fortified one, which has not passed through a "fire of London."

Our water supply is good—that is, we have a private company, which is prepared to supply any amount of good water from the Mendip Hills in Somersetshire; but I am sorry to say many of the landlords of poor tenements refuse to take it in, and there is no power to compel them. In many of the courts here the poor have only excessively hard water, in every case contaminated with organic matter. Should cholera enter these courts the inhabitants will suffer severely in spite of all other good arrangements. The chief magistrate of the city and the Common Council, as well represented at the Board of Health, are alive to the danger which threatens the United Kingdom, and in my opinion Bristol is as well prepared for the coming ordeal as any place in England. Time will show whether I am right or wrong.

At present the powers of officers of health are too feeble to do all that is required, but it is in the power of the Government to amend this deficiency.

PARAFFIN.—Two sisters and a brother, named Thompson, residing in Finsbury, were severely burnt on Friday by the bursting of a paraffin lamp.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

DERBYSHIRE GENERAL INFIRMARY.

LIGATURE OF THE EXTERNAL ILIAC ARTERY FOR INGUINAL ANEURISM—RECOVERY.

(Under the care of J. WRIGHT BAKER, Esq., Surgeon to the Infirmary.)
[Reported by W. G. CURGENVEN, Esq., House-Surgeon.]

THIS case, in which an abscess communicated with the femoral artery so that a false aneurism was formed, is a very important one. It brings to mind an affection which, while it is so rare that it may easily be left out of consideration when a diagnosis is being formed, is one which it is most important to recognise at once, for if the condition of things is misunderstood, the Surgeon will probably either do that which is very likely to cost the patient his life—open a large aneurism which he has taken to be an abscess, or he will leave undone that by which recovery might, perhaps, have been secured—the ligature of the artery above the seat of disease. There are now a sufficient number of cases on record to prove that large arteries are occasionally opened by ulceration of their coats where they lie in contact with an abscess. Mr. Liston first called especial attention to this fact in a paper(a) in which he related the particulars of his well-known case in which he opened a cyst communicating with the internal carotid, believing it to be an abscess, and in which he was obliged, in consequence of the gush of blood that followed the puncture, to tie the common carotid. In this paper and its appendix are given several instances in which large arteries communicated with abscesses. Mr. Busk has recorded an instance(b) in which an abscess opened the arch of the aorta.

In the Museum of St. Bartholomew's(c) is a specimen which shows an opening between the arch of the aorta and a mediastinal abscess. Mr. Crowfoot gives a case(d) in which a tuberculous abscess in the lung perforated the wall of the pulmonary artery.

Other examples of the same occurrence might doubtless be readily found.(e) The published cases, of which the subjoined is typical, are strikingly like each other in many of their features. They have been met with in children or young adults, in whom common aneurism is extremely rare. The average age in ten cases was eighteen, and in five the patients were under twelve. The abscess has generally been acute and of an unhealthy character, and with which we may suppose ulceration was very likely to be associated—in many instances strumous, in some following scarlet fever. The diagnosis has often been very obscure. In some cases it is distinctly stated that no bruit could be detected (in the present case it will be noticed that the bruit, although distinct at one period, became inaudible afterwards), and in several there has been no pulsation.(f) The condition is attended with extreme peril to the patient: the collection of blood usually increases very rapidly, so that rupture of the cyst soon occurs. When this event has taken place, or when the Surgeon has inadvertently made a puncture, large and quickly repeated hæmorrhages have carried off the patient in a few hours, or at the longest in a very few days. Death occurred in almost all the cases in which the aneurismal sac was opened either by bursting or by puncture. In some instances recovery followed ligature of the artery above the diseased part, as in Mr. Baker's case.

Charles H., aged 24, an iron turner, was admitted into the Derbyshire General Infirmary on June 15, 1865, with an aneurism over the left common femoral artery.

He states that three months previous to his admission he was suffering from an abscess in the left groin, for which he could not account, as he had never had gonorrhœa or syphilis.

The abscess attained a large size, and was opened by a Medical man, pus escaping freely, and with it a small quantity of blood. A month subsequently to this, he suddenly felt

pain at the upper and inner side of the thigh, and after some little time noticed a small swelling, which was situated over the region of the femoral artery a little below Poupart's ligament. The swelling increased in size, and he poulticed it, thinking that another abscess was forming. Mr. Baker was now summoned to attend him, and, finding that he was suffering from an aneurism, advised his immediate removal to the Infirmary.

On admission, there was a firm, pulsating tumour extending from Poupart's ligament downwards for about four inches, the vertical axis corresponding with the position of the femoral artery. Transversely the extent measured seven inches. The circumference of the thigh over the most prominent part of the tumour measured twenty-one inches and a-half, as compared with sixteen inches on the sound limb. The integument over the tumour was very tense and slightly reddened; at one point it was of a deep purple hue, and seemed inclined to burst. He suffered severe pain at times of a sharp lancinating character down the whole length of the limb, with dull, heavy aching in the knee. There was no œdema of the limb. The bruit, which was distinctly heard by Mr. Baker shortly before his admission, was now no longer audible. At the upper border of the tumour was a sinus, through which a small quantity of dark sanious fluid escaped. This the patient stated was the point where the incision had been made into the abscess three months previously. His countenance was very pale. Pulse 130, feeble. No heart or lung affection, or any disease of arteries or veins.

June 17.—As the case was one requiring immediate attention, and pressure could not be borne on the vessel above the aneurism, Mr. Baker, after a consultation with his colleagues, Mr. Fearn and Mr. Dolman, proceeded at once to tie the external iliac artery. The patient having previously had his bowels opened by an enema, and chloroform having been administered, an incision about four inches long was made half an inch above and parallel with the outer half of Poupart's ligament. The abdominal muscles and transversalis fascia were cautiously divided, the peritoneum was pushed upward, and the artery felt beating at the bottom of the wound. The sheath of the vessel was then scratched through, the aneurism needle passed around the artery from within outwards, and the vessel tied. Little hæmorrhage occurred during the operation. The wound was brought together by sutures, and a firm pad of lint applied. He was removed to bed and the limb enveloped in cotton wool.

18th.—Passed a good night after taking an anodyne. Complains a little of pain of a stitchy character in the left iliac region. The limb is warm and comfortable. The measurement of the thigh over the aneurismal tumour has decreased by an inch and a-half. Pulse 130.

20th.—Complains of flatulence and a feeling of heaviness at the epigastrium. No tenderness anywhere in the neighbourhood of the wound. Skin hot; pulse 136; tongue furred.

22nd.—Going on favourably. Pulse 120. Bowels open. Both limbs of the same temperature. Circumference of the limb over the tumour now measures 18½ inches. Dark sanious fluid still continues to ooze from the sinus at the upper border of the tumour.

July 2.—The integument over the most prominent part of the tumour, which was of a purple hue, has burst, and a dark sanious fluid escapes through a small opening. On making some slight pressure on the tumour, blood escapes, both from the opening above mentioned and from the sinus at its upper border, showing that they each communicate with the aneurismal sac.

8th.—The ligature has come away (twenty-one days after the operation). The sac of the aneurism is now almost empty, and the sinus above appears to be closing. The wound caused by the operation has healed everywhere, except at the situation of the ligature.

August 5.—The patient expressing a wish to go out, left the Infirmary to-day. He was directed to return and show himself occasionally to Mr. Baker.

September 28.—The patient presented himself at the Infirmary to-day. He is much improved in health. The limb is warm and comfortable, and he states that he can walk with ease about two miles daily. He suffers a little pain in the knee if he walks too much. All the sinuses have closed. There is no difference now in the circumference of the two thighs. No pulsation can be felt either in the popliteal or posterior tibial arteries, but the collateral circulation is thoroughly established.

January 4, 1866.—The patient again presented himself at the Infirmary. All trace of the sac has now disappeared. He enjoys excellent health, and has pursued his work since September.

Remarks.—The aneurism in this case occurred at an unusually early age, and it was evidently connected with the abscess in the groin. Though the origin of this abscess is uncertain, it seems quite clear that it began independently of the aneurism. The patient denied having suffered from gonorrhœa or syphilis. It was probably, therefore, a strumous abscess, and considering its large size, was acute. If that were so, the cause of the aneurism would be similar to that by which the internal carotoid artery is sometimes opened, when suppuration has taken place in the tonsil or deeper cervical glands. The coats of the vessel being in close contact with the abscess, become ulcerated and give way, and the blood filling the cavity converts the abscess into an aneurism. The sinus at the upper border of the tumour, which at first slowly discharged a little dark fluid blood, probably communicated with the aneurismal sac, although this was not clearly made out at first. The aneurism up to the time of the patient's admission continued to increase. With regard to the treatment, the femoral vessel could not be compressed above the aneurism, as the latter was situated too high, but compression of the abdominal aorta might have been attempted as proposed, and successfully carried out in a case of aneurism of the abdominal aorta by Dr. Murray, of Newcastle-on-Tyne. This plan of treatment, although suggested on account of the spare frame of the patient, was not pursued, as the symptoms seemed so urgent, the patient suffered so much, the tumour was extremely tense, and in all probability would have soon given way.

SATURDAY, MAY 5.

THE HEALTH OF THE COUNTRY.

From more quarters than one we can perceive indications that people are anxiously looking in the direction whence the advent of our dread enemy—cholera—may be expected.

The recent death of a seaman at Bristol from what is stated to have been cholera of the Asiatic type is well calculated to inspire feelings of mingled hope and fear,—hope that in the main we shall be found better prepared to meet the attack than on previous occasions; but fear, also, that in particular instances the destroyer will but too probably find an easy prey.

The Quarterly Report of the Registrar-General on the state of the public health during the three months ending March 31—the "winter" quarter as it is officially reckoned—supplies data from which one may reasonably draw conclusions of a not very re-assuring character.

There is, it is admitted, a certain relation, traceable within limits, between the meteorological character of a season and its death-rate. In winter we expect a low temperature, and with it a high mortality from diseases of the respiratory organs, as well as from typhus and other causes of a like nature. *Cæteris paribus*, cold is more inimical to health than heat. But a high temperature has also its attendant evils, which are, however, more readily controlled by precautionary

measures than those which follow cold; and cholera, diarrhœa, etc., lie dormant through the winter only to realise the truth of the French axiom "*reculer pour mieux sauter.*" Rapid transitions from heat to cold, and sudden atmospheric changes of all kinds are likewise unfavourable to health; under those conditions we get a share of the dangers of two extreme seasons. It is precisely this unsettled state of the meteorological elements which is greatly chargeable with the high mortality rate of which the Registrar-General's return speaks. In the short space of three months we have gone through nearly all the possible climatic changes. According to Mr. Glaisher, January was warmer than in any year since 1851, yet in that month we had stormy weather and gales of wind, as well as the heavy fall of snow which converted our streets for the time into a Slough of Despond. The high temperature of January (6° daily above the average) was continued till the middle of February, whilst from that date to the middle of March the air was almost continuously cold, to the extent of a daily defect of 3°; and from thence to the end of March we had alternations of heat and cold every few days. Vegetation has flourished abundantly, but not so the health of those for whose use vegetation is so bountifully designed. Thus we learn that the deaths in the quarter were 138,233, which implies a rate of mortality above the average of ten previous winters. The mortality in the quarter was at the rate of 26·5 deaths per annum to 1000 living, the average of ten previous winter quarters being 25. And here is the conclusion which the facts supply:—

"But it is a remarkable circumstance that this excess above the average was contributed entirely by the large towns; for in the country districts the death-rate (22·5) was actually lower than the average (23·0). In the districts comprising the chief towns it was 29·7, against the average 26·8. These results confirm the conclusion that there were other destructive causes at work besides unfavourable states of the weather—that the diseases above mentioned (scarlatina, measles, whooping cough, etc.) which commit so much havoc in towns, were still more extensively fatal, and only acquired additional vigour from influences peculiar to the season."

This brings us round to the point we had in view when we projected this article. The weak joint in our harness is precisely that at which the enemy will most vigorously assail us. And no one can mark the weekly rates of mortality prevailing in our chief centres of industrial and commercial activity without fervently praying that a visitation of cholera may be averted. We have had very recently a mortality in Liverpool at a rate of not less than 57 per 1000 per annum, and although the rate has now subsided considerably, it is fearfully high still. Taking the whole quarter, the mortality in Liverpool borough was at the rate of 46 deaths annually to every 1000 persons living, whilst in London the rate was only 26 per 1000. On this subject generally the Registrar-General writes:—

"If the map of England were shaded to represent the rates of mortality of last quarter in the registration districts, the eye, travelling from the lighter south to the darker north, would be instantly drawn to a spot of portentous darkness on the Mersey; and the question would be asked whether cholera, the black death, or other plague, imported with bales of merchandise, had been lately introduced into its busy and populous seaport. Happily this has not been the case; but fever, probably developed or aided by the mild and damp atmosphere of the season, and by overcrowding in an increasing population, has been busy and fatal in Liverpool, and in other towns of the same county and of Yorkshire. The annual mortality of the borough of Liverpool in the three months was excessive, and demands immediate and earnest consideration; it rose to 4·593 per cent. This implies that if this death-rate were maintained for a year, forty-six persons out of a thousand in the population would die in that time, or fifteen more than died in Glasgow, its northern rival, nineteen more than in London. The mortality of the city of Manchester, though far less than that of Liverpool, was higher than in any other of the thirteen selected towns of the United Kingdom; it was 3·742 per cent., and that of Leeds was hardly less."

We regret that we have not space at this time to notice a very able paper by Mr. Leigh, the Registrar of a sub-district of Manchester, "On the Causes of the Vitiation of the Atmosphere of Manchester," which the Registrar-General appends to his Report. But we hope to recur to the subject on a future occasion, when we can give it the attention its importance demands.

Meanwhile we earnestly press upon our Medical brethren, especially such as hold the responsible post of "Health Officer," the necessity, urgent as we believe it to be, of taking energetic action whilst there is yet time. In Liverpool, Dr. Trench has the satisfaction of knowing that the municipal authorities are ready and willing to give him due support; which is unhappily the opposite of the experience of some of our London colleagues. Those towns wherein no health officer has been appointed should delay no longer, but should choose the best man they can find, pay him liberally, and back him up against all opposition. Only in this way can we hope to meet cholera in the field successfully.

THE CHOLERA.

When we say that the cholera is likely to come, we must never forget that what comes is no mere abstraction, but something really existing in a material form. Possibly it may be borne on the wings of the wind, in the shape of dry dust or stinking wet fog, each defiled with cholera germs. And we must confess that we cannot bar out the wind. But, luckily, the cholera is far more likely to come, as it has done during the last week, in the gross material form of some unfortunate English sailor who has drank the venom at a North German port, or some sordid German emigrants who make England a halting place on their road to America. The late case at Bristol shows us that the disease may lie latent in the body of the sufferer for 36 hours; and the cases on board the steamer *England* show that it may lurk in filthy clothes for a much longer period. Surely there can be no objection to rational quarantine measures for all immigrants from infected places, such quarantine to include simple detention of the passengers, whether on board ship or in some building ashore, and the disinfection of their persons and clothing by means of hot water and soap.

We may congratulate ourselves that as yet the disease has not got a footing amongst us. The case at Bristol fell luckily into the hands of a man of great resolution and experience, and the Bristolians, humanly speaking, are safe in Mr. Davies's hands. At Liverpool, as we learn from Dr. Trench,

"There are two cases of cholera; the first, a man, apparently Dutch, but of whom no correct history can be obtained, is supposed to have landed at Hull and crossed over to Liverpool by railway. He was brought into the Workhouse on Monday, the 30th April, in a state of collapse. Reaction soon took place. He has not been purged since his arrival in Hospital, but the suppression of urine continues. The other case is a woman (Dutch), admitted May 1st. This latter is a more marked case than the first, which, as we are told, would not have been called cholera if it had not come from Rotterdam. Cases very similar to these, however—that is, isolated and not very marked cases of the disease—were seen before the epidemic in the summer of 1854."

The outbreak of cholera at Rotterdam has, as far as we have been able to ascertain, assumed no very alarming proportions. It appears that the total number of cases which have occurred up to the present time amounts to four, and of these two have proved fatal. The authorities in England have received no information beyond the fact that cholera has made its appearance at Rotterdam, and that measures have been adopted with the view of guarding against the spread of it. The Rotterdam journals of the latest dates make no mention of any additional cases beyond the four original ones; and had there been any, the public would, according to the general custom, have been made acquainted with the fact.

THE WEEK.

THE CATTLE PLAGUE RETURNS.

The Report of the Veterinary Department of the Privy Council is at length in the hands of the public. We merely refer to it to note that the contents fully corroborate the view which has been propounded by Dr. Farr in reference to the rise and fall of Rinderpest; that the decline commenced long before the Cattle Diseases Prevention Act came into operation. The series of diagrams show that Rinderpest attained its height February 17. The Act passed on the 20th, but did not come into operation at once; indeed, not until the beginning of March. The real decrease was possibly earlier even than that stated (February 17), because the stage of incubation would still account for the appearance of a large number of attacks, ten days after an actual fall in virulence had taken place. If the influence of the incubatory stage be taken into account, Dr. Farr's theory becomes still more sustainable.

QUECKETT MICROSCOPICAL SOCIETY.

At the ordinary monthly meeting, held on Friday, April 27, in the library of University College, Mr. M. C. Cooke (V.P.) in the chair, a paper was read by Mr. Samuel Highley, F.G.S., F.C.S., "On the Application of Photography and the Magic Lantern to Microscopical Demonstrations." The author gave a short *resumé* of the early history of the subject, incidentally noticing that Wedgwood was the first who applied photography to microscopical purposes, a description of the apparatus used for taking negatives, and, lastly, proceeded to exhibit the *results* of various workers by projecting on a large screen, 8 or 9 feet square, by means of his achromatic oxy-hydrogen lantern, a magnificent series of enlarged photographs selected from all departments of nature. Amongst others were uric acid crystals, diatoms, sections of vegetable stems, palates of molluscs, spiculæ of sponge, starch granules, fleas, lice, blood corpuscles, salicine, and a host of other substances. We may mention that the eye of the fly appeared on the screen about 6 or 7 feet in diameter. The uric acid crystals and blood discs were especially well displayed. This mode of illustrating structural peculiarities is a most useful one, and its success was highly appreciated by the very full attendance, the room being completely filled. The Chairman announced that arrangements were being made for field excursions during the summer for the purpose of obtaining and comparing together actual specimens of interesting objects in natural history. Seven members were elected and fourteen candidates proposed.

NEW VIEWS ON LIGHT.

A recent number of the *Fortnightly Review* contains a paper by Dr. Akin, being a discourse delivered before the Natural History Society of Cambridge on the Nature of Light. The author observes that whilst we pay great attention to the *propagation*, we omit that which should be the primary topic of every complete account of light and its phenomena—viz., luminosity itself, the actual emission of light dependent upon the conditions of ponderable particles of matter. There are three sets of rays, Newtonic (luminous), Herschellic (caloric), and Ritteric (chemical). These, it would appear, are mutually more or less transmutable. Dr. Akin especially notices what is called *ray-renovation* in proof of this opinion, and he takes the particular instance of phophorescence by irradiation for illustration. Vincenzo Casciarolo, the Bolognese cobbler, in 1630, observed that luminosity resulted from the previous exposure of a certain object to light. It was subsequently found that the colour emitted by the "phosphori" was the same even when the latter were exposed to different coloured rays of the spectrum. Wilson afterwards made out that the light was emitted by phosphori not only *after* but *during* the action of the incident light; but it was left for Seebeck, Matteuci, and Becquerel to show that not only ordinary but even Ritteric (chemical) rays were capable of inducing phosphorence. Professor Stokes, in 1852, during his investigations on "internal dispersion," found that this phenomenon was due to the emission of Newtonic (light) rays by renovation, in consequence of the incidence of rays of different refrangibility, even of Ritteric rays; he named the occurrence fluorescence, but it is now acknowledged that the phenomena of phosphorescence and fluorescence are the same in kind. It remained yet to be shown that the visible Newtonic could be produced from the invisible Herschellic (calorific) rays, the converse, as it were, of fluorescence, to which Dr. Akin applies the term *caleescence*. Dr. Akin awaited an opportunity of putting the hypothesis to test, by cutting off all but the Herschellic from passing through a prism, and thus giving rise by renovation to Newtonic rays; but in the meantime Professor Tyndall succeeded by experiment in producing such a result. We know, therefore, that the different kinds of rays are mutually convertible, as it were—a fact which harmonises well with the great doctrine of the correlation of physical forces.

ROYAL COLLEGE OF PHYSICIANS.

On Tuesday afternoon Professor Du Bois Reymond, of Berlin, delivered, at the Royal College of Physicians, a discourse upon the "Difference in the Action of Acids, Alkalis, and other Substances on the Contractility of the Muscles and the Excitability of the Nerves." The learned lecturer observed that, though the subject had some relation to practical Medicine, yet it was at present a distant one. No doubt at some future time important facts would come to light and guide us very materially in therapeutical operations. There would appear to be much ground for believing in the truth of Haller's original view that the muscles themselves are excitable, independently of the nerves. Until lately, the arguments adduced in reference to this subject have seemed, however, to indicate an equal likelihood that the muscles are alone excitable through the intervention of the nerves. The experiments of Claude Bernard with curara have apparently proved that the muscle remains irritable, although the nerve ceases to be excitable—an experiment based upon the identical principle upon which those of Harless, of Munich, with ether were conducted. Before, however, the Professor attempted this particular experiment, he performed another, intended to demonstrate that the nerves are, in point of time, excited before the muscles. He connected two muscles with two moveable flags, laying the nerve of one muscle along the body of another muscle, so that a current passed along the latter might also affect the superlying nerve running to the other muscle; on sending a shock along the course indicated, the flag connected with the muscle to which the nerve ran moved before that connected with the muscle towards which the current was directly sent, thus showing that nerve is excited before muscle. The lecturer then returned to Claude Bernard's experiment,—the leg of an animal poisoned by curara was attached by one end to one flag, by the other to a fixed point. Another leg of a non-poisoned frog was connected in like manner with a second flag. When a current was passed directly through both muscles, the flags moved simultaneously; when through the nerves, the flag connected with the muscle of the non-poisoned animal only moved. This experiment seemed to show that the nerves are killed, not only outside, but within the muscle; but that direct stimulation of the muscular fibres still produces contraction, that the muscle is irritable *per se*, independently of the nerves. A strong objection has been urged against this explanation, however. There is at both ends of the sartorius muscle of the frog a certain limited portion wherein no nerves can be found, and which behaves differently from other parts supplied by nerves, and the want of excitability made evident in experiments with

curara is said to be due to an absence of nerve filaments. The curara, it is said, acts on the part of the nerves contained within the muscle, but does not affect that still nearer—that is, within the sarcolemma of the muscle; if the minute filaments were destroyed, the muscle tissue would be like that in which no nerves are found—non-contractile by direct stimulation. The experiments with curara, then, cannot settle the question.

Prof. Du Bois Reymond then observed that all the stimuli generally employed acted equally alike on nerve and muscle, but that it was possible to solve the question by the employment of chemical agencies. It is easy to discover bodies which act differently on nerves and muscles. Strong hydrochloric and nitric acids act alike on nerves and muscles, but a weak solution of hydrochloric acid excites contraction when applied to the section of a muscle, but has no effect of this kind when applied to the motor *nerve* connected with its muscle. Experiments to this effect were exhibited. Strong glycerine, on the other hand, does not produce the least effect when applied to the cut section of a muscle, but causes strong tetanus when brought into contact with the afferent nerve of a muscle. Ammonia produces contraction of a muscle even when its fumes alone are allowed to reach the surface of a section, but the nerve is at once killed by it without the production of any contraction of the muscle, and the attempt to produce contraction by passing a current through a nerve treated in this way signally fails. The evidence of contraction in these experiments was the raising of a little flag by the shortening of the muscle. Dr. Du Bois Reymond then attempted to illustrate the proposition that there is an inherent excitability of muscle quite independent of all nervous influence. It is imagined that this excitability is brought about by some change in the relative condition of the ultimate molecules of the muscular structure.

THE ST. PANCRAS "LAYING-OUT" CASE.

Mr. Farnall has held his inquiry into the case of the child whose treatment was brought under public notice by Mr. Hillocks, and the Poor-law Board have given their opinion on the matter. It is contained in a lengthy letter addressed by them to the directors of St. Pancras, some extracts from which are found below. Discreditable as many of the circumstances are, it appears to us that, when divested of the sensational colouring imported into the case by Mr. J. Hillocks, the facts, as stated at the investigation, considerably lighten, even if they do not altogether remove, the *odium* cast upon the Medical officer.

The inference drawn by the public from the original statements was that the child was prepared for burial, and might have been buried alive; or, by exposure whilst awaiting burial, might have perished. The evidence, however, shows that it was neither thus prepared nor thus exposed. It was in its ordinary garments, and not in such as would have been placed upon a corpse. It is probable that the pauper nurse was to blame, and that fact forcibly illustrates the wickedness of confiding the sick and dying to those who possibly themselves are almost in need of support and attendance, or who, from defective education and want of special training, are totally unqualified for such posts, and who, moreover, have not the motive to exertion which a paid officer would find in the fear of losing a situation. It would appear, as regards the Medical officer's part in the matter, that on the Monday previous to the death of the child he did not think it near its end, and if this were so, it might not have been necessary for him to visit it again on Tuesday. On Wednesday he gave directions that all the children should be taken to him in the Lying-in Ward, and it is to be regretted that this child was not taken to him, nor his attention specially drawn to it; but for that omission he can hardly be held responsible. The chief defect in the workhouse arrangements appears to be the absence of a paid nurse in charge of the infants. The proper administration of wine or other stimulants—which, by the way, should always be ordered in writing—would then be secured, and this duty would not be left to irresponsible and ignorant pauper attendants. On the whole, we think that any one who heard and considered the evidence will arrive at the conclusion that, as Mr. Hillocks thought it right to move in the case, he would have exercised greater discretion had he seen the Medical officer or the matron, or, if it were needful, stated the case to the directors. There was even open to him the alternative of an appeal to the Poor-law Board—a course certainly more dignified, and we believe quite as effectual, as a sensational letter addressed to a newspaper.

*** The letter of the Poor-law Board, dated "Whitehall, April 26, 1866," signed by Mr. Fleming, and addressed to Mr. Plaw:—

"The Board, having carefully considered the Report, together with the evidence taken at the inquiry, are of opinion that the Medical officer of the workhouse is censurable for not having seen the child from Monday, March 12, on which day his attention was drawn to it, until its death on the following Thursday. He ought, according to the tenor of his instructions, to have duly visited the nursery on Wednesday. It appears, however, that on that day he did not go into the nursery, but directed that the infants who required his aid should be brought to him in an adjoining room, and that this child was not brought to him with the others. The Board think that this is not a sufficient excuse for his omission duly to attend to a case for which he had prescribed on his previous visit; and they consider that the duty of the Medical officer was not, on this occasion, discharged in a satisfactory manner.

"The Board are further of opinion that the resident midwife, who had the general charge of the nursery, is seriously to blame for not having, under the circumstances, either sent for the Medical officer subsequently to his seeing the child, or taken care that his attention was called to it on March 14. They further think that, even if Medical aid could not then have been of any avail, it would have been a proper precaution on her part to have procured the attendance of the Medical officer when the case was brought to her notice by Mr. Hillocks.

"The act chiefly complained of—namely, that the child's face was bandaged while it was still breathing—was the act of the pauper nurse, and shows her to be unfit for the duties entrusted to her. It is alleged, however, that the child had been lying in an apparently cold and insensible state for some hours, and was thought by the other women in the room, who were watching it, to be dead; and that the nurse loosened the bandage as soon as she perceived a slight motion in the child's lips. It should also be observed that the child was lying in its ordinary clothes, and was not laid out for burial.

"Although the Medical officer did not give a written order for the allowance of wine for the child, the Board see no reason to doubt that the wine was given; and it had not only milk allowed for it, but it was placed in the care of the mother of another child, in order that she might suckle it, together with her own child.

"The Board request that their opinion as to the conduct of the officers referred to may be communicated to them by the directors. They think it necessary that a paid and trustworthy nurse should at once be appointed to the nursery, and that she should be made responsible for the supply of the nutriment or of any stimulants ordered by the Medical officer for the children; also, that the Medical officer should be required to keep the Medical Relief Book (Form C), according to the order of the Board of August 21, 1856. There will then be a record of his visits and a written direction given by him for any extra nourishment which he may consider necessary in any case.

"The Board further desire to draw attention to Article 89 (No. 16) of the same order, which requires the master of the workhouse to give immediate information of the death of any pauper in the workhouse to the Medical officer."

FROM ABROAD.—ACTION CONCERNING NYSTEN'S DICTIONNAIRE—GERMAN LUNATIC ASYLUMS—FRENCH SCIENTIFIC CONGRESS—DISLOCATION OF THE MAXILLA DURING LARYNGOSCOPY.

An interesting trial took place recently in Paris. Most of our readers are acquainted with the "Dictionnaire de Médieine de Nysten, refondue par Littré et Robin," which, consisting of about 1800 pages with double columns, and profusely illustrated, is sold for about fifteen shillings, and has met with immense success. Nysten died in 1818, and seven or eight editions of the work have successively appeared under the editorship of various men of talent, and latterly under that of MM. Robin and Littré. During this repeated process of re-editing, as might be expected, the original text of Nysten has disappeared, but still the name has been continued on the title-page, especially because it has become a title of the book rather than the name of the author, people speaking of the Dictionary as a Nysten just as they would say a Buffon. This, Nysten's widow has complained of for some time as a grievance, and, in a letter addressed to MM. Littré and Robin, observes,—"The moral and philosophic spirit of the old dictionary has entirely disappeared from the edition of which you are the editors, and I beseech you in honour and conscience to remove the name of Nysten from a book which, in

consequence of the changes you have made has ceased to be a work of his hands." This protest having been found unavailing, Madame Nysten had recourse to the *Tribunal Civil*, which ordered that in future editions the name of Nysten should be suppressed completely, but mulcted the plaintiff in costs. This she did not feel disposed to submit to, and having appealed against the judgment to the Paris Court of Appeal, the following decree was rendered:—

"Seeing that the rights and duties of husband and wife which spring from marriage do not all finish with the marriage itself, and that the wife partakes with her children of the honour and consideration which attach to the memory of her husband, and that she has a right personally when these are sought to be injured to demand reparation; and seeing that the Dictionary to which Nysten gave his name has undergone, in the course of successive modifications, a complete re-casting; that the spiritual system in which he conceived it has entirely disappeared under the pen of its new editors; that Baillière and Son were wrong in maintaining, after reiterated reclamations, the name of Nysten on the title-page of a book which had no longer anything in common with the philosophical and moral doctrines of the original author; and that they have thus caused damage to Madame Nysten by offending against the memory of her husband and by obliging her to resort to legal procedures, it is therefore decreed that the judgment appealed against be annulled and amended so that Baillière and Son be condemned in 2000 francs damages and to the expenses of the original action and this appeal."

Dr. Laehr has recently published an account of the German Lunatic Asylums, and his general statement may interest our readers. From this it appears that at the beginning of 1865, in the whole of Germany, comprising 11,459 square (German) miles, and containing 46,000,000 inhabitants, there were 141 Asylums, 92 of these being public and 49 private establishments. There were also 28 Asylums building or in process of reconstruction. These 141 Asylums contained a total of 19,550 patients, viz., 17,823 (9426 males and 8397 females) in the public, and 1727 (900 males and 827 females) in the private Asylums. The entire cost in 1864 amounted, in the public establishments, to 2,573,655 thalers, or 122 thalers per patient. There are 261 Medical appointments, viz., 83 Medical directors, 54 chief Physicians, and 124 Assistant-Physicians. The Asylums are distributed in the various German monarchies as follow:—*Prussia*, with 5094 square miles and 19,252,363 inhabitants, has 32 public Asylums, with 4796 patients, and 27 private, with 944 patients, the number of Medical officers employed being 89. *Austria*, as far as regards the German territories, with 3586 square miles and 13,000,000 inhabitants, has 14 public Asylums, with 3065 patients, and 4 private, with 150 patients, the Medical officers amounting to 45. *Bavaria*, with 1388 square miles and 4,807,440 inhabitants, possesses 9 public Asylums, with 1850 patients, and 2 private, with 19 patients, 24 Medical men being attached to them. *Saxony*, with 271 square miles and 2,343,994 inhabitants, possesses 4 public Asylums, with 1955 patients, and 5 private, with 137 patients—Medical attendants, 23. *Hanover*, with 698 square miles and 1,923,492 inhabitants, has only one State Asylum, at Hildesheim, for 856 patients, having 8 Medical attendants; there is also 1 private Asylum, and recently two new Asylums have been built at Göttingen and Osnabruck. *Wurtemburg*, with 354 square miles and 1,748,328 inhabitants, has 2 public Asylums for 309 patients, and 6 private for 342, the Medical officers amounting to 26. Almost all the lesser States possess one or two Asylums, but the details of these would not prove generally interesting.

The thirtieth French Scientific Congress will be held at Amiens from the 1st to the 10th of August. It will be, as heretofore, divided into five sections—1. Physical, Chemical, and Natural Sciences; 2. Agricultural, Trade, and Commerce. 3. The Medical Sciences. 4. History and Archæology. 5. Literature, Philosophy, Social Economy, and Belles-lettres. Among the subjects which are announced for discussion in the third section are the following:— Laryngeal exploration; diagnosis of diseases of the bladder and urethra by means of the endoscope; physiological and pathological advances due to the ophthalmoscope; application of the dynamoscope as a means of ascertaining the certainty of death; causes of the presence of sugar in the urine; therapeutical application of ice; causes and effects of emboli; hypodermic injections; transfusion of blood in hæmorrhage; is there any foundation in the alleged transmission of diseases by vaccination; has the recent epidemic of cholera given rise to any changes in our ideas concerning the disease? Trichiniasis; the practical value of thoracentesis in acute pleurisy; origin of entozoa in the human body; vivisections in a surgical and physiological point of view; the means of dissipating prejudices against certain alimentary substances, especially horse flesh; should the preparation and sale of absinthe be prohibited, as also the sale of alcoholic substances above a certain degree? Here is, at all events, variety enough, and these form only part of the matters to be taken into consideration.

Dislocations of the jaw from muscular action, as in yawning, laughing, etc., M. Guinier, of Montpellier, observes, are not infrequent; but he believes that he is the first to record an instance in which the accident has been produced during laryngoscopic exploration. In order that the mirror may give an efficient and complete reflection of all the accessible portions of the vocal apparatus, the patient must be in an active state, and, by a co-ordinate exertion of muscular movements, endeavour to afford as large a display of the vestibular orifice of the larynx as possible. Flattening the base of his tongue, or maintaining it out of the mouth by the fixation of its extremity, and especially lowering and, at the same time, advancing the lower jaw—such is the combined procedure most favourable for laryngoscopic examination. This movement, which is entirely voluntary, becomes in some measure automatic, and is sometimes effected with a certain degree of energy by persons habituated to the laryngoscope and very desirous of obtaining the benefit of its employment. The carrying the jaw downwards and forwards, either gradually or suddenly in an exaggerated manner, may give rise to its dislocation, especially in some women whose articulations are very loose, and in whom the articular ligaments bear a certain amount of distension.

The case which gave rise to these observations was that of a phthisical woman, 38 years of age, suffering from chronic ulcers of the larynx, and in whom complete dislocation forwards was twice produced at intervals of a month, while cauterisation was being applied by means of the laryngoscope. It was easily reduced by pressure with the thumbs on the last lower molars, and drawing forward the ascending ramus embraced by three fingers of each hand. The accident may easily be prevented by cautioning the patient to moderate his co-operation, so as not to effect with too great energy the double movement of depressing and advancing the lower jaw. An excess of action in the external pterygoid muscle seems to be the chief agent in effecting the dislocation. With even a moderate separation of the jaws, such as is requisite for the employment of the mirror, the condyle of the jaw is already carried forwards; and the external pterygoid, then brought into action, exerts strong traction on the condyle, so that in predisposed persons, dislocation may readily take place.

PARLIAMENTARY.—CONTAGIOUS DISEASES BILL—BUILDING FOR THE UNIVERSITY OF LONDON—QUEEN'S UNIVERSITY BUILDINGS IN IRELAND—ISLE OF MAN LUNATIC ASYLUM—INSPECTION OF ASYLUMS—QUARANTINE AND CHOLERA—CAPITAL PUNISHMENT AMENDMENT BILL—CATTLE DISEASES PREVENTION ACT.

In the House of Commons on Thursday, April 26,

The House went into Committee on the Contagious Diseases Bill.

Clauses from 1 to 14 were agreed to.

Mr. Ayrton proposed to amend the 15th clause, which related to women submitting themselves voluntarily to periodical

*

Medical examination by requiring them to make a declaration that they were persons which the law recognises only to punish.

After some discussion, the House divided with the following result:—For the amendment, 5; against it, 76; majority, 71.

The Bill was then ordered to be reported to the House.

On Monday, April 30,

The House went into Committee of Supply.

A long discussion took place on the proposal of a vote of £20,000 for erecting a building for the use of the University of London. The Government proposition is that the new building should be located on the northern side of the garden of Burlington House. The whole sum to be expended is £65,000, £20,000 of which are to be spent this year. Other sites were mentioned by various speakers, such as the Thames Embankment and the space for the hitherto unbuilt wings of University College, but ultimately the vote was acceded to without a division. We congratulate the members of the University on the prospect of so satisfactory a settlement of the question.

£7000 were voted for the Queen's University Buildings in Ireland.

£2000 for the Isle of Man Lunatic Asylum.

£9735 were voted for the officers and Commissioners of Lunacy and the cost of inspecting lunatic asylums.

On the vote of £1444 for quarantine expenses,

Mr. Bentinck desired to know what were the duties of the officers on board the quarantine hulks, when, owing to the absence of disease or of an epidemic of any kind, a state of quarantine was unnecessary.

Mr. Childers said this establishment was but a skeleton, and formed one of the smallest which could be kept up if it was the intention of Parliament to maintain quarantine. There were differences of opinion upon the subject, but at present Parliament retained the system, and made the Privy Council responsible for its observance. Under these circumstances it would not be prudent to dispense with this vote. As long as Parliament thought fit to make Government responsible, if anything were to happen which could be prevented by quarantine, the House would be very indignant if there should be any neglect on the part of the authorities. The sum that was asked, £1444, was not very large.

General Dunne said he did not think the House knew why this establishment was kept up. He had been in countries where quarantine was carried out with great strictness, but he should like to ask how quarantine was to be applied here. In the Mediterranean, and wherever quarantine was carried out efficiently, there are officers in each port to examine every ship. But what organisation was there in this country to carry quarantine regulations into effect? The Rinderpest had been imported, and so might cholera at any time. In Bristol, the other day, a man had been brought in stricken down with cholera. There was no organisation in this country which for one moment could keep out such a disease as cholera, which was now impending. As long as we had free trade, and men could enter the country without any difficulty whatever, a vote of £1400 would not keep out the disease.

Mr. Ayrton wanted an explanation of this item. In London the expenditure under this head was only £20, notwithstanding the number of persons that arrived there and the vast trade which it carried on. At Portsmouth, where nobody arrived, £800 was expended on the establishment, which consisted of eight mariners doing nothing, one mate looking after them, and one superintendent. At Rochester, where nobody went except at a general election, there was a mate looking after four mariners, and the expenditure amounted to £369; and at Southampton, where people did land, there were no mariners, mate, or superintendent, but there was a Medical Officer, who could be of no use without mariners to attend to the vessels on their arrival. In fact, from the nature of the expenditure, the whole thing was what might be familiarly described as a little job.

Mr. Childers said the superintendent, mate, and mariners at Portsmouth formed the crew of the hulk stationed there to receive persons from ships coming from abroad in a dangerous condition. The officer at Southampton was a Medical Superintendent, and it was his duty to visit ships coming from abroad, and to send persons who might be suffering from dangerous diseases to the hulk at Portsmouth. The same was the case with the hulk at Rochester, which received persons sent there from London. He could not give a satisfactory answer just then of the small expenditure in London, but he should look into the subject.

Mr. Pollard-Urquhart hoped the Government would not give up the quarantine establishment, as it might be made a most useful instrument for the prevention of disease. At Odessa and the towns north of the Black Sea, where plague used to rage at one time, quarantine had been established during the last thirty years, and there was no plague there now. The same was the case at Constantinople; as soon as they introduced a strict system of quarantine, the plague came to an end. In Malta the system was attended with similar success. With such undeniable facts before us, we ought not to be in a hurry to abandon quarantine in deference to some new-fangled notions.

Mr. Candlish said the sum asked for was either too much or too little—one or other conclusion was inevitable In the northern ports there were no quarantine establishments at all.

Mr. Sandford said that was a proper occasion for asking the Government what course as to the enforcement of quarantine regulations they intended to take with regard to the impending visitation of cholera. He would remind the House that last year when cholera was raging along the Mediterranean, Sicily, which, from the filthy habits of the people, was of all places that which cholera was likely to devastate, was guarded by a strict quarantine, and the consequence was that the island was entirely exempt. He had seen in a blue book which had been laid upon the table, that the authorities in that island invariably adopted a system of regulations which would deserve the attention of Her Majesty's Government in case this country were to be visited. He did not know what the Government were doing in this matter, but he hoped some member of it would rise and explain the nature of the precautions which they were going to take.

General Dunne thought that this vote ought to be discussed by the Committee. If the cholera was approaching, much more effectual measures should be taken than this vote would allow. If the whole of the ports of the United Kingdom were left open, with the exception of Rochester and Portsmouth, there was, in point of fact, no quarantine at all. Liverpool and the other great trading ports, not to speak of Ireland, which seemed never to be thought of, were all left open to the disease. There ought to be a Medical officer in every port to inspect vessels coming in. He had seen at Zante four men hanged by Sir Thomas Maitland for breaking the quarantine regulations. He did not wish to see such a stringent exercise of the law in this country; but it was just now of peculiar importance that stringent quarantine regulations should be enforced, if it were true that the cholera had arrived in Holland, and was now coming over here. He hoped, then, the Committee would be informed what precautions were to be taken, and why Portsmouth and Rochester should be sealed while all the other ports were left open.

Mr. Childers said the hulks at Rochester and Portsmouth were, as he had stated, for the reception of persons afflicted with dangerous diseases who might arrive in the Thames or at Southampton, and £200 a-year for Medical attendance at the latter place was money well laid out; for a large number of persons arrived at Southampton, and it was desirable that they should be looked after. As ports were known to be infected, no doubt they would be proclaimed. The Privy Council was armed with very great powers, and when the time should come for their exercise proper precautions would be taken. He was sorry he had no authority to answer the question put by the hon. member for Maldon. His right hon. friend (Mr. Bruce) who had charge of such matters was, unfortunately, absent in consequence of some family affliction.

Mr. Sandford inquired whether Rotterdam had been proclaimed?

Mr. Childers said he was not aware.

Mr. Brady said that the great means of preventing the invasion of cholera was the establishment of a large permanent body, who should have power to carry out a proper system of quarantine in the different ports of the kingdom.

Mr. Bentinck said the Secretary to the Treasury had failed to answer the question he had put—namely, what the officials who had charge of the hulks did when there were no sick persons on board? It was but seldom necessary that persons afflicted with disease should be sent to these hulks.

Mr. Childers admitted that the subject was one which he had not very much studied; but he hoped to be able to answer the hon. and learned gentleman in a few days.

The vote was then agreed to.

The Contagious Diseases Bill was read a third time and passed.

On Tuesday, in the House of Lords,

The Lord Chancellor, in moving the second reading of the Law of Capital Punishment Amendment Bill, stated that the measure had been drawn up in accordance with the recommendations of a majority of the Commissioners who had been appointed to inquire into the subject. A minority of those Commissioners had been in favour of an entire abolition of capital punishment, but he concurred with the majority in thinking that the retention of the highest penalty for crimes of the blackest dye was necessary for the good of society. After dwelling upon the deterrent effect of capital punishment, the Lord Chancellor pointed out that murder was punishable by death in almost all countries, the exceptions being rare and insignificant. The Bill which he now invited the House to sanction divided murders into two classes—murders of the degree, wilful and premeditated, which were to be visited with capital punishment, and murders of the second degree, committed under circumstances of a less heinous character, for which the extreme penalty should not be inflicted. There were some points upon which at a future stage he should desire to propose amendments, but with the recommendation of the Commissioners that executions should in future be inflicted in a less public manner than at present he fully concurred, believing that the deterring influence of the punishment would not be diminished by an avoidance of the shocking scenes which had marked so many executions of late years.

Lord Malmesbury agreed generally with the Commissioners, but took exception to their recommendation of private executions, being convinced that punishments, like rewards, had greater weight when administered in public, and consequently the deterring effect of the penalty would be diminished by substituting private executions. He thought it would be useful if capital sentences were to be executed in the localities where the crimes were committed, instead of always at the county towns.

The Bishop of Oxford spoke, from his experience as chairman of a Committee which had inquired into this subject, of the great advantage which would be derived from conducting executions in a less public manner than at present, and suggested that the awful nature of the punishment might be impressed upon the public mind by a black flag being hoisted or a bell tolled at the time of the execution.

Lord Romilly believed that the balance of evidence and of reason was in favour of the total abolition of the death punishment, as, of the two objects of all punishment—deterring other offenders and reformation of the criminal—neither was attained by taking life. In cases of murder periodical flogging could be added to perpetual imprisonment; and in such cases the ordinarily natural objection to corporal punishment could not be made.

Lord Redesdale objected to the classification of murders, as tending to lead to an inference that crimes of the second degree were more or less excusable, and referred to the increase of infanticides, which he attributed to the undue leniency which had been exhibited in such cases.

Lord de Ross, comparing the English and French systems of military executions, argued that a solemn public proceeding exercised a greater deterrent influence than one conducted in comparative privacy.

The Duke of Argyll did not believe that society could at present safely dispense with capital punishment, and remarked that Lord Romilly had omitted all reference to the retributive element of this as of all other punishments.

Lord Houghton commented upon the lawless and disgusting scenes which presented themselves on the occasion of all public executions, and accepted gladly the change proposed in the Bill until the time should arrive when capital punishment would be unknown to British laws.

After some remarks from Lords Cardigan and Belper,

Lord Shaftesbury approved the Bill, and especially that part which related to private executions.

The Lord Chancellor briefly replied, and the Bill was read a second time.

In the House of Commons,

Mr. Cheetham asked the Secretary of State for the Home Department if the Government would suspend the operation of Part I. of the Cattle Diseases Prevention Act, relating to the slaughtering of animals and compensation for the same after May 10.

Sir G. Grey said these clauses, as originally enacted, were to remain in force only till April 15, but they were continued by Order in Council till May 10. The Privy Council had not yet been called to consider the question of their continuance beyond that period; but from the communications which had reached him from different parts of the country, where great advantage had resulted from the operation of these clauses—in fact, the diminution of the cattle plague was attributed very much to their operation (hear, hear)—he thought he might say an Order in Council would be passed to continue the operation of these clauses beyond May 10.

THE USES OF THE MEDICINAL SULPHITES AND HYPOSULPHITES IN ZYMOTIC DISEASES.

(From a Correspondent.)

The extent and value of Dr. Giovanni Polli's researches, experimental and clinical, as to the uses of the medicinal sulphites and hyposulphites in zymotic diseases have not been duly appreciated in this country. With the cholera impending, and typhus still prevalent, and the cattle plague not yet "stamped out," we shall do good service by calling special attention to the results of Dr. Polli's labours, as stated in his latest papers on the diseases caused by a morbific ferment and their treatment, communicated to the Royal Institute of Lombardy, at Milan(a). His first paper appeared in the eighth volume of the *Memoirs* of the Institute, and described researches into the chemistry of morbific ferments and their treatment by anti-zymotic chemicals. Whatever be the theory as to the cause of the so-called zymosis (and either Liebig's albumenoid, or Pasteur's animalcular, or any other theory may be adopted), the practical facts, according to Polli, are, that there are two morbid elements in the blood in these zymotic diseases; the one is of the nature of a ferment or excitor of change, the other is the material capable of fermentation. When either of these is absent from the blood zymosis is impossible; but when both are present, then such a reaction takes place that zymotic phenomena result. Now, the ferment may be rendered innocuous, although it may not be readily destructible itself, by destroying the fermentable material, or by at least so changing its composition that fermentation is effectually hindered. Anti-zymotic agents are already numerous, the majority of which seem to act both upon the ferment and the fermentable material, and would therefore seem *à priori* to offer all that is needed.

But the very qualities upon which their anti-zymotic powers depend, render them dangerous in practice, because they are for the most part efficacious in proportion as they are destructive to the vital processes themselves. A safe anti-zymotic was, therefore, still needed. After a series of experimental researches Dr. Polli affirms that he has found in the sulphites and hyposulphites of potass, soda, and magnesia, medicinal agents which do not act upon the ferment, nor upon the vital processes, but upon the fermentable something without which the ferment is innocuous; and in this way they constitute safe and efficacious anti-zymotics. In the memoir under review he indicates the diseases in which they may be administered either for prevention or cure—their doses, modes of administration, and in short entire natural history, as therapeutical agents of their class.

The fundamental fact of his researches is this:—He selected a number of dogs; a proportion of these he dosed with the sulphites, while the remainder were left without. He then killed them all, the weather being warm. He found that the urine, the blood, the viscera, and the flesh of the sulphited dead dogs resisted putrefaction for many days, while the same elements of the unsulphited animals were already putrid.(b) The obvious conclusion from

(a) "Sulle Malattie da Fermento Morbifico e sul loro Trattamento." Memoria Secunda. (Parte Clinica) 1864.

(b) Memorie del R. Instituto Lombardo, vol. viii., section viii. of Memoir.

so striking a fact is, that as the sulphites prevented putrefactive fermentation in the dead body, they would *à fortiori* prevent it in the living. He accordingly instituted a series of comparative experiments on the living. He selected two or three dogs as nearly equal in size and state of health as possible, and inoculated them with the nasal mucus of a glandered horse. One of the dogs had had previously administered to it from four to five scruples or more of the sulphites of soda or of magnesia daily for some days; another was treated by sulphites as soon as inoculated; a third was left without treatment, either prophylactic or curative. The result was that the third animal suffered much more severely than the other two. The like results followed after injecting pathological ferments into the veins, such as fresh and putrid pus, and putrid blood. Encouraged by these results, Dr. Polli proceeded to test the effects of the sulphites and hyposulphites on men in health and disease. He found in man, as in dogs, that they are not ordinarily decomposed in the stomach, but pass unchanged into the blood, or at least appear in a brief period unchanged in the urine, and only after a while as sulphates; that they may be traced in the organism for from 24 to 36 hours after being taken; that they slightly increase the renal secretion, and are mildly cathartic in large doses.

The clinical researches extend over a series of local and general forms of zymosis, and have been conducted chiefly by Italian Physicians. That the salts have been extensively used is deducible from the fact that three chemical houses in Milan have sent out more than 1000 kilogrammes (2204 lbs. avoirdupois) of the sulphite of magnesia—a salt which Dr. Polli says can have no other use in the arts and pharmacy in Italy than those he has indicated. We will note the uses in the order Dr. Polli arranges them.

External Uses.—In all suppurations, sloughings, and ulcerations the solutions are useful in soothing pain, removing fetid odours, and exciting healthy action. The sulphites of soda and potass are the best; they neither stain nor corrode the linen, as the solutions of metallic oxides, and being without smell are not offensive, like the chlorides, phenic acid, etc. They have the advantage, also, of being highly soluble. In gangrene and sloughing, foul ulcers, and suppurations of all kinds, a more or less concentrated solution of the sulphite of soda is the best. This salt is soluble in four times its weight of water, but it may be advantageously used in the proportion of one part salt to five to ten of water. The solution may be applied as a wash, or lint or a compress wet with it, or it may be injected into sinuses and sloughing cavities. The solution may also be mixed with glycerine, and the powdered salt may be sprinkled on the part affected. The sulphites of lime and magnesia have a somewhat caustic action, and are, therefore, best adapted for indolent ulcers. The immediate effect of the salts is to arrest putrid fermentation. In cases of purulent absorption (pyæmia) and septicæmia the internal use should be combined with the external. Dr. Polli recommends the sulphite of magnesia in thirty-grain doses every two hours.

2. *Pyæmia* and *septicæmia*, and all the class of fevers, with putridity and purulent absorption, such as Hospital fever, puerperal fever, anatomical inoculation, and the like, have been treated by the sulphites with advantage. According to the clinical observations of Professor Burggraeve, of Ghent, it is necessary in those cases to give the sulphite of magnesia, so as to saturate the organism rapidly with it, and cause the fluids, of the body—urine, saliva, sweat—to contain it. Half-drachm doses every one or two hours may be given with this purpose. Reports from twelve Italian Physicians testify to its beneficial effects in ameliorating all the symptoms of 18 cases of purulent infection. Dr. Polli recommends it to be given as a prophylactic in Surgical cases, bad cases of labour, etc. From four to six drachms of the sulphite of magnesia or the hyposulphite of soda may be given during the first 24 hours in divided doses, and from six to nine drachms during the next 24 hours to prepare a patient for an operation or a labour. If, when the patient is attacked, there is excessive diarrhœa and vomiting, these must be relieved, otherwise the system will not be saturated, or else clysters of the solution must be administered. A little caustic magnesia added to the solution of the sulphite of magnesia causes it to remain better on the stomach. For the diarrhœa opium may be combined. After a while the remedy being retained will take effect in relieving the diarrhœa, and the opium may be discontinued.

3. *Endemic* or *miasmatic fevers* are numerously reported on by Dr. Polli's correspondents; in some instances in a tabular form, as to hundreds of cases of quotidians, tertians, and quartans treated by the sulphites. Comparative trials of quinine and sulphites were made by some Physicians both for the prevention and cure of intermittents. The results of these observations are very striking. The sulphites were found to cure a larger number of cases than quinine; to cure more completely and with less tendency to a return of the fevers, and to cure radically cases that were utterly rebellious to quinine. In others of this class the conjoined administration effected a cure when neither cured singly, The sulphites do not, like quinine, cut short the fevers; they gradually diminish the intensity of the symptoms. The sulphite of magnesia is the most efficacious, and may be taken to the extent of an ounce or an ounce and a-half in the twenty-four hours in divided doses, either in a cup of water, or in sugar, or any confection. It may be taken during the accession as well as during the remission. A change for the better, if the remedy is likely to be efficacious, is manifested in from three to five days. All acids and acidulous fluids are incompatible with the sulphites, and should therefore be forbidden. To prevent malaria taking effect, Dr. Polli recommends a solution of the hyposulphite of soda to be taken in any vehicle which serves to mask the bitter taste of the salt. A prophylactic mixture (the "*liquore solfitico antifebrile*") of about a litre or 1¾ imperial pints, containing fifty doses, may be thus made:—Hyposulphite of soda, 7721 grains; water, 9765 grains; tincture of essence of anise, 2316 grains. Two small tablespoonfuls to be taken every morning fasting in a cup of water. It may act on the bowels for the first day or two; but this effect ceases in a while, and the remedy is borne perfectly well, although a good deal of sulphuric acid is formed in the intestine. When the remedy is not effective in a few days, in a case of intermittent, quinine or iron may be combined. Its prophylactic value is increased in anæmic persons in the same way.

4. *The Exanthemata and Typhus Fevers.*—Dr. Polli suggests the use of the sulphites in yellow fever, and prints thirty-seven reports from numerous correspondents of their value in measles, scarlatina, small-pox, erysipelas, and typhus. The general results reported are to the effect that they mitigate the intensity of the febrile exanthem, render the confluent and malignant forms benignant, shorten the course of the milder forms, and in all cases accelerate convalescence. In typhus gravior with fetid dejections and putrid symptoms, they are found useful. Dr. Polli does not venture to assert that they will prove available in the cure of cholera and plague; but he thinks there is reasonable ground for concluding that they will be highly useful as prophylactics in destroying the fermentable material upon which the malignancy and fatality of those pestilences chiefly depend, and thus rendering an inevitable attack mild. They may have no effect on the ferment, but they will deoxidise the fermentable stuff. In all these zymotic diseases the same principle applies.

5. *Syphilitic infection* and constitutional syphilis have been efficiently treated by the sulphites, but facts are not given. Pellagra, too, and tuberculosis, it is thought, may be benefited.

6. *Cattle Plague and Epizootics.*—Dr. A. Colaprete, di Campo di Giove (the Abruzzi), has used it in the cattle-plague, and

cured a third of the animals attacked. (c) And Dr. Polli refers to other instances in which the sulphites have been administered in epizootics, either to prevent or cure, or both, as in the epizootic aphtha of cattle.

6. Finally, Dr. Polli speaks favourably of the uses of the sulphites to anatomists and others. Corpses or viscera can be preserved for many weeks in a solution of sulphite of magnesia or of soda, without change either in colour, or density, or otherwise, and without acting upon the scalpel or other anatomical instruments when dissection is made; in these respects being superior to alcohol, arsenic, corrosive sublimate, or the sulphates and chlorides of iron, zinc, etc.

Some hints as to the administration of the sulphites may be useful to those who may be induced to try them in the various diseases in which Dr. Polli recommends them. They appear in the urine twenty minutes after being taken into the stomach unchanged, but are gradually changed in the system into sulphates. The saliva and sputa contain them. They are not decomposed in the stomach under ordinary circumstances, but when they are, there is a manifest production of sulphurous acid gas. When this is the case a little magnesia must be added to the sulphite to neutralise the acids of the stomach. The sulphites of soda and magnesia are tolerated in large doses if dissolved freely in water. A concentrated solution is apt to lie heavy on the stomach and cause a frontal headache; the more diluted, as a general rule, the better. They are decomposed by all the vegetable acids, however weak. Hence their beneficial influence will be counteracted if the patient takes citric, tartaric, malic, or oxalic acids, or foods or drinks containing them. This is important to remember when administering them in fever, inasmuch as lemonade, imperial, apple tea, and the like, are all incompatible drinks and destroy their efficacy.

The hyposulphite of soda is much more purgative than the sulphites of magnesia and soda, which are commonly more diuretic than cathartic in their action. There are individuals, however, whose intestinal canal is very sensitive to their action, in which cases a carminative and sedative are required to be combined. The purgation is, however, most commonly without pain or discomfort. The stools of those taking the sulphites lose all cadaveric or nauseous fetor. Upon the whole, the best mode of administering the sulphite of magnesia is in the form of powder, because of the large quantity of water it requires for solution, and because in that state it is most easily altered by the air. This sulphite has the least taste, and is the most active of all, and since it undergoes in the dry state the least change, it is to be preferred to all the others for medicinal purposes. From fifteen to thirty grains may be prescribed in powder, to be taken either in water or other vehicle, or it may be covered with gum or dextrine, and sugared and taken as troches or jujubes. The sulphites are better than the hyposulphites when a rapid curative action is required; but the latter may be advantageously substituted for the former when prophylaxis is aimed at. The great aim in administering them curatively is to saturate the system with them; and for this purpose four to five drachms daily must be the minimum quantity for an adult. Three or four times that quantity of sulphite of magnesia has, however, been administered with advantage; and a third or a fourth more (five to seven drachms) of the sulphite of soda will be borne well. Their long-continued use is apt to induce œdema and diseases of debility by their deoxidising qualities; otherwise, they have no influence on the system.

The numerous researches made by Dr. Polli and his correspondents merit careful consideration and trial by the Profession in England. Our experience, so far as we have tried the salts, is in favour of Dr. Polli's statements. It must be carefully remembered, however, that the sulphites cannot be fairly tested without strict attention to the conditions under which they can be reasonably expected to be available, and with such precautions as are required by a consideration of their chemical qualities and medicinal properties.

(c) *L'Agricultura* for April 15, 1864.

REVIEWS.

Notes on Cholera: its Nature and its Treatment. By George Johnson, M.D., Lond., etc., etc. London: Longmans. Pp. 112. 1866.

"When, in August, 1854," says Dr. Johnson, "I first publicly stated in the *Medical Times and Gazette* that I was giving castor oil as a *purgative* in cholera the announcement was received with a shout of dismay. Give a purgative to a patient whose blood has already been drained of all its liquid and thus rendered too thick to circulate! Fearful malpractice!" The short but exceedingly elaborate and closely argued work before us is a vindication of that practice of 1854. We proceed to give our readers a short account of it, in doing which we hope we shall bear in mind the terrible responsibility which rests on any one who writes on this subject at present.

Dr. Johnson quotes Buckle to the effect that—"There is no well-attested case on record of any theory having been abandoned because it produced dangerous results." Moreover, the author begins his book by saying that "There are few diseases the treatment of which has been more influenced by pathological theories than that of cholera." A weighty consideration, truly; and one that deserves to be borne in mind in constructing new theories, as well as in demolishing old ones.

It is generally admitted, Dr. Johnson says, that the symptoms of cholera result from a poison which may enter the blood either through the lungs or through the gastro-intestinal canal. Although in the earlier part of his book he assumes the existence of this poison, he afterwards devotes a chapter to an attempt to show that the assumption is a reasonable one. He believes that by vomiting and purging this poison is got rid of. Indeed, he thinks that these symptoms are as much parts of the natural process of cure as the eruption in the skin is of small-pox. No one, he adds, recovers from small-pox without eruption, and no one recovers from cholera without vomiting and purging; although a patient may die of small-pox without eruption, and a cholera patient may die without purging and vomiting. He dies if the poison stays in him; he may recover if it gets out. Again, just as a small-pox patient may die from the injury the skin receives from an abundant eruption, so the cholera patient may die of the exhaustion produced by extreme vomiting and purging. But Dr. Johnson thinks vomiting and purging have been over-estimated as causes of death.

Here lies the practical point of the subject.

The author puts one broad principle of treatment in fair antagonism against another broad principle of treatment, and thus we may collect evidence on the therapeutics of cholera with some precision, if with some narrowness. There is much value in this sort of work; whilst there is no hope at all in mere careless, heedless labour at drugmongering. We thoroughly agree with the author when he says—"I have not the faintest hope or expectation that a specific remedy for such a disease as cholera will ever be discovered." In cholera, the author tells us, the system tries to rid itself of the poison, although the process it adopts is a violent one, and the patient often dies under it, and, as he admits, occasionally *from* it. Are we to assist the "natural curative process" by giving purgatives? Now, in most cases of cholera the system does not at first glance appear to require this kind of help. The cholera "poison" seems to be in itself by no means a gentle aperient. Let us here remark, however, that to say that Dr. Johnson recommends *purgatives* is scarcely to speak of his method precisely. His aim is not to increase the drain from the blood, but to empty the intestinal canal of what is really already outside the system proper. And although he shows that a great variety of purgatives, among others calomel, *have been given* with more or less success, we must bear in mind that the purgative he himself recommends is the simplest one of all—castor oil. His plan is not eliminative in the strict sense, then; but only in the subordinate way of removing materials from the bowels which have been already eliminated from the system.

Now we come to the theory. Let us remark again that, good as this may seem—and we have rarely seen so brilliant a piece of pathology—we must judge the practice founded on it separately. In spite of Buckle, let us collect evidence in particular cases and see what does good and what harm; whether the plan of treatment have a theory in the background

or not. Theory will do good by suggesting remedies, but we must be empirics in our use of both suggestions of theory.

Admitting that a poison has got into the blood – that it may kill all at once, but that generally the system tries to get rid of it by purging and vomiting, and that the patient often dies during, if not of this process, we have now to see what action Dr. Johnson considers the cholera poison to have on the system that leads the system to adopt such violent, and often suicidal, means for its riddance.

The "one great central fact" on which he founds his theory is, that "during the stage of collapse the passage of blood from the right to the left side of the heart is in a greater or less degree impeded." The particular point at which it stops in this circuit is betwixt the right side of the heart and the lungs. The stoppage occurs before the pulmonary capillaries, since after death during collapse, the lungs are anæmic; and yet it is not in the large branches of the pulmonary artery, as after death these and the right side of the heart are found to be gorged with blood; it is in the smaller branches of this vessel. The cause of the stoppage is contraction of the muscular coat of these branches, and this contraction is brought about by the irritant action of the cholera poison. It is not, then, so much that the poison poisons the general system, as that it picks out muscular tissue in particular. Hence it causes the painful cramp in the limbs, and hence also by cramp of the pulmonary arteries the blood is prevented passing into the lungs. Thus, then, to use the Author's words, "choleraic collapse is a form of asphyxia."

The following quotations from a well-known text-book will show that the facts which Dr. Johnson adduces from the morbid anatomy of cholera, in explanation of the pathology of the disease, are generally admitted. Aitken says, "The most common appearances in the lungs are the presence of blood in the large vessels, chiefly or solely; the collapse and the deficient crepitation, arising from the more or less complete absence of air and blood, and from the approximation of the molecular parts of the pulmonary substance. In other cases there is more blood in the minute structure, a corresponding dark colour of the lung, and a variable amount of frothy serum. The right side of the heart and the pulmonary arteries were generally filled, and in some cases distended with blood. The left side and aorta were generally empty, or contained only a very small quantity of dark blood; the left side had evidently received little or no blood, but had continued to contract, in some cases even violently, on the last drop of blood which had entered it."

Now Dr. Gairdner, Dr. Wilks, and Dr. Ogle all speak of the lungs as being often congested in cholera, but we do not gather from their statements whether they are reporting appearances from patients who died in collapse or in the reaction which follows it. The reader must observe that Dr. Johnson does not say that there is anæmia of the lungs in those who have died of cholera, but in those who have died in choleraic collapse. According to Aitken's description, the lungs contain blood in some instances of death in collapse.

The blood, then, is locked up in the venous system, and the arterial system is comparatively empty.

There is no doubt much ingenuity in the speculation that blood is arrested at one point by spasm of the arteries. The whole theory is coherent, but, of course, this part of it does not admit of demonstration. We need not quarrel with it. The main point is, does the blood stream get stopped here? and the manner of the stoppage may be thus provisionally explained.

This sudden and more or less complete stoppage between the venous and arterial system explains, Dr. Johnson thinks, the shrinking of the body and the choleraic pulse. There are other theories, however, to explain the stoppage. One is, that the blood, after the drain from it by the purging, becomes too thick to pass the pulmonary capillaries. In this theory Dr. Johnson has no belief whatever. He thinks the thickness of the blood is an indirect consequence, rather than a cause of the pulmonary obstruction. Loss of fluid cannot, at all events, be the cause of death in those cases in which the patients have died suddenly. There are, however, we believe, some who hold that sudden death is due to sudden drain of fluid from the bleod, although the fluid passes into the intestines only. Dr. Johnson relates experiments by Blake to prove that some poisons – *i.e.*, certain salts—introduced into the veins do kill suddenly, and also that they appear to kill by arresting the circulation at the point where he thinks the cholera poison stops it. Air introduced into the veins, he tells us, kills in a similar way. He next relates the case of a woman suffering from mitral disease of the heart who died suddenly. She became pulseless, blue, cold, gasped for breath, and presented "the shrunken appearance of the features exactly resembling the collapse of cholera." Although she seemed likely to live but a few minutes she did not die until after forty-eight hours. The cause of her death was fibrinous coagula in the branches of the pulmonary artery. It may seem to some that during the forty-eight hours that the woman lived, there ought, on Dr. Johnson's theory, to have been purging; but in cholera the venous blood behind the obstruction contains a poison which acts as a purgative, and thus tends to eliminate itself.

Now we come to certain other striking symptoms of cholera. When the blood cannot get into the lungs, there is, of course, a stoppage of oxidation, and, of course, an arrest of certain chemical changes. There is loss of heat—and this is one of the most striking symptoms of cholera—a scanty formation of urinary and biliary constituents, and the blood is dark and thick. The last condition, he states, bears no proportion to the loss of fluid. The views he here states are very interesting, and deserve careful consideration. They give a completeness to his theory. As to the suppression of bile, however, there is a difference of opinion. Dr. Gairdner says, "The suppression or retention of bile has been assumed, on account of its apparent absence in the dejections, to be one of the most characteristic features of Asiatic cholera. The assertion that the bile is suppressed, however, is obviously incorrect." The gall bladder generally contains bile. It is generally admitted that the secretion of milk is not interrupted. Dr. Johnson believes that this is because its constituents may, unlike the urinary and biliary constituents, be obtained from the blood without the addition of oxygen. Gairdner, however, says that the urinary secretion is the only one of the more important and constant glandular secretions which is suppressed in any stage of the disease. The secretion of bile, he tells us, is carried on to quite as great an extent as in most diseases in which digestion is totally interrupted, or as in healthy individuals when fasting.

So much for the constructive part of the book—what Dr. Johnson believes; now for the destructive—what he does not believe. In the first place, he is perfectly convinced that the theory that the worst symptoms of cholera are due to a drain of fluid from the blood is a wrong theory, and that the practice founded on it of stopping purging by opiates and astringents, as well as that of trying to restore to the blood the constituents it has lost by purging is an injurious practice. Now, of course, neither he nor any one else denies that there is in most cases of cholera a severe drain of fluids from the system, but he thinks this is not essential, as some patients die of cholera without any purging or vomiting at all. Again, he holds that when these symptoms occur, they are in no proportion to the malignancy and fatality of the disease. In support of this view he quotes Parkes (and Parkes appeals to Scott, Jameson, Orton, Kennedy, and Copland), who believes that "there is absolutely no relation betwixt the purging and vomiting and the symptoms of collapse," and who also says that cases in which there is little vomiting and purging are more malignant and more rapidly fatal than those in which there is much. This is certainly strong testimony. The author goes so far as to maintain that there is evidence of an inverse rather than of a direct ratio between the degree of collapse and the loss of fluid by vomiting and purging.

Then, approaching the same subject from another point, Dr. Johnson thinks the evidence shows that an excessive loss of fluid from the system does not produce the symptoms of cholera. We, however, pass this and much other important matter to speak of the treatment he adopts. We are bound to say, however, that his arguments are well put.

He gives emetics and purgatives to empty the stomach and bowels of fluids excreted into them. His object is not, as we have already said, to increase excretion from the blood. Whether there is an elimination of poison by the stomach and bowels or not, "no one can doubt," he says, "the existence of offensive *morbid secretions* which require to be cast off." He considers the success of the calomel treatment as evidence in favour of elimination by purgatives, and says that before cholera visited Europe Medical Practitioners not only used to give purgative drugs, but dared also to call them purgatives, and that several spoke highly of castor-oil in particular. Purgatives were given by Bell, Orton, Scot, Curtis, Twining, Christie, Rogers, Kennedy, Searle, and Corbyn, onno particular theory.

He tries to disprove the argument that remedies cannot be

absorbed in the stage of collapse by reference to some experiments made by Magendie, and, indeed, he says there is undoubted evidence that opium and alcohol become absorbed and produce narcotic effects. However, he holds that the remedies of real use in collapse need not be absorbed, and thinks calomel and castor oil act directly on the inner surface of the bowels, and thus excite sufficient contraction to enable them to expel their contents.

Those who have been long imbued with the old principles —old in this country at least—may almost arrive at a knowledge of Dr. Johnson's practice in collapse by the simple rule, that it is just the reverse of their own. They gave their patients stimulants; he, when the breathing is hurried, recommends bleeding. They give astringents; he gives purgatives and emetics. They give ice or iced water. He denounces ice because of its tendency to stop the vomiting; he persuades the patients to take hot liquids; he makes no attempt to feed the patient. But they must remark that he gives reasons for his practice, and like others appeals to results. He does not bleed to lower the system, but to relieve the distension of the right cavities of the heart of the blood by which its action is encumbered. In one instance he admits an old practice is right, but it is right by chance. He says of Dr Stevens's plan of treatment by salines that the practice is not far from right, although the theory is wrong. The temporary benefit from injection of hot solutions of salines is from the heat, which for a time relaxes the pulmonary spasm, and not from the saline fluid supplied to the blood. Indeed, he says in a contemporary that the use of saline injections with the view of supplying fluid to the blood is founded on a theory which, "by suggesting a mischievous plan of treatment, has in its day been the direct source of greater harm to the human race than any other erroneous pathological theory that ever held sway over Medical practice." Yet, although heat thus gives help for a time at least, heat applied by the bath is rather injurious, because, Dr. Johnson thinks, cutaneous respiration is interfered with. He, however, thinks Dr. Murray's plan of injecting hot fluids into the rectum is worthy of trial, and advises *hot drinks* to warm the blood.

Such is the theory and such an outline of the practice which Dr Johnson puts forward, and we do not criticise at present. We think that any one who reads his book will come to the conclusion that it may be the best plan to do *nothing* in the stage of collapse, except nurse the patient carefully, and soothe him as much as possible. Be it observed, in conclusion, that the treatment of *diarrhœa*, in an epidemic season, be it called premonitory, or choleraic, or cholerine, is quite a different matter. Little as we can do in blue cholera, the experience of mankind has shown that a great deal can be done in diarrhœa.

On the Curability of Certain Forms of Insanity, Epilepsy, Catalepsy, and Hysteria in Females. By BAKER BROWN, F R.C.S., etc. London: Robert Hardwicke, 192, Piccadilly, W. 1866. Pp. 85.

SURELY this book is an "anachronism," as the penny-a-liners say of anything that seems not to suit the times. As we rub our eyes in reading it, we are tempted to ask, Are we under Queen Victoria or the Empress Messalina? Are we in the 19th Christian century or in Pagan Rome of the Empire? Surgery, such as is detailed in this book, ought surely to have been celebrated in the 6th of Juvenal! It would have suited the time when chastity was secured by infibulation, and when even eunuchs were not safe guardians of the marriage bed. Had Tiresias been a pupil at Mr. Brown's Hospital, he need not have lost his eyesight. He would never have agreed with Jupiter when he joked with Juno, and is said—

"Major vestra profecto est
Quam quæ contingit maribus dixisse voluptas."

Does Mr. Brown believe in the *lex talionis?*

"Neque enim lex justior ulla
Quam necis artifices, arte perire sua;"

or, again, as the same poet says:—

"Qui primus *pueris* genitalia membra recidit
Vulnera quæ fecit, debuit ipse pati?"

He may thank the gods that he lives when police constables abound, and not in times of "classic antiquity," else, verily, the women would have mobbed him, and served him worse than they did Orpheus.

To come to matter of fact, however, this is a book of which we can only say that we are sorry it ever was published, and that the task of reviewing it has fallen upon us. There is no need to wash dirty linen in public; and if there be an occasional suspicion of a vice amongst women which it is degrading to allude to, men of position and character need not write about it; all that needs be known or done can be managed quietly and delivered by word of mouth without wounding the honour of women, or the self-respect of the Medical Profession. We are sorry to see the author's undoubted energy and cleverness and boldness diverted from genuine Surgery and wasted on a subject so unfruitful of good.

Mr. Brown's book really treats of solitary vice in women. Every reader of a country newspaper knows what is paraded there in the advertisements about the consequences of similar irregularities in the male sex. Heaven grant that we may never see similar advertisements directed to "mothers!"

Mr. Brown gives a list of maladies, or, as he calls them, "stages of the disease," which he asserts may be traced to this malpractice. This list includes—"1. Hysteria, including dyspepsia and menstrual irregularities. 2. Spinal irritation, with reflex action in uterus, ovaries, etc., giving rise to uterine displacements, amaurosis, hemiplegia, paraplegia, etc. 3. Epileptoid fits, or hysterical epilepsy. 4. Cataleptic fits. 5. Epileptic fits. 6. Idiocy. 7. Mania. 8. Death." All these—which include or may be made to include, by the bye, one-half almost of female diseases—he traces as so many steps of "the disease." We give him credit for great ingenuity and delicacy in naming the actual practice in question, which he veils under the terms "peripheral irritation," etc., and likewise for the host of "authorities" whom he quotes, although they really do not support his practice.

Well, "the disease" being given, and a pretty comprehensive one it is, he gives a diagnosis. He describes those visible characters of the organs of women which he believes to be pathognomonic, and in these he includes even a "peculiar, straight, and coarse hirsute growth." His cure is excision of the clitoris.

Repeating what we have said, that it is a great pity that a topic so painful should ever have been written about, we must add that Mr. Brown's book seems to us by no means a safe guide for the Practitioner. The symptoms ascribed to self-irritation include those of every case of hysteria, even arising from mental trouble, mental weakness, or other innocent causes, in which sex has no share. A Practitioner might be led by this book into inquiries most painful to his patient and injurious to himself. We cannot help thinking that many most pure and innocent-minded girls, utterly unconscious of evil, might, if cross-questioned, give answers which might be interpreted into confessions utterly unintended and baseless. A good many fathers and brothers might be apt to resent the Doctor's conduct, if he mooted such points. We take for granted that the cases of hysteria, etc., on which Mr. Brown would operate, are of long standing, and severe, and such as can be traced, as he believes, to unnatural excitation; but we think it an omission that he has not treated of the physical conditions which produce irritation and itching of the external female organs, for surely it were better to relieve these causes than to perform a painful operation. He does not give due weight to measures, local or general, for rendering those parts less sensitive to irritation. To assume that this vice can only be cured by operation, is, we think, a mistake. On this point, we would refer Mr. Brown to a most careful and conscientious writer, who has a right to be listened to on any matter relating to the gravest derangements of the nervous system. "There are other almost incurable propensities," says Dr. Sankey, in his lately published Lectures, "such as . . onanism . . which will require some little exertion of ingenuity, but may be overcome with kindness and persuasion and with watchfulness. The worst case of onanism in a female that I ever met with (and I believe the cases are much rarer than is supposed) was cured by taking cod-liver oil and wine. When she grew fat and strong, the propensity disappeared. Cause and effect are often the reverse of what is at first imagined, and often, in fact, result in each other. Onanism is often supposed to be the cause of the pale and emaciated looks and feeble health of a patient, whereas in some, at least, the irritability and debility have induced to onanism." This is much more like philosophical practice than Mr. Brown's. We believe that a healthy, robust person, of either sex, would scorn the vice in question. Feebleness, nervousness, want of air and exercise, irritability, and the fretfulness of an ill-nourished nervous system—the first steps, in fact, of nervous disease, are the first steps of sexual irregularity. Sickly men

and women, too, are far most prone to rash and improvident marriage.

To resume. Mr. Brown assumes that because some hysterical girls may be tempted to these malpractices, that the malpractices made them hysterical, just as because some idiots suck their thumbs, some sages think thumb-sucking a cause of idiocy. Some of his own cases (as case 6) and his own comments, tell directly against the benefits of the operation, which, surely, was a cruel one to perform on a mere hysterical girl, even if it cured her, which it did not. He is quite silent as to occasional ill-consequences of the operation, although these have been brought forward by no less an authority than Dr. West, and surely need notice. Nothing can be more precise than Dr. West's charges on three points (see his "Lectures on the Diseases of Women," third edition, p. 663)—1st. That wrong diagnosis is possible, for he gives the case of a respectable lady, aged 53, whose youngest child was 20 years old, who was operated on, although, as Dr. West asserts, there was not the smallest foundation for it, and she had never been guilty of the vice in question. 2nd. That the operation was performed without the patient's knowledge, a thing contrary to strict rules of Professional conduct. (With regard to this charge, we do not learn that it was Mr. Brown who performed the operation, and we must not make him responsible for the misdoings of persons who imitate him.) 3rd. That the operation was followed by three years of "almost ceaseless anguish." We say again, that with the knowledge of these charges against the operation, Mr. Brown would have done well to have given his readers a salutary caution. It is not every Surgeon who may have the skill in diagnosis requisite to justify the operation, or the self-control to resist the suggestions of the clergyman, if, as the *Church Times* says, these reverend pastors begin to interest themselves in this department of physical morality. Anyhow, we can but fear that great obloquy must fall on the Medical Profession, if the custom of proposing such an operation, so degrading to the subject of it, and of making the preliminary inquiries, should become too common.

GENERAL CORRESPONDENCE.

THE RECENT CASE OF CÆSAREAN SECTION.

LETTER FROM DR. R. GREENHALGH.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to thank you for your flattering comments on my Cæsarean case at page 370 of your valuable journal of April 7, 1866. It may interest you and your readers to learn that the whole of the abdominal wound healed by the first intention, that my patient was able to leave her bed on the 12th day, and that she left town for Essex on the 22nd day after the operation. My patient further volunteered the following statements: that she had never felt so well at the same time after her three previous natural confinements, and that she believed the operation had cured her of the cancerous disease, as she had no pain, no fetid discharge—in short, no symptoms whatever of any internal disease. It is my intention to publish full details of the case as soon as my occupations will permit.

I am, &c.,

77, Grosvenor-street, W, April 25. R. GREENHALGH.

CHOLERA QUARANTINE.

LETTER FROM DR. JAMES MCCRAITH.

[To the Editor of the Medical Times and Gazette.]

SIR,—If the following observations concerning "Cholera quarantine" seem of sufficient importance or interest at this moment, when a cholera congress or conference is sitting at Constantinople, you will give them a place in your columns.

Cholera is an infectious disease, and the sphere of its infection is more extended than that of most other diseases in the category to which it belongs. Experience has demonstrated the utter inefficiency of quarantine, as at present put in practice, to stop its march. This depends on the sphere of its infection being so extended. The infection may, I conceive, be carried a considerable distance by currents of air, up drains, along corridors, etc., etc. It may also be carried by water, and the dejections being so abundant, the infection from one case may be propagated widely. Such I believe to be the reason why present quarantine is ineffectual against it. I believe in perfect isolation,—that is, "perfect quarantine;" but in Europe, or wherever trade and commerce exist, this quarantine, it is evident, cannot be put in practice. The cure would be worse than the disease; the suffering inflicted thereby worse than any the disease could cause.

The disease, as a rule, though there are many exceptions, attacks a patient only once. This explains why, on a first attack, there are many more attacks and deaths than on any succeeding occasion,—generally as three to one. I believe that every one in a town who has had an attack of diarrhœa, has really passed through cholera, if the disease be prevailing in such town at the time. Like other diseases of like nature (scarlatina, for instance), when epidemic, some have it slightly (scarcely count themselves ill), others severely, and die thereof, but all remain with an immunity against second attacks.

Why, if so infectious, do we find it confined to one quarter of a town; why pass over intervening towns in its march; why, as is asserted, attack all the houses at one side of a street? We do not know, I would answer; the instances are certainly rare where it acts so capriciously; and scarlatina and small-pox do the same. Currents of air blowing steadily in one direction, more especially if the drains flow in the same direction, would in a great degree explain these exceptional circumstances.

Now, all this being premised, there is, I believe, one very effectual way of proceeding in our power to stop cholera, and it is the following:—Establish an efficient sanitary commission, with full powers, at Mecca, and stamp out the disease there. Cholera has invariably come to Europe from Mecca. The disease, from whatever quarter of India (its birthplace) it may have come, passes through Mecca. It first comes there, and there it might, could, and should be met. All the governments of Europe should combine to establish an efficient sanitary police at Mecca. If all the smuggling of exciseable articles took place from thence, and the revenue of the different states suffered severely thereby, as their health and lives do from cholera, they would not be long in devising an effectual Custom-house check to put a stop to such. But the Profession knows well that it is easier to cheat a man out of his life than out of sixpence. The Indian Government should "put its shoulder to the wheel," and strictly enforce a rule "prohibiting all pilgrimages to Mecca from infected localities. Unfortunately, it is at such periods of infection that superstition has most power to stimulate mankind to such acts of "devotion" or "propitiation."

On all the great routes leading to Mecca, at one or two days' distance, more especially at the Indian side, and with regard to pilgrims from India, sanitary stations should be established, where a certain number of days should be passed before entering the holy city. If in Mecca itself any suspicion should arise, all further entrance of pilgrims to be stopped for that year. Fortunately the telegraph will do good service in this way. For that year all pilgrimages should be stopped, and the utmost precaution taken with regard to all leaving Mecca for the West. It would not be a bad plan to make the pilgrims from East to West take their turn of coming on alternate years; all from the East (and more especially India) on one year, and all from the West on the following, and so alternately. At all events, it is perfectly possible, and all civilised nations should insist, that measures be taken to stamp out the disease at Mecca. All should assist. Mahomet Ali stamped out plague at Alexandria (its birthplace). We cannot do as much, perhaps, by cholera in India; but, at all events, as it must pass Mecca, we can lay wait for it there, and destroy it. Nowhere else but at Mecca is this possible. Now, once the disease reaches the Mediterranean, it is useless establishing quarantine. When the disease reaches England or France, do either of those countries put their chief towns in quarantine with each other? Is Dublin or Liverpool ever in quarantine with London? or Toulon or Marseilles with Paris? Yet this is what our wise sanitary authorities have done in Turkey. They have put, and most likely will again put, Smyrna and Alexandria in quarantine with Constantinople. Now, if Liverpool is never put in quarantine with London, why should Paris or Constantinople be put so, especially when all experience demonstrates the futility of such proceeding? The quarantine which may be effectual is quite impossible; then why persist in a quarantine which brings nothing but suffering in its train? Abolish all quarantine in the Mediterranean and in Europe, and direct all your measures and all your energy to Mecca and India, as far as pilgrims to Mecca from thence are concerned, and save

all the unnecessary expense, all the hindrance to commerce, all the loss of revenue, all the suffering and loss of life even, which the present system entails. You have all the mischief centreing in Mecca, all the enemy collected there—surely means can be devised for crushing him there. If allowed to escape from Mecca, every day's journey the enemy makes will render his capture or destruction a thousand times more difficult.

The Conference at Constantinople will very likely be made a political tool of. There will be crochetty heads amongst the number—one-idea men—and probably a system will be elaborated most injurious to the interests of Turkey. This may suit in certain regions politically. English trade and commerce will suffer by any other system than the one I have given a sketch of. I speak from experience, having seen many lives sacrificed by such conferences of many nationalities; they end by compromises, than which, in the present case, nothing can be more disastrous.

I am, &c.,
JAMES MCCRAITH, M.D., F.R.C.S.

Smyrna, April 18.

LANCISI AND THE CATTLE PLAGUE.

LETTER FROM DR. W. O. MARKHAM.

[To the Editor of the Medical Times and Gazette.]

SIR,—Permit me to point out a somewhat important historical error which Dr. Farr has made in his reading of Lancisi. Dr. Farr has used, as an illustration of his theory of the natural progress of the Rinderpest epidemic, the supposed fact that in the epidemic at the beginning of the last century, it ran its course in Italy in nine months—arose, spread, and disappeared—and he quotes Lancisi as his authority. Now, Lancisi tells a very different tale; and so far from his history corroborating Dr. Farr's theory, it does precisely the reverse. The cattle plague, Lancisi tells us, first appeared in Italy (in the Po district) in 1709, and continued its ravages there until 1713. It is quite true that the disease was extinguished in the Roman States in nine months, but Lancisi expressly states that Rome and the Campagna were thus freed from the disease solely by reason of the energetic measures adopted by the Sacred College for its suppression; and by way of warning and contrast, he refers to the fact that in other parts of Italy, where no such stringent measures were carried out, the disease raged for four years—until, in fact, it had nearly devastated the country. You will see from this that Dr. Farr's main illustration goes exactly against his doctrine.

I am, &c.,
W. O. MARKHAM.

THE WORKHOUSE INFIRMARY MOVEMENT.

LETTER FROM MR. BERKELEY HILL.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your "Editorial" of the 21st April on the Workhouse Infirmary movement you make some grave complaints against the promoters of that movement.

Some words of explanation from one who, interested like yourself, has carefully watched its proceedings, will, I trust, show you that your strictures have been passed in misapprehension. You accuse the Association of "beginning this movement by wounding the feelings of noblemen and gentlemen whose benevolent devotion to the sick and poor of their own parish is unquestionable." The Association, while recognising it, has nothing to do with the benevolence which no doubt actuates many of the guardians in the discharge of their duties, but it has set itself the task of calling public attention to the prevailing condition of Workhouse Infirmaries, which, being incontestably bad, reflects great disgrace on the present administration of the Poor-law. In doing this the Association has carefully avoided imputing blame to individuals, or even to corporate bodies, otherwise than by publishing the faults of their management. And hitherto no Board of Guardians has been able to disprove any single statement of their mismanagement published by the Association. The fact that some few Boards of Guardians are free from blame in the performance of their duties is doubtless true, but that does not exonerate the majority of them.

The "second act of injustice, no doubt an unintentional one," is, you say, an attempt on the part of the Association to lower the public estimation of the Workhouse Doctors, and, moreover, charge them with sparing the supply of drugs to their patients in order to increase their own emoluments. This would be an act of very great injustice towards a most hard-working, much-enduring body of men, but it has not been committed by the Association, which, on the contrary, has spoken with the greatest respect for the Poor-law Medical officers; it has urged most strongly that they shall be more highly paid, their duties much diminished, and that they shall be relieved from the cost of the medicines supplied, a charge which the Association has shown, at the present rate of payment, must in many cases equal, and in all form a large part, of their salaries. If this treatment can be construed into advocating "that the future Medical officers are to be unsalaried, and that general Practitioners who cannot afford unsalaried places are to be shut out," I am unable further to defend the views of the Association on this subject.

The suggestions for better nursing, also, do not meet your approval. You ask if it is "intended that no pauper is to do any of the functions of a nurse?" You suggest that "many infirm or decrepit family servants are still competent to do some of the nursing the sick require." Surely an infirm or decrepit person requires nursing and attendance himself, and has only been admitted into the Workhouse when his services have become valueless; if he is still in the position to perform the toilsome and delicate duties of a nurse, he would seek a more remunerative field for his labours outside the Workhouse. It is insisted by the advocates for reform, and I feel convinced you will on reflection agree with them, that satisfactory nursing can only be procured by employing persons trained to their duties and enjoying bodily health and vigour.

You next imply that the Association has blamed the Guardians because the Workhouses are overcrowded and insufficient space is allotted the inmates.

This is again a misconception; the Association has pointed out how monstrous it is that the sick pauper should be granted less than half the space found necessary for the sick soldier or sick felon, and less than one third that allotted to each bed in all our public Hospitals, but in doing this the blame was thrown upon the system, not on the individuals engaged in working that system.

No one, I apprehend, dreams of imputing the present faulty method of representation of the people in Parliament to the evil conduct of individual members of the House of Commons, but rather to the imperfect means at the command of the nation for representing its opinions and interests. So the Association urges that legislation is necessary to amend the present rules for governing the sick poor. The Guardians may, I think, justly shelter themselves under the rule of the Poor-law Board, which permits this small amount of cubic space to be maintained.

In your concluding paragraph you express an intention of returning to the discussion of the Association's proposals; I hope you will do so, that they may have the benefit of criticism in your columns, and that we may have the advantage of your opinion in reviewing them.

I am, &c.

14, Weymouth-street, April 21. BERKELEY HILL.

ROYAL INSTITUTION OF GREAT BRITAIN.—The annual meeting was held on Tuesday, May 1, Sir Henry Holland, Bart, M.D., D.C.L., F.R.S., President, in the chair. The annual report of the Committee of Visitors for the year 1865 was read and adopted. Thanks were voted to the President, Treasurer, and Secretary, to the Committees of Managers and Visitors, and to Professor Faraday, and the other Professors, for their services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—*President:* Sir Henry Holland, Bart., M.D., D.C.L., F.R.S. *Treasurer:* William Spottiswoode, Esq., M.A., F.R.S. *Secretary:* Henry Bence Jones, M.A., M.D., F.R.S. *Managers:* Warren de la Rue, Esq., Ph.D., F.R.S., Sir George Everest, C.B., F.R.S., John Hall Gladstone, Esq., Ph.D., F.R.S, William Robert Grove, Esq., M.A., Q.C., F.R.S., Cæsar H. Hawkins, Esq., F.R.S., Sir John Lubbock, Bart., F.R.S., Pres. Ent. Soc., John Carrick Moore, Esq., M.A., F.R.S., William Pole, Esq., M.A., F.R.S., William Frederick Pollock, Esq., M.A., Lewis Powell, M.D., F.S.A., Lt.-Gen. E. Sabine, R.A., D.C.L., LL.D., Pres. R.S., Earl Stanhope, D.C.L., F.R.S., Pres. Soc. Antiq., Joseph William Thrupp, Esq., Charles Wheatstone, Esq., D.C.L, F.R.S., Colonel Philip James Yorke, F.R.S.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 24, 1866.

A paper, by Dr. JOHN HARLEY, was read on

A CASE OF HYDATID DISEASE OF THE LIVER, AND REMARKS ON THE TREATMENT OF SIMILAR TUMOURS.

Mr. B. G——, aged 29, the subject of an enormous hydatid tumour of the liver, had been under the author's care for more than two years before final proceedings were taken for his relief. In June, 1863, the lower part of the chest and abdomen were greatly distended by a dull, elastic, fluctuating tumour; the lungs and heart were displaced upwards, and the rounder lower border of the tumour could be felt two fingers' breadth above the pubes and Poupart's ligament. The centre of the swelling was at the epigastrium; the hypochondria were enormously distended, and the lower parts of the chest-wall were widely spread outwards. The patient was much deformed by the swelling, and he measured forty inches and a half around the body midway between the ensiform cartilage and the umbilicus, where the tumour was most prominent. During the next two years this measurement gradually increased to forty-two inches and five-eighths, and the tumour descended a little from the chest. On July 17, 1865, the patient was seized with a severe pain in the right iliac region. On the 26th the measurement round the body at the line above indicated was forty-four inches and a half, and, fearing rupture, the author resolved to puncture the tumour, and next day Mr. Bright, of Forest-hill, introduced a medium-sized trocar at a point in the median line midway between the ensiform cartilage and the umbilicus. On withdrawal of the trocar clear fluid like water was ejected with great force, and nineteen and a half pints, containing many minute hydatid cysts, were removed. The last two pints were of a bright yellow colour from admixture with bile. The whole tumour appeared to be in an actively growing condition, and a little of the turbid fluid presented, when examined, vesicles about one-thirtieth of an inch in diameter, with from five to nine scoliers attached to them; very numerous free scoliers, some with retracted, others with everted hooklets; and hundreds of detached hooklets. The patient was greatly relieved by the operation. The subsequent treatment consisted in maintaining permanent communication between the interior of the sac and the surface of the body. The canula was retained for the first forty days, and its place was then supplied by an elastic catheter, and the passage was gradually dilated by the introduction of others until three No. 12 elastic catheters could be introduced within the sac. The catheters were constantly retained six or nine inches within the sac. A free discharge of bilious fluid (about twenty ounces daily) and a few fragments of hydatid membrane continued, with occasional slight obstruction, up to September 16, and the patient progressed without a single bad symptom. On the 16th severe febrile symptoms with slight jaundice arose from retention of the discharge. The evacuation of a large quantity of fetid fluid caused great amelioration, but on the 17th considerable hæmorrhage from the liver occurred, and the sac became distended with blood. Grumous blood and cyst-wall continued to be discharged, and oozing of blood into the sac continued for some days. On September 28, and again on October 11, large thick fragments of dense, blood-stained fibrous tissue—evidently portions of the sac which had been connected with the liver—came away. After the hæmorrhage had been controlled the discharge consisted of diluted bile, and after the sac was washed out, half an ounce of pure ropy bile could for many days be collected as it flowed from the catheter in the course of a few minutes. About this time the discharge averaged sixteen ounces daily. On October 11, after the opening had been dilated so as to admit three No. 12 elastic catheters, the whole of the remaining cyst-wall, which had caused continued obstruction to the discharge, was evacuated in the form of yellowish-green laminated membrane of various thicknesses. Henceforward there was no difficulty in completely washing out the sac. For the first four months the alvine secretions were almost continuously destitute of bile, and they were occasionally very offensive. On November 25 the discharge had decreased to three ounces, and the cyst was contracted into the right hypochondrium and epigastrium. On December 12 the last trace of bile disappeared from the now purulent discharge, and the catheter was finally removed on the 22nd, when the cyst was completely contracted and obliterated. The patient resumed his usual occupation on January 1, 1866, and a few days afterwards the fistulous opening was cicatrised. The patient has improved in health up to the present time. The spleen remains a little enlarged, but the lungs have recovered from their compression, and the heart is restored to its normal position. Throughout the treatment the abdomen continued flaccid and free from pain. Now the liver dulness is normal, and only a thickened cord-like mass can be felt in the epigastrium. The patient is a little stouter than he was before the operation, and the measurement around the same part of the body is now thirty-one and a half, which is thirteen inches less than the measurement on the day of the puncture, and nine inches less than when the patient first came under the author's notice in June, 1863. The main difficulty in the treatment consisted in the evacuation of the membranes of the ruptured hydatids. The utmost attention and perseverance were required to overcome the impediments to the discharge which these membranes continued to offer so long as any portion of them remained within the sac. While endeavouring to secure free discharge of the fluid formed within the sac, the author had two other objects in view—viz. (1), to prevent decomposition of the fluid within the sac; and (2) to excite inflammatory action in its interior. These were attained by the injection of iodine and creasote water; one drachm of the compound tincture of the iodine of the London Pharmacopœia was injected into the cyst three days after it was punctured. This was continued morning and evening for about a week, when the amount was increased to two drachms twice a day. From the 14th to the 23rd of August one ounce of the tincture was injected daily, and the evening injection was then discontinued on account of profuse night-sweats which the injection of so much iodine appeared to produce, and six drachms were injected every morning only until September 17, when it was discontinued altogether. During these seven weeks upwards of thirty ounces of the tincture of iodine, diluted with an equal quantity of creosote water, were thrown into the sac. No pain was ever produced, but when the sac became a little tender a feeling of warmth in the epigastrium followed the injection. When hæmorrhage took place from five to ten grains of nitrate of silver dissolved in a few ounces of water were daily injected for a week, the sac being previously washed out with creosote water. Afterwards the sac was washed out every morning and evening with a solution of sulphate of zinc in creosote water (one drachm to ten ounces). Throughout the treatment the lower part of the chest was supported by a broad laced bandage, and the abdomen was also tightly bandaged, a compress being placed on the right side so as to press the contracting sac towards the right hypochondrium. For a considerable portion of the time during which the patient was under treatment, bile was either altogether absent from the intestine, or it was deficient in quantity. To supply its place twenty grains of inspissated ox-gall were given in the form of a bolus every night at intervals. So long as the discharge continued free the appetite was good, and the bowels acted regularly; and during the greater part of the time the patient took a mixture composed of perchloride or pernitrate of iron and quinine. Having observed this complicated case with much interest, and given it close attention, and subsequently studied the histories of those recorded cases in which cure has been attempted by operative proceedings, the author is convinced of the necessity of observing the following rules in the treatment of hydatid tumours of the liver:—1. They should be punctured above the umbilicus, because the sac, however large, possessing great elasticity, ultimately contracts into the epigastric or hypochondriac regions. 2. As soon as operative measures are determined upon, the sac should at once be punctured with a large trocar, and the canula retained. 3. The canula should be retained until it is loosened by suppurative action and tends to slip out. Its place should then be supplied by two or three elastic catheters, and their size gradually increased until three or four of No. 12 size can be readily introduced. A single catheter or a single very wide silver tube is ineffectual for emptying the sac of its fluid and membranous contents, as the latter form most complete valves for closing the orifice of a single instrument. By using three or more catheters, and advancing the ends of two beyond the others, and causing their eyes to look inwards towards each other, the pliable cyst-wall does not so completely envelope the ends of the instruments, and the fluid runs away through the interstices. 4. To facilitate disintegration of the cyst-

wall, and to excite inflammation and adhesion of the sac, iodine should be freely injected until after some time it produces a sensation of a glow of heat within the sac. Then its use should be discontinued. 5. To prevent decomposition of the fluid within the sac, creosote water (thirty minims to thirty-six ounces) should be freely injected morning and evening. Injected down one catheter it is allowed to flow away by the others, and thus the sac may be thoroughly washed out. 6. After all the cyst-wall has been discharged the sac should be washed out in the same manner morning and evening with a solution of sulphate of zinc in creosote water (two drachms of sulphate of zinc to thirty-six ounces of creosote water). If this or other astringent solution be used before the expulsion of the disintegrated hydatid membranes, they may become hardened by the solution, and their expulsion thus retarded. 7. The previously distended parts must be constantly kept tightly bandaged. It must be remembered that the adhesions of a large hydatid tumour are very extensive, and that if the parts distended by its growth be not brought and retained together, the contraction of the sac will be retarded, if not in some cases prevented. The paper was accompanied by a synoptical table of seventy-nine recorded cases of hydatid tumour of the liver treated by various operative measures, or resulting in rupture through the abdominal walls. From an analysis of these cases, the author has endeavoured to show that obstruction to the discharge of re-accumulated fluid within the sac, and its retention and decomposition, are the chief causes of death in the fatal cases, and he strongly advocates the formation and maintenance of a free communication between the interior of the sac and the surface of the body. The tumour in the case above described was of unusual size, and apparently the largest that has been successfully treated, and yet, apart from the hepatic hæmorrhage and diversion of the biliary discharge, no bad symptom ever resulted from opening it, so long as the contents of the sac were freely evacuated. Since, therefore, so large a tumour can be radically cured by the treatment above detailed, much less danger is to be apprehended when the same treatment is applied to smaller ones.

Dr. Cobbold considered that so remarkable a case as the one just described ought not to be passed over without some discussion. Undoubtedly there was no case on record where so large an hydatid tumour had called forth similar operative procedures. Whilst Dr. Harley was to be congratulated on the successful issue of the case, he (Dr. Cobbold) was of opinion that the measures adopted in this case were not necessary in the more common forms of hydatid tumour of the liver. The case was quite exceptional. Nature often effected a cure by herself. It was seldom advisable to make such large openings. Dr. Harley in the course of the paper had alluded to the circumstance of the patient having been accustomed to eat underdone meat. This habit could have nothing whatever to do with the formation of the hydatid in question. The true explanation of the source of the parasite was very different. The patient probably obtained the larva when he drank (stagnant) water obtained from a locality to which dogs had access. In fact, the prevalence or otherwise of hydatids in any country bears an almost strict relation to the number of dogs permitted to go about at large. It explains the great number of echinococcus cases in Iceland, where dogs are, on other grounds, so essential to the peasant. In Denmark the disease seemed more abundant than in our own country. Dr. McGillivray had recently published twenty cases occurring at the Bendigo Hospital. Probably the disease was rather frequent throughout the Australian colonies. It was a very difficult matter to arrive at any correct estimate as to the actual prevalence of hydatid in this country. Dr. Murchison has told us that "out of 2100 post-mortem examinations recorded at the Middlesex Hospital between April 19, 1853, and August 25, 1865, hydatids were found in only 13, or once in 161 cases; and in only 7 of the 13 cases, or once in 300 cases, could they be said to have occasioned the fatal event." The expression "only" conveys the notion that the number of cases and deaths is small. In Dr. Cobbold's opinion, however, it is rather large. If such an estimate could be accepted as a criterion of the prevalence of this disease throughout the civilised world, it would give us upwards of 100,000 deaths annually from hydatid disease alone. To those who had not gone thoroughly into the subject, such an estimate might appear extremely absurd, yet, independently of the special Hospital data afforded by Dr. Murchison, he (Dr. Cobbold) had, from other considerations, honestly arrived at the conclusion that the above figures were not very much above the mark. In conclusion, to show the many dangers which Dr. Harley's patient had escaped, Dr. Cobbold related the case of a schoolboy who died from the effects of a blow on the right side. The blow was slight, given during play, yet in a very short space of time the boy ceased to exist. The tumour in this lad's case was comparatively small.

Mr. Hutchinson felt much indebted to the author of the paper for the careful narrative of a very interesting case, and for the valuable tables he had collated. He could not, however, wholly agree with the rules laid down for the treatment of these tumours. He preferred an early puncture and closure of the orifice to the plan of delaying an operation to the last moment, and then endeavouring to establish a fistula and to remove the cysts. The latter plan was, he thought, productive of needless risk to the patient in more than one direction. If the tumour had developed to the size described in the author's case, then he admitted that the treatment adopted was the best; but the question he wished to raise was, whether the tumour ought to have been allowed to increase to such dimensions. He next related the particulars of three cases in which he had adopted the plan by puncture with a very fine trocar and closure of the wound. In the first the patient was a woman, under the care of Dr. James Jones, in the Metropolitan Free Hospital, and the tumour of large size, filling the right side of the abdomen. A washhand-basinful of clear hydatid fluid was drawn off through a very small canula. Some inflammation of the cyst followed, and air was secreted into it, but in the course of a fortnight the air had disappeared and the cyst was contracting. The patient recovered perfectly, the tumour wholly disappearing. When seen some months afterwards the woman was in good health. The second case was that of a patient seen in consultation with Dr. Hughlings Jackson and Mr. Marsh, of St. John-street. This woman was extremely ill, and suffered from constant vomiting. She had a large tumour filling the epigastrium, and bulging below the umbilicus. The diagnosis of an hydatid cyst having been formed, after some persuasion, she consented to a puncture, but not until her state had become very critical. About two pints of clear fluid were drawn off. She made an uninterrupted recovery, her symptoms having been at once relieved by the operation. Two months later she was in excellent health, and had no fulness whatever at the site of the tumour. The third case was that of a woman in the London Hospital, under the care of Dr. Parker. The hydatid cyst occupied the epigastrium, and bulged prominently. It had been diagnosed as such both by Dr. Parker and Dr. Hughlings Jackson before he (Mr. Hutchinson) saw the patient. With a very fine trocar, from one to two pints of clear fluid containing echinococci were drawn off. The cyst refilled during the next fortnight, but never became painful. Afterwards it again diminished, and at the present date—six months after the puncture—she is in excellent health, and there is no fulness whatever to be discovered in connexion with the liver. In all these three cases the simple evacuation of the fluid sufficed to destroy the vitality of the parasites, and was followed by the shrinking up of the cyst. In none of them were any of the secondary cysts removed. Mr. Hutchinson stated that he used an exploring trocar of the size of No. 1 catheter, and allowed as much fluid to escape as would freely do so, but was careful not to make any rough pressure. In withdrawing the canula, he always did so quickly, and with the orifice closed by a finger, so as to prevent the risk of any fluid escaping into the peritoneum. He did not feel to care much whether adhesions existed or not. In two of his cases it was certain that they did not. Mr. Hutchinson added that he thought the estimate of 1 death in 300 as due to hydatids was too high an estimate as regards English practice. He had seen a few cases of death from these tumours, quite sufficient to show in a strong light the importance of Surgical treatment; but still they were very rare. In common with all who make post-mortems, he had met with many instances of collapsed—spontaneously-cured—hydatids in the bodies of those who had died of other diseases. In one case under his own care he had, he believed, witnessed the spontaneous cure of a very large hydatid tumour. The patient was a young Irishman, and the tumour, which almost filled his abdomen, certainly contained from one to two gallons. The operation was repeatedly urged upon him, but he refused to consent. At length he was laid up with an attack of severe pain, which led to apprehensions that the cyst would burst; still he refused to have it punctured. After this the cyst diminished to half its former size, and subsequently the man returned to his work,

and Mr. Hutchinson had been assured by the man's sister that the tumour eventually disappeared. He had not, however, had an opportunity for verifying this statement himself. He concluded his remarks by relating the particulars of a case still under his observation, in which a girl of 5 years old had become the subject of an hydatid tumour in the liver. He had watched this patient for two years, during which the parasite had slowly increased. It appeared still, however, to have a thickness of liver-tissue in front of it, and he had deferred the puncture. The great question as to the puncture of these tumours was when should it be done? Since a large number undergo spontaneous cure, the Surgeon ought not hastily to interfere; still, however, he (Mr. Hutchinson) felt confident that an early operation by the method he had recommended was far preferable to the plan of waiting until the patient's life became endangered.

Dr. A. P. Stewart regretted that Dr. Greenhow and Dr. Murchison were not present to speak on cases of hydatid disease which had been under their care in the Middlesex Hospital. Dr. Stewart then alluded to cases of hydatid of the liver in which there had been a great diminution in the size of the tumour, and referred to a striking case in illustration. In the instance he related the patient afterwards died of peritonitis, after exposure to cold. A large hydatid cyst was found in the liver at the autopsy. Dr. Stewart then referred to the case of a patient who had been sent in for operation by Dr. Murchison, but in this instance there was a consultation, and the patient being afraid of the suggested application of caustics, left the Hospital the same day. She afterwards went to another Hospital, but soon left it also, and afterwards died at home. There had been, Dr. Stewart said, four cases of operation for hydatid tumour of the liver, and in each case the patient did well after the operation. Dr. Stewart referred to another case now under his care, in which there had been bulging of the chest wall. When this bulging had subsided, the abdomen increased in size, and he intended in this instance to encourage the operation. There did not seem, Dr. Stewart said, to be any material risk in the operation.

Dr. Hare had listened with great attention to the paper and to the observations on it. He alluded expressly to the observation on the diminution or disappearance of such swellings. In the instance of a patient under his (Dr. Hare's) care, who had two hydatid tumours, one of them disappeared and the other decreased in size. In this case he had hesitated to operate, because he had not watched the patient long enough, and because the liver tissue over the cyst was too thick. Dr. Hare then remarked that hydatid tumours of the liver were often multiple. It was, he said, very important to know whether we have to deal with one or more. In some cases, when the tumours are of good size, we may determine the question. Dr. Hare here entered into the points by consideration of which a diagnosis might be made, and related a case in which he had declined to recommend an operation, on the ground that there was more than one cyst. At the autopsy, three cysts were found, one of them being enormous. Dr. Hare then spoke of the occasional existence of peritonitis. This he thought ought not to be interfered with by treatment, as the existence of adhesions rendered the operation of tapping more easy.

In answer to the foregoing remarks, Dr. Harley stated that the duration of simple puncture advocated by Mr. Hutchinson and Dr. Stewart, and so successfully practised by the former, was fully considered in the analysis of the synoptical tables appended to the paper. It appeared therefrom that radical cure had been effected in several cases by this mode of treatment, but that it was unsuccessful when applied to tumours of greater capacity than one or two pints. Re-accumulation of fluid was a common result of tapping under any circumstances, and might in any case cause sufficient distension of the cyst to rupture it; and since capillary puncture did not appear to be a safer mode of proceeding than any other, to say nothing of the ulterior object of effecting a radical cure, he preferred in any case retaining command over the fluid in the sac by inserting a full-sized trochar, and preserving an open passage. Dr. Harley would not at so late an hour detain the meeting by further observations, but would, in conclusion, direct the attention of the Fellows to the morbid preparations (hydatid cyst wall, fibrinous sloughs, biliary discharge, and specimens of the echinococci) upon the table, and informed them that the subject of the paper was present amongst them, and was quite willing to submit himself to examination if any one wished it.

THE PATHOLOGICAL SOCIETY.

Tuesday, March 20.

Dr. Sibson, Vice-President.

A report, by Mr. Hulke and Mr. Sibley, on Mr. Curling's specimen of disease of the testes.

The reporters gave a minute description of the microscopic structure of the disease. The disease was situate betwixt the seminal tubes, which were in a state of degeneration, and were filled with granular matter. The tissue betwixt the tubes was made up chiefly of nuclei, larger than blood corpuscles, with a few cells and a few fusiform fibres. Most of the nuclei contain a single nucleolus. The reporters added, "The disease differed in structure from a typical—*e. g.*, a scirrhous—cancer in the remarkably uniform infiltration of the diseased tissues among the natural structure, and also in the absence of the varied forms of cell structure seen in such cancers. At the same time such an exuberant formation of cell elements, with but little tendency to the development of fibre, and the general dissimilarity of the tissues to the natural structure of the testicles, cannot be regarded without suspicion of malignancy."

Mr. Curling said that the disease in this case presented remarkable features, different in some respects from anything he had recognised before. He would particularly call attention to its double character. It was extremely rare to find diseases not originally constitutional—such as carcinoma, enchrondroma, and cystic—attacking both testicles at the same time. He could find only one instance of encephaloid cancer attacking both these organs simultaneously, a case of Professor Denonvilliers, and he knew of no case on record of double cystic disease. Another circumstance of interest was the slow destructive power of the morbid growth. In carcinoma of the testicle the tubular structure sometimes remains intact for a time in consequence of being spread over the surface of the tumour, but when cancerous disease commences in the body of the gland, the tubuli seminiferi are rapidly destroyed, and all distinction between the testicle and the epididymis is soon lost. But in this specimen, though the disease occurred at an early period, both in the testicle and in the epididymis, the distinction between the two parts was well preserved after fifteen months, and the tubules, though degenerated, were largely present, and might be recognised even with the naked eye. The great abundance of cell structure, and the outgrowth in the spermatic cord, indicate a probable recurrence of the disease in the internal parts, and led Mr. Curling to conclude, with Messrs. Sibley and Hulke, that the tumour was likely to prove to be malignant.

Dr. Dickinson showed a specimen of

MALFORMATION OF THE LIVER.

The peculiarity of this liver was that the right and left lobes were quite distinct.

Dr. Cobbold remarked on the interest of the case. In the lower vertebrata the liver was often divided into many parts. The specimen tended to resemble the normal condition of the liver in the lower animals.

Dr. Dickinson showed specimens of

DISEASED CARDIAC VALVES FROM CASES OF PYÆMIA.

The specimen was from three cases. The valves seemed to be infiltrated with what looked like pus, and in some of the specimens the valves were nearly broken down in their centres.

Dr. Cobbold showed a specimen of

NEW HUMAN TAPEWORM.

Dr. Cobbold remarked that the existence of this parasite as a new and hitherto undescribed species was founded on a preparation preserved in the museum at the Middlesex Hospital. In the old MS. catalogue it was marked *Tænia solium*. At first he believed it to be an example of Kuchenmeister's ridged variety of tapeworm from the Cape of Good Hope; but he since satisfied himself that this could not be the case. The specimen now exhibited to the Society Dr. Cobbold proposed to name *Tænia lophosoma;* its specific characteristics, so far as the specimen enabled us to judge, standing as follows:—"Strobila of moderate length, probably not exceeding nine feet; average breadth of the segments one-fifth of an inch their greatest thickness being one-thirteenth; final mature proglottides from a half to three-quarters of an inch long; reproductive papillæ very prominent, uniserially disposed at the left margin throughout the entire chain, imparting to most

of the segments a pentangular figure; average diameter of the eggs about 1-850th of an inch." The head and neck were wanting. If it was thought that this was only a variety of either the beef or pork tapeworm, Dr. Cobbold objected to that view from the circumstance that in all the monstrous forms of *T. solium* and *T. mediocanellata*, hitherto met with, the position of the reproductive papillæ had irregularly alternated. Dr. Weinland, of Frankfort, had already described one small species of human tapeworm with the papillæ uniserially disposed. The present species, however, cannot be identical with Weinland's *Tænia flavopuncta*. In Weinland's opinion, we ought to elevate such forms into a new genus. (See his "Beschreibung Zweier Neuer Tænioiden aus dem Menschen." Jena. 1861.)

Dr. CAYLEY showed a specimen of

OBSTRUCTION OF THE THORACIC DUCT.

A young man, nineteen years of age, had been ill five or six days. He died of peritonitis, which had been caused by extravasation from rupture of the receptaculum chyli. The duct was much dilated, and the obstruction was found to be at its point of entry into the subclavian.

Dr. QUAIN, for Mr. Williams, brought forward a specimen of

RUPTURE OF AN ANEURISMAL DILATATION OF ONE OF THE BRANCHES OF THE PULMONARY ARTERY.

Mr. Williams gave the history and described the specimen. A man, thirty years of age, had had a cough five months. He had been ill nine months, and was much emaciated. He had not brought up blood before his admission. He died suddenly of hæmoptysis, although the quantity of blood expectorated only amounted to two or three ounces. At the autopsy, there were several cavities found in the lung full of blood, the source of which was a rupture of a dilatation of a branch of the pulmonary artery. A similar dilatation was found on another branch.

(To be continued.)

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The lowing gentlemen having undergone the necessary Examinations for the Diploma were admitted Members of the College at a meeting of the Court of Examiners on the 26th ult., viz.:—

Messrs. Barnabas Walter Lamb, Stourport, Worcestershire; James Brierley Hughes, Congleton, Cheshire; William James Tattersall, Bacup, Lancashire; Henry Beaumont Pattinson, Heavitree, near Exeter; and Isaac Coalbank, Old Dalby, Leicestershire, students of St. Bartholomew's Hospital. Clement Samuel Blythman, Swinton, Yorkshire; William Monckton, Brenchley, Kent; Frederic William Parsons, Bayswater; and Charles Kelly, Market Deeping, of King's College. William John, Haverfordwest; and William Joseph Richards, Redruth, Cornwall, of Guy's Hospital. Moses Taylor, Walsall, Staffordshire; and James Lawson Cooke, Market Drayton, of the Birmingham School. Henry Child Buckley, Llanelly, Carmarthen, of St. George's Hospital. Thomas Edward Bowkett, Poplar, of the London Hospital. Arthur Hill, L.S.A., Pimlico, of the Westminster Hospital. Edward Malins, Liverpool, of the Edinburgh School, and Alexander Riddoch Gray, M.A. and M.B. Univ. Aber., Aberdeen.

At the same meeting of the Court, Mr. David Bowen Thomas, of Greenwich Hospital, passed his Examination for Naval Surgeon. This gentleman had previously been admitted a Member of the College, his diploma bearing date April 11, 1861.

The following gentlemen were admitted Members on the 27th ult, viz.:—

Messrs. Samuel Key Watson, Jersey; George Rolph Raine, Billericay, Essex; Joseph Riley, Barnes, Surrey; William French Thurston, Nottinghill; and William Nathaniel Hiron, Chipping Camden, students of Guy's Hospital. Joseph Smith, Weaverham, Cheshire; Richard Walter Owen Withers, Shrewsbury; and Robert Temple Wright, Norwich, of King's College. Edmund Exell, Yeovil, Somerset; Arthur Walter Read, Coventry; and Martin Luther Heelas, Wokingham, Berkshire, of St. Bartholomew's Hospital. Henry Albert Richardson Thomson, Spencer-square; and George Arthur Kenyon, Doncaster, of St. George's Hospital. George Airey, Bayswater; and James Augustus Hayden, High Wycombe, of Charing Cross Hospital. Joseph Oakman, Wimbledon, of the Westminster Hospital. George Chapman, Brierley Hill, Staffordshire, of the Birmingham School. William Davies, Llanpumpsaint, Carmarthen; James John Ilott, L.S.A., Bromley, Kent, of the London Hospital. Augustus Constable Maybury, Frimley, Surrey, of St. Thomas's Hospital. George Newman Dunn, Dublin; and William Carter, M.D. Edin., Mid Calder, near Edinburgh.

It is stated that 12 out of the 98 candidates who offered themselves for Examination failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their Hospital studies for six months.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 1st inst., and when eligible will be admitted to the Pass Examination:—

Messrs. George Vaudrey, William Turner, E. Sainthill Pearse, Alfred C. Taylor, Rawland E. Daniel, John G. Hurford, John Guy and J. Aylwin Beaan, students of Guy's Hospital. W. Bezley Thorne, Frederick H. Waylen, Thomas E. Scobell, Frederic E. Aldrich, Edward R. Johnson, and Charles H. Newstead, of St. Bartholomew's Hospital. Peter A. Young, A. Dunbar Walker, and Robert W. Foss, of Edinburgh. A. Justus Baker and Herbert N. Chilcote, of the Westminster Hospital. Alexander P. Fiddian, of King's College. Richard Minors, of St. Mary's Hospital. Henry G. Hall, of Dublin. Robert Pollock, of University College. George Moore, of Birmingham, and J. Bills Southam, of Manchester.

The following gentlemen passed on the 2nd inst.:—

Messrs. Essex T. Williams, Richard A. Rouse, Baron A. Rugg, Dean Longrigg, and William J. Scott, students of University College. Edward E. Rastrick, Robert Harris, L. C. Achille Carré, and H. Eccles Walker, of Guy's Hospital. Edward T. Pearce, William E. Phillips, James E. Peirce, and Frederick H. Moses, of St. Bartholomew's Hospital. Washington Lee, Charles F. Bedford, and Saltern G. Littlejohn, of St. Thomas's Hospital. M. Welldon Rice and H. Johnstone Pritchard, of St. George's Hospital. E. Buchanan Baxter, of King's College. Alfred Steward, of Manchester. Henry Cox, of Birmingham. Horace Chaldecott, of the Middlesex Hospital. Charles H. Furnivall, of the Westminster Hospital. Aaron Atkins, of the London Hospital. William MacDonald, of Edinburgh. Gordon Archdall, of Dublin, and William Henderson, of Glasgow.

The following gentlemen passed on the 3rd inst.:—

George W. Brumwell, John Carr, George R. Munn, Arthur H. Morrill, F. Viney Cardozo, and Charles R. Brown, students of Guy's Hospital; Arthur F. Greenhill and Francis C. Brett, of St. George's Hospital; E. Hawley Woodward and Cecil A. Bindley, of Birmingham; J. L. W. Forder, of University College; Edward Landwell, of Charing-cross Hospital; David E. Morris, of St. Bartholomew's Hospital; G. F. J. Schott, of Gottingen; A. Perry Newman, of Dublin; and Henry Godson, of Manchester.

It is stated that 32 out of the 100 candidates who offered themselves for examination failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their studies for three months.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 26, 1866:—

George Bown Millett, Penzance, Cornwall; James Haslam, Church-road, Islington; John Hilton, Croston, near Preston; Archer Farr, Dunstable, Bedfordshire; John Chamberlin Eaton, 5, Fitzroy-square; William Square, Plymouth; William Greenwood Sutcliffe, Ashville-place, Battersea-park; Edward Butler Ruttledge, Ingatestone, Essex.

Of the seventy-one candidates who presented themselves at the Preliminary Examination in Arts on April 27 and 28, 1866, the following gentlemen passed and received Certificates of Proficiency on General Education, viz.:—

G. P. Applin, Jas. Wm. Ayres, John James Barnes, Robt. Holme Betts, John Hanbury Bonser, Henry Bradford, Henry Brimacombe, Joseph Brice Bunny, John E. B. Burroughs, J. H. Chapman, Frederick Cheesman Clark, A. C. Collinson, Thos. Arthur Crockle, John Ellis Edwards, Joseph William Ekens, George Ellis, Thomas Evans, Edward Fayrer, Thorpe William Fowke, Richard Galpin, Alfred Haines, Napoleon A. R. Harrison, Edward John Hutchings, John Ingham, Hildreth Kay, John Lang, Willoughby George Levy, William Livesay, Isidor I. Lyons, Charles Martin, Thomas May, W. A. Maybury, E R. Morgan, Malcolm Morris, W. J. Newbury, Frederick Stephen Palmer, Arthur Daniel Parsons, Sydney Parsons, Frederick George Passmore, Edgar J. Pugh, Charles Sayer, Thomas Snaith, Vincent Stone, P. F. B. Stoney, John Sutcliffe, Roland F. Tuckett, Frank Wacher, John Barnley Walker, Thomas Law Webb, James Scaly Whitaker, Herbert Workman.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

AIREY, G., M.R.C.S.E., has been appointed House-Surgeon to the Charing-cross Hospital.

EAGER, R., M.R.C.S.E., has been appointed an Honorary Medical Officer to the Surrey County Hospital, Guildford.

GLEESON, M. A., has been appointed Assistant to the Resident Medical Officer of the Holloway and North Islington Dispensary.

HARRISON, S. N., L.R.C.P. Edin., has been appointed Surgeon-Accoucheur to the Kilham Lying-in Dispensary.

KEMPTHORNE, H. L, M.D. Lond., has been elected Assistant Medical Officer to Bethlem Royal Hospital.

NORRIS, HUGH, L.R.C.P. Edin, has been appointed Resident Medical Officer to the Wiveliscombe Dispensary.

TAYLOR, H. S., F.R.C.S.E., has been appointed an Honorary Medical Officer to the Surrey County Hospital, Guildford.

BIRTHS.

BALFOUR.—On April 24, at 18, Lynedoch-place, Edinburgh, the wife of G. W. Balfour, M.D., of a son.

BLACKMORE.—On April 26, at 21, Douglas-road, Canonbury, the wife of J. T. Blackmore, L.R.C.P. Edin., of a daughter.

COTTER.—On April 19, at Stocks-hill, Holbeck, the wife of A. H. Cotter, L.R.C.P., of a son.

FOLKER.—On April 18, at Hanley, Staffs, the wife of W. H. Folker, M.R.C.S.E., of a daughter.

GARRINGTON.—On April 25, at 22, St. George's-square, Portsmouth, the wife of A. M. Garrington, M.D., of a daughter.

KNAGGS.—On April 29, at Osborne-place, Manchester, the wife of H. Knaggs, Staff Assistant-Surgeon, of a daughter.

MCCONVILLE.—On April 26, at 99, Douglas-street, Glasgow, the wife of John McConville, M D., of a daughter.

MONCKTON.—On April 26, at Alrewas, Staffs, the wife of W. Monckton, M.R.C.S., of a daughter.

WHITLING.—On April 24, at Croydon, the wife of H. T. Whitling, M.R.C.S., of a daughter.

WYMAN.—On April 26, at the Grove, Highgate, the wife of W. S. Wyman, M.D., of Hatfield Broad Oak, of a son.

MARRIAGES.

BREW—LENCY.—On April 21, at Bray, H. M. Brew, M.D., to Henrietta, daughter of John Lency, M.D.

HILL—CHINERY.—On April 26, at St. Thomas's, Lymington, W. R. Hill, M D., to Mary Elizabeth, eldest daughter of E. Chinery, Esq.

ROBINSON—BRIGHT.—On April 23, Dr. Craven Robinson to Sophia, youngest daughter of the late M. Bright, of Sheffield.

DEATHS.

GITTENS, JOSHUA MAYERS, M.D., at Barbadoes, West Indies, on April 3, aged 53.

GRAPE, W. P., M.R.C.S., at Bromyard, on April 16, aged 86.

HARRISON, JOHN, M.D., at Highgate, on April 28, aged 33.

HODEN, HENRY, M.S.C.S., at Sedgley, near Dudley, on March 14, aged 58.

REES, N., M.R.C.S.E.; of Llandilo, Carmarthenshire, on April 11, aged 78.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Dewsbury Union.—The Workhouse is vacant. Salary £40 per annum.

Leigh Union.—Mr. James Craston has resigned the Atherton District; area 7590; population 14,045; salary £45 per annum.

APPOINTMENTS.

Alcester Union.—Joseph Morris, M R.C.S. Eng., L S.A., L.R.C.P. Edin., to the Inkberrow District. John W. Leacroft, B.M. Marischal Coll., Aberdeen, L.S.A., to the Feckenham District.

Chard Union.—Frank H. Browne, M.R.C.S.E., L.S.A., to the First Ilminster District.

Droitwich Union.—John W. Leacroft, L.R.C.P. Edin., L.S.A., to the Stock and Bradley District.

Hartley Wintney Union.—Thomas J. Biddle, M.R.C.S.E., L S.A., to the Heckfield District.

Stoke-upon-Trent Parish.—John Allen, M.D. St. And., M.R.C.S.E., L.M., L.S.A., to the Longton District.

Tonbridge Union.—Charles F. Buchan, M.B. Aberd., M.C. Aberd., to the Third and Fifth Districts and the Workhouse.

Weardale Union.—George Hood, M.D. Edin., to the Thornley District.

Wem Union.—Samuel B. Gwynn, L.S.A., M.R.C.S.E., to the Wem District and Workhouse.

Witney Union.—Thomas Smallhorn, L.R.C.P. Edin., M.R.C.S.E., L.M. Edin., to the Ensham District. George B. Prickett, M.R.C.S.E., to the Bampton District.

Wrexham Union.—Alfred Eyton, L.R.C.P. Edin., L.F.P. and S. Glasg., L.M., to the Fourth District.

THE LEVÉE.—At the Levée held on Wednesday, by H.R.H. the Prince of Wales, on behalf of Her Majesty, the following presentations took place:—Assistant-Surgeon John Brake, by the Secretary of State for India; Dr. Stanley Haynes, by his father, Mr. Joseph Haynes; Dr. J. Picthall, Surgeon, Bengal Army, by the Secretary of State for India. The Levée was attended by Doctors Lyon Playfair, C.B., Priestley, Edward Meryon, Francis Hawkins, Scot Alison, and Professor Owen.

UNIVERSITY OF LONDON.—The successful candidates will be admitted to Degrees at a meeting to be held at Burlington House on Wednesday, May 9, at 2 p.m.

UNIVERSITY COLLEGE.—The distribution of prizes in the Faculty of Medicine will take place on Monday, May 7, at 4 o'clock p.m. precisely. The Hon. G. Denman, Q.C., M.P., will preside.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Council, held on Tuesday, May 1, the following gentlemen were elected examiners for the ensuing year—viz., to examine candidates for Letters Testimonial and Fellowship—Christopher Fleming, M. Harry Stapleton, Benjamin W. Richardson, Edward A. Stoker, George H. Porter, Jolliffe J. Tufnell, and John Barker, Esqrs. To examine candidates in Midwifery: Edward J. Quinan, James Isdell, and John Cronyn, Esqrs. To examine candidates in general education: Thomas Byrne, John Murray, and George F. Shaw, Esq.

CAMBRIDGE.—The friends of the Rev. W. Clark, M.D., who lately resigned the Professorship of Anatomy, have determined to offer to the University a marble bust of that gentleman, with a view to its being placed in the Museum of Comparative Anatomy, which they hope the University will agree to call the Clarkian Museum, in honour of Dr. Clark, to whose exertions and liberality the existence of the Museum is in great measure due.

COUNT BISMARCK'S PHYSICIAN.—The King of Prussia has bestowed the Order of the Red Eagle on the Physician who attended Count Bismarck in his recent indisposition.

HYDROPHOBIA.—A fatal case is reported at Middleton-on-Bow, near Darlington. The sufferer, the parish clerk, had been bitten by a dog six weeks previously.

THE EXPLOSION AT ASPINWALL.—In the list of those killed by the explosion of nitro-glycerine on board the steamer *European*, at Aspinwall, on the 3rd ult., we regret to find that the name of Dr. Burrows, the Surgeon of the ship, occurs.

NEW MEDICAL SOCIETY IN THE WEST OF ENGLAND.—At a general meeting of the Medical Practitioners of Plymouth and Devonport, held on April 27, it was determined that a society should be formed under the name of the South Devon and East Cornwall Medico-Chirurgical Society, to meet at some central room once a fortnight for the purpose of reading and discussing papers on subjects connected with Medicine, Surgery, Midwifery, etc., and for the exhibition of Pathological Specimens. The officers elected for the ensuing year were Mr. Square, President; Mr. W. Swain, Vice-President; Dr. Prance and Mr. R. Rendle, Committee of Management; Dr. C. A. Hingston, Secretary.

ROYAL MEDICAL BENEVOLENT COLLEGE.—On Thursday, April 26, the anniversary festival of this institution was held at Willis's Rooms, King-street, St. James's. Sir Wm. Fergusson presided, and was supported by the presence of many of the most eminent Medical men in London; indeed, a list of those entitled by distinction to mention would read like a page from the *Medical Directory*. The meeting was a pleasant one, and Sir W. Fergusson made an admirable chairman. There are at present resident in the College at Epsom 24 pensioners, each of whom is provided with three comfortably furnished rooms, an ample annual allowance of coals, and 21*l.* a year in money. The full complement of 200 boys are now in the school, and in addition to these there are many day scholars, who receive all the advantages of a first-class education on payment, but who are not necessarily the sons of Medical men. The Council are, however, earnestly desirous of increasing the number of foundation scholars and of placing their maintenance and that of the pensioners upon a footing independent of the somewhat precarious support of annual subscriptions. To this end they appeal to the public on behalf of a class of Professional men from whom the country derives so much advantage at so little regard to aggrandisement, and under so heavy a load of responsibility and actual danger to themselves and their families, do so much good almost unknown and almost unrequited. Sir William Fergusson brought these points of the report briefly but strongly before the guests. The best proof of the success of his appeal is to be found in the fact that between 600*l.* and 700*l.* was at once subscribed in the room towards the maintenance of the charity.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of the members of this Society was held at 53, Berners-street, W., on the 26th ultimo. The balance-sheet of the year 1865 was read, from which it appeared that some sixty-five widows and orphan children of deceased members of the Society had received during the year ordinary relief to the extent of £2150, besides other grants. The following officers and directors of the Society were elected for the following year:—*President.*—Martin Ware, Esq. *Vice-Presidents.*—Everard A. Brande, Esq.; Peter M. Latham, M.D.; John Bacot, Esq.; D. Henry Walne, Esq.; A. J. Sutherland, M.D., F.R.S.; Geo. Burrows, M.D., F.R.S.; John Miles, Esq.; C. H. Hawkins, Esq., F.R.S.; James Paget, Esq., F.R.S.; Charles Hawkins, Esq.; Thomas Hammerton, Esq.; Sir Charles Locock, Bart., M.D. *Treasurers.*—James Thomas Ware, Esq.; Geo. Hamilton Roe, M.D. (acting); Richard S. Eyles, Esq. *Directors.*—Henry Sterry, Esq.; Henry Jeaffreson, M.D.; H. S. Illingworth, Esq.; Francis Hawkins, M.D.; T. B. Curling, Esq.; Jno. Hilton, Esq.; Jno. Love, Esq.; Henry A. Pitman, M.D.; John Adams, Esq.; Robert Druitt, M.R.C.P.L.; J. C. Forster, Esq.; Edward Tegart, Esq.; John Scott, Esq.; Henry Lee, Esq.; C. Collambell, Esq.; Richard Quain, M.D.; Geo. Johnson, M.D.; C. F. Du Pasquier, Esq.; E. N. Berry, Esq.; Samuel Solly, Esq.; John Morgan, Esq.; Richard Barnes, M.D.; George Budd, M.D.; William Bowman, Esq. The annual dinner is appointed to be held on the

16th instant, for particulars of which, and the district within which Medical men must live to become members of the Society, we refer to the advertisement in our present number. We hope that many of our readers will join this most useful Society.

THE CHOLERA ON BOARD THE "ENGLAND."—The following letter has been addressed to the Editor of the *Times* by Mr. Hamilton, of Liverpool :—

"Sir,—The outbreak of cholera in its most virulent form on board the steamship *England*, a few days after leaving this port for New York, fuller particulars of which have now come to hand, is a warning to us of such vital importance that we shall be most culpable if we do not take heed to it.

"Without recapitulating the facts already published regarding this outbreak, I would draw attention to two or three points. It is clearly established that the cholera appeared first among the German passengers, and that it spread rapidly among them—satisfactory proofs that they brought the disease on board, as the *England* is quite a new vessel, this being her first voyage. Now, where did these Germans come from? From the very country where we learn by the latest intelligence that cholera has made its appearance—namely, Holland. They were East Frieslanders, and have been described to me as of the lowest class, stunted in growth, filthy in habits, dressed in linsey-woollen clothing, and, in preference to the wholesome food provided for them, subsisting almost entirely on their *saur-kraut*, an abominable mess, of itself sufficient to disorder an Englishman's stomach. I mention these particulars, as, with over-crowding superadded, what happened only confirms an hygienic axiom that if such conditions exist such results are pretty sure to follow.

"The next question is, how did they come to this country? And that is what we have to do with, for it concerns us most nearly. They came *viâ* Rotterdam to Hull, and from there, by special arrangements with the East Lancashire Railway, to Liverpool, where they remained two or three days before sailing. Within the last few months this has become a much frequented route, offering in its cheapness and its directness great facilities to emigrants for America from the north of Europe.

"The cholera has broken out in two or three different places in Holland. It is therefore advisable that stringent measures should be at once taken to prevent these emigrants, either on their arrival at Hull or in their transit in the railway from Hull to Liverpool, or while remaining at the latter place, leaving, as it were, the germs of the disease among us, as these latter would only need the hot months of summer to burst forth.

"We have had an escape in that the cholera did not break out among these poor Germans before they left our shores, and so spread to ourselves. Let us profit by the warning that the poison may exist and be carried about long before it developes into the disease, and that it can even remain innocuous if deprived of all favouring conditions.

"The extreme importance of the subject must be my apology for asking a short space in your valuable columns for this letter.

"I am Sir, yours, &c.,

"ROBERT HAMILTON, F.R.C.S."

THE CONVEYANCE OF FEVER PATIENTS IN PUBLIC CABS.—Dr. Horace Jeaffreson's letter on London fevers and London cabs, which appeared in the *Times* of March 5, has been reprinted for the benefit of the Hospital Carriage Fund. Dr. Jeaffreson states, on his personal knowledge, that from 700 to 800 cabs are annually used for the purpose of conveying fever and variolous patients to Hospital. Should we have this year an epidemic of cholera, how many more will be employed for a similar purpose? The Hospital Carriage Fund have now in process of construction two ambulances—one for the Fever and one for the Small-pox Hospital. We hope that liberal subscriptions to their funds will enable the Society to provide a similar carriage for every London Hospital where cases of contagious disease are admitted.

"IF the amateur friends of the destitute and needy really want to do some good to their involuntary clients, why do they not take municipal and parochial offices? Instead of dwelling solely on the sensational and dramatic aspect of destitution, why do they not turn to its business and practical aspect? Let them become guardians and overseers, and act as assessors to the relieving officers and masters of workhouses. But this would be so dull and uninteresting. There would be nothing picturesque or dramatic or flashily heroic in fighting over accounts with sordid and narrow-minded shopkeepers, or in remonstrating with parochial churls. There would be no appalling stories of misery and horror to relate to admiring friends at dinner, with the narrator playing the part of delivering angel. It would give no colouring to transcendental speculations about the destiny of man and the mysteries of life. Such attempts on the part of the well-to-do people, with leisure, to rescue the poor from those who are only a shade less poor than themselves, would be unspeakably useful. But it would require a genuine sacrifice, and this would spoil all the pleasure of the pursuit. What is wanted is, humanity made easy."—*Saturday Review*, March 3.

CAUSE OF GOITRE.— M. Maumené is led from his observations and experiments to believe that the cause of goître is the presence in drinking water of fluorides. These, he asserts, are peculiarly abundant in the water of goîtrous districts. M. Maumené gave for a period of five months fluoride of potassium to a dog, at the end of which time a swelling similar to goître appeared in the neck ; the dog then made his escape, but three years afterwards was again discovered with a swelling which appeared to M. Maumené to have all the characters of goître.

PRESERVATION OF LEECHES.—Among the various means for the preservation of this useful animal, M. Stanislas Martin states that there is nothing so good as the deposit of a bed of silex, formed of pieces of various forms, but not exceeding a nut in size. The leech delights in remaining in the cavities formed by these, and while penetrating into them rubs its body against their asperities, thus effectually cleansing its surface from the filamentous mucus which adheres to it, and if not removed leads to the destruction of the animal.—*Bull. de Thér.*, *April* 15.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending April 21.	Week ending April 14.	Week ending April 7.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

Note.—28 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Cambridge, 1; Chester, 3; Derby, 1; Hampshire, 1; Lincoln, 1; Denbigh, 1; Flint, 4; and Scotland, 16. These Inspectors returned 330 cases last week.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The treatment of choleraic diarrhœa and cholera, according both to theory and practice, will be treated of in our next.

We are sorry that our space will only allow us to publish the deaths of Medical Practitioners—not of their families.

The writer of a review in the *Church Times* of Mr. Baker Brown's book on the Cure of Epilepsy, etc., calls our attention to a letter by Dr. Rogers in the *Medical Times and Gazette* of April 7. The writer in the *Church Times* says that he did not desire the clergy to make prurient inquiries, but that he wished them to "bring under the notice of Medical men" the treatment recommended by Mr. Brown. "They (the clergy) are to suggest to Medical men the remedy, and not to suggest that remedy to their poorer parishioners." We would only remark that we think the clergy had better mind their own business.

E.—Dr. Wilbraham Falconer has published a very useful blank form for registering temperature in disease. Write to him at Bath.

A Member, Poplar.—*No* oration was delivered at the College this year. It is a biennial affair. Mr. Hilton will deliver the next.

Dr. H.—Blisters were introduced in Italy during the year 1576. Taliacotius died in 1553. Consult the Roll of the Royal College of Physicians by Dr. Munk.

An Old Reader of the "Medical Times and Gazette."—Any man may practise Medicine if he use no Medical title; but any one practising and charging for attendance and Medicine is liable to prosecution under the Apothecaries' Act. It were better to wait, but if there be a *bonâ fide* intention of completing the examination at College and Hall, and if that be carried out, no great harm can follow.

COMMUNICATIONS have been received from—

St. Mary's Hospital School; Dr. J. E. Smyth; Apothecaries' Hall; Westminster Hospital School; Dr. Yull; Mr. Berkeley Hill; Dr. McCraith; Society for the Relief of Widows and Orphans of Medical Men; Dr. Markham; A. E. Wilmot; Dr. C. Hingston; Dr. Greenhalgh; J. N. Villier; Royal Institution; Mr. R. B. Carter; Dr. Bowen; Mr. David Davies; Mr. E. Bellamy; Dr. George Johnson; Dr. Hughlings Jackson; Mr. Spencer Wells; Dr. Ogle; Dr. Handfield Jones; Mr. J. Hutchinson; Dr. Lionel Beale; Mr. J. Chatto.

BOOKS RECEIVED—

Sankey's Lectures on Mental Diseases.—Grimshaw's Thermometric Observations in Fever.—Foster, On the Use of the Sphygmograph in the Investigation of Disease.—Fox, On the Action of Fungi in the Production of Disease.—Ophthalmic Hospital Reports. Vol. V. Part 2.—Ellis, On the Safe Abolition of Pain.—The Mystery of Pain.—James, A Visit to Vichy.—De Hovell, On Medicine and Physiology.

NEWSPAPERS RECEIVED—

The Sunday Gazette—The Morning Journal (Jamaica)—The Indian Medical Gazette.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN APRIL, 1866.

The following are the Returns of the Metropolitan Association of Medical Officers of Health:—

	Total Solid Matter per Gallon.	Loss by Ignition.(a)	Oxydisable Organic Matter.(b)	Hardness.	
				Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	20·43	1·31	0·34	15·5	4·5
West Middlesex	19·41	0·90	0·40	14·0	3·0
Southwark and Vauxhall	20·40	0·80	0·36	15·0	4·0
Chelsea	20·39	0·95	0·30	15·0	4·5
Lambeth	20·00	1·25	0·38	14·0	3·5
Other Companies.					
Kent	27·62	0·72	0·02	20·0	7·5
New River	19·00	1·10	0·18	13·5	4·5
East London	21·60	1·42	0·37	15·5	4·0

(a) The loss by ignition represents a variety of volatile matters as well as organic matter, as ammoniacal salts, moisture, and the volatile constituents of nitrates and nitrites.

(b) The oxydisable organic matter is determined by a standard solution of permanganate of potash, the available oxygen of which is to the organic matter as 1 is to 8; and the results are controlled by the examination of the colour of the water when seen through a glass tube two feet in length and two inches in diameter.

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 28, 1866.

BIRTHS.

Births of Boys, 1080; Girls, 1107; Total, 2187.
Average of 10 corresponding weeks, 1856-65, 1874·5.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	764	728	1492
Average of the ten years 1856-65	628·2	603·9	1232·1

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·877 in. The barometrical reading decreased from 30·29 in. on Sunday to 29·29 in. on Saturday.

The general direction of the wind was E., E.S.E., and calm.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 50·8°.

APPOINTMENTS FOR THE WEEK.

May 5. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Professor Huxley, "On the Methods and Results of Ethnology."

7. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

Odontological Society, 8 p.m. Meeting.

Royal Institution, 2 p.m. General Monthly Meeting.

Western Medical and Surgical Society, 8 p.m. Nomination of Officers. Dr. Marcet, "On the Therapeutical Properties of Mineral Waters."

8. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Ethnological Society of London, 8 p.m. John Crawfurd, Esq., "On the Migration of Cultivated Plants in Reference to Ethnology." Dr. John Shortt, "On the Fishermen of Southern India."

Royal Medical and Chirurgical Society, 8½ p.m. Mr. Toynbee, "On Disconnection of the Incus and the Stapes." Mr. Durham, "On a New Operation for the Radical Cure of Hernia."

Royal Institution, 3 p.m. Professor Ansted, F.R.S., "On the Application of Physical Geography and Geology to the Fine Arts."

9. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Microscopical Society, 8 p.m. Meeting.

10. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

11. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Professor Ansted, "On the Mud Volcanoe of the Crimea."

ORIGINAL LECTURES.

ON

MECHANICAL DISEASES AND THE SECONDARY CHEMICAL DISEASES THEY PRODUCE.

By H. BENCE JONES, M.D., F.R.S.

Part V.—Lecture XII.

(Concluded from page 438.)

The number of mechanical accidents which fall under the care of the Physician is far greater than at first sight you would suppose. Some of them closely approximate to Surgical accidents; for example, how slight is the difference between intussusception and inguinal hernia. How closely do different diseases of obstruction resemble Surgical accidents. I might give you a long course of lectures on different obstructions, and on the secondary chemical diseases to which they gave rise. Then there are mechanical diseases of internal ruptures, as of the semilunar valves of the heart, or of healthy or diseased vessels constituting the large class of hæmorrhages. Then there are more chronic mechanical diseases, as emphysema of the lungs, dilatation of the bladder in some rare cases, varicose veins continually. I might almost include in mechanical Medical accidents the large class of embolic diseases, but these arise from a slight antecedent chemical wrong, and are therefore like calculi, primarily chemical, secondarily mechanical, and tertiary chemical diseases again; and as I have already said, these tertiary chemical diseases are far more dangerous than the primary chemical causes of these complaints.

Of these Medical accidents I will take one a quick and the other a slow mechanical disease, to show you again how mechanical wrongs set up chemical complaints.

I will read you a few short notes of a case of mechanical rupture of the aortic valves, which I saw in St. George's Hospital. It is recorded in Dr. Latham's work, On the Diseases of the Heart, vol. ii., p. 193.

A stableman at Anderson's, twenty-eight years of age, was admitted into St. George's Hospital. He was suffering, and had suffered for twelve months, severe palpitation of the heart, and was able to mark distinctly the moment of its commencement. It was one day just after running a horse down the yard to show off his paces to a purchaser. He had never had acute rheumatism. His lips were blue, his breath short, and his left side painful. He had a dry cough. His bowels were confined and his urine free. It was ten weeks before his admission that his cough and dyspnœa had begun to be particularly distressing. Auscultation found dulness in the præcordial region, over an extent of four inches square. The heart's impulse increased, and its first sound prolonged, with a low blowing endocardial murmur over the aortic valves, and its second sound indistinct. He was bled three times under the urgency of his cough and dyspnœa. These, however, continued to increase. Five weeks after his admission his legs became œdematous, and in two weeks more he died.

On examination after death three pints of fluid were found in the right pleura, and the heart was enormously large. In length it reached from the second to the eighth rib, and across the base of the ventricles it measured six inches. The left ventricle was moderately hypertrophied, and very largely dilated. The mitral valve was healthy, and the aorta was slightly thickened, and moreover had suffered rupture of a peculiar kind; one of its septa was torn away from its attachments, and thus two of its pouches were reduced to a single irregular one. The right ventricle was dilated, but both the auricles preserved their natural states. In the ascending aorta and in its arch there were atheromatous deposits. The liver was very large, and the spleen and the kidneys were healthy."

How, then, did this Medical accident set up this chemical disease?

The aortic valves bear the pressure of the whole column of the blood, and resist the tension of the arterial textures. So that the highest pressure of each ventricle-full of blood that comes into the arteries is exerted on these valves. As soon as they are broken the pressure falls on the interior of the ventricle, and this being much less resisting than the structure of the valves, dilates; and hence throughout the whole arterial system a state of lessened tension of blood, and consequently of lessened pressure of the arteries on the blood, is produced; and if the left ventricle were as feeble as the auricle, the blood would hardly move in the small arteries, and passive congestion of the capillaries and then of the veins would soon follow from the rupture of the aortic valves.

But the heart reacts on the increased pressure. Quicker and stronger the muscular structure endeavours to drive the blood through the system. This increased action causes a greater supply of blood to the muscular structure of the heart itself through the coronary arteries, which, contrary to other arteries, receive blood freest and easiest when the heart is most dilated during the diastole. This increased supply of blood and increased function give rise to hypertrophy, and when it is established this hypertrophy increases the force with which the blood circulates through the vessels, whilst the dilatation increases the quantity of blood sent forward at each systole of the heart. Thus, the tension in the small arteries again may reach the amount that prevents congestion of the blood in the capillaries and in the veins.

Before this compensation can be reached, the diminished tension in the small arteries allows the blood to stagnate in the capillaries and in the veins; as the tension in them increases the watery part of the blood, or even this with fibrin diffuses from the increased pressure into the textures, and a more or less resisting œdema of the cellular tissue is thus produced. This œdema may exist in all the textures, and the obstructed circulation may give rise to diminished chemical actions of oxidation and nutrition; this alteration is most apparent when the obstruction takes place in any of the secreting organs. When in any secreting organ diminished pressure arises in the small arteries, increased tension is caused by the stoppage in the veins. The capillaries from which the secretion takes place become distended, the supply of oxygen and of substances from which the secretion is formed becomes insufficient for the formation of healthy secretion; altered and less oxidised products form; constituents of the blood unchanged may escape on the free surface of the gland, and generally quantitative and qualitative chemical errors in the products of the glands occur. Thus, for example, in the kidneys the congestion from heart disease may cause slightly albuminous urine or even fibrinous liquor sanguinis to pass into the urine; or with extreme pressure, even blood-globules may be forced through.

Thus the whole chemistry of oxidation, nutrition, and secretion may be entirely changed by the pressure produced by a mechanical accident—so changed that even mortification may in extreme cases occur. Such was not the course of events in the patient with ruptured aortic valves. The heart did its best to enlarge and to strengthen itself, but the tension in the veins and the stoppage in the capillaries was too great a weight for it to overcome. Effusion of fluid in the extremities and in the pleura came on, and the mechanical obstruction and the chemical want of action soon put an end to his sufferings.

In the *Transactions* of the Pathological Society, vol. 10, p. 92, you will find another case reported by Dr. Peacock. "The left angle of the posterior segment of the aortic valves was torn from its attachment so as to allow the edge of the valve to be retroverted and free regurgitation to take place from the aorta into the ventricle. The heart was large, weighing twenty-three ounces avoirdupois. The cavity of the left ventricle especially was considerably increased in size, and its walls were thicker than natural. He died three months and a-half after the accident which ruptured the valve, of extreme dyspnœa. The lungs were found congested, œdematous, and very sparingly crepitant throughout.

The slow mechanical disease which will furnish me with a good illustration of the production of secondary chemical disease is vesicular emphysema of the lung. This is caused by the mechanical dilatation, perforation, and obliteration of the pulmonary membrane of the air cells by the jerking force of coughing which presses at the same time equally downwards as well as upwards.

As the emphysematous cavity enlarges the air cells that were broken up to form it disappear, and hence the amount of membranous surface is lessened through which the process of oxygenation and decarbonisation of the blood and textures is carried on. A great diminution of the amount of capillary vessels in the lungs is thus produced, and the quantity of blood that comes to be aërated is thus diminished, and the resistance to the circulation in the pulmonary artery is increased.

This resistance acts immediately on the right side of the heart, and tends to, and ultimately produces, dilatation of the right side of the heart. The slightest impediment in the right side of the heart acts immediately on the systemic venous system, causing first increased tension of the veins, then obstruction, and finally dropsical effusion.

In health the air cells are distended with elastic gases, and the pulmonary membrane is pressed inwardly by the direct weight of the atmosphere, and outwardly indirectly by the pressure on the ribs and abdomen. The elasticity of the lungs is equal to a column of mercury about one-fourth of an inch high; this elasticity, with the weight of the air on the abdomen and ribs, gives a slight pressure resisting the dilatation of the air cells. Cough consists in the sudden more or less violent pressure on the air in the tubes and cells by the contraction of the diaphragm and muscles of the chest and the muscles of the bronchial tubes and trachea, the larynx being closed. This sudden contraction increases the pressure of the air on all parts of the vesicular structure of the lungs and by long continued, often repeated mechanical pressure, the elasticity of the cells is lost where there is least resistance, and the pressure of the air in the vesicles more or less rapidly causes dilatation and perforation and ultimate obliteration of the pulmonary membrane; for each mechanical cough whilst forcing part of the air out acts with an equal and opposite force upon the inelastic air cells.

The dilatation and destruction of the cells necessarily occasions the destruction also of the capillaries on each side of the pulmonary membrane, and as the amount of obliteration increases, a mechanical obstruction to the passage of blood through the lungs is produced, and from this the chemical process of the aëration of the blood is impeded. In consequence of the mechanical injury, the absorption of oxygen and the escape of carbonic acid may ultimately be reduced to such an extent that the whole blood may become more venous than arterial, and general loss of power from imperfect oxidation and general loss of substance and alteration in chemical composition from imperfect chemistry of nutrition may result.

Moreover, the mechanical impediment to the passage of the blood through the lungs increases the tension of the blood in the veins, and congestion, dilatation, and effusion may be caused throughout the venous system. Dropsical effusion in the textures occurs, not because the left side of the heart fails to send the blood through the veins as in insufficiency of the aortic valves and in dilatation of the left side of the heart, but because the right side of the heart cannot empty itself, even though sometimes by its increased action it ruptures the blood-vessels of the lungs in its endeavour to overcome the obstruction. General suboxidation and subtrophic action are not the only chemical errors caused by vesicular emphysema of the lungs. The general venous congestion affects the chemical actions in the secreting glands. The passage of the sluggish blood through the liver is made more slow, and chemical derangements in the secretion of the bile result. The capillaries of the kidney become congested, and the secretion of urine is diminished and its composition changed; ultimately fatty liver and jaundice, and albuminous urine and fatty degeneration of the kidney and uræmia may result from the primary mechanical injury by which the vesicular emphysema of the lung was produced.

Whilst speaking of Medical accidents, I must for a moment here allude to another large class which, as they are in their commencement chemical and not mechanical, therefore belong to the first part of this course of lectures. The vast subject of poisons may be comprised in this class of accidents. Poisons, according to their quantity and quality, suddenly or slowly act chemically on the body, and thus give rise to chemical and mechanical changes which sometimes cause the instantaneous stoppage of all action—that is, death; and sometimes produce the most protracted increased or diminished chemical and mechanical actions—that is, more or less acute or chronic disease. Almost every vegetable and mineral medicine which we use, when taken in sufficiently large doses, acts as a poison. Hence you will at once see how the full knowledge of these in Medical accidents may give you clear ideas regarding the effect of medicines in promoting or retarding the action of the mechanical, chemical, muscular, and nervous forces that cause disease. But I must now leave this vast subject, of which I will endeavour to draw a most unfinished sketch in an appendix to this course of lectures.

And here, before I conclude, I must add one word of apology for so exclusively dwelling throughout this course of lectures on the chemical and mechanical actions of disease. I have done so because I could thereby obtain a degree of clearness and a connection of ideas which is very far beyond that which the present theory and practice of Medicine, with its "vitality," "degeneration," and "phlogistic action," can offer. Moreover, even now the knowledge of the chemical and mechanical actions in the body is still in its infancy; but it daily grows, and will grow, stronger, broader, and deeper until it will carry away our present theories of Medicine, and bring us new materials for the construction of a perfect building, of which I have tried in this course of lectures to trace the outline.

The present wide-spread disbelief among Medical men regarding the existing theories of disease and the mode of action of remedies, and the utter disagreement which so frequently exists between those who ought from the same therapeutical knowledge to adopt almost identical practice, and the complete wreck of all authority in Physic, proves that the theory and the practice of Medicine are now in a transition state; that the ground is being cleared for a new building based on the theory of the conservation of energy. The science and practice of Medicine will quickly advance to perfection as soon as the progress of the physical sciences enables us to obtain clear ideas of the action of each force, and of the relation of all the forces that exist in every substance within us and around us. As soon as we possess and can use this knowledge our Profession will regain that union, that power, and that position which must of necessity be ours when we are able to advise with certainty upon the separate and conjoint action in the body of all the forces that bring good and harm to mankind.

ORIGINAL COMMUNICATIONS.

OBSERVATIONS ON THE MEDICINAL SPRINGS OF HARROGATE.

By GEORGE KENNION, M.D., F.R.C.P.

There are two reasons which induce me to offer to your readers a short account of Harrogate and its Medicinal springs. One reason is that so little is generally known about the place, and the vast resources which it presents to invalids; the other, that, to the large and valuable *répertoire* which Nature has already so bountifully given us, we have lately had a very important addition in the discovery, by Professor Sheridan Muspratt, of the existence of proto-chloride of iron in considerable quantity in one of our springs—thus constituting it a chalybeate water of, in all probability, very great therapeutic value, and one which, in respect of this constituent, is without a prototype.

Harrogate is commonly divided into two parts, which are respectively named High and Low Harrogate. The greater part of what is called High Harrogate is built upon a high table land, which is elevated 420 feet above the level of the sea, and commands a magnificent and extensive view, while Low Harrogate is situated in a basin, which is bounded on the east and south sides by the high ground on which High Harrogate is built, and on the west by "Harlow-hill." The upper stratum of the soil is sandstone, below this is a bed of shale in some parts, of clay in others, and below this again is carboniferous limestone. The air of Harrogate is peculiarly pure and bracing, and, as is commonly remarked, possesses more of the freshness and elasticity of the sea air than almost any other inland place. The position of Harrogate being such as I have described it, gives us the advantage of two distinct climates: the air of Low Harrogate being comparatively warm even while a strong and cold wind may be blowing over the "Stray" or common which extends throughout High Harrogate, and around which many of the best hotels and houses are built. The sandy nature of the soil allows of the paths being immediately dried up, after even the heaviest rains; and, whatever may be the cause, the fact remains that while cholera, in different epidemics, has been raging all round, not a single case has ever occurred in Harrogate. Rinderpest so far, I am thankful to say, is unknown in the place, and fevers, brought here by visitors, never spread. The country around Harrogate is, for the most part, well cultivated, the scenery picturesque, and the objects of interest for excursions are very numerous. Such is a brief topographical description of Harrogate. I proceed now to describe that which especially has conduced to the reputation of the place, viz., its Medicinal springs:—

It has long been a general opinion, and one which is shared

in by very many, even in the Medical Profession, that the only, or at all events the principal, mineral water in Harrogate is the well-known sulphur water—"the Harrogate Water" *par excellence*, and further, that the chief class of complaints for which this "Harrogate water" is a remedy, is the large and troublesome class of cutaneous diseases. I will enumerate the different kinds of water which are found here:—

1. Strong sulphureous waters, rich in chlorides.
2. Mild sulphureous waters, containing alkaline salts.
3. Saline chalybeate waters.
4. Pure chalybeate waters.(a)

This statement of the distinct varieties of waters which are found here will show how mistaken the former opinion is—viz., as to the existence of only one kind of water, and I will point out as I proceed, that there are many kinds of cutaneous diseases which are much more satisfactorily treated by some of the saline chalybeate waters, and which are indeed aggravated by the sulphur waters. As regards the variety of waters here, I believe that I am correct in asserting that in no place, either in this country or in Europe, is there so great a choice of mineral springs, all of them valuable as therapeutic agents, and all in constant use in the large variety of cases which present themselves here for treatment.

The sulphureous waters are used externally as well as internally. The important difference between the two classes of sulphur water which I have above named, consists not only in the relative amount of sulphuretted hydrogen which they contain,(b) but also in the quantity, as well as the quality of their saline ingredients. The stronger waters contain, according to Dr. Hoffman's analysis, about gr. 15 of sulphide of sodium (representing about c.i. 26 of sulphuretted hydrogen gas) in each gallon, and nearly gr. 1100 of saline matter, of which about gr. 780 consists of chloride of sodium, the remaining salts consisting chiefly of the chlorides of calcium, magnesium, and potassium. The milder sulphureous waters contain very much less of sulphide of sodium, (on an average—for there are at least four of these springs—they contain about gr. 2 in each gallon), and about a fourth part of the amount of saline matter which exists in the stronger waters; and whereas in these the most active saline ingredient is chloride of sodium, in those the comparatively predominant salts are alkaline carbonates. I need hardly advert to the great advantage which we possess in having this variety in the constitution of the sulphureous springs.

The physiological effects of sulphuretted hydrogen in moderate doses appear to be chiefly exerted on the great nervous centres, on the mucous membranes, and upon the skin. On the nervous system it acts at first as a stimulant, but if its use be too long continued, or if it is taken in too large a quantity, it acts powerfully as a sedative, or even as a narcotic poison. On the skin and upon the mucous membranes it has a directly stimulating effect, and peculiarly is this the case as regards the bronchial mucous membrane, for which it would seem to have a remarkable affinity. M. Claude Bernard, M. Demarquay, and others have clearly shown that when sulphuretted hydrogen is injected into the blood, it is immediately (*i.e.*, within twenty-five seconds) eliminated from the lungs. Böcker believes that under its continued use carbonic acid is more largely exhaled from the lungs, and uric acid excreted in larger quantities from the kidneys. I think that my own observations tend to confirm the latter opinion; but it appears to me probable that both these effects, the former directly and the latter indirectly, are only the natural result of the quickened passage of blood through the lungs.

From this brief account of the physiological effects of sulphuretted hydrogen, we can readily understand how important is the part which it must play, when its energies are rightly directed against disease of those organs or tissues upon which its influences are chiefly exerted; and, when we find its action associated, as it is in these waters, with that of the salts which they contain, we need not wonder at the reputation which the waters of Harrogate have obtained, nor that the number of diseases to which they are applicable is so large.

On the physiological and therapeutic effects of these saline matters I need not dwell for a moment, and I therefore proceed to mention some of the chief classes of disease which are amenable to the action of these waters, and in doing so I will commence with cutaneous diseases.

In the frequent cases of lepra, psoriasis, and pityriasis, these waters are peculiarly beneficial in their external as well as their internal use. There are few of these cases which are not more or less connected with a gouty predisposition, and the stronger sulphureous waters, acting as they do very powerfully upon the liver, the portal system, and the kidneys, by removing congestion and increasing secretion, have in this their eliminative action a directly curative effect upon these diseases. The external use of these waters has, probably, something more of a specific effect in these diseases, particularly if the opinion of Hebra is correct that sulphur, in the form of alkaline sulphurets, induces a hyperæmic state of the affected integuments, stimulating the growth of epidermis, and thus accelerating the metamorphosis of tissue. In pustular diseases of the skin, of which we may take impetigo as a type, these waters are almost invariably useful, both in their internal and external use. In all these cases there is probably some morbid condition of the blood (allied, as I am disposed to think, to that hyperfibrinous state which exists very often where there is a tendency to boils), to get rid of which Nature establishes this discharge, and we help her in this effort by so administering the waters as to produce their eliminative action through the different emunctories of the system.

In vesicular diseases of the skin, as a general rule, I do not think the internal use of the sulphureous waters so beneficial as in the squamous and pustular diseases. My usual practice in these cases is to combine the external use of the sulphur water (which I consider invaluable in these diseases, either in the stronger or the milder variety, according to the nature of the case) with the internal administration of one or other of the saline chalybeate waters. The results of observation lead me generally to use the same mode of treatment in most of the papular diseases of the skin, such as lichen and prurigo, in which, while the inflammatory condition of the skin is of an asthenic character, there is a want of healthy tone of the general system.

In the pustular diseases which attack the face—acne, sycosis, and mentagra—connected as they almost always are with a thickened unhealthy condition of the blood, I find the external use of the sulphur waters very beneficial; but I find the internal administration of the saline chalybeate waters produce the greatest amount of benefit to the general health. Thus we see that sulphur waters are not necessarily a cure for cutaneous diseases, and that their salutary influence is chiefly felt by their power of removing those morbid states of the general health which are the parents of these diseases. It seems, indeed, almost an absurdity to press this truism; but the daily experience of this place, and of the preconceived views of the subject with which many invalids come here, shows that it is not unnecessary to do so.

Of what are commonly called "blood diseases," I may mention cases of secondary and tertiary syphilis as being very much benefited by the use of sulphureous waters and sulphur baths. The same remark applies to a very large proportion of scrofulous cases. The observations of M. Grimand, Andrien, and others go far to prove the value of sulphurous waters in cases where there is actual deposit of tubercle in the lungs.(c) To a certain degree this effect may be due to the generally improved condition of health in which such cases are placed by the use of mineral waters of this class, and by the pure air which they breathe here; (d) but the remarkable circumstance already alluded to, and first ascertained by M. Claude Bernard, of the pulmonary mucous membrane being the chosen point of elimination from the system of sulphuretted hydrogen, cannot fail of engendering the belief that as upon the skin in some cases, so in others upon this membrane sulphuretted

(a) In mentioning these four varieties I must be understood as merely indicating them as varieties; there are, I believe, no less than fifty different springs.

(b) Strictly speaking, as many of my readers are aware, sulphuretted hydrogen does not exist, as such, in these waters as they arise from the spring in this their pure state; the chemical condition in which sulphur exists is in combination with sodium, as sulphide of sodium. Exposed, however, for a short time to the air, this combination is destroyed, and free sulphuretted hydrogen and soda are the results.

(c) I am aware, indeed, that my friend, Dr. Edwin Lee (*vide* "Watering Places of England"), is disposed to break a lance with me on this subject, chiefly on the ground that the quantity of saline matter in the sulphur water so rapidly excites the alimentary mucous membrane, that it does not give time for the sulphuretted hydrogen to be absorbed into the blood. In these cases, however, where the desideratum is to produce a constitutional, and not a purgative effect, it is very easy so to regulate the dose, as well as to choose the particular spring, as to allow of the system being thoroughly impregnated with sulphur. It is true, as Dr. Edwin Lee suggests, that I have not seen any such cases *cured* by this mode of treatment; but I can testify to the great improvement in the general health, and strength, and nutrition, which many cases of this kind do experience here. Beyond this I certainly cannot go; but is not this in itself a great point gained?

(d) Dr. Thorowgood's remarks upon this subject are very valuable ("Change of Air in the Treatment of Phthisis," second edition).

hydrogen may produce a specific effect, increasing the local circulation, stimulating the growth of epithelium, and accelerating the metamorphosis of tissue. It is probably due to some such cause that cases of chronic bronchitis are so often benefited here, and that the peculiar follicular disease of the throat, known as "clergyman's sore-throat," not unfrequently yields to this mode of treatment.

In gout and rheumatism, with all their widely-spread ramifications, these waters are remarkably beneficial, acting powerfully upon the secretions and excretions, purifying the blood, as they thus do, from so much that contaminates it, renovating the powers of the digestive organs by removing those local congestions which interfere with the healthy discharge of their functions, we should naturally expect, what we actually find, that their efficacy in these cases is immense; and when we bear in mind how large a proportion of chronic functional disorders have, as their basis, a foundation of gout, we cannot fail to remark how wide a field of successful practice is here opened to us. In one form, indeed, both of gout and of rheumatism, viz., where the effusions round or within the joints have become hard and concrete, we must, I fear, in all fairness, concede the palm to Buxton. I do not mean to imply that such cases are not cured here (the contrary, indeed, is the case), but I must frankly admit that Buxton does more good in these cases than Harrogate can effect. I believe, however, that much benefit accrues even to such cases as these, if they come here and drink the sulphur water before they go to Buxton. The reverse plan is often tried, but with much less advantage to the patient. I am happy in being corroborated in this opinion by my friend, Dr. Robertson, of Buxton, whose ample experience in all that relates to that important place is so well known. In reference to this class of cases I have been in the habit of observing that while Buxton deals with the past, Harrogate deals with the present and the future. Connected as such cases are with a gouty diathesis, I may here remark upon the great relief which patients experience here who are afflicted with "gravel." The thorough washing through which the tubes of the kidneys undergo during a course of these waters mechanically clears away any sandy deposit which may have lodged in them. If this deposit has gone on to the extent of forming a small calculus, their effect is to dislodge it before it is too large to pass through the ureters; while the increased flow of urine helps to carry it through the bladder. The mild alkaline sulphureous spring, which is largely resorted to for this purpose, has a solvent effect upon these deposits almost as powerful as some of the springs at Vichy; indeed, patients who have been at Vichy have told me, not infrequently, that they have derived more advantage from drinking this particular spring than from the use of any of those at Vichy. Another form of blood disease which is almost invariably removed by the action of these waters is that of lead-poisoning—I do not remember to have seen a case which was not greatly relieved, if not cured, by their use.

There is another class of cases which are most frequently benefited by the use of the stronger sulphureous waters—viz., those of uterine congestion, either active or passive: cases where we find menorrhagia on the one hand, and on the other hand dysmenorrhœa, or even amenorrhœa.

As a general rule I do not advise the internal administration of these waters in organic affections of the nervous system. There are some cases, however, of paralysis of old standing in which the external use of the strong sulphur water is beneficial; and in that peculiar and, until lately, little understood disease known as *progressive locomotor ataxie*, Dr. Althaus and others have found much benefit from the use of sulphureous baths. Dr. Brown-Séquard also recommends a trial of these baths in some cases of reflex paralysis.

In the large majority of the diseases to which I have adverted as being remediable by the action of these waters, there exists, or has existed, a disordered condition of some portion of the digestive organs, and there can be no doubt that in a very large proportion of these cases, the organ which is chiefly in fault in the first instance is the liver. Passive congestion of the liver, vascular as well as biliary, with all its long train of consequences—congestion of the portal system, thickened bile, constipation, indigestion. I cannot describe these cases in more graphic words than those of Dr. Chambers (Lectures, Chiefly Clinical, p. 524). "In these cases," he says, "there is a dinginess and darkness of complexion, and the stools are scanty. The skin gets greasy and opaque, the countenance puffy and bloated, sometimes thin and pale, the lower eyelid especially, sallow and discoloured. The sebaceous follicles on the alæ nasi are stopped up with black matter. There is seldom" (at first) "any decided emaciation, nor is there always even loss of muscular power, but there is great sluggishness of body and apathy of mind, and there is a miserable want of decision and energy." "The natural end of this state of things, if left unchecked, is gradual progress from bad to worse. The decrease of destructive assimilation loads the tissues with effete matter, useless for the purposes of life, and a constant source of general discomfort. This impedes the constructive assimilation of food; growth is arrested; the blood is not renewed; and hence progressive anæmia, weakness, want of nervous and muscular power, and probably, in the end, the degeneration of one or more of the viscera, and death."

I know of no treatment by which cases of this description are so much benefited as by the use of these (the sulphureous) *or*, according to the circumstances of each individual case, *the saline chalybeate waters;* and hence it is that so very large a number of these cases are completely cured by the treatment which they undergo here.

It has been frequently made a question as to how far the benefits which patients derive from the use of mineral waters is dependent upon the actual imbibition and immersion to which they are subjected, while they are "using a course of waters," or upon the change of air and scene, and the complete release from the ordinary duties of their position in life, be that position what it may. Now, it has always appeared to me, that at a place like Harrogate, where we have so great a variety of waters, we have a fair opportunity of testing this point: indeed, I may say, it is frequently tested *for* us. It is a matter of every-day occurrence, that people come here for the purpose of drinking "the water" and bathing, who are either directed by their Medical advisers at a distance (who, naturally, cannot be conversant with the different waters which there are here, and their very different effects), or, acting on their own judgment, or the advice of those whom they meet with here (all invalids think that what has cured them will cure their friends!) as to the particular waters and baths which they should use, after being here perhaps for two, three, or four weeks, find that they are not deriving the benefit which they had expected, or perhaps that they are "getting worse" every day, and then they apply for Medical advice upon the spot. It is found, perhaps, that they have been drinking "the wrong waters," or too much water, or too little, or that in some way the waters have disagreed with them. They are then put upon a fresh plan of treatment, which results in a relief, or a cure of their symptoms. Now these patients have had from the first all the advantages which change of air and relaxation could bring them, but instead of improving in health, they have lost ground every day; then beginning a new and a better regulated plan as regards the use of the waters, they gradually regain their health, and at length go away more or less cured. Cases of this kind, I say, always appear to me a very conclusive test as to how much of the benefit which patients derive here is due to these adjuvantia, (adjuvantia undoubtedly they are, and of a very high order), and how much is really due to the waters.

A very few words will suffice to bring under the notice of your readers the important chalybeate springs with which Harrogate abounds; indeed, a bare enumeration of them is all which is required, for it would be almost an impertinence to occupy your columns, or the time of your readers, with any description of the cases which call for their use.

There are two principal springs from which the saline chalybeate waters are obtained: the one is popularly called the Kissengen spring, from a certain resemblance in its composition and its effects to the Ragozzi spring at Kissengen; the other is that alluded to in the early part of this paper as containing protochloride of iron in considerable quantity. The former spring has been extensively used for several years, and is exceedingly valuable as a remedial agent in those very frequent cases—cases of every day's experience—where we require the combined action of an aperient, a diuretic, and a chalybeate. To some of these cases I have already adverted; others will at once present themselves to the recollection of my readers.

Of the effects of the new spring alluded to as containing the protochloride of iron, I am unable as yet to write very confidently; but so far as we have tried it during the few months which have elapsed since Dr. Muspratt first discovered the existence of this salt in the water, my own observation and that of the other Medical gentlemen in the place concur in leading us to form a very high opinion of its therapeutic value.

Theoretically, from its composition (e), we should expect it to be very useful; practically, I think we shall find that in this spring we possess one of the most valuable, perhaps *the most valuable chalybeate water in Europe.*

In addition to these two very important springs, there are two powerful pure chalybeate springs, where the iron is found in the normal form of a bicarbonate.

P.S.—The lapse of two months since the above remarks were written has afforded me opportunities of using this newly-discovered spring somewhat extensively, and the result has been to confirm very amply the expectations which were raised of its great therapeutic value. Amongst other obvious cases where it may be used with advantage, I am now able to write with confidence as to its efficacy in cases of fatty degeneration of the heart.

Harrogate, April.

RAPID AND EXTENSIVE EMBOLISM OF THE HEART IN A PHTHISICAL SUBJECT —SPEEDY DEATH.

By J. E. GROSS, Medical Officer, Gibraltar Prison.

J. D., a delicate lad, aged 21, was brought to Hospital at 6 a.m., March 11; moribund, with small rapid pulse, skin moist; unconscious, face pale, lips livid, breath cold, and breathing rapidly and with the utmost difficulty. A large sinapism was applied over the front of the chest, and brandy and water was freely administered. His pulse improved in volume for a short time, but rapidly fell, and he died in two hours.

History.—He had been at Gibraltar about sixteen months, and had suffered all the time from chronic phthisis, but had always kept at his work, which on the day before his death was cleaning bricks, close to the prison. The weather had been unusually cold for the past week, with a sharp northerly wind blowing. He had complained to his fellow-prisoners of feeling this cold much, and of his cough being more troublesome at night. On the evening of March 10, his cough was very troublesome and his breathing much hurried, but not sufficiently so to induce him to apply for admission into Hospital. Nothing unusual was noticed by his fellow-prisoners during the night, but in the morning, when he did not get up, they spoke to him, and he then requested to be sent to Hospital immediately, as he said he was dying.

Autopsy twenty-six hours after death.—No symptom of decomposition. Rigidity well marked everywhere. Features much more swollen than during life. The jugular veins and the minute ramifications of the veins over the sides of neck, upper surface of shoulders and arms down to the finger ends were full of blood. This condition of the upper surface of the body, coupled with the suddenness of the symptoms, led at once to the opinion that embolism of the heart would be found. Thorax:—Lungs universally adherent by old firm adhesions to walls of chest. Much tubercle in masses and various stages scattered throughout both lungs. Right lung.—Three cavities, lined, each the size of a pigeon's egg and communicating in the upper lobe. Great and recent congestion of lower lobe. Left lung pale, hollowed out, and pressed close to ribs by enlarged pericardium, which contained six ounces of clear serum, but no lymph. Heart very much distended, more particularly the right cavities, the walls of which were very thin, pale, and not exceeding two lines and a half in thickness. On laying open the right ventricle, the whole of the cavity was occupied by a firm white, almost glistening, clot entangled amongst the chordæ tendineæ. It extended upwards into the right auricle, which it completely filled, and also into both branches of pulmonary artery, wholly blocking it up. There was also a small quantity of blood-stained serum in the ventricle. The left ventricle also contained a smaller, but equally white clot, which extended up into the auricle, just over the mitral valves, being blood-stained on the one side where the current passed over it.

Remarks.—I think this case of embolism worthy of recording for these several reasons. Its occurrence in a case of phthisis which presented no features out of the common, and in which the subject of it was still engaged at his usual work. Its short duration, rapidity of formation, great extent, and apparently small exciting cause. The thin fatty heart here was probably unequal to the small amount of extra work thrown on it by the engorged lung, and from its inability to empty itself became the primary cause of the subsequent changes.

(e) I subjoin the analysis of this water as made by Professor Sheridan Muspratt, and Professor Miller, of King's College:—

Analysis of Chloride of Iron Spring.

	gr. in one gall.
Oxide of manganese	A trace
Chloride of calcium	138·43
Chloride of magnesium	84·39
Chloride of sodium	205·92
Chloride of potassium	3·84
Chloride of barium	6·78
Protochloride of iron	14·49
Protocarbonate of iron	11·62
	cub. in. in one gall.
Carbonic acid	26·28
Nitrogen	8·08

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

LEICESTER INFIRMARY.

TWO SUCCESSFUL CASES OF OVARIOTOMY.

(Under the care of Dr. C. H. MARRIOTT, Surgeon to the Infirmary.)

Case 1.—L. P., sent to me by my friends, Mr. Whitchurch and Mr. Barwis, of Melton Mowbray, was admitted into the Leicester Infirmary December 1, 1863. Aged 39; single; household servant; parents living, healthy; no special disease on either side of the family. She reports that about five years ago she suffered from prolapsus uteri, followed in a year after by hardness and enlargement of the bowels. The swelling was uniform over whole abdomen, and gradually increased to its present size. Has had no pain till last two months, and then it has been in leg and thigh. Both legs have occasionally been very much swollen. Catamenia till two months ago.

Present Condition.—Rather below the average height, of nervous temperament; face pale and anxious, with pallid complexion; extremely emaciated; papular eruption, more or less over whole body; moves with difficulty; respiration considerably affected; heart and lungs normal; abdomen enormously distended, measuring at umbilicus forty-one and a-half inches; fluctuation; perfect dulness over whole front of intestinal walls, and flanks; both legs and thighs œdematous, right more than left, great pain in the leg and foot; uterus pushed down to entrance of vagina; os uteri size of pinhole.

December 19.—Tapped an inch and a half below umbilicus, thirty and a-half pints of pale greenish limpid fluid drawn off, containing a large quantity of albumen, sp. gr. 1010. Examined microscopically it showed blood-corpuscles, granules, and some spherical granular cells not containing nuclei.

21st.—No substance to be felt in abdominal cavity; uterus in its normal position.

26th.—Sent to her home in the country for two months.

February 23, 1864.—Re-admitted; looks much better, has gained flesh considerably, and is able to walk about with ease; appetite very good, and in excellent spirits. Pulse 96. Measures at umbilicus thirty-three inches; abdominal parieties can be moved over the tumour, except close to the point where she was tapped; percussion at the upper edge of the tumour is dull, and is not affected by full inspiration. The uterus is forced downwards and backwards nearly to the entrance of the vagina; percussion on the tumour over the abdomen is felt by the finger in the vagina; catamenia appeared three months ago, natural in time and quantity; urine contains lithates; no trace of albumen or sugar. Owing to a troublesome cough, the operation was deferred.

Operation.—March 21, 12.30.—The room was heated to 75° Fahr. Chloroform being administered, an incision four and a-half inches long was made from a point two inches below the umbilicus to an inch and a half above symphisis pubis. By a little careful dissecting the abdominal cavity was opened, and the cyst showed plainly of a whitish colour. The hand was now passed through the wound, and easily broke through some adhesions over the left front, between the parietal peritoneum and the cyst; no further adhesions could be felt. A large trocar was plunged into the cyst, and after about two pints of fluid had escaped the trocar slipped out; but as the cyst had been partially withdrawn, none of the fluid found its way into the abdominal cavity, and the instrument was instantly replaced. The cyst was easily

drawn through the incision. The pedicle was short and two inches wide. A double ligature was passed through it, and the cyst cut off about an inch and a-half above it. The stump was drawn outside the abdominal cavity. Three deep silk sutures were passed from within out through the peritoneum, and through the whole thickness of the parietes; and four superficial ones were added. A small clamp was then fixed on the pedicle. The intestines were just seen once or twice, but were easily kept from protruding. 5.30 p.m. (four hours and a-half after operation).—Has been slightly sick once; has taken no food. Inclination to pass water; catheter used; seven ounces drawn off. To have a little brandy and arrowroot. Pulse 80. 9 p.m.—Feels sick; has not slept. To take morph. acet., gr. $\frac{1}{4}$; acid hydrocyan. dil., mii.; aquæ, ʒss.

22nd, 9.30 a.m.—Pulse, 72; she slept well; sick once in night; no flatus has passed *per anum;* urine drawn off three times a-day. To have a little iced brandy-and-water occasionally, and to suck ice *ad libitum.* 9 p.m.—Pulse 76; at 7.30 p.m. vomited more than a pint of green bilious fluid, after feeling sharp pain in the stomach for an hour before. Ordered beef tea, ʒiv.; brandy, ʒvi., to be injected every three hours, and opium to be added while the pain is severe.

23rd, 9.30 a.m.—Pulse 80; has had a comfortable night; face pinched and drawn; had severe griping pain at 6 a.m., followed at 7 a.m. by bilious vomiting, slight hiccough; abdomen tympanitic; bears moderate pressure without pain; wound healthy. 2 p.m.—Pulse 92, small; vomited again at 11·30 a.m., and at the same time a moderate quantity of serosanguinolent fluid was discharged through the centre of the wound. Ordered creasot., mi., in a pill every two hours. 9 p.m.—Pulse 96; was sick after the creasote, and was ordered tr. opii., miii., in a teaspoonful of brandy and a teaspoonful of water every two hours; vomited again at 7·30 p.m.; hiccough less violent; tympanitis increased since morning.

24th, 10 a.m.—Pulse 100; fuller and less compressible; vomited at 1.30 a.m.; at 4.30 a.m. (sixty-four hours from the operation) passed a large quantity of flatus *per anum* for the first time, soon followed by two small liquid motions; hiccough has ceased; abdomen notably less tympanitic; countenance more natural. 9.30 p.m.—Pulse 92; vomited green bilious fluid at 11.30 a.m.; bowels acted again 12.30; catamenia came on freely in the afternoon. Increased brandy to ʒi. in each injection.

25th.—Pulse 100; has passed a comfortable night; four upper sutures, two deep and two superficial, removed; strip of plaster put across; wound healthy. To have injection and medicine every four hours, and a tablespoonful of beef-tea by the mouth.

26th.—Pulse 96; slept well; bowels open twice; complains of pain at the clamp; slight blush and swelling around and below it; two other sutures removed.

27th.—Pulse 96; passed a large faculent motion yesterday; considerable discharge of pus from under the clamp. Injections cause pain; to be given every eight hours.

28th.—Pulse 92. Discontinue the injections. Clamp removed (seven days); skin red and swollen, and excoriated from the pressure, which, owing to the great distension of the abdomen, had been very considerable.

29th.—Pulse 92; appetite good. To have boiled sole for dinner. From this date she improved rapidly.

April 2.—Ligature on the pedicle being removed (twelve days), the lowest of the deep sutures was also taken away. It had been so drawn inwards as to be entirely out of sight before; it had cut its way out of the right margin of the wound, but was still deeply imbedded in the left; scarcely any irritation was caused by it.

17th.—Wound healed. Allowed to get up (twenty-seven days).

29th.—Catamenia appeared on the 26th, naturally; ceased to-day.

May 10.—Has taken regular walking exercise for last three weeks; now feels quite well and strong. Discharged cured.

This patient called on me a month ago (one year and seven months after the operation, looking remarkably well, and stated that she had for some time past been living in London, in active service as housekeeper, and that her health had never been so good for many years.

Case 2.—F. S., aged 52; single; native of Leicester; admitted December 3, 1864. Parents had been healthy, but were now dead; no special disease on either side of the family; one sister died of general dropsy, but the bowels were scarcely, if at all, swollen; patient has had no illness except those of infancy, and variola at 3 years of age, of which she now bears the marks. Five years ago noticed a uniform swelling of the abdomen, not more on one side than the other. At this time her urine diminished in quantity, and the catamenia, which had been regular up to this time, ceased and have never returned. Her general health was good, and she suffered no pain.

In April, 1864, I first saw her, and tapped her. One large cyst was emptied, and about three gallons were drawn off. Some solid growths were now felt, and seemed to be immoveably fixed in the left iliac fossa.

September 2.—Tapped again; twenty-eight pints drawn off, and the solid growths were then noted as follows:—Solid growths slightly enlarged, but decidedly not adherent; diagnosis—intracystic growths.

December 23.—Tapped a third time; twenty-six pints drawn off; also a small cyst about the size of a cricket-ball; growths not large, and perfectly free to be moved in all directions; fluid highly albuminous.

27th.—Feels comfortable, and improved in general health. Made out-patient.

January 17, 1865.—Re-admitted. Feeble in strength, and face pallid. Ordered generous diet and ferri citr. three times daily.

24th.—Pulse 84, small. Measures at umbilicus 38½ inches; skin moveable over tumour. On a full breath being taken, the hand, laid on the abdomen, can feel a grating as the cyst moves against the abdomen parietes. Percussion, dull at the upper limit of the tumour, becomes of an intestinal note when a deep inspiration is taken.

Operation.—Urine drawn off; chloroform administered; an incision of five inches long was made, beginning about one and a-half inches below umbilicus; the peritoneal cavity was soon opened, and the cyst showed plainly of a dead opaque white colour; several ounces of ascitic fluid now escaped. In the vicinity of the wound it was free from adhesions, but owing to great distension of the cyst, I could not pass my hand around it. Feeling pretty sure it was free to be removed, I at once tapped it, without further enlarging the incision. From the great distension, the fluid was forced by the side of the trocar, and flowed over the pubes and legs, but I doubt if any got actually within the pelvic cavity, as a sponge was instantly placed below the canula. After the greater part of the fluid had flowed out, the cyst was entirely withdrawn, but many smaller ones showed unemptied, and two in particular sprang from the very bottom of the pedicle; these two were tapped. The pedicle was now seen to be made up of the left broad ligament, with the Fallopian tube lying right across it, and the uterus continuous with its right border. The pedicle, as may be imagined, was extremely short, so much so, that there was great difficulty in fixing the clamp, there being only just room to apply it between the Fallopian tube and the uterus; when this was done, it dragged so that the fimbriated end of the Fallopian tube protruded out of the wound, and the lower end of the clamp rested with great force on the symphisis pubis. Four deep silk sutures were put in, as in the first case, and one superficial one, near the top of the wound. In spite of these, the fimbriated end of the Fallopian tube passed through at the extreme lower limit of the wound, and lay on the abdomen. To obviate this, it was pushed back into the pelvis, and held there with a director, whilst another suture was applied as low down as possible. During the operation, which lasted about thirty minutes, she vomited several times and became very faint; afterwards she was placed in bed on her back with pillows under the knees and hot bottles to her feet. Ordered teaspoonful of brandy occasionally and a grain of opium as a suppository, if pain should come on. Pulse 72, very small. The cyst, when opened, showed thousands of small cysts—some single, but many clustered one within another, so as to make a solid tumour. When cut through, greyish glairy fluid exuded. Between the cysts was a considerable solid growth, so as to give a close resemblance to a honeycomb. After the cysts were emptied, it weighed altogether exactly two pounds avoirdupois. 6 p.m.—Pulse 84; has vomited once; suffers great pain at bottom of wound. Pil. opii. gr. iij. directly, as suppository. 9 p.m.—Has vomited about a pint of watery fluid, with brown flakes in it; still in great pain at clamp; does not like the brandy; to have a tablespoonful of tea occasionally, which she is very anxious for, but nothing else by the mouth. To have the following injection every three hours:—

Strong beef tea, 2 oz.; brandy, ʒ ij.; and liq. opii. sed. ♏ x. to be added whenever she suffers much pain.

January 27, 10 a.m.—Pulse 88; has slept well, and had three injections with the liq. opii in them during the night; feels little pain; no tympanitis, but some tenderness in left groin; urine cannot be passed naturally; to be drawn off three times in 24 hours. 9 p.m.—Pulse 96; feels comfortable.

28th, 10 a.m.—Pulse 100; slept well; at 7 p.m. felt pain at lower part of wound; considerable tympanitis; no flatus passed *per anum*; no sickness; wound united by first intention in its greater part; three sutures removed, and strips of plaster applied; increase the beef-tea to ʒiv., and brandy to ʒss.; injections every three hours. 10 p.m.—Pulse 112 to 116; feels less pain; increase brandy to ʒvj.

29th.—Pulse 112; slept well; bowels acted slightly, and some flatus passed at the same time; tympanitis not increased; clamp lies lengthwise on the incision.

30th.—Pulse 100; clamp lifted slightly, and found to press a little to the right of the line of incision; patient has taken a few grapes.

31st.—Pulse 88; bowels acted again yesterday afternoon, and twice in the night; has passed a little urine naturally twice in the night; has taken a little beef-tea, and about ʒj. of brandy.

February 1.—Pulse 104; allowed a teaspoonful of port wine occasionally; bowels open three times.

2nd.—Pulse 104; has eaten a small piece of fish to-day; clamp removed, and likewise the remaining sutures (seven days); stump of pedicle, greyish in colour, with a bright spot of granulation in its centre; wound united deeply, but granulating healthily at the skin level; tympanitis still very considerable, especially at upper part of abdomen; to have injections every four hours.

3rd.—Pulse 100; vomited at 6.30 p.m. yesterday, and was much collapsed after it, for which she was ordered brandy ʒj., and beef-tea ʒiij. every three hours as injection.

4th.—Pulse 92; tympanitis greatly decreased; injection every four hours.

5th.—Pulse 88; has passed a true fæculent motion, for the first time since the operation, all the others looking more like beef-tea than real fæces; abdomen normal in size; to have injections every six hours.

6th.—Pulse 92.

7th.—Pulse 88; to have chicken to-morrow, and to discontinue the injections.

March 9.—In good spirits; appetite excellent; wound healed, except one spot of granulation where the pedicle was; allowed to get up and walk about.

23rd.—Wound thoroughly healed.

I saw this patient about a month ago, and she is perfectly well and strong.

Veterinary Surgeons.—The Bill laid before Parliament by Mr. Holland imposes a penalty upon any one who, not being a member of the Royal College of Veterinary Surgeons, shall assume the title of Veterinary Surgeon; but the Bill is not to affect persons who have assumed the title six months before the passing of the Bill.

Claim by a Chiropodist.—At the County Court yesterday, before J. K. Blair, Esq., judge, Mr. Siemms, a chiropodist, of this town, claimed from a person named M'Ginn two guineas on an I O U, which he had received from him under the following circumstances, as appeared from the plaintiff's case:—In the course of his business he was visited by the defendant, who sought his assistance with respect to some corns from which he was suffering. Defendant, after having his feet examined, handed plaintiff one guinea, and gave him an I O U for two guineas, plaintiff's fee being three guineas. —Plaintiff was cross-examined, but he denied that he had promised to perform a cure.—The defence was that the plaintiff was not entitled to recover, inasmuch as he was not a registered Surgeon and the evidence of the defendant was to the effect that he gave the I O U upon the understanding that he had been completely cured, but instead of this he subsequently suffered to the same extent as he had done previously.—The judge, without deciding upon the merits of the case, expressed his opinion that the legal objection was a fatal one to the case of the plaintiff. The duty of the chiropodist constituted an operation within the meaning of the Medical Act, under which the plaintiff was not registered.—Judgment for the defendant.—*Liverpool Mercury*, May 4.

SATURDAY, MAY 12.

THE CATTLE PLAGUE REPORT.

The long promised Report of the Secretary to the Veterinary Department of the Privy Council on the "Origin, Propagation, Nature, and Treatment of the Cattle Plague" from information received at the office from June, 1865, to March 20, 1866, has at last made its appearance. It is not, by any means, so voluminous as we might have anticipated, seeing the time during which it has been in the incubative stage; but of this we ought not to complain, because of the less difficulty we shall have in laying before our readers a brief analysis of the conclusions at which Dr. Williams has arrived. With a commendable desire to avoid controversy, he expressly states that he gives no opinions of his own, but simply "the hypothesis which is most fully borne out by the evidence" in his possession; and, therefore, it seems to us we cannot do better than summarise the different sections of the Report without interpolating any remarks or criticisms of our own, which we can hereafter more satisfactorily offer in a succinct form. It should be distinctly remembered that the Report deals exclusively with the progress of the disease from its commencement to the end of last year only, and takes no cognisance of what has happened since.

1. The origin of the cattle plague in this country is not determined by any evidence of a satisfactory and conclusive character. As to whether it is of spontaneous origin or whether it was imported from abroad, an extensive correspondence has only resulted in conflicting statements. Medical men possess more scientific knowledge of epidemics than Veterinary Surgeons have acquired regarding epizootics; but it appears that the general verdict places the cattle plague amongst the *exanthemata*, and on this assumption the probability of its spontaneous origin would be certainly set aside by modern pathologists. Indeed, it seems that experience has to a great degree settled this question, for of the comparatively few cases reported as self-originating, subsequent inquiry has either inferentially or directly decided against the supposition.

"It may, however, be said that, although throughout the country districts of England there is no evidence of the propagation of the disease except by contagion, yet in the London dairies it may have arisen spontaneously. If, however, it be admitted that epidemics and epizooties are to a great extent due to the same causes and governed by the same laws, and that our theories with regard to epidemics embrace the whole of the knowledge which has been collected upon the subject, it must be conceded that it is *more probable* that an epizootic disease, having a constant habitation only in the Russian Steppes, and which has not prevailed to any large extent, if at all, in this country for the last century, was introduced by direct contagion than that such disease should have acquired a new centre of spontaneous origin in a country where it had existed and died out on several previous occasions. I do not consider that the after-

spread of the disease in this country is incompatible with the hypothesis of its importation. Reasoning by analogy, we know that to propagate an epidemic, we must not only have the germ of the disease, but also the soil and climate, so to speak, necessary for its cultivation. And thus, though animals infected with this disease may have been introduced at various times and in various places into this country, yet the germ may only in June, 1865, have found in the overcrowded London dairies the surrounding circumstances necessary for its reproduction; for it has been observed in our epidemics, that although they require to be first nurtured under circumstances only to be found among the lower classes, yet when once they have become naturalised they do not require these circumstances for their rapid after-propagation."

2. Whatever may be the origin of the disease, there is no doubt that it is highly contagious, and that its "propagation" depends upon contagion, either direct or indirect; but the difficulty of tracing the source whence the germ of disease was derived, leaves the exact mode of propagation an open question. The terms *contagion* and *infection* are used indiscriminately, but as "the germ must by some means or other have been brought in contact with the living tissues in which it has produced the disease," there would seem to be no need for the use of the term *infection*. The progress of the disease has varied greatly in the different counties of England, and many attempts have been made to account for this variation. Amongst others the geological formation of certain localities has been held to account for their comparative immunity from the disease, and a table is given showing out of 2989 isolated outbreaks the numbers occurring on the different formations. 952 occurred on the tertiary and post-tertiary formations, of which two-thirds were on the clay; 783 on the new red sandstone; 402 on the coal measures; 400 on the chalk formation; 268 on the oolite formation; 102 on the lias; and the remaining few on the silurian and igneous rocks. The practical commentary on these results supplies a highly interesting piece of information:—"On analysing these figures, however, it will be found that, as a rule, *those formations having the largest amount of outbreaks have also the largest amount of pasture land.*" The relation existing between the progress of epidemics and *elevation* is well known to exist, and in cholera especially its effect is most marked. This connexion appears also to be satisfactorily established in the epizootic now under consideration, and with the view of testing the theory as completely as time and other circumstances would allow, Dr. Williams selected one county and worked out the subject therein. Yorkshire, as the largest county, and offering a wide range of external physical features, was judiciously chosen; and from the investigation it appears that "the higher we ascend, the less are the ravages of the Cattle Plague, and that when we attain an elevation of 1000 feet the Cattle Plague disappears." Further and more extended inquiry may possibly modify this statement, but we have no reason to believe that it will be materially affected. The only other local circumstance as affecting the progress of the disease which Dr. Williams notices (we shall take the liberty by-and-by of pointing out one or two important elements which ought, we think, to have been referred to) is the size of the farms. "The smaller the farms the more rapid the progress of the disease, unless modified by other circumstances;" a close proximity between the centres of infection would no doubt aid in spreading the disease, and there would be greater difficulty in thoroughly isolating diseased animals where the communication between farm and farm is frequent. The effect of slaughter in checking the spread of the disease will of course be differently valued by the advocates and opponents of the system. Dr. Williams, whilst admitting that other circumstances occasionally counteract the beneficial effects of early slaughter, asserts that "in the greater number of instances it has been attended with marked results in reducing the ratio of increase," and he endeavours to show that the operation of the Order in Council (August 26th) permitting inspectors to slaughter had the effect of diminishing the increase of outbreaks in the ratio of 10 to 3. Into this point we do not now enter, as we shall discuss it at a future opportunity; we only desire to warn our readers against accepting Dr. Williams's conclusion without first verifying it for themselves.

3. The "nature" of the disease was at first doubtful, but now it is almost universally held to be "similar to, if not identical with, the Rinderpest of the Russian Steppes."

"It has been called by different observers typhoid or enteric fever, typhus fever, malignant fever, and various other names. It has been said to be identical with small-pox and other known eruptive fevers, and the wildest notions of its character and origin have been entertained and forwarded to this office. But none of these hypotheses will bear the test of investigation. The Cattle Plague appears to be a disease *sui generis*, belonging probably to the class 'exanthemata,' or eruptive fevers. It is highly contagious; has a period of incubation; rarely occurs more than once in the same animal, and is attended with an eruption."

The period of incubation ranges from six to twenty-one days; and the duration of the disease is variously stated from twenty-four hours, or even less, to ten or twelve days. The disease has varied in its character not only in different districts, but at different times; and it is a matter of congratulation to find Dr. Williams admitting that "*the returns appear to indicate that the disease gradually acquires a milder form as it continues its course.*"

4. The results of a special inquiry into the different systems of "treatment" adopted are thus classified:—

	Number treated.	Recovered.
Antiphlogistic . .	1389	27·5 per cent.
Tonic and stimulant .	3842	25·9 ,,
Antiseptic . . .	2970	26·4 ,,
Special	1507	25·8 ,,
Total . . .	9708	26·3 ,,

The above percentage of recovery on all the cases (26·3) is far in excess of "the experience of independent authorities who have investigated the results of treatment, both in cases under their own care, and also under the care of the appointed inspectors." This anomaly is ascribed to the natural tendency to exaggerate, even unconsciously, the effects of a favourite system of treatment, although this argument would seem to us as applicable to one set of reporters as to another. Reviewing the results of treatment generally, Dr. Williams speaks very despondingly, and rests all his hopes for the future on preventive measures, and the "gradual dying out of the disease which has been observed to take place after a time in human epidemics of a similar character." Yet he admits that the percentage of recoveries has been increasing week by week, and we see no reason to expect otherwise in the future, for if the virulence of the poison is subsiding, if the disease *is* dying out, it is natural, and according to all experience, that medicine will gradually regain its power. So we counsel Dr. Williams to be of good cheer, and look forward to the day when the occupation of the Veterinary Department, so far as Rinderpest is concerned, will, like that of a celebrated Shakespearian character, be "gone."

But what will be said to the following sentence anent the much lauded Aberdeen system of "stamping out?"—

"So far as an isolated district in an infected country is concerned, this process appears to have had a fair trial in Aberdeenshire, and the result arrived at does not appear so thoroughly successful as could be wished, there having been up to the present time eight outbreaks of disease in this county, and nearly 500 animals slaughtered."

It may be true that the adoption of stringent measures on the first appearance of the disease would under some circumstances be attended with success; but such measures are more easily carried out in countries where the will of the ruler is the inflexible law of the land, than in England, where individual rights and privileges have so wide an influence.

The statistics of Dr. Williams's Report are hardly of much

interest now that they are three months behindhand, and the deductions drawn from them require modification by the light of present experience. But he appends a series of shaded maps which illustrate the progress of the disease from its commencement in June, month by month up to the end of the year, and these are really valuable. If their production has been the cause of the delay in bringing out the Report, we are disposed to condone the fault for the sake of the increased interest afforded.

WORKHOUSE INFIRMARIES.

It is probable that great good will result, directly or indirectly, from the movement made by the Association for Improving the Condition of the Metropolitan Workhouses; but whether by introducing an entirely new organisation or by improving the old it were premature to speculate. It is said that Dr. E. Smith's investigations will confirm the allegations made against some of the older Workhouses as being incurably bad; others, again, may be expected to be found good; and others capable of great improvement. Everywhere we hear of improved ventilation, of attempts at better nursing, and in some cases of an increase of the Medical officers' salaries. The only wonder is, that all this was not known to and recommended by the Inspector of the Poor-law Board long ago. It may be taken for granted that a considerable amount of reconstruction and enlargement will be considered essential; and then the question will arise, whether it be better to do this in or near the old sites (supposing such a thing possible), or on new sites to be acquired for the purpose; and if the latter, whether the new buildings shall be under the existing organisation and government; or whether under a new and independent system. Other collateral questions will then unavoidably come to the surface respecting the ordinary "Voluntary Hospitals;" for if an enthusiastic feeling is to be excited in favour of sending the Workhouse Hospitals into the country, it will be difficult to show why the Voluntary Hospitals should not follow them. Questions will further be put as to the number of pauper cases that really require Hospital organisation; and whether at present a large number of poor, aged, broken-down creatures are not put on the sick list and sent to the Workhouse Infirmary merely because of the better diet which is obtainable thereby; and consequently whether, when we hear of one Medical attendant to a large number of sick, it is not the fact that three-fourths of these are sick only in so far as they are old and incurably infirm, and require not so much Medical treatment as good food, comfortable warm lodgment, and religious consolation. When the number and nature of the cases for which a regular Hospital organisation to be carried on in new buildings is precisely fixed upon, then will come the question whether these shall, as heretofore universally in England, be governed by the *local authority*, or whether some new Board should be created, with powers and functions entirely new; and it may be questioned how far such a proposition would be favourably received by the House of Commons, even if Government should be willing to take it on its shoulders. The general opinion seems to be that in England, whether as regards gaols, workhouses, or lunatic asylums, the details must be left to the local functionaries, be they magistrates or guardians, who represent the pockets of the contributors; whilst, as a check, there should be independent inspectors, to represent the conscience of the nation and the interests of the poor creatures who are inmates of the institutions. Just as in the case of passenger steam-boats, the Government sends an officer to certify to the soundness of the engines, the number of boats, and the competency to carry a given number of passengers, so in the case of Workhouse Infirmaries, Government should certify to the adequate capacity and ventilation of the building; should require a certain staff and appliances, and then must leave the details to the local functionaries. After all the case resolves itself into one of *Medical inspection*. We want a responsible functionary who shall be able to report publicly on the accommodation, the air, the food, the drugs, the nursing, and the Medical management; and let us say that it would be a happy thing if the inspection were extended to the voluntary Hospitals likewise. Then the reports of the Medical inspectors would be a means of creating a generous rivalry amongst the governing bodies of all such institutions as to which should be foremost in the art of doing good.

BATHS.

Perhaps we owe an apology to our readers for bringing to their notice matters apparently so trivial as those of which we are about to treat. We trust that their importance and the fact that such subjects are but little understood by the younger members of our Profession may be accepted as a sufficient excuse.

We propose to treat, first, of baths, their various methods of application, their action, and their uses.

Baths, as is well known, are of various kinds. The water composing them may be hot, cold, or tepid. They may be used generally or locally. To the water various substances are sometimes added.

It may be accepted as proved that none of the constituents of baths are absorbed by the skin. Many experiments have been made to ascertain the truth of this statement. None of the ingredients that were added to the bath could be found either in the urine or in the other excreta. Nay, it is highly probable that even the water itself is not absorbed by the skin. Thus the effects they produce on the system must be due to their action on the skin in virtue of either their moisture, their temperature, or of the ingredients that the water may contain.

We shall first speak of the general cold bath—baths composed either of simple or of sea water, and whose temperature varies from 40° to 75° Fahr. These baths produce their effects by virtue of either their moisture or their low temperature. This latter property may act either by its influence on the cutaneous nerves, thus producing shock, or by abstracting heat from the body. It is probable that they produce their effects by means of all these properties. By their moisture they cleanse the surface of the body, and thus promote the proper functions of the skin.

But cold baths are given for other effects than these. If properly used, the cold bath becomes one of the most powerful tonics we possess. If improperly applied, it may inflict serious mischief on the person using them.

The remarks we are now about to make apply to both cold simple and cold sea baths, but especially to the latter. We shall subsequently point out in what way these two kinds of baths differ.

On entering a cold bath a feeling of depression is first experienced. The pulse is greatly quickened, but loses much in force. The respirations are hurried and irregular. There is a feeling of chilliness with great diminution of the temperature of the surface of the body. This condition, however, quickly changes. The surface of the body glows; the pulse gains in force. There is a sense of increased vigour both of mind and body, the spirits are greatly exhilarated. This continues for a variable period, and is then again followed by a feeling of depression, accompanied by chilliness and a feeling of languor and exhaustion.

Baths, as we have stated, are given for their tonic effects. To secure these it is necessary that the patient should leave the bath during the second stage. If left at this time the condition of that period remains during the rest of the day. Thus given, the appetite is increased and digestion and assimilation improved. There is increased vigour of the body, with a desire for exercise. The patient is cheerful, the spirits more buoyant.

*

If, however, the bath be remained in, the depression of the last stage becomes permanent. The patient remains languid, fretful, irritable. The appetite is lessened. Much chilliness may be felt during the day. He is disinclined to exertion, and often experiences a sinking at the epigastrium. These results are to be most carefully avoided.

How long should persons remain in the water in order to obtain the greatest tonic effects? To answer this question in an individual case two points must be kept in mind—namely, the strength of the bather and the coldness of the water. With persons whose health has been impaired by excesses of any kind, by over-work, bad air, or who are convalescent from an acute disease, the first two stages pass quickly by, and they speedily pass into the stage of depression, which becomes permanent for many hours afterwards, and often for the rest of the day. Hence the time the patient be ordered to stay in the bath must be regulated to the vigour of his system. It is also most important to recollect that if the shock be very great, no second stage may occur, but the patient passes at once into the third stage and remains languid and depressed, with an impaired appetite during the remainder of the day. Thus it is important to regulate the shock to the strength of the patient. The amount of shock is dependent on the coldness of the water. Water, moreover, in motion, as is the case with the shower bath, produces much more shock than water at rest.

These principles teach us how to administer baths to persons in different degrees of health, and will explain the directions we are about to lay before our readers. These rules, however, are not merely deduced by the principles just stated, but they are the conclusions arrived at by those who have enjoyed a wide experience of baths.

Persons unaccustomed to bathing, if in health, should only stay in the water ten to fifteen minutes. Should they prolong their stay in the water, the bath is liable to produce much depression, and consequently fails to produce the desired tonic effect. By habit, however, the system becomes accustomed to bathing, and thus after their frequent use persons can often remain in the water half an hour or longer with good result. The length of time that the bath should be used depends on the temperature of its water. The colder the water, the shorter the duration of the bath, as we have seen that the amount of shock is in proportion to temperature of the water and time it is used. With weak people the duration of the bath must be considerably shortened. The time must be strictly regulated to their condition of health. The weaker the patient the shorter the time, as we have seen that in such persons the second stage lasts but a short time, and is quickly lost. Such persons can seldom remain in the water more than five minutes without suffering harm. If the patient's health be much depressed, he should be directed merely to dip into the water and allow a billow to wash over him, and then immediately to leave the water.

In determining the temperature of the water we must have regard to the strength and condition of the patient, for if the shock be too great we obtain only depression, and thus if the patient be very weak the water must not be very cold.

Persons of plethoric habit must bathe with much caution, for the excitement produced in such people may be too great, and thus headache, giddiness, congestion of the brain may follow the use of the bath.

Children under two years of age should not have cold sea or fresh-water baths given them. At this early period of life they are easily influenced, and may be seriously injured. Warm sea bathing for such is preferable, or the cold bath may be administered in the following way:—The child must be placed (or, if too young to stand, held) with its feet in warm water, and before a good fire, and cold water should be poured over the body for one to two minutes. The water should not be applied to the head. When administered in this way, very young children may have cold baths given them with the very best result. The same method should also be adopted with older children if they be weak, or if the weather be very cold, or the water may be slightly warmed in addition.

May pregnant women bathe? If they have had previous abortions, if they be nervous and irritable, baths had better be abstained from. Under other circumstances, both the mother and child will be much benefited by sea bathing. It is also unadvisable to commence a course of bathing at the time of menstruation, and at first bathing should be discontinued at these periods.

Patients who are very weak should not at once commence to bathe in the cold sea; with such the system may be so weak that only depression will result from the use of the bath. In such people cold bathing is apt to cause shiverings, trembling, a feeling of excessive fatigue, and with loss of appetite and other symptoms, and these results continue for the rest of the day, and often much longer. If such symptoms occur, or if the patient be considered too weak for cold bathing, tepid baths should be used, and the temperature of these should be daily lowered until the temperature of the sea is reached. It has been stated that water in motion produces a greater shock than water at rest, and we have seen that the amount of shock must be regulated to the condition of the patient; consequently, weak people should bathe in a calm sea. Persons of stronger health may choose a rough sea; for the action of the billows on the body is pleasurable and exhilarating to the spirits, and in such persons produce great tonic effects.

Too much exercise in the water should be avoided by weak people, as such are liable to be easily fatigued, and then depression follows. Patients should have directions given to them in respect of the time of day and season of the year at which they will profit from sea bathing.

At what time of the day can patients bathe with the best results? At that time when they are least liable to be depressed. Early in the morning, when the system is fasting, such a result is very liable to occur. Invalids, therefore, should be prevented from bathing before breakfast. But due time must be allowed for the digestion of the meal, as any strong impression on the mind or body is liable to arrest or destroy digestion. Therefore two hours should elapse after breakfast, and three after dinner, before the bath be taken. At this time also the water is warmer. It is preferable to take the bath after breakfast than later in the day. Even strong persons unaccustomed to bathing are liable to be much depressed by a bath taken before breakfast. Children should never bathe before ten or eleven. The patient must be directed to plunge at once into the water, and not to stand shivering for some time until the surface of the body is cooled. He should dip down and allow each wave to pass completely over him. It is the temperature of the sea to which we must have regard when we give direction to patients at what time of the year they may bathe with advantage. If the patient is not much debilitated, the months of May and September are good, and they should choose a shore on which the billows are rough. If, on the other hand, the patient be weak and depressed, the summer months are preferable, and a calm sea should be chosen.

The hair often falls off greatly at the commencement of bathing. This causes much alarm to the patient. Their fears may be quieted by the assurance that it will grow again more luxuriantly than ever.

If the patient be very weak, he must not indulge in much physical or mental exertion after the bath, as such exercise is apt to cause over-fatigue. Thus patients should have careful directions given them in this respect. Horse exercise is often good, as this does not require much exertion; but if the patient be very weak, carriage exercise is to be preferred. It is stated that persons who have commenced a course of sea-bathing are easily influenced by wine.

Various irregularities of the various functions of the body

are apt to occur at the commencement of a course of bathing. Thus constipation is not infrequent. This must be remedied by purgatives, diet, or exercise. It need not hinder the bathing. If dyspepsia or diarrhœa occur, it is better to suspend the baths for a short time. Irregularities of the menses need not cause the patient to desist from use of baths. Restlessness at night sometimes occurs at their commencement. If this be not very great, the baths may be continued. The diet of the patient should be carefully regulated. Stimulants should mostly be abstained from previous to the time of going to bed. Before entering the bath care should be taken that the body be not overheated by exercise; on the other hand, the patient should not be cold and chilly. Thus it is often desirable that slight exercise should be taken previous to their use.

All strong emotions should be avoided before bathing, and if they occur, especially if of a depressing kind, the bath should be omitted. It follows that children who dread the water should not be compelled to enter the sea, but should be coaxed in. If timid children be violently plunged into the water, they may be made very ill for several days. On leaving the bath a short walk should be taken. Two baths a-day can seldom be indulged in.

THE WEEK.

THE PREVAILING EPIDEMIC.

Influenza is very prevalent in London at present, and is one of many other signs that forbode a probable invasion of cholera. The symptoms we have noticed are shivering and malaise, followed by dry heat of skin (but in one or two cases in which the thermometer was used it did not indicate any abnormal rise of temperature), great sneezing and defluxion, tickling cough, and muscular pains. Children seem to be greater sufferers than adults. The old-fashioned stimulating diaphoretic, composed of Liq. am. acet. and nitrous ether, with conium for the cough and plenty of nourishment, seem to have been successful remedies, and the epidemic has been extensive rather than severe.

THE CHOLERA AT LIVERPOOL.

Two or three portentous facts stand out in the history of the cholera which has broken out on board the German emigrant ships. One is the existence of an European population so filthy, debased, and brutalised, as is described in the letters of our Liverpool correspondents. More serious still is the length of time between their departure from the Continent, and the outbreak of the cholera; for it is thus shown that passengers apparently healthy may carry cholera in their persons, clothes, or baggage. As to the dirty habits of the emigrants, they are described in the following terms by the highest sanitary authority in Liverpool:—

"I have asked the Medical inspector of emigrants, and one of the chief managers of the National Navigation Steam Company, about the condition of the passengers on board the *England* when she left this port. Both these gentlemen concur in saying that there was no appearance of sickness or of debility among them; but the manager states that the emigrants by the *England* were the dirtiest of the whole lot which have been passed this year. If he be correct, the statement is important, for the Dutch and Germans on board the *Helvetia* are the dirtiest people in their habits whom I have ever seen. The Surgeons assure me that not unfrequently they rinse out with water the pan used for the reception of the excrement and urine of their children, and then employ it as a cup for drinking and for their dinner mess; and no power or persuasion will prevent them leaving their dejections on the floors, the bedding, or the clothes. The water of the *England*, and, indeed, of all the ships sailing from this port, is supplied from the same source as the town itself. One of the chief passenger brokers of the people conveyed by the *England* says that the greater number of them came from South Germany and Switzerland, and merely passed through Rotterdam and Antwerp. The whole system by which these unfortunates are picked up, or rather trepanned, in Germany, and, for a fixed sum of money, hurried through to the ocean steamers for America, is very blameable, and should be placed by the several Governments under regulations and restrictions."

The latest report from Liverpool states that cholera has appeared amongst the Germans or Dutch who have been removed from the *Helvetia* to the depôt at Birkenhead. The father of the child who died last week is stated to be ill of cholera in the workhouse; and five deaths from the disease have occurred on board the Hospital ship *Jesse Munn*. Seven more cases were under treatment on board the same ship. The town is flooded with Dutch and German immigrants. All the lodging houses are full, and 200 had to be accommodated by the parish authorities on Tuesday last. These people mostly arrive at Hull from Hamburgh and Rotterdam, and it seems clear that if quarantine measures are to be of service, it is at Hull they must be put in force. It is proved that a mere Medical examination is no safeguard. Detention of the apparently healthy may seem a harsh measure, but it is the only one which can be relied on, and the facts of the present importation seem amply to justify it.

THE ARMY AND NAVAL MEDICAL SERVICES.

We would direct the attention of our readers to the extremely unsatisfactory reply of the Marquis of Hartington to the question of Colonel North.

It is notorious that the publication of the recommendations of the late Committee attracted a better class of candidates at the last examination for the Army Medical Service. This was all that was required for the purposes of the Government, of course. We have long held the opinion that little or nothing would be done so long as the authorities could obtain candidates, and the statement made by the War Minister on Tuesday last goes a long way to confirm it.

The remedy is in the hands of the Profession. Young Medical men should not be tempted by a delusive bait, but they should clearly abstain from entering the public services until the authorities have made up their minds as to what is the future pay, position, and prospects held out to Medical officers.

As to the Navy, the candidates for that service have been so few of late that it may be almost said there have ceased to be any.

RUDMAN *v.* ARMSTRONG AND ANOTHER.

The practice of Medicine had need have its special rewards, for certainly it has its special dangers. The following case illustrates very forcibly one species of the latter. A Medical man, even the unpaid officer to a public charity, is never safe from vexatious and vindictive law proceedings if he should be unlucky enough to treat a patient who is prompted by greed or malice, or even the dictates of insanity or hysteria, to bring an action for malpraxis against him. Dr. Armstrong and his son obtained a righteous verdict truly, but this does not repay them all the annoyance they must have suffered, and all the legal expenses in which they have been mulcted. The case was tried last week in the Court of Exchequer before Mr. Baron Channell and a special jury:—

"The defendants were Dr. John Armstrong, who has practised for thirty-three years at Gravesend, and his son, Mr. John C. Armstrong, who is in partnership with his father; and the plaintiff, Sophia Emily Rudman, was between 18 and 19 years of age, and the daughter of Thomas Rudman, a boot and shoe maker, in a humble way, living in the neighbourhood of Hackney. The case for the plaintiff was briefly as follows:—In 1864 her father kept a shop in Gravesend, and lived in lodgings in Edwin-street, in that town. She had always resided with her parents, had been employed in shoe-binding, and was represented to have invariably enjoyed good health. On a Sunday in November in that year, while walking across the room, she fell down, according to her own account, without

any apparent cause, and hurt her knee. The limb swelled and grew rapidly worse, and she became an out-patient of the Gravesend Dispensary, of which the defendants are two of the honorary Surgeons. She attended regularly about once a week, and was seen by one or the other of the defendants, who gave her advice and prescribed medicines, which were made up at another branch of the institution upon the payment of a fee of a penny on each occasion. She ceased going to the Dispensary by the beginning of June, at which time she was said to be in a weaker state of health. Afterwards the plaintiff's father engaged Dr. Armstrong to Professionally attend her at her own home, and continued to do so until 1865. Notwithstanding his treatment she grew worse, and showed all the symptoms of excessive salivation by mercury. Her mouth became so sore and her teeth so loose that she could only eat with difficulty, her nails were affected and some came off, while sores broke out on her hands and feet. It was also stated that her hands and feet were contracted by the action of the mercury, which it was alleged had been improperly administered. When the plaintiff's solicitor wrote to the defendants threatening an action, they denied that the girl had been improperly treated, and expressed their readiness to contest the point, sending their claim for Professional services, which amounted to £8 18s., for that purpose.

"The plaintiff, who was carried into court in an apparently helpless state, was briefly examined. Afterwards, on the suggestion of the learned judge, she was taken into his private room, and examined in private by four Medical men, two representing each side.

"Mr. Bonny was then examined, who said he was a Surgeon. He had formerly lived at Greenhithe, and happened to call at the plaintiff's father's while she was under treatment at the Dispensary, and he was shown the girl's knee, and the piece of flannel on which the ointment was applied. The plaintiff appeared to him to be in a state of salivation. Her mouth was sore, her gums spongy, teeth loose, and other signs of extensive salivation.

"On cross-examination, he stated he called about some boots the plaintiff's father was making for him, and did not attend the plaintiff Professionally, but acted as a friend. He was a duly qualified Medical man, and had been registered two years. The plaintiff was now under his care. He was now in practice at Horsleydown.

"The witness underwent a long cross-examination as to the effects of mercury in producing salivation and generally as to the state of the plaintiff, during which he behaved in so flippant a manner as to call forth a severe rebuke from the learned counsel.

"Mr. J. Vinall, a Medical Practitioner at Hackney, deposed that he was applied to last October to attend the plaintiff, and examined her, and found she was of a weakly constitution and out of health. He declined to attend her unless some arrangement was made as to payment, and the mother told him that they had got a law suit against the Doctor who had been attending the plaintiff, and that he should be paid out of the money they would get. He declined to look to any such source for payment, and ceased to attend her.

"Upon cross-examination he stated that when he examined her he saw no traces of salivation, or the effects of it, and considered the plaintiff chiefly required tonics, fresh air, and proper living.

"In the course of the trial a box of ointment, which the plaintiff's mother said had been prescribed by the defendants, was produced. The contents were to be applied twice a day to the knee, and she deposed that whenever that was used by the plaintiff it produced suffering, and made her worse. The composition was proved to be ordinary mercurial ointment.

"The defence was that the defendants treated the plaintiff according to the best of their knowledge, skill, and judgment as Medical men, but that she was of a weakly constitution, and the nature of her occupation and the circumstances under which she lived, the whole family residing in two rooms, and probably not having a sufficient quantity of nourishing food for one in her condition, retarded her recovery. It was also said that if mercury was used it was only after all other remedies had failed, and then only in the proper manner and in the right quantity. They stated they heard no complaints from the girl or her parents as to the mode in which they had been treating her until they received the lawyer's letter; and there was a suggestion that the action was only a solicitor's one to recover costs.

"Mr. J. C. Armstrong said he saw so many patients at the Dispensary that he could not recollect the particular nature of the prescriptions he wrote, but he gave the plaintiff nothing to produce undue salivation. He rarely used mercury in his practice, and, as a rule, he was opposed to its use. He had no knowledge of the box of ointment, and was inclined to think he had never prescribed it.

"Dr. Armstrong, the father, said that, after having tried fairly and honestly the effect of medicine on the plaintiff without making a cure, he came to the conclusion that the impediment to her cure was the want of proper food, fresh air, and exercise. He added that the atmosphere of the room in which he always saw her was very impure and offensive, and that no person suffering from any complaint who lived in it was likely to get better. He seldom resorted to mercury, and his son used less. The witness said the whole of his prescriptions for the plaintiff were in court.

"Mr. Solly, of St. Thomas's Hospital, who had examined the plaintiff, deposed that he could not discover the slightest possible trace of salivation by mercury upon her. He also expressed a positive opinion that her knee was free from disease, and that she had the perfect use of it. He thought she could walk from the court into the hall, but with this qualification—that owing to her weak state from long confinement she might perhaps require a little assistance. With regard to the use of mercury in cases of disease of the joint, he said it was often employed with effect when iodine had failed. Sometimes the appearances of salivation presented themselves without the use of mercury, particularly when iodine had been taken. He was quite certain the plaintiff could walk into the hall, or else his experience of forty years went for nothing.

"The trial occupied nearly the whole of two days, and the jury, after consulting together, intimated that they were already agreed that their verdict should be for the defendants.

"Mr. Serjeant Robinson, the counsel for the defendants, said that there were in attendance several very eminent Medical men, who would have given similar evidence to that given by Mr. Solly, namely—Mr. Le Gros Clark, one of the Council of the College of Surgeons, and Surgeon at St. Thomas's Hospital; Mr. Cooper Forster, Surgeon at Guy's Hospital; and Dr. Braxton Hicks, Physician at Guy's Hospital.

"Mr. Baron Channell said he was now at liberty to express his opinion on the case, which he could not do until the jury had expressed theirs. He had thought at one period of the case that he ought to stop the case and nonsuit the plaintiff; but considering it to be of such vast importance to the defendants that such a charge as that of ignorance or negligence in their Professional conduct should be fully inquired into, he came to the conclusion that it was better it should go on. He must say he entirely concurred in the verdict of the jury, and he thought he might go further, and say that there had not been the slightest evidence of want of skill or care on the part of either of the defendants.

"On the conclusion of the case, Messrs. Armstrong were warmly congratulated by their friends and Medical brethren."

We congratulate Dr. Armstrong and we congratulate the Profession on the result of this trial; but our action ought not to end here. For months upon months this woman has been holding the threat of trial over the head of Dr. Armstrong. At any time he could have stopped the whole matter by a few pounds, but he determined that the case should go on without compromise—his own honour, the honour of the Infirmary, the honour of the Profession lay involved in that step. He has taken the step and won the day, but at what a sacrifice of time, health, and money! The question is, shall we allow him to sustain this without a word of sympathy and support? We are glad to say not. We understand that Dr. Richardson has already taken steps to form a provisional committee to organise a movement for expressing in a substantial way the thanks of the Profession to the Messrs. Armstrong, and we feel assured that the effort will be as successful as it will be energetic and to the point.

FROM ABROAD.—MIALHE ON SECRETION AND DIABETES.

M. Mialhe communicated last week a paper to the Académie de Médecine upon the influence of the nervous system on glandular secretion, with a new theory of diabetes. He regards the action of the nerves on the glands as completely analogous to the chemical action which the current of the pile

exerts upon them, as various other physiologists have, indeed, already done. It is an error, therefore, to believe that secretion is solely or principally a work of elimination, the gland finding in the blood which surrounds or traverses it all the materials for the composition of the secretion it gives forth. In all the secretions, the secreted liquid differs chemically from that whence it is derived, the difference not being alike marked in all cases. Thus, the minimum of chemical difference is found in the excrementitious secretory apparatus, properly so called—as the kidneys, the secretory apparatus of which derives ready formed from the blood the principal constituents of the urine. Still, even here the secretion of urine will not be found to consist solely in the direct passage of the principles of the blood through the renal glands. True chemical reactions take place during this passage, and it is thus that in the carnivora the uric acid of the urates contained in the blood is set free, and that alkaline and earthy phosphates, when neutral or even basic, pass into the condition of acid phosphates, etc.—an alkaline liquid, under the intervention of the nervous system, giving rise to an acid excretion. In secretions, properly so called, or recrementitial secretions, as that of the liver, the chemical difference between the secreted fluid and that whence it is derived is far greater; and besides the chemical phenomena of the nature just alluded to, there are others of a purely physiological character, which are developed under the influence of certain ferments so entirely resembling the digestive ferments that, in fact, the elaborating functions which the glands exert upon the organic matters of the blood, in order to render them apt to fulfil the physiological action which has devolved on them, are really special digestive metamorphoses.

These views have led M. Mialhe to the formation of a new theory of diabetes. Until recently he had believed that glycosuria was solely due to an insufficient alkalinity of the blood, which rendered the complete destruction of the glycose in the animal economy impossible. At present, still retaining the opinion that it is solely through the intervention of the alkalies of the blood that glycose and its congeners are decomposed, oxidised, and burnt, becoming true calorific elements, he thinks that the primary cause of glycosuria does not solely reside in the abnormal composition of the blood, but rather is an essentially nervous affection—a nervous affection, not limited, as supposed by M. Claude Bernard, to the pneumogastric nerve, but consisting in a general neurosis.

"Diabetes is, in fact, a chronic neuropathy affecting all the nerves which regulate the secretions. It is now twenty years since, founding our view on our researches concerning diabetes, we laid down the position that this affection must be of much more frequent occurrence than was then supposed, and clinical observation has only too well justified the conclusion. But our opinion was supported by an observation the bearing of which we exaggerated, supposing, in fact, that the defective alkalinity of the economy was solely due to a too animalised regimen, the result of which was to give rise to the production of acids, and thus lessen the alkalescence of our humours. At the present time it is evident to us that this latter phenomenon is dependent upon nervous disturbance depending upon the same causes as those which render mental affections daily more prevalent."

PARLIAMENTARY.—THE CHOLERA AT QUEENSTOWN AND LIVERPOOL—THE SLAUGHTER OF CATTLE—HOSPITAL SHIPS—THE COMMONS (METROPOLIS) BILL—PROPOSED REPRESENTATION OF THE LONDON UNIVERSITY, THE SCOTTISH UNIVERSITIES, AND THE QUEEN'S UNIVERSITY (IRELAND)—REDUCED DUTIES ON WINES IMPORTED IN BOTTLE—THE INCOME TAX—THE LABOURING CLASSES DWELLINGS BILL—DEFEAT OF THE IMPERIAL GAS COMPANY'S ATTEMPT TO ERECT GAS FACTORIES NEAR VICTORIA-PARK—THE REPORT OF THE COMMITTEE ON THE ARMY AND NAVY MEDICAL SERVICES—THE MEDICAL OFFICERS OF THE GUARDS—METROPOLITAN WATER SUPPLY—THE VETERINARY SURGEONS BILL.

In the House of Commons on Thursday, May 3,

Mr. Maguire stated that the authorities of the city of Cork had been in communication with the Irish Government as to placing an old man of war in that harbour as a floating Hospital, and he had just received a telegram from the Mayor of Cork to the effect that cholera had appeared on board an emigrant ship which had arrived in the harbour. Two deaths had occurred, and as there were no means of quarantine the Mayor had ordered the vessel back to Liverpool. He appealed to the Government to take prompt measures for meeting the emergency. In 1833 application was made to the Government, and they placed at the disposal of the authorities in Cork an old man-of-war, the *Inconstant*, which proved to be of great service in preventing the spread of the disease.

Sir G. Grey wished that the Mayor of Cork had telegraphed to Her Majesty's Government as well as to the hon. gentleman. The Government had heard nothing from Cork; but about an hour before they had received a telegram from the Mayor of Liverpool, stating that a ship on its way to that port had touched at Queenstown with cholera on board. On receipt of the telegram he at once communicated with the Vice-President of the Privy Council, and directions would be given forthwith for the adoption of such precautions at Liverpool as might be advisable. He had no doubt that since it was now known to the Government that a vessel with cholera on board had touched at Queenstown, the Privy Council would give such directions as might be desirable in the case of that port also.

Mr. Read asked the Home Secretary whether it was the intention of the Government to continue, by Order of Council, the slaughtering clauses of the Cattle Diseases Act of 1866 after May 12, and whether any special exemptions from slaughter of diseased animals would be made for the purpose of testing the effect of any supposed curative treatment.

Sir G. Grey said it was the intention of the Government to issue an Order in Council extending the period during which those clauses were to remain in force beyond May 12. With regard to the hon. gentleman's second question, the decision of the Privy Council must await the report of the Cattle Plague Commission.

On Friday, May 4,

In answer to a question by Mr. Maguire, in reference to the recent appearance of cholera in Cork Harbour, asking whether the Government intended sending a hulk to that port, to be used as a Hospital-ship in case of necessity,

Sir G. Grey said he quite agreed that what was done as a means of precaution against cholera should be done immediately, and the Government had certainly acted in that spirit; for so long ago as July, 1865, when cholera was reported to be at Alexandria, they thought it right to address a circular to the municipal authorities of all the ports in Great Britain, calling their attention to the necessity of taking precautions against its introduction, and directing then, in case, unfortunately, of its introduction, that proper Hospital accommodation should be provided for the reception of the patients. He really did not know what steps had been taken by the municipal authorities in consequence of those warnings, except that at Liverpool there is a Hospital specially prepared for the reception of cholera patients. It was very doubtful whether a ship was the best kind of Hospital for cholera patients, and whether it would not be much better that provision should be made for them on shore; but the hon. gentleman was probably aware that for six years a sick ship was kept at Queenstown, but was never used, except on one occasion for a few days. It was therefore thought desirable to discontinue it and save expense. At present it was impossible for the Admiralty to provide ships for cholera Hospitals at the different ports; but if there was any urgent necessity at Cork the Admiralty would be prepared, if there was any difficulty in providing the necessary accommodation on shore, to place a ship at the disposal of the municipal authorities as a temporary expedient, those authorities undertaking the general charge and superintendence. He only spoke for his own department; but he should say that in such a case the municipal authorities ought to apply to the Admiralty, stating the circumstances which induced them to think such an arrangement desirable. With regard to any general system of quarantine, he could only say that in consequence of information from Liverpool received by telegram, and since confirmed by letter, the Privy Council had met, and were considering the terms of an order which would give municipal authorities additional powers to deal with ships that might arrive with cholera patients on board.

Mr. Liddell inquired whether the expense occasioned by the Hospital accommodation provided at the various ports to meet

the great danger of cholera would be borne by the municipal authorities or by Government subsidies.

Sir G. Grey believed that under the present law that expense fell on the local funds administered by the municipal authorities.

On Monday, May 7,

In answer to a question by Sir W. Jolliffe,

Mr. Cowper said that in the event of the Commons (Metropolis) Bill being read a second time he should be prepared to refer it to a select committee.

The Chancellor of the Exchequer in the course of his speech on the Redistribution of Seats Bill stated that the Government proposed to give one seat to the constituency of the University of London, and another seat to the Scottish universities. In introducing the Reform Bill for Ireland, Mr. C. Fortescue said that the Government proposed to throw open the Queen's University to all students applying for degrees, irrespective of their place of education. For that purpose it would be necessary to grant the Queen's University a supplemental charter. The Government intended to put the Queen's University on the same Parliamentary footing as the London University, and to give it the right of returning a member to that House.

In Committee on Ways and Means the House agreed to the reduced scale of duties on wines in bottle. One shilling duty is to be charged on wines containing less than 26 degrees of proof spirit verified by Sykes's hydrometer, and 2s. 6d. on wines containing less than 42 degrees.

On a resolution for the renewal of the income-tax, Mr. Hubbard, Mr. Alderman Lawrence, and Mr. Whalley protested against its inequalities and injustice.

The Chancellor of the Exchequer declined to discuss the question at that time.

On Tuesday, May 8, in the House of Lords, the Labouring Classes Dwellings Bill was read a second time.

In the House of Commons the Imperial Gas Company Bill was disposed of after a short debate. Mr. Tite moved its rejection, and the House turning a deaf ear to the undertaking of Mr. Staniland (who had charge of it) to strike out all the clauses relating to the erection of gasworks near Victoria Park, he ultimately withdrew it.

Colonel North asked the Secretary of State for War whether it was the intention of Her Majesty's Government to carry out the recommendations as regards increased pay, etc., of the Committee which was appointed to inquire into and report upon the grievances of the Medical officers of the army and navy, and if there was any objection to lay the report upon the table of the House?

The Marquis of Hartington said that the recommendation of the Committee involved not only a considerable increase of pay to Medical officers of both services, but questions of the expediency of placing the Medical officers of the two services on a different footing. The recommendations of the Committee were receiving due attention, and as soon as a definite decision was arrived at he would communicate the result to the hon. member. He did not, however, think that it would be expedient to lay the report asked for upon the table just now.

Sir R. Anstruther, in calling the attention of the House to the proposed alteration in the system of promotion among the Medical officers of the Brigade of Guards, and in moving for an address for copies of the warrant or order of 1860, under which a change in the system of promotion among the Medical officers of the Brigade of Guards is to be made, and of any communication from the War Office or the Horse Guards to the officers commanding the three regiments of Guards, intimating the proposed change of system to the officers affected by it, said he believed that the motion affected the whole of the Medical department in her Majesty's service, and, through that department, the whole Medical Profession throughout the country. It could scarcely be expected that first-class men of the Medical Profession would enter her Majesty's service unless they could be certain of the rules under which their promotion was to be regulated. It was supposed by some that this motion went further, and affected the authority of the Crown over its own army. He should be the last man to wish to see the power of the Crown over the army controlled in any way, and he should regard it as a great misfortune were that House to take the control of the army into its own hands; but they had a right to expect that the recommendations which were given to her Majesty by her advisers should be made with a due regard to existing and ancient interests, and that any innovation upon the ordinary rules should be preceded by ample notice to the parties likely to be affected by such changes. The promotion to the position of Surgeon in the Guards had hitherto been regulated by seniority, and he had heard of no reason why a system which had endured for so many years should be altered. It appeared that in 1858 a royal warrant was issued, founded upon the recommendations of the Royal Commission of 1857, which ordered that the Assistant-Surgeons should as a general rule be promoted to the rank of Surgeon in the order of their seniority of service, unless exceptional circumstances should prevent them being so promoted. The Medical officers in the Guards did not imagine that that warrant affected them, as it had hitherto been supposed that when the Guards were not especially mentioned in a warrant they were not affected by it. The warrant in question contained no special mention of that particular branch of the service, and, therefore, the Medical officers in it were justified in believing that they were not affected by it. Either they were or they were not affected by it—if they were not, then his argument held good; if they were, then there was no necessity for any subsequent warrant. It now turned out, however, that, in 1860, a special warrant was drawn up, which decided that the promotion to the rank of Surgeon in the Guards should go by seniority in the brigade of Guards. He was not there to dispute that warrant, but he thought that the gentlemen affected by it should have been informed of its existence. The noble lord the Secretary of State for War had, on the 9th April, admitted that that warrant had been neither seen nor promulgated. Doubtless the noble lord in his reply would state that, although the warrant had not been promulgated, the Medical officers in the Guards were fully acquainted with its tendency; but he found, upon inquiry, that they were entirely in ignorance of its import. In the face of the warrant, however, Assistant-Surgeon Kerin was appointed, in 1863, over the heads of the Assistant-Surgeons of brigades, and Surgeon Wylde was promoted in a similar manner. He thought it extremely hard that an officer entering the Service before the warrant was signed should suddenly find his prospects destroyed without the slightest warning. At the time the warrant was signed, many officers, he was informed, would, if it had been promulgated, have resigned and sought advancement in other walks of life; but now they found that all the time they had spent in the Profession had simply been of no advantage to them. The discontent which existed among the members of the Medical branch of the army was not, he thought, surprising, when it was found that the Professional prospects of those officers would be so suddenly destroyed. On the contrary, indeed, he thought it was but natural that such discontent and distrust should exist. In addition to all the objections which might fairly be urged against the warrant itself, the time of its promulgation was about the worst that could possibly have been chosen. He had, he ventured to think, brought the matter forward in the interest of the Service itself, as well as in the interest of the Medical men. The Assistant-Surgeons of the brigade of Guards did not ask that the warrant should be repealed. They did not say that it was a bad warrant, and they would even admit that it might possibly be a good one. What they asked, however, was that it might not have retrospective action. The hon. member concluded by moving an address for copies of the Warrant or Order of 1860, under which a change in the system of promotion among the Medical officers of the brigade of Guards was to be made, and of any communications from the War Office or Horse Guards to the officers commanding the three regiments of Guards, intimating the proposed change of system to the officers affected by it.

The motion was supported by Lord H. Percy, Mr. Corry, and Mr. Ingham.

The Marquis of Hartington: Although I am unable to admit that the papers for which the hon. Baronet has moved are documents which the House has any right to claim, still, as I shall have to refer to them in the course of my reply to his questions, it will only be in accordance with the rule of the House if I lay them upon the table. I therefore make no opposition to his motion. I have, however, to make one or two observations with respect to his remarks and the request which he has made, and I hope I shall succeed in placing the matter before the House in a somewhat different light from what it is in now. It is quite true, as was stated by my hon. and gallant friend, that up to the year 1850, and I think I may say 1860, the rule of promotion from the rank of Assistant-Surgeon to Surgeon in the brigade of Guards was by seniority in the regiment. However, in 1858, as has already been stated, a warrant was published altering in almost every particular the *status* of the Army Medical officers—altering their position with regard to pay, relative rank, allowances, promotion,

and pensions. The rule of promotion from the rank of Assistant-Surgeon to Surgeon was, save in some exceptional cases which were specified, to be by seniority in the service. Now, it has been stated that, the Guards not being specially mentioned in that Warrant, there was nothing to show that its provisions affected them. Does my hon. and gallant friend, however, deny that the Surgeons and Assistant-Surgeons of the brigade of Guards have taken advantage of every provision in that Warrant which tended to their benefit? Does he deny that the Assistant-Surgeons are at this moment in receipt of the increased pay given by that Warrant, and that in the brigade of Guards two at least of the Surgeons of the regiment have attained the rank of Surgeon-major simply through the operation of that Warrant? There was no objection on the part of the Surgeons of the Guards to accept those provisions of the Warrant which tended to their advantage; and surely, if they had any doubts on the subject of promotion, it would not have been too much trouble for them to make inquiries as to any provisions which were to be set aside in their case. A great deal has been said about what has been called the Warrant of 1860, but that term is hardly applicable to the document in question. The history of it is as follows:—In 1860 a vacancy took place in the office of Surgeon in one of the regiments of the Household Cavalry, and the Colonel of the 2nd Life Guards, Field-Marshal Lord Seaton, according to custom, recommended the appointment of the senior Assistant-Surgeon in his own regiment. At that time the Assistant-Surgeon of the brigade of Guards, Mr. Kerin, was not only Assistant-Surgeon of the Household Cavalry, but also senior of that rank in the Army. His Royal Highness the Commander-in-Chief, in a letter to Mr. Herbert (afterwards Lord Herbert) in recommending that the appointment should not be given to the Assistant-Surgeon to the 2nd Life Guards, but to Mr. Kerin, the senior Assistant-Surgeon of the brigade of Guards, took occasion to state the way in which he proposed to carry out the provisions of the warrant of 1858 with respect to the Household Cavalry and the brigade of Guards, so as to fulfil the intention of that warrant, and at the same time to preserve, not the rights of the Assistant-Surgeons—who, it seems, he did not think had any rights at all to regimental promotion—but the rights and the privileges of the colonels of the Guards, who had hitherto had the power of recommending promotions. That letter of his Royal Highness, and the reply of Mr. Herbert, I shall be able to lay on the table of this House. The reply of Mr. Herbert will show that he had no doubt whatever about the propriety of the promotion of Mr. Kerin; the only doubt that existed in his mind was whether or not the limitations proposed by his Royal Highness that promotion should go by seniority in brigade were in contravention of the warrant. The result of that correspondence between Mr. Herbert and his Royal Highness was a document which was submitted for the approval of Her Majesty, and which became what was designated the Warrant of 1860. That document, as I have explained, is not a warrant, but merely a submission by the Commander-in-Chief to Her Majesty of explanations of portions of the Warrant of 1858 applying to Surgeons of the brigade of Guards. Therein it is laid down:—

"That on the appointment of Surgeon becoming vacant, if in the Household Cavalry, the colonel of the regiment should be permitted to recommend for the succession the Senior Assistant-Surgeon of those three regiments, if duly qualified, and he thought proper to do so, or, if he considered it more desirable, to recommend the transfer of a Surgeon from the cavalry or infantry of the line, or the promotion of the Senior Assistant-Surgeon of the whole army, to fill the vacancy; and that the same rules should be observed on any vacancy becoming vacant in one of the regiments of Foot Guards, the promotion being given on the recommendation of the colonel either to the Senior Assistant-Surgeon of those three regiments or the vacancy filled by the transfer of a Surgeon or the promotion of a Senior Assistant-Surgeon of the army if duly qualified."

After this document came from the Queen there was no necessity for keeping the knowledge of it from the brigade of Guards; and I admit that through an inadvertency that document was not well known, and that this is a circumstance to be regretted. (Hear, hear.) However, for reasons I have mentioned, I do not think that that circumstance was sufficient to make it necessary to postpone the operation of the provisions the document contained. For I maintain that the Warrant of 1858 is the only warrant under which the Surgeons of the Guards, in the same way as the Surgeons of the whole of the rest of the army, are placed. If they wanted to become acquainted with the regulations affecting their promotion, they had only to look to that Warrant, and if they thought that exception should have been made in their case they should have applied for it. As it has been admitted by the hon. baronet who moved the address, the decision arrived at on this subject has been perfectly well known to the Surgeons in the brigade certainly since the year 1861. With regard to the case mentioned by my hon. and gallant friend, in which he said there had been a regimental promotion, he has omitted to mention circumstances which fully show that instead of the promotion of Assistant-Surgeon Hayward being an infringement of the Warrant, it was in conformity with the principle laid down in it—viz., that not the Surgeon who has served longest in the brigade, but longest in the army, should be promoted. My hon. and gallant friend has also referred to Surgeon-Major Wylde. Now, the Warrant of 1858 and the submission of 1860 did not refer in any way whatever to any promotion excepting the promotion from Assistant-Surgeon to Surgeon. The regimental Surgeon-Major, the hon. baronet is aware, is one of the peculiarities of the regiments of the Guards, which does not exist in any other regiments, and my hon, and gallant friend will remember that what applies to the Medical department of the lower ranks of the army no longer applies to the higher ranks. Considering, therefore, the decision arrived at in 1860 was in strict accordance with the principles laid down in the Warrant of 1858, and that the Surgeons of the brigade of Guards have without exception acted under it, and that it has not been shown that they were ignorant of the decision arrived at in 1860, I do not think any cause has been stated for setting it aside.

Sir R. Anstruther said that the Secretary for War had misunderstood him, arguing that he admitted that the Assistant-Surgeons of the Guards were aware of the Warrant. What he had said, however, was that there was absolutely no communication to them till 1865, and the communication then sent referred to a very small part of the submission from which the Secretary for War had quoted.

The Marquis of Hartington: I understood the hon. baronet to say that, although it had never been officially promulgated, the Assistant-Surgeons of the Guards were perfectly aware of the decision which had been arrived at in 1860. If my hon. friend does not admit this, I am prepared to assert on information which I possess, that the greater part, if not the whole of the Assistant-Surgeons of the Guards, previous to 1865, were aware of the decision, and that it underwent considerable discussion among them. With regard to the question of merit, I do not think it necessary to enter upon it at the present time. I do not see why what has been generally adopted in the army at large should not be adopted in the Guards. The hon. member for Leitrim contended that faith had been broken with these officers, who were naturally dissatisfied that juniors should be promoted over their heads. But that is the very thing this regulation was intended to avoid, and the objection of the hon. member for Leitrim therefore fails of its point. As to the passages which my hon. friend read out from the report of a Committee, which has not been laid on the table, but which, on the contrary, is a confidential document, I do not know how he obtained it, and I must decline to follow him into those passages, more particularly as the report is one which has no special bearing upon the case. For the reasons which I have stated, I regret that I shall not be able to advise the Commander-in-Chief to postpone the operation of the Warrant of 1858 with regard to Assistant-Surgeons; but rather that matters shall be left upon the footing on which they were placed in 1860.

The debate was continued by General Peel, Captain Vivian, Col. Annesley, Lord Dunkellin, Col. North, Col. Knox, and Col. Jervis. The first-named officer considered that the question was not one on which Parliament should be called to decide.

Sir R. Anstruther, in reply, insisted on the hardship of bringing parties under the operation of the warrant when the noble lord himself admitted they had never seen it. He had not the least wish to interfere with the prerogative of the Crown in this matter, but he begged very respectfully to submit to the noble marquis and the Commander-in-Chief, not as a question of right but of justice, that the action of the warrant should simply not be retrospective. He thanked the noble lord for having agreed to lay the papers he required on the table.

The motion was then agreed to.

Mr. Hankey moved for a Committee to inquire into the

water supply of the metropolis, but ultimately withdrew his motion.

On Wednesday the Veterinary Surgeons Bill, which forbids the assumption under penalty of the title of Veterinary Surgeon except by diploma from the College of Veterinary Surgeons, was read a second time, Mr. Bruce, on the part of the Government, intimating that at a future stage he should suggest a relaxation in its stringency.

CONFLICT OF TRUTH.

(From a Correspondent.)

It is a bad thing for science when one of two apparently conflicting truths is seized upon exclusively, and the other disparaged. This used to be the case with the doctrines of contagion and non-contagion. Some denied that diseases were transportable, and pointed to local impurity as their cause; others neglected cleansing, and trusted to quarantine. We are wiser now, and know that each party is right in what it asserts, but wrong in denying the position of its antagonist. So we do our best both to keep infected persons at a distance and to clean up our dirty places as well. Just now there are similar indications of exclusiveness with respect to the scientific doctrine that epidemic diseases have inherent periods of rise, increase, and decline on the one hand, and the practical maxim on the other, that it is within our power—if not to "stamp out,"—at any rate, to limit the ravages of epidemics by limiting the sources whence contagious germs proceed, and by preventing their propagation. For our own parts, we hold each doctrine in its proper place and measure. Supposing the cattle plague to visit a new and hitherto uninfected district, what should we do? Assuredly try to "stamp it out" by putting six feet of quicklime and earth between the infected carcase and the upper air; and by repeating this, combined with the "most stringent" measures of disinfection, so long as it seemed at all probable that any such sacrifice would stop the spread of the disease. But if the whole herd were infected—if sources of contagion were all around, no matter from which quarter the wind blew—and if the virulence of the epidemic were abating as shown by the ratio of recoveries, of course it would become a question what is the mode of saving the greatest quantity of beef? and then warm mashes and disinfectants would take the place of poleaxe and disinfectants. This, we think, would seem common sense to most of our readers.

REVIEWS.

Medico-Chirurgical Transactions. Published by the Royal Medical and Chirurgical Society of London. Second Series, Vol. xlviii. Longmans. 1865.

It may be thought a work of supererogation to review the transactions of a society in a journal where reports of all that is said and done in that society regularly appear. But if it be necessary to find an excuse for so doing, it is furnished by the excellency and practical importance of the papers which the Royal Medical and Chirurgical Society admits into its yearly volume. The two series of "Medico-Chirurgical Transactions" give, probably, a more worthy and favourable picture of the progress of Medicine and Surgery in England during the present century than any other serial publication we possess. They contain the best work of the best workers, the most carefully-sifted observations of the best observers, the cream of experience obtained in the great Hospitals and schools of London and the provinces. In spite of the rivalry of young and vigorous competitors, the Society still maintains its lead, not merely as a club to which the *élite* of the Profession are admitted by ballot and considerable pecuniary contribution, but as the foremost Medical and Surgical Society in Great Britain, challenging competitorship in scientific achievement as securely as in Professional status.

We should far exceed our allotted space did we notice all the papers in the present volume. We hope that our selection will not be construed into depreciation of those which we omit. Like an epicure who, glancing down an elaborate *carte*, pricks his dinner, we can only, in sight of so many good things, choose here and there, sighing the while over the limitation of our powers. Mr. Nunneley, of Leeds, under the name of Vascular Protrusion of the Eyeball, treats of that affection which was described by Travers as Aneurism by Anastomosis of the Orbit. In a former volume of the *Transactions*, Mr. Nunneley recorded four cases in which he had tied the common carotid artery for this disease; he now adds to them records of three others and an account of the post-mortem appearances in those of two patients who, having been treated by deligation of the carotid, died a considerable time afterwards from causes unconnected with the operation. The disease, as is well known, may be of spontaneous or of traumatic origin. There have been two theories as to its nature: one that of Mr. Travers, who believed the affection to be of the same nature as the erectile tumour described by John Bell under the name of Aneurism by Anastomosis; the other that of Mr. Busk, who, reasoning from the sudden accession of the disease, its rapid increase, and the powerful pulsation occurring in the tumours when recent and small, concludes that these conditions are best explained by supposing the formation of a true aneurism of some vessel within the orbit. Mr. Nunneley demurs to both these explanations of the morbid phenomena. He rejects the aneurism by anastomosis theory, on the same grounds as Mr. Busk; but whilst he concedes to that gentleman that true aneurism may occur in any of the intra-orbital arteries, and that possibly some of the reported cases may have been of that nature, he nevertheless holds that in several of the few recorded cases there has been no aneurism at all, and that where there has been aneurism, it has been within the cranium and not in the orbit. Further, he believes, "that the prominent symptoms are not essentially dependent upon an aneurism, either true or false, whether in the orbit or in the cranium, as a primary or necessary cause, but are, so to speak, secondary to it; indeed, that they may arise from other and varied causes, which produce post-ocular pressure upon the ophthalmic veins." The two cases in which post-mortem examination was obtained confirm Mr. Nunneley's view of the nature of the affection. In one there was cancerous tumour of the orbit, which extended backwards through an opening in the apex of the orbit to the side of the sella turcica. The ophthalmic vein had been pressed on until it was lost in the mass; the cavernous sinus was obliterated. In the other case there was a circumscribed aneurism of the ophthalmic artery; not intra-orbital, however, but situated at the side of the sella turcica, whilst the intra-orbital portion of the artery, both trunk and branches, was of very small size. In the majority of cases of spontaneous origin the obstruction to the return of blood through the ophthalmic vein—which, according to Mr. Nunneley's view, is the real cause of the disease—will, he believes, be produced by aneurism of the internal carotid as it emerges into the cranium or of the ophthalmic artery near to its origin. In the majority of traumatic cases he believes the pressure will be generally produced by the effusion of blood or of the products of inflammation near to or within the cavernous sinus. Less formidable degrees of protrusion of the eyeballs Mr. Nunneley is inclined, in like manner, to refer to posterior venous congestion. Tumours of any kind in the orbit, cranium, or neck may produce the necessary obstruction to the return of blood. Thus he accounts for the connexion of bronchocele with prominent eyeballs. The staring eyeballs of asthma, emphysema, and bronchitis are to be explained on the same principle. Obstruction to the return of blood to the right side of the heart or to its escape from the heart's cavities may be sufficient alone, if long continued, to produce a degree of ocular protrusion, but such a condition will be soon accompanied by some effusion into the loose post-globular tissue of the orbit, and thus the effect on the eyeball is increased. The condition of anæmia by favouring exosmosis, if accompanied by a slight impediment, readily becomes associated with protrusion of the eyeball. Mr. Nunneley's paper, of which we have given a very imperfect sketch, presents, it will be seen, points of the greatest interest both to the Physician and Surgeon, and would furnish a good text for a discourse on the essential oneness of the science and art of healing.

The chief point of interest in Professor Longmore's paper "On Osteo-Myelitis consequent on Gun-shot Wounds of the Extremities" is the substitution which he proposes of careful and complete removal of the sequestra for the more formidable operation of exarticulation or further amputation. He founds his suggestion on the history of cases in which the removal of

dead bone was followed by a sound state of the stump, and on an examination of preparations of diseased portions of bone removed by exarticulation from patients in whom osteomyelitis had followed amputation for gunshot wound. To quote Professor Longmore's own words :—

"The result of the cases I have just named where stumps have been preserved without exarticulation or further amputation, and a careful examination of the diseased conditions in the preparations I have brought before the Society, where stumps have been removed by exarticulation, or where death has occurred, as in the case from which the preparation of the femur was taken, without operative interference, have led me to the conclusion that in all cases, however severe, of endosteitis and endosteitic necrosis after gunshot injuries, before resorting to the extreme measure of exarticulation, as urged for all cases by M. Jules Roux, and recommended in certain cases by Baron Larrey, the opportunity of effecting a cure by careful and complete removal of sequestra should invariably be tried. The judgment of the Surgeon will be tested in determining the precise period when the process of sequestration is sufficiently advanced to admit of operative interference with advantage; and his qualities as a Physician will be put to the test in the support he must afford to the patient's constitution while subjected to the irritation inseparable from this protracted ordeal. But when the period has arrived of nearly complete sequestration of the dead bone, then the stump should be opened if amputation has been previously performed; or the steps taken such as are employed in ordinary necrosis if no amputation has been performed; and the necrosed portions be entirely removed, and the case treated on general principles."

Professor Longmore's proposal is founded on the best established principles of Conservative Surgery, and if it become, as we think it must, a canon in practice, it will confer fresh honour on that illustrious school of Military Surgery of which he is a worthy representative.

Dr. Hillier has contributed to the present volume a remarkable case of "Congenital Hydronephrosis" in a boy 4 years old, in whom recovery took place after repeated tapping. In this case there was a large cyst springing from the right side of the abdomen, which was suspected to be connected with the right kidney. The first operation of tapping confirmed the diagnosis, for the fluid drawn off, amounting to 102 oz., had all the characters of dilute urine. The history of the case establishes that the cyst did not usually communicate freely with the bladder, but from time to time, when much distended, its contents were partially poured into that viscus. The large quantities of urea in the fluid drawn from the cyst proved that a certain amount of renal tissue existed on that side. Albumen was present in the cystic fluid, and this circumstance is believed by Dr. Hillier to explain the fact that ferrocyanide of potassium administered to the patient by the mouth appeared in the urine passed from the bladder, but not in the fluid of the cyst; for in a patient with albuminuria this salt was not detected in the urine after the administration of twenty grains. The same experiment was tried, however, with gallic acid, which, when administered, was detected in albuminous urine, but not in the cystic fluid. Dr. Hillier thinks this may be explained by supposing that the gallic acid passed only through the kidney on the left side, or else that there was not a free communication between the part of the cyst in which the canula was inserted, and that part into which the kidney first emptied itself. The cause of the intermitting flow of urine down the ureter might, the author suggests, have been valvular, or the presence of a calculus. Dr. Hillier subjoins a retrospect of the published cases, and in discussing the question of treatment notices a suggestion that the cyst might have been removed from behind. He, however, as we think very properly, decides against such a proposal on the grounds of risk of interference with the sympathetic nerve near the semilunar ganglia, risk of hæmorrhage and peritonitis, and on the fact that removal of the kidney in the lower animals has always proved fatal.

Dr. William Roberts's paper on the "Solvent Treatment of Urinary Calculi," has excited, we believe, more attention than any other contribution to the archives of the Medical Societies during the past year. The demonstration which he affords of the possibility of dissolving uric acid calculi by a properly-pursued and regulated alkaline treatment, constitutes an era in the treatment of these affections. We may state that we have obtained unmistakeable success in the treatment of uric acid renal calculus by the large doses of bicarbonate of potash he recommends, and this after the carbonate and citrate of lithia had comparatively failed to produce alleviation of the symptoms. Dr. Roberts has shown that uric acid calculi are susceptible of solution out of the body by the action of alkaline solutions of the salts of potash, and in the body, by urine rendered alkaline by the same salts; that the requisite alkalinity of the urine is to be obtained by the administration of citrate, acetate, or bicarbonate of potash, in repeated doses of from forty to sixty grains; that this method of treatment holds out a prospect of success in vesical uric acid calculi which must not be expected from the injection of alkaline solutions into the bladder. With regard to other calculi, he has arrived at the conclusion that oxalate of lime calculi are practically insusceptible to acid and alkaline solvents, but that phosphatic calculi, although insusceptible to the action of alkaline solvents, offer an encouraging prospect for the use of acid injections into the bladder.

Mr. Henry Lee's mode of amputating the leg by long rectangular flap from the calf is a modification of Mr. Teale's plan of operating. The external incisions are made according to Mr. Teale's plan, but the long flap is obtained from the back instead of the front of the leg. Mr. Lee finds that the long flap thus obtained is much thicker than when taken from the front. It is hence less liable to slough, affords a more efficient protection to the ends of the bones, and a thicker and softer pad on which to rest the weight of the body when an artificial leg is worn.

Dr. Benjamin Howard, of the United States Army, has contributed an important paper on the "Application of Sutures to Bone in recent Gun-shot Fractures." His proceeding consists in cutting down upon the seat of fracture, as in ordinary resection, removing all the fragments and spiculæ of bone, making a clear section of the fractured ends of the shaft, effecting perfect apposition, maintaining it by metallic sutures, and securing rest by a light splint. He publishes a case of extensively comminuted fracture of the humerus which was successfully treated in this manner. In a case of fractured femur, also thus treated, a like satisfactory termination was not obtained. The patient was an old man of 60, and of a broken-down constitution. The fracture was extensive, and the patient was subjected to removal in the ambulance train the day after operation. He died on the road three days after. Dr. Howard's operation seems intended especially for cases which occur on the battle-field, and which must be subjected to all the contingencies of transit. He, however, suggests that it may be useful in cases of compound fracture with great displacement occasionally met with in civil practice. The use of sutures in the treatment of ununited fracture is, of course, not a new proceeding. Dr. Howard only takes credit for having first used them in the primary treatment of fractures from gunshot.

"Fibroid Degeneration of the Lungs" is treated at great length by Dr. Henry G. Sutton. He draws a distinction between fibroid transformation or fibroid phthisis and the tubercular or scrofulous phthisis. The former consists of a form of induration of the lung, which is shown by the microscope to be made up of such elements as are considered to denote fibroid changes (granular corpuscles, cells, spindle-shaped fibres). This degeneration, he finds, is most frequently associated with a like degeneration of other organs, as the kidneys, liver, capsule of the spleen. The conclusions he draws are too numerous and lengthy to be transferred to this notice, and they are too important to justify abbreviation. We commend the paper to the careful perusal of all our readers who are studying the diseases of the respiratory organs.

Here we must stop. We hope that we have written enough to prove that this volume of the *Transactions* is worthy to take its place by the side of those which have preceded it.

THE CHOLERA ON BOARD THE "VIRGINIA."—It is mentioned as a singular circumstance that the cholera broke out on the *Virginia* in about the same place on the ocean at which the passengers of the steamship *England*, another of the National Steam Navigation Company's vessels (afterwards detained at Halifax), were attacked. This is important, as it tends to confirm the theory advanced by a few persons that certain states of the atmosphere, sometimes found in belts, are peculiarly adapted for the development of cholera.—*New York Herald*, quoted in the *Liverpool Weekly Mercury*, May 5.

CHARLOTTE WINSOR.—The Court of Exchequer has confirmed the unanimous decision of the fifteen judges in the case of this notorious criminal. She is now left a third time for execution.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

May 7.

On April 24 we received the first intimation of the outbreak of cholera on board an emigrant steam ship—the *England*—a newly-built and well-appointed screw steamer belonging to the National Steam Navigation Company; in fact, it was her first trip. She sailed from this port on March 28 with 1202 passengers, and with a crew of nearly 100. About 400 of these passengers were German emigrants, and it appears that all were in perfect health till the fifth day after the *England* left Queenstown, when cholera of a very virulent form broke out among the German passengers. Under these circumstances, the captain considered it desirable to put into the nearest port, and accordingly steered for Halifax. The number of deaths that occurred previous to the *England* reaching that port were 46, and in a few days afterwards 94 more succumbed to the disease, five of the crew being among the number.

The Governor of Halifax sent down 80 tents for the accommodation of the healthy survivors on McNab's Island, while the suspected were received on the hulk *Pyramus*. The death-rate at first was 25 per diem. Dr. Slayter, the Halifax Physician who attended the cholera patients, has since died of that disease.

On the 3rd of May the *City of New York* brought the intelligence of the outbreak of cholera on board the *Virginia*, another emigrant vessel belonging to the same company. The disease, as in the *England*, commenced among the Germans; and, indeed, occurred in almost the same latitude, and about the same period after her sailing. The cabin passengers in both ships were entirely free—the Germans for the most part were its victims, very few of the Irish or English being attacked. Thirty-eight deaths occurred on the voyage, and after her arrival nine more took place, while 34 were on the sick-list. The *Virginia* sailed from Liverpool on April 4 with 1043 emigrants, and 37 more were received at Queenstown.

On her arrival on the other side the Atlantic, the *Virginia* was placed in quarantine, and the sick were removed to the Hospital ship *Falcon*, while the unaffected steerage passengers were received on board the steamer *Illinois*. The cabin passengers, since they were not allowed to land, preferred remaining on board the *Virginia*. Shortly after the news by the *City of New York*, the people of Liverpool were alarmed by a telegram from Queenstown stating that cholera had appeared on board the *Helvetia*, which had sailed from Liverpool the previous Wednesday, *a third* emigrant vessel belonging to the same Company, that she was returning to Liverpool, two deaths having already occurred.

Upon inquiry it was found that while the *Helvetia* was in the river one, if not more, of the German passengers was sent on shore, in consequence of showing some suspicious symptoms; however, when she sailed all the passengers appeared in perfect health; but soon after she had put to sea the disease developed itself, and on her arrival at Queenstown Admiral Ker refused to permit the vessel to enter the harbour, as there were no facilities at that place for combating the disease, and ordered her back to Liverpool. The *Helvetia* carried 925 emigrants, 400 of which were Germans, and 70 of that number had passed through Rotterdam. The *Helvetia* arrived in the Mersey on Friday afternoon, and was at once visited by the authorities. It was found that there was only one case on board, and that a mild one, and the alleged two deaths were not corroborated. There were a few cases of simple diarrhœa. The Mayor of Liverpool, although not legally justified in doing so, immediately on the arrival of the ship, ordered that no person should land, and that no one should visit her, except those authorised by him to do so.

Dr. Buchanan has been sent down by Government, and he expressed his approval of the arrangements which the Health Committee proposed. The National Company have provided two hulks, one for the healthy and one for the sick, which latter is under the management of the Select Vestry and their Medical officer. The *Helvetia* is now lying in the river with a white flag. A hulk has been already fitted up with every necessary in case of further outbreak.

Dr. Buchanan and Dr. Trench, the Medical Officer of Health for Liverpool, visited the *Helvetia* on Saturday morning, and found, I understand, the state of things satisfactory; there had been no recurrence of the disease, and the patient who had been attacked was convalescing; but in the evening two fresh cases were reported. Both are Germans: one is a child, which is not expected to recover, the other a man, who is not so severely ill. The 500 British subjects, passengers on board, are to be transferred at once to a hulk, and in a few days the Germans are to be placed on another vessel in order that the *Helvetia* may be disinfected. The *Helvetia* is under the charge of the river police, and an order has been received from Whitehall empowering the Mayor to refuse persons landing for the present.

It does not appear that there was illegal overcrowding on board any of these vessels, as it was proved they were all short of the full number of passengers they were permitted to carry. There cannot be the slightest doubt that the cholera was introduced into these three vessels by the Germans, among whom the disease was latent until ripened by ship crowding and the depression induced by sea-sickness, which, combined with the proverbially filthy habits of the race, broke out in all its horrors. Some of these Germans are miserably clad, and generally possessed of a very limited wardrobe.

We were again startled on the 2nd instant from the ascertained fact that the cholera had occurred in the town—amongst three German families (intending emigrants), numbering upwards of twenty persons, who had been received into the Liverpool Workhouse Infirmary, the Emigration Medical Officers having refused to pass them on account of the state of their health. They were admitted from a German lodging-house in Hanover-street.

Some very important facts were elicited as to the state of such houses. It was discovered that there was an attempt to overcrowd twice as many into rooms as they were licensed to hold, and that in a house 150 slept in one night. In another case forty slept and lived in the same room. These lodging-houses are now visited daily by the authorities, and no further outbreak in the town has taken place. Of the cases of cholera admitted into the Workhouse Hospital one was a Dane, the other a Dutch woman; they were in a state of extreme collapse on admission, and have since died. Besides these two there was a third—a child, who died on the way to the workhouse, upon whom an inquest was held, and the post-mortem verified the conclusion that it was a case of cholera. No further cases of disease have occurred among the Germans in the workhouse.

It is a very fortunate thing that such prompt and stringent measures have been adopted in Liverpool, and we trust they will prove effectual.

I may just mention that the National Steam Navigation Company has issued the following notice:—"No foreign emigrants will be taken by the *Denmark*."

GENERAL CORRESPONDENCE.

LANCISI AND THE CATTLE PLAGUE.

Letter from Dr. W. Farr.

[To the Editor of the Medical Times and Gazette.]

Sir,—I do not desire to discuss the laws of epidemic disease controversially; my views are meantime correctly stated(a) in your journal, and I hope ere long to be able to publish the further results of some inquiries into this very difficult question.

The experience of the course which the epizootic took in Italy is full of interest, and it is important that its description by Lancisi should be correctly given. Lancisi, as is well known, described the epidemic in the Roman States. And to his observations I referred in the following terms:—

"The cattle plague in Rome, which Lancisi has so well described, lasted less time than our calculation gives. It began about August 1, 1713, and left no vestiges of its existence in May, 1714. . . . The most minute instructions of the Pope and the College are given by Lancisi, but no authority to slaughter; and apparently not a single head of cattle was slaughtered by authority in the Papal dominions. Yet the cattle plague subsided in nine months."(b) After referring to the law of the plague curve, I then assign reasons for believing that, "although Rinderpest will remain in the

(a) See also in *Journal of Social Science*, edited by Dr. Lankester, No. 6, p. 349, letter to editor, and reprint of letter to *Daily News*.

(b) *Daily News* letter, dated February 15.

country as a sporadic disease, liable to other eruptions, it will subside spontaneously as an epizootic."

My friend Dr. Markham points this out to you as "a somewhat important historical error which Dr. Farr has made in his reading of Lancisi. Dr. Farr has used, as an illustration of his theory of the natural progress of the Rinderpest epidemic, the supposed fact that in the epidemic at the beginning of the last century it ran its course in Italy in nine months—arose, spread, and disappeared—and he quotes Lancisi as his authority." A somewhat similar statement appeared in Dr. Markham's excellent journal, at which I was surprised, as the statement implies that in the beginning of the eighteenth century the Pope ruled over the whole of Italy—a grave error in geography, as Dr. Markham will discover on turning to his map, or looking up his history of Italy. The Papal dominions were nearly the same in 1713 as they were up to the reconstruction of Italy under Victor Emmanuel. Dr. Markham gives another reading of Lancisi different from mine. "The cattle plague," he says, "Lancisi tells us, first appeared in Italy (in the Po district) in 1709, and continued its ravages there until 1713." Now, in my edition of his works (Geneva) Lancisi tells us that the cattle plague first appeared in MDCCXI. I read this 1711: Dr. Markham apparently reads it 1709. I refer this question, as well as the question of geography, to you and your readers, as well as to Dr. Markham himself. The date 1711, I may add, agrees with that given by Ramazzini. Then, Dr. Markham's date, "1713," is evidently erroneous; so is his assertion that Lancisi ascribes the extinction of the plague in nine months "solely" to the stringent measures for its suppression.

To have done with controversy, I proceed to give a short account of the Italian observation as described in Lancisi's work—"De Bovilla Peste ex Campaniæ finibus anno 1713, Latio importata."

Italy, divided by the Appenines, consisted of several states at the beginning of the eighteenth century. Lancisi mentions Venice, Milan, Naples, Latium, or the ecclesiastical dominions. Then there were Sardinia, Parma, Modena. Lancisi had recommended the slaughter of diseased cattle. I cited him to prove that, contrary to the current opinion, his advice was not adopted, and that the cattle plague ceased in nine months within the Papal dominions. The disease, he says, following Ramazzini, began in the Paduan territory in the summer of 1711, and gradually spread among the remaining flocks of Venetia, soon reached Milan, then Ferrara, and about two years afterwards Naples (denique duobus ferè abhinc annis Neapolitanum Regnum), whence it extended over the Campania to Rome in the middle of the summer of 1713. It began there in the month of August, 1713, and ceased in April, 1714 (novem scilicet mensium spatio), so that among the flocks of the Roman States (Romanæ ditionis armenta) no vestige of the plague remained in May. Lancisi does not enable us to trace the ravages of the cattle plague through all the other States of Italy. It raged, he says, more fiercely and much longer among other people, and was not extinct in the Transpaduan territory when he wrote (c) (anno 1715). When the cattle plague ceased in all Italy I do not know, but we learn in an epistle of Fantonus to Lancisi that it was entirely extinct in Piedmont in August, 1716. I infer from a passage in the same letter and from the published lecture of Ramazzini, that the system of slaughter was not followed in Italy, where the ox takes the place of the horse in England. This is well touched by Ovid in the Metamorphoses (lib. xx.):—

> Quid meruere boves, animal sine fraude dolisque
> Innocuum, simplex, natum tolerare labores?
> Immemor est demum, nec frugum munere dignus,
> Qui potuit curvi demto modo pondere aratri
> Ruricolam mactare suum; qui trita labore
> Illa, quibus toties durum renovaverat arvum,
> Tot dederat messes, percussit colla securi.

The last line might not clash harshly on the ear of a butcher, but it was otherwise in Italy, which felt almost an Indian affection for the ox. The supporters of Lancisi's rejected policy of the pole-axe admitted that on its face it had the appearance of great cruelty! Such an argument could not be urged in a country where people only eat the ox; and certainly would have told with very little effect in the House of Commons, containing many men eminent in many ways, and many sportsmen who devote no small part of their lives to fox, hare, partridge, and pheasant killing.

The cattle plague was an evil much more formidable in Italy than in England, and a large part of the regulations in Lancisi was devoted to arrangements for securing the cultivation of the fields, which were ploughed invariably by oxen. A famine of grain as well as of meat was apprehended.

Meat was neither scarcer nor dearer than usual. The cattle plague travelled over the different states of Italy, killed many beasts in many places, and, although slaughter was not resorted to, appears to have ravaged no single territory so long as four years.

Mr. Baring's valuable historical memorandum on the cattle plague shows that it pursued a somewhat similar course in the counties of Great Britain, where it long roamed about with periodic eruptions in some counties. The poleaxe policy was in full force under Acts of Parliament, and the plague was "stamped out" in fourteen years!

A large portion of the Papal regulations refer to religious ceremonies. The Pope appealed to the religious feeling and imagination of his subjects. Not only prayers, but indulgences were profusely scattered abroad, and Pope Clement XI., himself in a state of great infirmity, as described by his devoted Archiater, went in procession through the streets. All the devotional decrees in Latin and Italian are reprinted by Lancisi, and, as I read it, the speedy extinction of the cattle plague in Rome is ascribed as much to the superior sanctity of the Pope, and to the efficacy of his prayers as to secular regulations. There are many passages to that purpose, and they express sincere conviction in the efficacy of the Pope's intercessions. Lancisi was an honest man, as well as a courtier, and believed in the efficacy of Papal prayer; Dr. Markham believes in "stringent" regulations; Professor Gamgee believes in the poleaxe; I believe in the laws of biology—(and this faith, I may remark, is incompatible with none of the others)—while without it we fall into deplorable practical absurdities and alarms perfectly senseless.

I am, &c. W. Farr.

OVARIOTOMY IN DRESDEN.

Letter from Dr. Bowen.

[To the Editor of the Medical Times and Gazette.]

Sir,—Having been for some weeks past on a Professional visit to this city, and having assisted Dr. Küchenmeister, the celebrated helminthologist, in operating in two cases of ovarian disease, I think some account of these cases may be interesting to your readers. I may premise that for some time previous to the publication of Dr. Küchenmeister's work on Parasites, which was translated and published some years ago by the Sydenham Society, he has devoted especial attention to the diseases of women, and has obtained a large practice in this capital. He has nearly completed a German translation of the first volume of Mr. Spencer Wells's work on Diseases of the Ovaries, which is now in the press, and is enriched by copious annotations and tables. He, however, had not performed ovariotomy himself until the 7th of this month when I assisted him.

The girl was about 22 years of age. The tumour, a multilocular one of three years' growth, springing from the left ovary. At 11·30, all being ready, I chloroformed the girl; and then Dr. Gerhard, Dr. Moldau, Dr. Lehmann, Dr. Fiedler, Dr. Curt, and Dr. Michalsky were introduced, and the chloroform being handed over to Dr. Gerhard, I took my place on the right, opposite to Dr. Küchenmeister; and the assistants being placed and told their duties, Dr. Küchenmeister cut down upon the cyst (a large one), the length of the incision being exactly 3½ inches midway between the umbilicus and the symphisis pubis. Mr. Spencer Wells's trochar having been introduced, the large cyst was emptied, and slight traction made as soon as the claws on the canula had embraced and locked the punctured edges of the cyst. The trochar was next made to pierce the nearest enclosed cyst, which it did; but the jelly-like contents would not flow away; so, holding the sides of the incised abdominal walls firmly and securely, by a slight lateral dragging movement, the opposing cyst was brought to the surface, pierced with a scalpel, and the contents squeezed out. Three others were similarly treated, and with a little gentle force the whole cyst then escaped (two enclosed cysts of fair size remaining uninjured). A portion of omentum adhered to the surface of the cyst anteriorly, which I carefully separated (six or seven inches of it), and there was no bleeding. A clamp was put on, but there being a slight twist of the pedicle Dr. Küchen-

meister eased the screw and re-secured the pedicle. The galvano-caustic knife was used to cut through the pedicle; it had partly done so when the battery ceased to act, and the division had to be completed with a scalpel. There being some oozing from two vessels of large size, Dr. Küchenmeister gave an extra turn to the screw of the clamp which, working in a metal of soft material, the screw ceased to hold, and the pedicle slipped back into the abdominal cavity, the blood flying in a stream from the cut vessels. Dr. Küchenmeister—all credit to him—with courage, coolness, and lightning speed, brought the pedicle back to the surface in his fingers. The two large vessels (the only ones bleeding) I secured quickly, waited a moment to see that there was no more bleeding, and the pedicle (a very short one) I took hold of, and to the left side, where no traction was caused, I held it with my left forefinger, introduced an acupressure needle in a slanting direction, caught one extreme edge of the pedicle in the transfixion, passed the needle over the pedicle, and pierced the other extreme edge, and returned it through the abdominal wall. Thus the pedicle was securely fastened, and all danger of bleeding prevented, even had the slough, caused by the cautery, given way. After Dr. Küchenmeister had satisfied himself that not a drop of blood flowed, he sponged out the blood that had escaped into the cavity until it was quite clean, felt the right ovary, which appeared healthy, and then closed the wound by four deep and three superficial sutures, strapping, lint, and bandage were properly applied, and the patient carried to bed. A little opium was given by rectum, and afterwards four drops of solution of the acetate of morphia were injected under the skin of the forearm to relieve pain. Up to midnight all did well; urine secreted and drawn off; skin perspiring freely; pulse 80. Ice given to suck. During the night the pulse rose, but by seven the following morning, when I saw her again for the fifth time, it was reduced to 90 before I left her.

The cyst, a multilocular one, had been growing three years and more. The fluid drawn off measured about twenty pints. A good deal was lost, however. The emptied cyst weighed 3 lbs. One of the uninjured enclosed cysts was cut open afterwards, and contained pus-like fluid with hair. The clamps were rendered useless, owing to that portion which receives the screw being made of soft metal, and in pressing the screw home it no longer held, but turned round and round.

On the afternoon of the 8th Dr. Küchenmeister reported all as going on well, but he sent for me early on the morning of the 9th, when I found the patient bathed in perspiration, the room very hot, and pulse was very weak. We gave stimulants by rectum and mouth. There was no pain complained of anywhere, and I withdrew the needle without any inconvenience, and it came out as clean almost as when put in, and not a drop of blood. At noon, or soon after, I was with the patient again; she was dying then, some fifty hours after the operation.

Dr. Küchenmeister examined the body, but was only permitted to open the abdomen. He found effusion of serosanguinolent fluid in the pelvis, and considered that septicæmia was the cause of death. There had been no bleeding. The returned piece of omentum had formed an adhesion to the pedicle, which Dr. Küchenmeister had to pull asunder. I believe the galvano-caustic knife, or, better still, the galvano-caustic wire applied in the same way as the écraseur, will sear the pedicle and keep it safe. In this case the galvano-caustic knife left a hard leathery-like coating, about which no sign of inflammation appeared after fifty-two hours.

The second case appeared on examination to be one of ovarian disease of the multilocular kind. The patient, a lady over fifty years of age, had been twice tapped, but the fluid collecting again rapidly, and much inconvenience being felt, the operation was performed on the 15th inst., in the presence of several of the resident Medical gentlemen. The chloroform was admirably administered by Dr. Lehmann. An enormous quantity of a pale yellowish fluid—quite free from blood—filled the peritoneal cavity, and after the fluid was evacuated the tumour, hard and in size rather more than a man's closed fist, proved to be intimately connected with the left ovary, uterus, and rectum. By grasping the tumour—which the gentlemen present agreed with me in thinking was fibroid—we were able to move the uterus freely. The attachments were too formidable to do anything more, and Dr. Küchenmeister abandoned the idea, and the wound was closed in the usual way. The patient did remarkably well for two or three days following the operation, when she began gradually to lose ground, and to refuse nourishment by the mouth. It had therefore to be given by the rectum, but she got weaker and weaker, and died about eighty hours after the operation. The family objected to any post-mortem examination of the body being made. I am, &c.

Dresden, April 20. FRANCIS BOWEN, M.D.

WANTED, CANDIDATES FOR THE NAVY!

[To the Editor of the Medical Times and Gazette.]

SIR,—The recommendations of the Committee of which Admiral Sir Alexander Milne was the president, on the vital question of tempting Medical men to enter and to remain in the navy, have been some weeks before the public, and Lord Clarence Paget in Parliament has declared the intention of the Admiralty to carry out these recommendations. The Royal Colleges of Physicians and of Surgeons, London, have (conditionally) approved of the labours of the Committee; but these corporate bodies must recollect that Admiral Milne's summary or report is not based on the opinions of those naval Medical officers called in evidence before the Committee. The national Medical colleges of Ireland and of Scotland, with a caution to be commended, have as yet waited for the Admiralty Warrant defining the rank, the pay, the distribution of prize money, good service pensions, honorary distinctions; whether the Admiralty exacts a life-service from all Assistant-Surgeons who may enter the navy; whether the candidates are to be examined at one common portal with the army and East India Company's service; whether the right of petition is still to be denied naval Surgeons, as it is at present; whether Medical men are to be allowed to retire from the navy under the conviction that competency and honour do not belong to those who faithfully give, to a life of privation and discomfort, their best years. The publicity of Admiral Milne's report has brought no influx of candidates! The men who have avoided the navy and its ten shillings per day are not to be tempted by an additional half-crown. The ship service, it may be, up to 55 years of age gives no reasonable period of retirement with family and friends. The advice of the body of naval Medical officers to their friends is not to enter the navy. The authorities have to deal liberally and honestly with those in the service before they can expect Assistant-Surgeons for the navy; and it will take years of good works to do away with the bad impression which more than half a century of illegality and injustice has created. The inspectorial class ask for an increase to their emoluments; for an addition to their numbers in the active list of the inspectorial officers; that there should be a naval Medical school or college, or that Netley Hospital should be made available. The surviving Surgeons ask for retirement at twenty years' full pay service on one pound per day, and it will take nearly a quarter of a century, on an average, to complete such full pay time. The senior Surgeon on the active list, Dr. Patrick Martyn—promoted to that rank in 1833,—has not yet completed twenty years' full pay service. This venerable officer is attached to H.M. ship *Winchester*, at Aberdeen, and, being without an Assistant-Surgeon, he must dispense the medicines for the sick of the *Winchester*.

A naval Surgeon from foreign stations gives the opinions of his brethren on Admiral Milne's report:—"It is a great disappointment that the retirement should be so miserable as to starve us into continuous service when we ought to be abandoning the miseries of naval life for family and friends. The trick is this:—After twenty years' full pay service we can purchase our discharge by offering the Admiralty £100 per annum as 'black mail.' If we are worn out they will not deprive us of the £100, provided that a Medical Board say there is no more work in us. After that period nothing but broken-down health or 55 years of age will see us out of harness. This retirement allowance, as Dr. F. J. Brown calls it in his comments, is a 'pecuniary punishment.'"

An equitable retirement with good pay will get Medical officers for the navy, but not the present dreary prospects of continuous ship-board service.

The last March Navy List shows thirteen Staff-Surgeons retired, but it does not explain if these officers had twenty-five years' full-pay service to give them 18s. per day. Of retired Deputy-Inspectors-General there are twenty-seven, but about twenty-two are merely honorary titles given to Staff-Surgeons who have completed twenty-five years' full-pay service, but giving no increase of retiring pay and no consideration in the widow's pension. Of retired Inspectors-General there are seven, and five of these are honorary promotions from the active list of Deputy-Inspectors to the retired list of the higher rank, but giving no increase of emolument; and these have been the highest prizes of retirement.

Of the active list of Inspectors-General there are 7; of Deputy-Inspectors, 15; of Surgeons, 281; of Assistant-Surgeons, 270. One Surgeon in the last eighteen months has been promoted to be Deputy-Inspector-General, and has to commence service in this rank at Hong-Kong. Candidates for the navy should well ponder over the dreary prospects before them. There is no money that will compensate for a life-time of privation and confinement between the decks of a ship.

I am, &c. P. P.

"NYCTALOPIA."

Letter from Mr. R. B. Carter.

[To the Editor of the Medical Times and Gazette.]

Sir,—Your columns have recently contained several communications descriptive of isolated cases of nocturnal blindness, and hence I am led to suppose that some more detailed account of this affection may not be unacceptable to your readers.

Perhaps it will not be out of place to say a few words upon the question of nomenclature. It would be difficult to find any better illustration of the inconvenience and confusion caused by the introduction of a jargon of sham Greek into Medical literature. Two words, nyctalopia and hemeralopia, have been coined to express nocturnal blindness and its opposite; but nobody knows from what these words are derived, or what they mean. A few writers, like your recent correspondents, would trace nyctalopia to νὺζ, αρτιν, or αλαος and οψις, and would mean by it nocturnal blindness. They would regard hemeralopia as a similar compound, meaning diurnal blindness. The great majority, however, think that nyctalopia is derived only from νυζ and ωψ, or οψις, and that it means nocturnal *vision;* or the condition in which, from deficiency of pigment or from some other cause, the sight improves as daylight fades. With them, hemeralopia is supposed, of course, to mean diurnal vision, and hence, by inference, nocturnal blindness. I do not profess to decide between the two views, and am content to say first, that almost universal usage is in favour of the latter; and secondly, that I myself prefer to avoid obscurity by the employment of plain English.

Nocturnal blindness is seen in this country only occasionally, and is usually confined to persons who have recently returned from tropical climates, or who have been exposed to the glare of a bright day, reflected from a surface of snow, or who are the subjects of pigmentary retinitis. In a few cases, however, it exists as a simple torpor of the retina, an inability to be stimulated by a small amount of light. In such instances it may be due to the imperfect development of a hypermetropic eye, or it may be a consequence of the extension of the retinal tissues in cases of increasing myopia.

Professor Laycock, in describing the patients that he saw, makes very sweeping and general statements, such as that "no morbid change of any kind could be discovered in the organ of vision," and again "during the day vision was in all respects satisfactory." To me these statements appear incredible, and I cannot attach to them the weight that the Professor's reputation would seem to deserve, because he expressly states that he made no examination with the ophthalmoscope, so that he had no means of ascertaining whether the most probable morbid change was present or not. Furthermore, he does not notice the refraction of the eyes; and, in the absence of any information about matters so important, I may be pardoned for the inference that he did not accurately test the range or the acuteness of vision, or the extent of the visual field. Ophthalmic Surgeons are familiar with the fact that persons whose vision is highly defective are often quite unconscious that such is the case.

If the patients seen by Professor Laycock are suffering from pigmentary retinitis, it will probably be found that they have acute central vision, but that the visual field is reduced in size. The ophthalmoscope would show fine irregular black lines and stripes upon the retina, chiefly in the equatorial region, and forming an irregular circle. If they are hypermetropic, with imperfectly developed retinæ, vision for distant objects would be improved, after the instillation of a solution of atropine, by the use of convex spectacles.

During the last ten years, the subject of nocturnal blindness has been much studied by various writers. As a mere symptom of pigmentary retinitis, it forms part of that most intractable disease; but it is also seen as an independent affection, concerning which certain facts have been ascertained.

In 1857, Dr. R. Förster, of Breslau, described a series of experiments intended to test the periodicity of the disorder. By his ingenious photometer he was led to the conclusion that the defect of vision depended entirely upon the withdrawal of light, and that it had no relation to the position of the sun or to the hour of the day. It was simple torpor of the retina, and was always manifest in an artificially-darkened room.

In the same year Dr. Grosz published his treatise upon the eye diseases of the inhabitants of the great plains of Hungary. In those regions nocturnal blindness is common, and in some localities endemic. Dr. Grosz attributes it to the glare of the sun, acting upon persons enfeebled by insufficient nourishment, unwholesome dwellings, and personal filth. He asserts that it is more common, in the proportion of 100 to 1, among the Rouman than among the Magyar population; and he ascribes the difference to the prolonged and exhausting fasts of the Greek Church.

The disorder has appeared at various times and places as an epidemic in prisons, orphanages, and similar establishments. Dr. Alfred Graefe, at Halle, and Drs. Bitot and Netter, at Bordeaux, have observed and studied such outbreaks. Dr. Alfred Graefe asserts (*Arch. f. Ophth.*, 1859) that the pupils, in cases of simple nocturnal blindness, were always much dilated; while in pigmentary retinitis they are somewhat contracted. The dilatation was little diminished by exposure to light, but readily by irritation of the fifth nerve by the application of a drop of tincture of opium to the conjunctiva. He also states that in waning light some disturbance of the function of accommodation was always present, even before the darkness reached the degree at which the nocturnal blindness became manifest, and in most of the patients there was debility of the internal recti. Dr. Bitot mentions (*Gaz. Hebdom.*, 1863) the occurrence of a pustular or phlyctenular eruption around the cornea, and states that the size of the spots bore a constant relation to the degree of the impairment of vision, that their first appearance preceded the appearance of the impairment, and that the sight was restored as the spots disappeared. Dr. Netter, on the contrary, (*Gaz. de Paris*, 1863), who saw the same epidemic, believed that the connexion between the phlyctenulæ and the nocturnal blindness was only accidental. An epidemic of nocturnal blindness attacked the crew of the Prussian man-of-war *Arcona* during an expedition to Eastern Asia. In this case Dr. Eitner, who has described it (*Deutsche Klinik*, 1863), thought it due almost entirely to dazzling.

Careful researches into the whole subject have been made by Macs, whom I regret only to be able to quote at second hand. He divides nocturnal blindness into the acute and the chronic. The acute is often due to exposure to strong light, in which case it affects chiefly the central portion of the retina, and is speedily cured by keeping the patient in comparative darkness for a time. When not thus produced, it affects chiefly the periphery of the retina. The chronic form is seen as a congenital and hereditary affection; a simple torpor of the retina, which remains unchanged throughout life. When not congenital, it is usually only a symptom of pigmentary retinitis, which leads very slowly to entire loss of sight.

It appears from the foregoing that nocturnal blindness, when not dependent upon pigmentary retinitis, nor upon a congenital and incurable imperfection of the retina, is usually produced by over-exposure to light, either alone or combined with various causes of depressed vitality. It follows that the diminution or exclusion of light, and, when necessary, an actively supporting treatment and dietary, should furnish the most effectual means of cure; and this conclusion is entirely borne out by the experience of the various writers that I have mentioned. In their hands dark blue spectacles, an abundance of animal food, cod-liver oil, tonics of various kinds, fresh air and exercise, have been found to exert an influence, either curative or at least highly favourable.

I am, &c.,

Robert Brudenell Carter.

Stroud, Gloucestershire, April 23.

THE EPIDEMIOLOGICAL SOCIETY.

Letter from Mr. Geo. Gaskoin.

[To the Editor of the Medical Times and Gazette.]

Sir,—Now the cholera is fast closing on us it will not seem surprising that I was desirous to hear what so lively and earnest a thinker as Dr. B. W. Richardson had to say on the subject. I therefore procured an opportunity of hearing his

paper at the Epidemiological Society on Monday last. It was a fair summary of all those views towards which we have been gradually advancing during these thirty years past—indeed, ever since we have emerged from those clouds of obscurantism which enveloped the beginning of the century; a state of things due then to certain active spirits who gained social position by furthering the commercial aims of the nation, to the incalculable detriment of science; displacing the springs of thought through the medium of their writings, till it became an inveterate habit of the mind to falter and deny. No way else could the firmest and most patent facts in the history and character of disease have been misinterpreted or overlooked. We know now that the contagious principle of cholera is a something; whether its vehicle be a cell or a flocculus, alkaloid or colloid, it has a real existence, and is not a mere distemperature, a chance medley of conditions, a fortuitous concourse of ill-assorted atoms. It is something we can deal with, and which as a nation we are free to accept or to reject.

In the discussion on the paper, some gentlemen of the Services spoke with a degree of sense and modesty, but as from outside, not as men sharing in a crisis or under the inspiration of duty, but rather as having experienced the futility of effort, and felt the rebuffs of power. I ask myself if society is at any time the better for that kind of knowledge ending ever as it begins? Action on the part of the Epidemiological Society there will certainly be none. The idea of the Society is noble. As it seems to me, they need the infusion of new material to keep them going, and Richardson will hesitate a second time before he puts his new wine into old bottles. In the meantime, is there no way of getting an expression of opinion from the Profession? Are we ever to stand with folded arms and closed lips before that "inexorable tyrant" Commerce? Dare no one utter the word "Quarantine?"

I am, &c.,

3, Westbourne-park. Geo. Gaskoin.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, March 20.

Dr. Sibson, Vice-President.

(Continued from page 485.)

DR. GREENHOW ON ADDISON'S DISEASE.

Dr. Greenhow exhibited for Dr. Dickinson two supra-renal capsules infiltrated with cancer. They had been taken from the body of a man, aged 56, who had presented no discolouration of skin nor any of the constitutional symptoms of Addison's disease. Malignant disease of the spine was diagnosed during life, and on post-mortem examination cancer of the lumbar vertebræ, pancreas, liver, heart, and other organs was found, together with cancer of the supra-renal capsules. Dr. Greenhow likewise exhibited the supra-renal capsules, tongue, penis, and scrotum taken from the body of a man aged 55. Addison's disease had been diagnosed on the day of the patient's admission into Hospital. The constitutional symptoms were characteristic, and besides slight general discolouration of skin there was deep discolouration of some cicatrices of burns, and also of penis and scrotum, and the tongue presented on its upper surface round the free edge irregular purplish stains. On microscopical examination the pigment causing these stains was found deposited in the papillæ in brown masses, the superficial layer of epithelium remaining uncoloured. The supra-renal capsules had undergone the peculiar morbid change usual in Addison's disease. In the lungs and other organs there were also tubercular deposits. Dr. Greenhow said that these two cases were good illustrations of the difference in the effects produced on the general health by different diseases of the supra-renal capsules. A discussion two years before at the Pathological Society, showing that doubts were still entertained as to the reality of Addison's discovery, and that these doubts were mainly fostered by the confusion of genuine and spurious cases, had induced him (Dr. Greenhow) to abstract from the British and Irish journals for the purpose of analysis all the published cases not of Addison's disease only, but of cancerous and other diseases of the capsules, and also of bronzed-skin without any disease of the supra-renal capsules. Subsequently his attention had been drawn to treatises on the subject by M. Virchow and M. L. Martineau, and he had translated from the original sources all the foreign cases quoted in their writings. In all he had collected 195 cases, which he had carefully analysed, and had found that in 127 the supra-renal capsules had undergone the particular morbid change characteristic of Addison's disease. In the other 68 cases the capsules were either healthy or had undergone cancerous or some other morbid change, or the change in them was too obscurely described to enable him to determine its nature. With a few explainable exceptions, none of these 68 cases presented either the constitutional symptoms or the peculiar discolouration characteristic of Addison's disease. On the contrary, among the 127 genuine cases, 95 presented either well-marked constitutional symptoms or characteristic discolouration of skin, and 72 of these presented both. In 20 cases some of the constitutional symptoms or some discolouration of skin existed, and in many instances both, leaving only 12 out of the 127 cases which presented neither any characteristic symptoms nor any discolouration of skin. These 12 cases were all among those complicated with advanced tuberculosis or with other serious organic disease, which appeared to be the causes of death rather than the co-existing disease in the supra-renal capsules. On the other hand, only 5 of the 95 cases presenting characteristic symptoms or discolouration were found among the number complicated with serious non-tubercular diseases, and not one among those complicated with advanced phthisis. These facts seemed to be a sufficient refutation of the theory current abroad that the discolouration of skin peculiar to Addison's disease is due, not to the morbid change in the capsules, but to the general tuberculosis frequently associated with it. At the same time his (Dr. G.'s) analysis of the 127 genuine cases showed that while 46 cases were reported as entirely or virtually uncomplicated, and 16 as complicated with other serious diseases without tubercle, no less than 65, or an absolute majority of the whole number, were complicated with tubercular disease of lungs or other organs, in all gradations of development; so that it was impossible to avoid the conclusion of a very intimate relation between Addison's disease and the tubercular diathesis.

Mr. Hutchinson suggested that the bronzing was a question of time, and that if the patient died early of Addison's disease there might be no bronzing.

Mr. C. H. Moore asked if Dr. Greenhow's cases of cancer of the capsule were cases in which both these organs were quite destroyed, or in which there was a cancerous tubercle in each. Mr. Moore then made some remarks on the variety of double cancer, and concluded by saying that cancer was a disease of a texture and not of an organ.

Dr. Bristowe mentioned a case in which both capsules had been affected by primary cancer.

Mr. Gaskoin thought it questionable whether there really was a relation betwixt the bronzing of the skin and the disease of the capsules. Dr. Greenhow had collected cases of Addison's disease, and thus might have excluded cases of disease of the capsules in which there had been no symptom of Addison's disease.

Dr. Quain said that he would wish to hear from Dr. Greenhow a clear definition of what he meant by the term "Addison's disease." The statistics quoted included a certain number of cases of bronzed skin without any disease of the supra-renal capsules, and a still larger number of cases in which there was more or less disease of the capsules and no bronzing of the skin at all. It did not seem altogether philosophical to take these two conditions and to say that it was their coexistence which alone constituted the disease. Dr. Quain then gave the particulars of an interesting case of fatal anæmia in a young gentleman, which he had seen with Dr. Addison, Dr. Bright, and Dr. Williams. It was one of the first two or three cases which had led Dr. Addison to state his views on the subject. In that case there was a deep ash-coloured pallor of the skin; the capsules were small, but not diseased. Dr. Quain thought there was still much room for investigating the character of the disease.

Dr. Greenhow said in reply that the cases collected by him were not of Addison's disease only, but of all diseases whatever of the supra-renal capsules which he had been able to find published from the time of Addison's discovery up to the end of 1865. He had only abstained from giving the well-known description of Addison's disease because he desired to be brief; but he thought it might be clearly defined as a particular lesion of the supra-renal capsules, manifested during life by a certain train of constitutional symptoms attended almost always by a characteristic discolouration of skin. No

doubt his collection included a few cases of bronzed skin without any disease of capsules, but the bronzing was not the discolouration characteristic of Addison's disease. It included also a certain number of cases in which the capsules had been diseased without any discolouration of skin; but, with one or two exceptions, the disease either was not Addison's, or, being Addison's, it had been masked by some other predominant disease which appeared to have been the cause of death. As Mr. Hutchinson had suggested, when the discolouration was altogether absent, death had probably taken place at an early period of the disease. As regarded the relation between the symptoms and discolouration of Addison's disease on the one hand and the characteristic change in the capsules on the other, he had no more doubt of its existence than he had of the existence of a relation between incompetency of the mitral valve or of acavity in the lungs and the physical signs of these lesions during life. He had at present three cases of Addison's disease under observation, and he was bold enough to say that he should be quite willing to leave the question of the reality of Addison's discovery to be determined by the result of the post-mortem examination in any one of the three.

Dr. MURCHISON said that as Dr. Greenhow had found the disease of the capsules to be invariably tubercular, other disease of the capsules, viz., cancer, not producing Addison's disease, it would seem that the symptoms were those due to tubercular disease, and not to disease of the capsule.

In reply to Dr. Murchison, Dr. GREENHOW thought that Dr. Murchison's suggestion was sufficiently answered by the fact shown by his analysis that, in proportion as the tubercular complications became general or acute, the constitutional symptoms and external signs of Addison's disease became less and less decided until they altogether disappeared.

Dr. RISDON BENNETT remarked on the peculiar irritability of the stomach in Addison's disease. There was paroxysmal vomiting, followed by alarming exhaustion.

Mr. BRUCE showed a specimen of

SALIVARY CALCULUS OF UNUSUAL SIZE.

It had been presented to the Museum of University College by Mr. Price. It weighed eleven grains and a-half, and measured three-quarters of an inch by a quarter. It was regularly fusiform, but nodulated. It appeared to consist of animal matter, phosphate of lime, magnesia, a small amount of sulphate—but this, Mr. Bruce remarked, was unusual—no carbonate.

Mr. BRUCE next exhibited a specimen of

VENOUS OBSTRUCTION.

The external iliac and femoral veins from the leg of a woman plugged by a large coagulum. The clot stopped somewhat abruptly at the point of pressure, where the veins crossed the brim of the pelvis. The pressure was from an ovarian cyst.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen having undergone the necessary Examinations for the Diploma were admitted Members of the College at a meeting of the Court of Examiners on the 8th inst., viz.: —

William Alfred Cox, Bath; Charles Barlow, Staleybridge; and John Knowler Hyde, Witney, Oxon, students of Charing-cross Hospital. John Quick, Penzance; and John William Hembrough, Waltham, Grimsby, of St. Bartholomew's Hospital. James Stothard, Hull; and William Wightman Cooper, Nottingham, of the Hull School. John Sykes, West Ardsley, Yorkshire; and Thomas Edward Scatchard, Thorp Arch, Tadcaster, of the Leeds School. Alderson Newsam, Totness, Devon; and John Jenkins, Cambridge, of Guy's Hospital. Francis Stewart Manistry, Gresford, Denbighshire; and Albert Arthur Napper, Cranley, Surrey, of King's College. William Charles Watson, Poal, Cornwall, of the Westminster Hospital. John Edward Grinfield Coxwell, Woburn place, of University College. James Beresford Ryley, Myshal, Co. Carlow, of the Dublin School. James Robert Fielding, Alfreston, Derbyshire, of the Middlesex Hospital. Henry Leigh Mallory, Knutsford, Cheshire, of the Manchester School. Thomas Silvester Gell, Stafford, of the Edinburgh School. Horatio Wood, Wednesbury, of the Birmingham School. Joseph Soane, Dock-street, Whitechapel, of the London Hospital; and Arthur Cromack Turner, Swinton, Yorkshire, of the Sheffield School.

Admitted members on the 9th inst. :—

Charles Edward Walker, Stainland, Yorkshire; Nathaniel Edward Davies, L.S.A., Llanrwst, Denbighshire; Ezra John Hardwicke, Bury St. Edmunds; Thomas Coles, Bath; and Josiah Paull, Camborne, Cornwall, students of St. Bartholomew's Hospital. John Coyte Bailey, L.S.A., Plymouth; William Draper, Grantham; James Wickham, Bideford, Devon; and William Augustus Bonney, Brompton, of the Middlesex Hospital. George Sampson Elliston, Ipswich; Herbert William Fagge, Hythe, Kent; and William Grimes Palmer, Loughborough, of Guy's Hospital. Thomas Joseph Quicke, Brixton: and Walter Moore, Myton, Warwickshire, of the Westminster Hospital. William Henry Firebrace Smith, London; and Frederick Boldero, Rattlesden, Suffolk, of King's College. Charles George Edmonds, L.S.A., Peckham, of St. Thomas's Hospital. Frederick William Strange, Beenham, near Reading, of the Liverpool School, and Frederick Dale, Yarm, Yorkshire, of the Edinburgh School.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 3, 1866 :—

Christopher Allcock, Nottingham; Arthur Humphry, Balham-hill; Albert Kisch, 2, Circus-place; Frederic William Parsons, Sutherland-place, Bayswater; William James Tattersall, Bacup, Lancashire; Isaac Coalbank, Old Dalby, Leicestershire.

The following gentlemen also on the same day passed their First Examination :—

J. G. Anderson, St. Mary's Hospital; Wm. Hy. Wood, St. Mary's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BARBER, OLIVER, has been appointed Dispenser to the Public Hospital and Dispensary, Sheffield.

BRADSHAWE, P., M.R.C.S.E., has been elected House-Surgeon to King's College Hospital.

BRYAN, EDWARD, M.R.C.S. and L.S.A., has been appointed Assistant-House-Surgeon to the Public Hospital and Dispensary, Sheffield.

DICKINSON, W. H., M.D., has been elected Assistant-Physician to St. George's Hospital.

FARRE, FREDERICK, has been appointed Physician to the Charterhouse.

KELLY, C., M.R.C.S.E., has been elected Resident Accoucheur to King's College Hospital.

MILLNER, F. LE FEVRE, M.R.C.S. and L.S.A., has been appointed Assistant-House-Surgeon to the General Hospital, Nottingham.

PALANQUE, JOHN A., L.R.C.S. Edin., has been appointed Assistant-House-Surgeon to St. Mary's Hospital, Manchester.

PHILPOT, C. W., L.S.A., has been elected House-Physician to King's College Hospital.

QUIBELL, WILLIAM, has been appointed Dispenser to the General Infirmary, Sheffield.

TONGE, MORRIS, M.D., M.A., has been appointed Lecturer on Physiology at the Medical School of Charing-cross Hospital.

BIRTHS.

ORR.—On May 3, at Idvies House, Forfarshire, the wife of J. H. Orr, M.D., C.B., Deputy Inspector-General of Hospitals, Her Majesty's Indian Army, of a son.

PATERSON.—On April 24, at Balbeggie, Perthshire, the wife of G. K. Paterson, L.R.C.P. Edin., of a daughter.

PARROTT.—On April 27, at Clapham-common, the wife of J. Parrott, M.R.C.S., of a son.

ROBERTSON.—On April 24, at the Towns Hospital, Glasgow, the wife of A. Robertson, M.D., of a son.

SMITH.—On May 8, at Hay, Breconshire, the wife of J. E. Smith, M.R.C.S., of a daughter.

WOLSTENHOLME.—On April 30, at Holywell, Flintshire, the wife of J. H. Wolstenholme, M.R.C.S., of a son.

MARRIAGES.

BROOKE—BURNETT.—On May 8, at St. Giles', Camberwell, T. L. Brooke, L.R.C.P. Lond., to Emily Alice, third daughter of J. Burnett, Esq., The Avenue, Gipsy Hill.

WILLIAMS—PERCEVAL.—On April 30, at Rathaspeek Church, R. P. Williams, M.B., to Mary, eldest daughter of the late R. Perceval, Esq., Haystown House, Co. Wexford.

ANDERSON—FAUX.—On April 2, at St. Peter's, Thetford, E. C. Anderson, M.R.C.S., to Emma, daughter of the late J. B. Faux, of Thetford.

DEATHS.

BALLY.—M. Bally, the "father" of the Académie de Médicine, has just died, at the age of 92, in the full possession of all his faculties.

LARMUTH, M. O., M.R.C.S.E., of Salford, on April 21, aged 42.

MICHON.—M. Michon, Member of the Academy of Medicine and Professeur Agrégé of the Faculty of Medicine, died last week, aged 63.

SHAW, W., M.R.C.S.E., of Hampstead, on April 27, aged 57.

SWIFT, J. M., M.D., M.R.C.S.L., at New South Wales, on December 12.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Banbury Union.—Mr. James Taylor has resigned the Hornton District; area 7740; population 3062; salary £61 8s. per annum.

Godstone Union.—Mr. C. M. Thompson has resigned the Eastern District; area 9302; population 2308; salary £73 per annum.

APPOINTMENTS.

Carlisle Union.—Daniel Anderson, L.R.C.P. Edin., L.F.S. Glas., to the Stanwix District.

Chipping Sodbury Union.—Edward M. Grace, L.R.C.P. Edin., M.R.C.S.E., L.S.A., to the Fifth District.

Clitheroe Union.—William E. Musson, M.R.C.S.E., L.S.A., to the Clitheroe District.

Keynsham Union.—Richard Colthurst, M.D. Edin., M.R.C.S.E., L.S.A., to the Workhouse.

Marlborough Union.—James B. Mauriec, M.D. Scot., M.R.C.S.E., L.S.A., to the First District.

Ongar Union.—Matthew H. Grattan, L.K. and Q. Coll. P. Irc., L.R.C.S. Irc., L.M., to the Workhouse.

Penkridge Union.—Thomas Crean, L K and Q. Coll. Phys. Irc., M.R.C.S. Irc., to the Breewood District and the Workhouse.

Redruth Union.—Henry Harris, M.R.C.S., L.S.A., to the Stithians District.

Wolverhampton Union.—Frederick Dunn, M.R.C.S.E, L.S.A., to the Second District.

Professor Hancock.—The course of lectures annually delivered at the College of Surgeons will be brought to a close by the above gentleman, who will deliver six lectures on the Anatomy and Surgery of the Foot. The course will commence on Monday, the 4th proximo.

Royal Institution of Great Britain.—At the general monthly meeting, held on Monday, May 7, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair, Samuel Osborn Habershon, M.D., and John Hogg, M.D., were elected Members of the Royal Institution.

The College Fellowship.—The Members of the Royal College of Surgeons, especially those anxious to obtain the Fellowship of that Institution, will be glad to learn that two important alterations have been effected by recent bye laws, in one case rendering a Member of eight instead of twelve years' standing eligible for admission to the Fellowship by examination; and in the other, abolishing what, in the present advanced state of science, might justly be considered the invidious distinction hitherto made between the metropolitan and provincial Hospitals and Schools—viz., the requiring three out of the six years spent in the acquirement of Professional knowledge to be passed exclusively in the London Hospitals and Schools. In the former case, it will benefit many Medical officers of the Army and Navy, who, from circumstances over which they had no control, have hitherto been unable to conform with the extended curriculum required for the Fellowship, and the latter alteration will give many hard-working provincial Surgeons an opportunity of obtaining this honourable distinction.

F.R.S.—The Council of the Royal Society recommend the following gentlemen for election to the Fellowship:—J. C. Bucknill, M.D.; Rev. F. W. Farrar; W. A. Guy, M.B.; J. Hector, M.D.; J. W. Kaye; Hugo Müller, Ph.D.; C. Murchison, M.D.; W. H. Perkin; Archdeacon Pratt; Captain G. H. Richards, R.N.; T. Richardson, W. H. L. Russell, Rev. Dr. Selwyn, R. Townsend, and H. Watts, B.A. Of these gentlemen four are members of the Medical Profession. Dr. Bucknill, the authority on Psychological Medicine; Dr. Guy, the accomplished statistician and Medical jurist; Dr. Hector, the explorer of New Zealand; and Dr. Murchison, the author of the exhaustive work on Continued Fevers.

Belfast Branch of the Royal Medical Benevolent Fund Society of Ireland.—The stated quarterly meeting of the committee of this branch of the above Society was held on the 2nd inst. in No. 33, High-street; Dr. T. H. Purdon, permanent president, in the chair. The treasurer reported having received subscriptions from Sir E. Coey; Dr. Johnson, Strangford; Dr. Musgrave, Lisburn; Dr. Thompson, Lisburn; Dr. M'Harg, Lisburn; Dr. Campbell, Lisburn; Dr. Pirrie, Dr. Moreland, Dr. Murney, J.P., Dr. Thomas Reade, Surgeon Thompson, Bangor, etc. This being the period of the year for recommending parties for grants at the annual meeting, several applications were now submitted, and, having been inquired into, each was recommended for assistance as far as the funds at the disposal of the Society would admit; and some further business having been disposed of, and the best thanks of the meeting given to the chairman for his most generous support of this branch, and for his exertions in promoting its truly benevolent objects, the meeting separated.

New Reptile.—The *Times* states that a dead specimen of a new species of Saurian reptile has arrived by the Black Ball packet *Young England* from Queensland. The following is the account, which reads very much like a hoax:—"The *Young England* has brought home also a tremendous specimen of the Saurian tribe, which, in the opinion of Australian *savans*, is more closely allied to the extinct reptilia of the pre-Adamite era than any living animal yet discovered. It inhabited the unexplored interior of Queensland, near the source of the Fitzroy river. The accounts related of the destruction caused by the monster upon the native population seemed perfectly incredible until the formidable jaws, armed with fangs of astonishing size, were beheld. Added to this, its claws of prodigious power, and its invulnerable skin, rendered it most formidable. In the contest which ended in its destruction one claw was torn off, but with this exception the body is in perfect preservation."

Quarantine and Cholera.—The supplement to the *London Gazette* publishes the following order issued by the authority of the Privy Council. After quoting the Act passed in the sixth year of George IV., cap. 78, the order states that:

"And whereas a certain infectious disease—that is to say, Asiatic cholera—is prevalent in certain foreign parts; and whereas it is expedient to cut off all communication between persons on board any vessel infected with that disease and the rest of Her Majesty's subjects:—

"Now, therefore, in exercise of the powers conferred upon them by the above-quoted section of the said Act, the Lords of the Council do order, and it is hereby ordered,—

"1. That in case of any vessel arriving in any port of the United Kingdom having such disease on board, no person shall land from such vessel for the space of three clear days after her arrival, without the permission of the local authority.

"2. The local authority shall forthwith cause all persons on board the said vessel to be examined by a Physician or Surgeon, and shall permit all such persons to land immediately who shall be certified by such Physician or Surgeon to be free from such disease.

"3. All persons certified by such Physician or Surgeon to be affected with symptoms of such disease shall be removed, if their condition admits of it, to some Hospital or place to be designated for such purpose by the local authority; and no person so removed shall quit such Hospital or place until some Physician or Surgeon shall have certified that such person is free from the said disease.

"4. In the event of any death from cholera taking place on board of such vessel, the body shall be taken out to sea, and committed to the deep, properly loaded, to prevent its rising.

"5. The clothing and bedding of all persons who shall have died or had an attack of cholera on board such vessel during her voyage, either at any foreign port or on shore at such port, or on her passage to the United Kingdom, shall be disinfected, or (if necessary) destroyed under the direction of an officer of the Customs.

"6. The local authority for the purposes of this order shall be the Local Board of Health, where there is such local Board; and in any corporation where there is no such local Board, the local authority shall be the Town Council of such corporation.

"7. All persons offending against this order shall be liable to such penalties as are imposed by the said Act of Parliament upon persons offending against the provisions thereof.

"Arthur Helps."

Capital Punishment Bill.—This Bill extends to England and Ireland, but not to Scotland. It is to be murder of the first degree, (1,) where a person murders another with express malice aforethought against the person murdered, or any other person, such malice being found by the jury as matter of fact; (2,) where a person murders another with a view to and in or immediately before or after the commission by such person of any of the following felonies, or for the purpose of thereby enabling himself or any other person to commit any of the following felonies, viz., rape, burglary, robbery, piracy, or unlawfully and maliciously setting fire to any dwelling-house, a person being therein; (3,) where a person murders another in the act of escape, or for the purpose of thereby enabling himself or any other person to escape from or avoid lawful arrest or detainer, immediately after committing or attempting to commit murder or any of these felonies; (4,) where a person murders a constable or any other peace officer acting in the discharge of his duty. Clauses 6 to 8 provide that on conviction for murder of the first degree, judgment of death may be pronounced in open court, and the offender shall suffer death as a felon; or the Court may order judgment of death to be entered of record, and this shall have the like effect as if judgment of death had been pronounced in open court, but execution thereof had been respited. All murders not of the first degree are of the second degree, the punishment of the latter to be penal servitude for life, or for not less than seven years. The indictment is to charge murder

of the first degree, or to charge murder of the second degree. It is made felony unlawfully and maliciously to wound a child or inflict upon it grievous bodily harm during its birth, or within seven days thereafter; and it is not to be necessary to prove that the child was completely born alive. On an indictment for child murder the accused cannot be found guilty of concealment of birth. Executions are to be within the walls of the prison. The sheriff or his deputy, the governor or chief officer of the prison or his deputy, the chaplain or an officiating minister attached to the prison, the Surgeon or chief Medical officer of the prison, and such other officers of the prison as the sheriff requires, shall be present at the execution; and any justice of the peace having jurisdiction, and such persons as it seems to the sheriff or visiting justices proper to admit, may also be present at the execution. The Surgeon's certificate of the death, a certificate from the above-named officials, and a duplicate of the coroner's inquisition on the body are to be sent to the Secretary of State, and copies are to be exhibited at the prison entrance for a certain number of hours. The body is to be buried within the walls of the prison.

Practical Homœopathy.—M. Reymond, in a recent lecture on Heine, the German wit and satirist, tells a good anecdote. Heine and his wife, travelling in the south of France, met Ernst, the violinist, who begged of him to take charge of one of the celebrated Lyons sausages for one of his friends, a homœopathic Physician. In those days railways were not, and the road was tedious. Madame Heine became very hungry, and could not resist a little piece of the sausage, which she found excellent. Presently, Heine joined her, and was quite of her opinion; and, in fact, the sausage was a great treat, and on their arrival at Paris had so diminished in size that Heine dared not forward the mere stump that was left to its destination. But he thought better of it, and cutting with a razor a slice as thin as paper he placed it in an envelope, together with the following note:—Dear Doctor,—"As a result of your investigations the fact has been acquired by science that millionths of parts produce the greatest effects. Accept, then, the accompanying millionth part of a Lyons sausage which Ernst charged me to remit to you. If homœopathy is indeed a truth, this little portion will produce on you the same effect as the entire sausage.—Yours, Henri Heine."

It has been well said, "If Physic be a trade, it is a trade of all others the most cut out for a rogue." To some people, a new sensation in Medicine is as necessary as a new hat, or a new bonnet, and sooner than not be gratified in their desires, they will accept the most exaggerated theory as eagerly as they will don the most extravagant costume. We have had "brandy and salt" cures, "movement cures," "mesmeric cures," "homœopathic and allopathic cures," "cancer cures" without number! We know not what may come next! Truly! exclaims a transatlantic confrère, the Medical man, and particularly the struggling one, has need to pray that he may not be led into temptation; but if he has none other than sordid motives, his prayer is a useless mockery.—*Introductory Address at King's College, London, by William O. Priestley, M.D.*

The following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending April 28.	Week ending April 21.	Week ending April 14.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

Note.—17 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Buckingham, 2; Chester, 2; Cumberland, 1; Derby, 1; Dorset, 1; Lancaster, 2; Lincoln, 2; Oxford, 1; Yorkshire, 2; "Metropolis," 1; and Scotland, 2. These Inspectors returned 129 cases last week.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Moxon's paper is in the printer's hands, and shall have early insertion.

A Member will see that his inquiry respecting the Fellowship of the College is answered in another page.

A Student, St. Bartholomew's.—Arrangements have been made to publish the course of lectures alluded to by yourself and Mr. F. W. H.

Inquirer.—It is not yet *compulsory* upon Boards of Guardians to supply cod liver oil and quinine at the cost of the Union. The Poor-law Board have recommended such a course, and the majority of guardians are falling in with the recommendation.

J. Barrett.—1. A captain's biscuit. 2. Brillat Savarin's Physiologie du Goût, either in the original French (which is the better) or in the English translation.

A Constant Reader will find his inquiry constantly answered in our advertisement columns, as he will see this day. Write to the Secretary.

Dr. Thompson, Liverpool.—Houses were established for the reception of leprous persons at Reading, and at Aylesbury in 1134, and all leprous persons hung if found after sunset.

Dr. Montgomery.—A paper was recently read before the Society of Arts, on the assumption of names, and a suggestion that the Legislature should interfere in the matter. The practice is extending into our Profession. Young men whose progenitors were content with the simple name of Snooks now adopt the prefix *de*, thus, Mr. De Snooks; and as for the large family of Smith, it will soon become extinct or swallowed up by the verdant Smyth, Harcourt Smyth, Pye Smith (no Pudding Smith appears). Our correspondent can prefix the "*de*" to his name if he thinks it will increase his practice.

A Collector.—The portrait of Dr. Glynn is rare. You will find copies in the libraries of the Royal Medical and Chirurgical Society and College of Surgeons. The following *jeu d'esprit* proves his physiognomy not to have been of so agreeable a cast:

> "This morning, quite dead, Tom was found in his bed,
> Although he was hearty last night;
> But 'tis thought, having seen Dr. Glynn in a dream,
> That the poor fellow died of the fright."

Dr. Glynn died in 1800, aged 82.

The Third and final Report of the Cattle Plague Commissioners has just been issued. It shall be noticed at length next week. In the meantime, we may say that the Commission have come to an opinion thoroughly contagionistic.

"It (the cattle plague) follows the lines of cattle traffic, and does not arise spontaneously." In short, all the facts obtained, both at home and abroad, "are conclusive evidence against the assumption of occult atmospheric conditions, and in favour of its spread by multiplication in the bodies of living animals." Sanitary conditions are believed by the Commissioners to be altogether subsidiary. Overcrowding, bad ventilation, and impure water cause the disease to spread faster and to be more fatal; but they neither produce the poison nor can the best sanitary conditions be relied on to exclude it. In some of the worst cowsheds in London the plague has not yet penetrated; in some of the best it has swept the stock entirely away."

"Artificial Tympanums."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I enclose a piece of paper, which I took from a large sheet, shown to me by a patient of mine, who had answered an advertisement in some paper, telling sufferers from deafness to send 5s. for artificial tympanums, which cure all cases of deafness. For the 5s. were returned a box of little pieces of cotton wool fixed to ends of cotton, and a small tube, the cotton to be passed through this tube and inserted into the ear, then the tube withdrawn, leaving the wool in contact with the membrana tympani. In the "directions for use," it was stated that the wool was to be wetted with the medicated fluid before being applied, which fluid was not sent. My patient therefore wrote for the fluid, and received an intimation that if 7s. 6d. more was sent she would receive it by return. I cannot understand this system, with Dr. Yearsley's name affixed to the paper, and shall be much obliged if you will have the kindness to explain it to me through your columns. I enclose my card. I am, &c.,

Bridport, May 7. A Constant Reader.

"The Artificial Tympanum, for the Relief of Deafness, attended by Loss or Injury to the Membrana Tympani, and for the Cure of Discharges from the Ear. The discovery of James Yearsley, Esq., M.D., M.R.C.S. Eng., &c.; Surgeon to the Metropolitan Ear Infirmary, Sackville-street; Author of 'Deafness Practically Illustrated,' 'Throat Deafness,' Aural Surgeon to Her Majesty the late Queen Dowager, &c., &c."

*** Probably Dr. Yearsley knows nothing about the matter, and may be glad to know in what way his name is used by the alleged possessor of the patent.

The Medical Profession and the Great Metropolitan Nuisance.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—It strikes me that at the present moment the Profession has a duty before it the performance of which will enhance its well-merited position in public esteem. Of course you are aware that inquiries are pending in Parliament relative to the price and quality of the gas supplied by the several metropolitan companies to their customers. There appears to be no doubt that the latter are ill-used in various ways. But this is not the point to which this letter points. I beg a moment's attention to one very much more important.

Simultaneously with the inquiries just referred to, companies are promoting bills which would enable them in some instances to double and treble their pernicious, pestilential manufacture in London or the immediate environs. The warning of constant peril to life and limb given by the Nine Elms disaster does not discourage boards of directors, confident in the potency of the purse and the effect of extensive private influence, from making demands directly at war with the safety, the health, and the comfort of the population. The hygienic consideration is that which the Profession is concerned with. The lowering, vitiating, and deleterious effects of the gas effluvia is notorious. The evidence of our senses tells us that these works are most offensive nuisances, and their operation is more actively injurious when there is any predisposition to disease in the lungs or stomach. Facts illustrative of this might be cited *ad infinitum*, but it will be sufficient to refer to the evidence taken in the opposition of the Corporation of London some years ago to that unhappy blunder, the renewal of the City Gas Company's charter, and again in the disputes between the Imperial Gas Company and the residents in Fulham and Chelsea. To be brief, the unwholesomeness of such works is notorious, and nothing known to science can alter it, for, to use Dr. Letheby's words, it is "unfortunately inseparable from the process of gas-making." The one item of consolation is the now well-ascertained fact that there is no necessity for making gas near the place of consumption. Indeed, several of the London companies supply, not their own neighbourhoods, but parts of town most distant from their factories. To quote again the authority of Dr. Letheby, "If the gas was well purified it would lose nothing by its journey. Last month I was testing the gas at Birmingham, and I could find no difference in the illuminating power of the gas at the works and in the town, and I may tell you that one of the stations of the company is at least six miles away." The truth is, that twenty miles would make no practical difference.

Here, then, we have an extensive and unmitigable source of sickness and disease on one side, and the facile means of removing it upon the other. If the latter object cannot be effected at once, it must, at all events, be the most monstrous thing in the world to wantonly and unnecessarily permit the aggravation of the evil. Surely no subject connected with sanitary progress can be more interesting at this juncture. Surely, wherever sanitary matters are discussed in the presence of a Medical man, he ought to raise his voice against the gross anomaly and crying evil on which I have commented. Nay, it should be made a point of duty by every conscientious Practitioner to be on the alert for opportunities to bring it under the notice of such persons of local or general influence as he may come into contact with. This would produce excellent effect; the influence of such conversations would filtrate their way to the Legislature's ear, and powerful aid would thus be afforded to the efforts which are on foot for averting the scandal of increasing a terrible, but removable danger and nuisance. A correspondent of yours, who wrote so well and tersely last summer on the occasion of the rejection of one of those pestilent "extension bills," would then be enabled to renew his congratulations, and the more cordially, as, if such attempts be now defeated, the defeat will be a final and decisive one.

I am, &c.,

A Veteran Practitioner.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·589 in. The pressure of the atmosphere fell to 29·30 in. on Tuesday, and rose to 30 in. on Saturday.

The general direction of the wind was variable.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 52·6°.

APPOINTMENTS FOR THE WEEK.

May 12. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

14. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

15. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Pathological Society, 8 p.m. Meeting.

Royal Institution, 3 p.m. Professor Ansted, "On the Application of Physical Geography and Geology to the Fine Arts."

16. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Hunterian Society, 8 p.m. An Open Meeting.

17. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Dr. Richardson will Exhibit his Instruments for Producing Local Anæsthesia. Debate, "On Infanticide in its Medical and Social Bearings."

Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

18. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Rev. C. Pritchard, "On the Teleseope: its Modern Form and the Difficulties of its Construction."

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

(Continued from page 464.)

Compound Fractures involving the Elbow-joint—Extract from a Former Report on this Subject—Details of Thirteen Recent Cases—Remarks.

COMPOUND FRACTURES INVOLVING THE ELBOW-JOINT.

It is scarcely necessary for us to speak of compound dislocations of the elbow-joint without fracture, since owing to the form of the bones entering into the articulation such a form of injury is scarcely ever met with. In compound fractures involving the joint we may, however, have very various degrees of displacement. The most common are, however, those in which there is but little displacement, but to which, quite equally with those apparently more severe, the dangers of traumatic inflammation of the joint attach. These cases constitute some of the most important and interesting with which we have to deal. Ten years ago I published in the *Medical Times and Gazette* a series of cases which had then recently occurred in different Hospitals and under the care of various Surgeons, illustrating this subject. To these in July, 1856, I appended the following comments. Since then I have had the advantage of considerable personal experience as to these accidents, the result of which I will presently relate. First, however, I will ask permission to extract the comments referred to *verbatim* :—

"COMMENTS ON THE SERIES.(a)

"Sir Astley Cooper remarks of compound fracture into the elbow-joint: 'In the most severe accident of this kind, the constitution is generally able to support the injury if it be *judiciously treated.*' He cites four examples of its occurring in his own practice, in three of which recovery ensued; in one death. He also narrates two cases from the practice of Mr. Macyntyre, in which the articulating extremities were excised immediately after the accident, and in both of which excellent results were obtained. In the "judicious treatment" above referred to, Sir Astley appears to include the dressing of the parts in lint soaked with blood, and strictly abstaining from poulticing.'

"Mr. Alcock(b), in his paper on Injuries to Joints occurring in Military Practice, states, 'Very serious injury of the elbow-joint often admits of the limb being saved.' Of excisions, he remarks that 'they have been performed with good success in cases of disease, and *are still more applicable to injuries.*' At the time he wrote, however, he was not aware of any instance 'of total excision of the articulating ends of the elbow in the annals of either British or French Military Surgery.'

"The following Conclusions appear warranted by the facts before us:—

"1. That primary amputation on account of compound fractures of the elbow ought never to be thought of unless, indeed, either the artery be torn through, or the soft parts in front as well as behind the joint hopelessly damaged.

"2. That the preceding rule requires little if any modification on account of the age, health, or previous habits of the patient. In case No. 6 of our series the man was upwards of 64, and in one given by Sir Astley Cooper the patient was a gentleman of 74, and of feeble constitution; yet in both these the result was excellent. In case 5 the patient was a cachectic, ill-fed boy of 14. In case 11 the subject was a brewer's drayman of most intemperate habits; and one of the most favourable of those given by Sir Astley Cooper occurred in a similar character.

"3. That the ill consequences to be feared are in inverse rather than direct proportion to the amount of external injury (laceration) inflicted; those cases being most serious in which the joint is crushed with but a very small opening in the skin.

"4. That in all cases sufficiently severe to warrant it, it is far better Surgery to freely enlarge the wounds behind the joint, and excise the projecting ends of the bones, than to be content with a simple reduction. Much less of suppuration and of constitutional disturbance appears to follow cases so treated, and the chance of good motion being obtained after an excision is infinitely greater than it is when the ends of the injured bones remain.(c)

"5. That, in the treatment of these injuries, poultices and warm fomentations should be avoided.

"6. That, when it has been decided to preserve the arm, it is the Surgeon's duty (excepting, perhaps, in case of sloughing) to persevere, in spite of discouraging circumstances afterwards. None of the patients in our list appear to have died directly from the effects of the injury; and, in the three cases which did end fatally, the event was due to a state (pyæmia) which amputation would have availed nothing to prevent. In several, on the contrary, recovery took place from a condition apparently of but little hope; and in one or two, the patient's own obstinacy in refusing amputation saved him his limb. Buffon described the genius necessary for the successful pursuit of natural history as consisting mainly in '*une assez grande aptitude de patience;*' and, assuredly, the quality is one no less necessary to the conservative Surgeon."

I will now proceed to relate the result of my experience in this matter during the ten years which have elapsed since these statements were written.

My subsequent observation has not in the least diminished my estimate of the dangers attending compound injuries to the elbow-joint. It has, however, I regret to say, somewhat reduced my hopefulness as to the results after excision, though still I think that the balance of evidence is clearly in favour of this practice. We will briefly consider the details of the cases to which I refer.

Case 1.—*Primary Excision of the Elbow-joint, with extensive Removal of Bone rendered necessary by the Injury—Favourable Result.*—In 1861, a man was admitted, under Mr. Curling's care, who had sustained a compound fracture, involving the right elbow, and a second of the left tibia and fibula. The crush of the elbow was most severe, and I have already referred to the case as an instance of dislocation of the bones of the forearm forwards. The soft parts behind the joint were most severely lacerated, and the bones were exposed in the wound. The only question which could be entertained was between excision and amputation. Mr. Curling performed excision, removing the lower fifth of the humerus and the extremities of the ulna and radius. The arm did remarkably well afterwards, and in the course of two months the parts were almost healed. The man, however, after a long illness in connexion with the compound fracture of his leg, ultimately sank. He died, I think, about five months after his accident. Secondary amputation of the leg had been performed, and pyæmia was the immediate cause of death. I think, however, that so far as the elbow was concerned, we may claim the excision as a success.

Case 2.—*Compound Fracture into the Elbow-joint—Destructive Inflammation of the Joint—Recovery, with Anchylosis.*—About the same time that the above case was under care, a German sugar-baker, of middle age, was also admitted under Mr. Curling's care with a compound fracture of the lower part of the humerus, which opened into the elbow-joint. The injury to the soft parts in this case was very trifling. Acute synovitis of the joint, however, followed, and the elbow became greatly swollen, and incisions were required. The man was very ill for some time, and the propriety of a secondary excision was several times discussed. Ultimately, he recovered perfectly, and the sinuses all healed. The elbow was firmly anchylosed, but at a right angle, and likely to be very useful.

(a) *Vide Medical Times and Gazette*, July 12, 1856, and preceding numbers of same journal.

(b) Medico-Chirurgical *Transactions*, vol. xxiii., page 254.

(c) "It may be worth a question whether, even in certain cases not usually deemed sufficiently severe to warrant it for the reason above-mentioned it might not be well, to enlarge the wound and excise the joint. Crushed elbows with but small external wound, undoubtedly, as a rule, do badly. The excision of joints during the acute or commencing stages of inflammation would seem to hitherto have been regarded with suspicion, though probably with no very definite reason. In cases of slight injuries, in which at the time it had been thought best to do nothing, but which have subsequently gone wrong, it might perhaps be good practice, to do *secondary* excisions, say within the first week or two. The immediate relief afforded by free incisions under such circumstances is well known, and it would probably be increased by the removal of the bones and their ulcerating cartilages."

Case 3.—Compound Fracture through the Base of the Olecranon into the Elbow-Joint—Destructive Inflammation of the Joint, with Sloughing of Soft Parts—Secondary Amputation—Death.—A healthy labourer, aged 56, was admitted under my care in 1863 with a compound fracture through the base of the olecranon. It was proved subsequently to have been compound, and to involve the joint; but at first we doubted on this point. The skin-wound was only large enough to admit a probe. There was very little contusion. The limb was placed on a splint, lightly bandaged, and bladders of ice were applied about the joint. During the fortnight following this patient's admission, I was out of town, and he was under the care of a colleague. When I again took charge of the wards, I found him exceedingly ill. There had been destructive inflammation of the joint, with sloughing of integument at its back, and burrowing abseesses in forearm and upper arm. His tongue was dry, and pulse rapid. It was clear that there was now nothing to be thought of short of amputation; and this I accordingly performed about three weeks after the accident. In spite of this measure the man sank a few days later.

Probably in this instance the man's age had something to do with the unfavourable result. A younger and stronger man might have pulled through; yet it is an instructive instance of the danger which attends even a slight compound injury to the joint.

In my next case I obtained an opportunity for an examination of the parts, owing to one of those most unfortunate occurrences—a death from chloroform—the only one, I am glad to say, which has ever happened in my practice.

Case 4.—Comminuted Fracture of the Lower End of the Humerus, with Perforation of the Soft Parts communicating with the Joint—Destructive Inflammation of the Joint.—The specimen which I now show you is the elbow joint and adjacent bones from the case alluded to. You will see that the lower part of the humerus has sustained what we might describe as a T shaped fracture, a kind of injury not very uncommon at this part. A more or less accurately transverse line of fracture crosses the shaft an inch or an inch and a half

Fig. 1. Fig. 2.

Fig. 1.—Diagram showing the lines of fracture in the lower part of the humerus in the case described. The character of the displacement is shown in the next cut—a side view of the same.

Fig. 2.—Irregular transverse fracture of the right humerus two inches above elbow-joint (by direct violence)—Displacement of the elbow and lower fragment forwards with overlapping—Partial union.

above the articular surface, and from the middle of this a vertical line passes downwards into the joint dividing the lower fragment into two. Usually there is also more or less of comminution of the lower fragments. It is, I believe, usually produced by direct violence, and the character of displacement accordingly may vary from what is the rule in fractures at this position by indirect force. In the latter, as I have already insisted, the elbow and lower fragment are displaced backwards. In our present case the injury was caused by the fall of a heavy chest on the elbow, and the displacement is of the elbow and lower fragment forwards.

In this instance, at six weeks after the accident, when we obtained the specimen, there were, as you see, bridges of ossifying material passing between the fragments, and portions of the latter are marked out for exfoliation. The cartilage of the several bones constituting the elbow-joint is extensively removed by ulceration. You will ask why better coaptation was not maintained? To this I reply that the inflammation of the limb, after the injury, was such as to entirely prevent our having recourse to any kind of extension.

To return to that aspect of our case which exhibits it in reference to our present subject—compound injuries to the elbow-joint. The patient was a healthy man, aged 34. He was brought to the Hospital, having had his right elbow crushed and fractured as I have described. The skin was considerably contused, and there was a small laceration on the inner side of the joint, which might have admitted the tip of the little finger. We were not certain that this communicated with the joint, but on the next day the discharge of synovia-like fluid made this almost conclusive. The limb was got into good position, placed on an angular splint, and surrounded by bladders of ice. During the next fortnight, the ice treatment was carefully and efficiently carried out. It did not, however, suffice to prevent a most acute attack of traumatic synovitis. The elbow and adjacent parts became very greatly swollen, and several abscesses required to be opened. The suppuration was very profuse, and at length, fearing that the man's health would give way and that we might be compelled, under very disadvantageous conditions, to resort to amputation, I advised excision of the ends of the bones. This was between five and six weeks after the accident. It was during the administration of chloroform, in preparation for the excision, that the man's death, as I have already stated, occurred. Afterwards I dissected the limb, and removed the specimen which I have shown (see woodcuts). The dissection, as I have said, showed that the parts were in progress of repair, and had no operation been attempted, I think it not improbable that the man would have struggled through and recovered with anchylosis at the elbow and union of the compound fracture. The malposition of the fragments would not have been of nearly so much consequence as the opposite and more common condition of displacement of the elbow backwards, since it would not interfere with flexion.

My next case is one of good recovery after primary resection of the joint.

Case 5.—Compound Fracture of the Humerus involving the Elbow-joint—Primary Resection—Recovery.—A publican, aged about 50, accustomed to a very free mode of life, fell from some steps and sustained a compound fracture of the left elbow-joint. It was the inner extremity of the upper fragment (inner condyle) which had perforated the skin, and synovia was escaping from the wound. The soft parts were much bruised. I explained to him the nature of the accident and its special dangers, and advised an operation, to which he consented. I performed a complete excision of the ends of the three bones in the usual manner, employing the T-shaped incision.

During the three weeks following the accident and operation the forearm was much swollen. A slight attack of erysipelas occurred, and the man also suffered from delirium, probably a complication of delirium tremens and the traumatic form. At length, however, he recovered completely. The wound healed soundly, and he left the Hospital at the end of seven weeks in a very satisfactory condition. I saw him repeatedly afterwards, when he was in excellent health and had good use of the injured arm, which he could extend and flex through a wide range.

In my next case I was obliged to remove about a third of the entire length of the humerus, yet the patient has done well.

Case 6.—Compound Fracture into the Elbow-joint—Primary Excision of the Joint—Subsequent Extensive Sloughing of Soft Parts—Resection of Lower Third of Shaft of Humerus, leaving

the Periosteum—Recovery.—A boy, aged 13, had his left elbow crushed by the wheel of a railway waggon, and was brought into the Hospital with synovia draining from a small wound close below the external condyle. The fracture extended obliquely through the latter. The degree of contusion, contrary to what we might have expected from such an accident, was but apparently slight. I enlarged the wound very freely, converting it into the T incision, and excised the ends of the three bones.

This boy had a severe attack of traumatic delirium during the next few days, caused, I have no doubt, by the sloughing of the soft parts which followed the contusion. The whole of the integument behind the joint sloughed to an extent almost as large as one's hand. There remained only a bridge of skin an inch wide in front of the elbow connecting the upper- and fore-arm. The bones were exposed in the wound. Several consultations were held as to the performance of amputation, and I obtained his father's consent to its performance. It seemed, indeed, for some time that nothing else could possibly be done, and we only waited for a favourable opportunity. At length, however, the sloughs cleared, and the wound granulated so well that I determined to try to save the limb. It was clear that unless we could shorten the limb healing of the very large wound which now existed could not possibly occur. I therefore excised another portion of the humerus, so as to allow the bones of the forearm to come in apposition with the humerus at about the junction of its middle and lower thirds. In doing this, according to my invariable rule, I preserved the periosteum. The latter membrane was very easily stripped off from the shaft, to which it adhered very loosely. Having done this, I cut away the portion of bone I now show. This

Fig. 3.

Fig. 3.—Lower third of left humerus of a boy which was excised four weeks after a primary resection of the elbow-joint for compound fracture. Its surface is covered with new bone.

second excision was performed about a month after the first. You will see that although the periosteum has been stripped off, the surface of the bone is still rough from the deposit of new bone which has occurred between the periosteum and the shaft, and adherent to the latter. This condition of things is very common in bones which have been exposed to irritation, and does not by any means imply that necrosis will follow.

After the second operation our patient did uninterruptedly well. Great attention was paid to the dressing of the limb, and in the course of a few weeks he was able to leave his bed with the limb on an angular splint. The wound at length healed soundly, with the exception of a small sinus which leads down to the end of the shaft, from which an exfoliation is in progress. A large amount of new bone has been formed by the bag of periosteum, which we were careful to preserve, and the bones of the former are firmly anchylosed to the humerus at a right angle. At present, I believe, the boy is in good health, and has a very useful limb.

Case 7.—Compound Fracture of Lower End of Humerus into the Elbow-joint—Sloughing of Soft Parts—Secondary Amputation—Death.—I assisted, a few months ago, at an amputation performed by a colleague on account of very severe injury to the elbow a week previously. The humerus had been fractured, as you see in this specimen, though the external condyle, and the fracture communicated with the joint. Acute inflammation of the elbow resulted, and the skin had very extensively sloughed. This sloughing involved such an extent that repair was clearly out of the question. After the amputation the man did well for a time, but eventually died of pyæmia.

Case 8.—Compound Fracture of the Olecranon—Destructive Inflammation of the Joint—Death.—An Irishwoman, aged 30, applied at the receiving-room during my week one day in the spring of 1865 with a compound fracture of her left olecranon. She positively refused to come into the Hospital, and consequently did not come under my observation until ten days later. The accident was caused by a fall on her elbow, and there was no great amount of contusion. She was, I believe, a temperate and healthy person. When admitted under my care ten days after the injury, she was very ill. She had had severe rigors, and the parts about the elbow were very much swollen. Her tongue was dry and pulse rapid. I thought her pyæmic, and therefore advised amputation; but to this she refused to consent. A few days later, when much worse, she was very anxious that the limb should be removed; but I did not then think it justifiable. She died a week after her admission. At the autopsy we found the cartilage of the elbow joint extensively eroded, and the joint containing dirty pus. The only fracture was that which I now show of the olecranon through its base. I must ask you to note that this patient did not contract the pyæmia of which she died—there had been repeated rigors—in the wards of the Hospital. The disease had set in before her admission.

Cases 9 and 10.—Two Cases of Successful Result after Primary Resection of the Elbow-Joint for Compound Fracture involving the Articulation.—The subjects of these two cases were both under the care of my colleague, Mr. Maunder, and you will find them mentioned in the second volume of our Hospital Reports. Both were men—one aged 47, and the other 28. In one a compound fracture of the ulna involved the elbow-joint, and in the other a similar condition of things had resulted in connection with a compound fracture of the humerus. In each Mr. Maunder performed a primary excision of the joint, and in each, after sharp traumatic fever, the patient recovered well.

Cases 11 and 12.—Two Cases in which Death occurred after Primary Resection of the Elbow-joint for Compound Fracture.—In the first of these, a man aged 50, under Mr. Maunder's care, died of pyæmia on the twentieth day after a primary resection of the elbow-joint. The original injury was a compound comminuted fracture of the humerus into the joint.

In the second the patient was a woman, aged 50, under Mr. Couper's care. The injury was very extensive and severe, both to the bones and soft parts. Traumatic gangrene followed, and the woman died on the tenth day.

I have now mentioned to you all the cases of compound injuries involving the elbow-joint, and not sufficiently severe to demand immediate amputation, which I can recollect to have seen during the last few years. I have yet one most instructive case to mention, which well illustrates the necessity for great care in diagnosis.

Case 13.—Compound Fracture of the Ulna close to Elbow-joint, but not involving it.—I was summoned one evening to the Hospital to a case of "compound fracture into the elbow-joint," and on arriving found the following condition of things. The patient, a healthy man, had been struck on the back of upper part of his forearm just below the olecranon by a revolving cogged wheel, and his ulna was severely comminuted. A portion of skin had been torn away and at the bottom of the wound lay the fragments of the smashed bone. The dresser of the case assured me that synovia had been draining from the wound, and taking for granted that the joint must be opened, I obtained the man's consent to an excision, and had him up into the theatre. When he was under chloroform, I examined the parts more carefully, and arrived at the conclusion that it was just possible that the joint had escaped. I could not find any flow of synovia. Although the bone was shattered at its posterior aspect, yet the olecranon still seemed to be in continuity with the shaft, and a probe did not anywhere find its way into the articulation. I therefore contented myself with picking away some detached fragments of bone, and then covered the wound with wet lint. A large ice bladder was kept in contact with the front of the elbow, and the limb at rest on an angular splint. The case did perfectly well, no inflammation of the joint ensued, and the man left the Hospital with the wound healed, and able to use his elbow-joint as well ever.

In conclusion, I can but repeat my opinion that although,

even after excision, these cases are very serious ones, yet the balance of evidence and argument is decidedly in favour of primary resection in all cases in which it is *quite certain* that a compound fracture involves the elbow-joint. It requires some boldness to decide on this practice in a case in which the wound in the skin is very small and the case as yet looks trivial. These, however, are the very cases which most demand it, and in which, if it be not done, serious inflammation is likely to follow. I hope it is scarcely necessary for me to add that if you do an excision it must be a complete one. The whole articular surfaces should be removed. The only question on this point is as to whether we might not save the end of the olecranon and attachment of triceps, and bring this into apposition with the cut surface of the ulna.

ORIGINAL COMMUNICATIONS.

BLEEDING IN CHOLERA.

By EWING WHITTLE, M.D. Lond.,

Member of the Royal Irish Academy; Sen. Hon. Surgeon to the Liverpool Dispensaries.

Though fully appreciating the justice of your observation, that a terrible responsibility rests upon any one who writes on the subject of cholera at present, I feel bound to lay before the Profession some observations on the views of the treatment of cholera lately set forth so forcibly by Dr. George Johnson. This is a subject on which I have a right to speak with some degree of authority; in 1849 I devoted much time to a careful study of the history and pathology of the disease, I was largely engaged in the treatment of cholera cases during the epidemic of that year, and had the charge of the Cholera Hospital of Toxteth-park, a township then containing more than 60,000 inhabitants.

As the result of my practice I showed that the judicious use of the lancet (as practised nearly fifty years ago in India), was the key to successful treatment; that by its use four cases out of five could be saved; that next to its use the administration of calomel was most to be relied on; and I believe I was the first to show that the good effects of calomel had no reference whatever to the supposed action of that mineral on the liver. A further experience of the epidemic in 1854 confirmed these views, and you will find the results partially recorded in the *Medical Times and Gazette* for October, 1854. So much for my claim to some attention on this important and now anxious question.

I am quite satisfied that Dr. Johnson is right in his theory that the passage of blood from the right side to the left side of the heart is impeded; this arrest of the blood in its natural course is what calls for relief by blood-letting. Whether this is caused by spasm of the small vessels or whether it be the result of nervous paresis, the fact does not admit of dispute; but I cannot so readily admit the truth of Dr. Johnson's theory, that the vomiting and purging is an effort of nature to carry off the poison. How often is vomiting a symptom of sympathy with a distant organ, as in nephritis, in hydrocephalus, in pregnancy? So much for theory; now with regard to practice. I have invariably observed that if these symptoms can be relieved the severity of the disease is abated; and *vice versa*, everything which increases the vomiting and purging aggravates the disease, and precipitates the collapse. Under this head may be included all stimulants, astringents, and opium; all alike injurious, not by stopping the discharges, but by increasing them, particularly the vomiting, which is always a most harassing and exhausting symptom. On the contrary, the action of the calomel is the very reverse; it stops the vomiting immediately, and after a few doses the purging. This I have observed myself; it never purges unless it is continued until reaction is fully set up. In support of the correctness of this statement, I can refer you to all the old Indian authorities; for instance, Dr. James Johnson says "that twenty grains of calomel will act as a sedative; and, so far from griping and producing hypercatharsis, it will soothe uneasiness and rather constipate than purge. Annesley and other Indian authors have made the same observation. This appears to me to be the weak point in Dr. Johnson's views, and this I wish to combat—viz., that calomel is given as a purgative or a cholagogue. In fine, one word upon your own remark, that those who read Dr. Johnson's book will come to the conclusion that the best plan is to do nothing in the stage of collapse; if they do, I can assure you that they will lose more patients than they ought to do. Let them open a vein in the arm in all cases; if collapse has gone so far that no blood will flow, the puncture will do no harm; if only a little blood flows, some relief will be afforded; and if the stream continues until the colour changes from black to red (as Annesley long ago recommended), the relief will be very decided, and the patient will in all probability recover, particularly if he has not been previously injured by the administration of stimulants and opium or other irritants. It is generally sufficient to take three or four ounces of blood, the red colour becoming pretty well marked by the time that quantity is drawn from the vein. A few doses of calomel and a spoonful of gruel every now and then, and the application of dry heat and sinapisms to the surface, was the only additional treatment which I found necessary in 1854.

Believing that there is much truth in what Dr. Johnson has advanced, and knowing that his views have made a profound impression on the Profession, I feel bound to enter a protest against what appears to me to be the unsound point both in his theory and practice. However, I am glad that he so far concurs with me as to recommend bleeding at all; this, I think, he did not do in 1854. I practised it with success both in that year and in 1849, and I would beg most urgently of my Professional brethren to give this mode of treatment a fair trial. If they do, they will not be disappointed.

Liverpool.

A CASE OF RECOVERY FROM REFLEX PARALYSIS.

By Dr. FRASER,

Senior Physician to the London Hospital.

The statement by Brown-Séquard, that the principal symptoms and affections of brain diseases may be caused by an irritation starting from any viscus, or any nerve of the skin, or mucous membranes, receives corroboration from the following case, supplied to me by the patient, Dr. Douglas, residing in West Maitland, Sydney. He has given his own case so graphically that if it were not for want of space the whole of the melancholy record would be read with interest. The heads will sufficiently explain the prominent points.

Having previously been in good health, he was, on January 22, 1864, attacked with dysentery, from which he recovered, and on February 28, having experienced during his illness great inconvenience from piles, he had a ligature placed on a pile. In his own words,—"I experienced intolerable pain, with indescribable sensation in the nates and rectum while sitting."

March 5.—Pile sloughed off. Experienced a sensation of numbness on left side of the body, and in the perineum.

6th.—Extensive ulceration round margin of anus; a fulness of left hip.

10th.—A sensation of fulness and general uneasiness of left hip and cheek; slight twitching and numbness of fingers and legs.

14th.—Speech slightly affected. Strychnine, in doses of $\frac{1}{24}$th part of a grain, ordered three times a day; but the characteristic spasms so soon followed that it was omitted. It was resumed on April 1, but again discontinued on the 5th, for the cause above named. Quinine and stimulants were now freely used.

On June 17 the symptoms had increased; there was oppressed breathing, restlessness, complete loss of sensation and motion in lower extremities. On July 10, quite helpless—cannot move either hands or feet. From this date a gradual improvement began, and on February 19, 1865, he was able to move about slowly, and now (November, 1865,) has completely recovered.

Irrespective of the illustration of the reflex theory of paralysis, this case presents an instance of the beneficial employment of stimulants and avoidance of depletion, thus giving a practical instance of a change of type in disease over this globe; for although the symptoms increased for some days after the use of quinine and stimulants, these aggravated symptoms could not be traced to the use of alcohol, as this remedy was uninterruptibly continued, and the successful result followed.

DESCRIPTIVE REMARKS ON A PECULIAR FORM OF FEVER IN A CATTLE PLAGUE DISTRICT.

By W. HARBORD, Esq., M.R.C.S.E., etc.

Much has been said and written on Rinderpest, and many speculations as to its nature have been suggested. What has been the result? is a natural inquiry. To this query we may reply—More facts with regard to the real nature and origin of zymotic diseases have been elicited than we were previously in possession of, and a better and more simple plan of treatment will be the result, based, as it must be, on the simple chemistry and philosophy of nature.

Rinderpest has been held to be peculiar to the bovine race, and not communicable to other creatures. Such an opinion is no longer tenable, for man, sheep, goats, cats (and if the report from India is to be relied on, horses) are all liable to the same morbific influence, either by infection or contagion. A close observation of facts and phenomena has convinced me of this, and I ask, why, if man is capable of receiving vaccinia and herpes from the cow, he should not be capable of receiving Rinderpest also? It is true that diseases may be modified materially by different animal organisms, but yet retain their original type—I will take as instances vaccinia, herpes, equinia, scabies, and many other diseases capable of propagation from brutes to man, and *vice versa*—but these modifications are not such as to bar identity; the visible sign is the same, whatever may be the effect of the particular class of disease on a particular race of creatures. Rinderpest is communicable to man by contagion, by infection, and by inoculation; its outward manifestations are similar, the symptoms progress in like manner, and the ultimate result corresponds in man and beast, save that in man it is much more amenable to treatment, owing, no doubt, to the greater simplicity of the digestive organs, and consequently not so fatal: a happy result, which is, moreover, aided by the greater facility with which local applications, especially artificial heat, may be applied, aliment administered, and strict cleanliness enforced. I have designated this disease herpetic fever.

The period of incubation varies from seven to twenty-one days, as does also that of maturation. The early symptoms are sense of fulness over the eyebrows and oppression about the chest, with listless anxiety, staggering gait and trembling limbs, rigors, followed by coldness, and an indescribable sensation along the spine, the least pressure on which causes the patient to shrink; distaste for food and drink, the most common reply being, "Leave me alone, I want nothing." After from twelve to seventy-two hours purging comes on, the previous stools having been green in colour, and of the consistence of stiff paint, and so nauseous in odour as to have caused the patient and his attendant to vomit. The odour is that of putrid fish. In severe cases there is not merely diarrhœa or dysentery, but free alvine hæmorrhage. In a few cases I have met with severe vomiting, but this is by no means uncontrollable. The skin presents a peculiar appearance, being somewhat wrinkled and covered with deep plum-coloured blotches and rings, which shine out very vividly on exposure to heat, and, as the disease goes on, patches of herpes simplex and herpes circinatus, and innumerable miliary vesicles show themselves, and decline with desquamation of the whole epidermis. The most prominent feature is the early appearance of small patches of herpetic vesicles on the lips, palate, and fauces, and in the vagina in the female and sometimes within the prepuce of the male. The mucous membrane of these parts presents a salmon-coloured surface with little ulcerated pits, and around the teeth the gum is swollen and ulcerated, and shows several streaks of a livid hue. The lacteal secretion is almost totally suspended, but returns again to its former quantity during convalescence. The urine is scanty—stinking like the stools—and of a greenish-brown colour, and during the convalescence contains the merest trace of albumen, with some pus and blood corpuscles. The countenance is expressive of anxiety throughout the whole course of the disease, yet in the greater number of cases no urgent pain is complained of. The tongue is usually swollen and corrugated at the edges, anæmic and with brown or orange-coloured fur in the centre. The pulse small, frequent, and from 100 to 130. In several instances there has been hæmorrhage from the lungs in conjunction with that from the bowels, and yet there has been no bronchial or pneumonic affection.(a) I have seen 175 cases of this singular disease and may thus classify them:—From inoculation, 5; from actual contagion, 5; taken ill after living on the heads of diseased oxen, no other cause being assigned, 4 (the eruption of vesicles and efflorescence very copious); from infection 161, in this class are those who resided a distance varying from 20 to 1700 yards from where cattle died and were buried. Many of these patients speak of the irritating nature of the gaseous effluvia with horror.

Were I to detail cases, I fear time and space would be wanting, and as the same general features are perceived in all with few exceptions—viz., some in which the attack was ushered in by epileptic convulsions, I will briefly detail the case of a family in which I had a fatal case and was enabled to make an autopsy. This little community consisted of a small farmer, his wife just out of childbed, two sons, two daughters, and an infant sixteen days old. One son and one daughter were convalescent from the disease at the time of their mother's delivery; she had an easy labour, and with her infant went on well until she joined her family ten days after, when she was seized with the train of symptoms already detailed. On the following day the infant was unwell in the same manner and improved for the space of two days, when respiration appeared difficult and scarcely any warmth could be kept up on the surface; the child from a condition of rapid emaciation became œdematous a few hours before death on the fifth day. My friend, Mr. Johnson, of Burgh, who assisted me at the post-mortem, saw similar cases in his district a few days before, and told me he thought them incompatible with any known description of disease in man. I recommended him to examine the vagina where practicable, in order to assure himself of the identity of his cases with mine, and with a view to necessary treatment of the little ulcerated pits often found.

Post-mortem, Thirty-six Hours after Death.—Face livid in irregular patches; cheeks hard and globular, as if stuffed with stone; an irregular, oval, plum-coloured patch over the sternal cuticle; lips and gums chalky white colour. On opening the thorax the heart was found very pale in colour, but full of dark, semi-coagulated blood. The pericardium full of fluid. The lungs healthy, but on tracing the bronchi to the trachea, a little above the bifurcation were a few little vesicles, a few minute shreds of lymph, and a few pus globules; the mucous membrane above this point was in its normal state. The liver presented several patches of ecchymosis beneath the serous covering, which gave it a spotted appearance. Stomach and bowels healthy. Kidneys rather congested.

As I have had no fatal case in which the bowel has been the chief seat of disease, I can only infer that such are more under the control of remedies, and that the hæmorrhage is rather the result of an asthenic condition of the blood-vessels than of active ulceration of the mucous membrane. A short time back I examined the carcase of a young Rinderpest beast, and found a condition in every respect similar, except that the lungs were emphysematous, which was not the case in the infant. There is a want of colour in the blood-discs, and their shape is altered: instead of a plain edge, they have a corrugated margin, which gives an idea of having been altered by some chemical action.

The period of maturation, varying from seven to twenty-one days, is followed by a tedious convalescence, during which the patient suffers more or less acutely from arthritic pains; the limbs are attenuated and trembling, and the sight is impaired. There is extreme proneness to relapse—the slightest error in diet, the least exposure to cold or fatigue, or too much conversation, so exhausts the patient and sets up a new source of irritation, that recovery is further protracted. The favourable symptoms are regular and uniform temperature of the surface, disappearance of the cutaneous congestion and appearance of herpetic and miliary vesicles on various parts of the trunk and upper limbs; the vesicles on the mucous membrane of the mouth and vagina now decline, small reddish scabs being detached, and little vermilion-coloured pits remain in their stead, which after a while disappear.

On the other hand, the prognosis is unfavourable when the heat of the body is irregular, when the temperature along the spine is so reduced as to become a constant source of anxiety to the patient, the cutaneous congestion is more diffused, and puts on the appearance of the blue skin of cholera; the vesicles in the mouth and vagina coalesce and form ulcers; hæmorrhage from the rectum occurs, and the urine is so small in quantity as four or six ounces in twenty-four hours of greenish-brown colour, very turbid, and con-

(a) For some further details of cases *vide* letter from Dr. W. Cholmeley, *Medical Times and Gazette*, February 17, 1866, p. 184.

taining some purulent matter; the pulse is feeble and intermittent; the patient is supine; there is continual twitching of the fingers; the tongue and mouth are cold; with all this the patient is conscious of the serious condition, but seems calm and perfectly resigned.

I have met with several instances in which the trachea has been implicated to an alarming extent, and a few in which pulmonary hæmorrhage has occurred, but without any marked symptoms of bronchitic or pneumonic inflammation.

To sum up. All these lesions of various organs have one common origin in the effect of an ammoniacal *materies morbi* acting on the components of the blood, and causing elementary separation or putrefaction, rendering the should-be vital fluid non-nutrient—a non-conductor of heat, and unable to stimulate the vessels containing it—hence, having lost its natural elasticity, it exudes through the capillaries. The consequence of this is apparent; the great nervous centres become oppressed; first, the ganglionic, and with it implication of the pneumogastric nerve; and, secondly, the brain and spinal cord.

With regard to treatment. Sulphate of magnesia and gallic acid, with alterative doses of hyd. c. cretâ occasionally, and chlorodyne to relieve pain and procure sleep are what, in the early part of the epidemic, I had recourse to; but since March I have used with marked benefit a preparation which has suggested itself to me as being applicable to the treatment of fever—viz, solution of sulphochloride of lime and magnesia. Under its use I find the tongue and fauces clean rapidly, and the skin to become moist and warm, whilst the secretions and excretions lose their putrescent condition. On a future occasion I will publish the formula for this remedy, and give some explanation of its action, of which I can only speak with feelings of great satisfaction.

Wainfleet, Lincolnshire.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

CASES OF ACUTE ORCHITIS TREATED BY PUNCTURE OF THE TESTICLE AND STRAPPING—REMARKS.

(Under the care of Mr. SPENCER WATSON.)

The following cases occurred in the out-patient practice of King's College Hospital, and from the difficulties of tracing the ultimate results of such cases, are necessarily imperfect in some respects. They may, however, serve to show that the experience already arrived at is not unfavourable to the plan of treatment by puncturing and strapping immediately—so far, at any rate, as the relief of the acute symptoms is concerned.

Mr. Watson remarked that the *rationale* of the treatment is so obvious that it is not worth while offering any explanation, but there is an analogous instance of similar treatment in another organ, to which he would especially wish to draw attention. The relief of pain and tension of the eyeball by puncture, or iridectomy, is a striking analogy with the relief experienced when the inflamed testicle is punctured. It is singular that the eye and the testicle are the only two organs in the body in which such a mechanical method could be adopted, or would be likely to be successful. Each is contained in a firm fibrous globular covering of which the only openings are those which admit the vessels and nerves: but while the anatomical position and relations of the eyeball prevent the relief of tension being followed up by mechanical compression, the testicle, being easily isolable, will allow of this being done, and a mere puncture is a means of temporary relief only in the one case as in the other; while the removal of a portion of iris from the eye, and mechanical compression in the case of the testicle, are necessary to make such relief permanent, by preventing a recurrence of those conditions which have produced the most distressing symptoms and destructive processes in each.

Cases still under treatment are not reported, but it is worthy of observation that of about 20 cases in which I have tried this plan in none have any bad results followed, so far as I have been able to trace them. It has been asked whether abscess did not sometimes occur; whether the testicle was not permanently injured; whether the swelling did not recur? To these questions I can answer that I have never seen abscess after an incision, though I should not be at all surprised if in a scrofulous patient such a result were to follow. As to the testicle being permanently injured, I have certainly heard of one instance (not in my own practice) in which atrophy occurred. But this has been known to occur frequently under any plan of treatment, and it would not be a strong argument against incision unless it could be proved to be a frequent result, or to occur in simple uncomplicated cases, or such as were not of a severe character. The mere fact of a testicle having wasted after it had been punctured for acute orchitis would perhaps only prove that the case was of such a severe kind that any other treatment would have been followed by the same result, or that no treatment would have been of any avail to prevent it.

In answer to the third question, whether the swelling did not recur? I find that in some such it has done so after a puncture only, and it is on this account that I have taken the precaution of strapping the testicle with adhesive plaster in order to prevent this. I may also observe that strapping alone has in one or two cases succeeded when the patient has objected to the use of the knife, but that where there has been effusion into the tunica vaginalis I should not expect this to succeed without puncture.

It is well to point out that epididymitis is a very frequent accompaniment of orchitis, or swelling of the body of the testicle, but that effusion into the tunica vaginalis seems equally frequent, although this fact seems to have been overlooked or very slightly noticed by authors; and that it is to the latter class more especially that this plan of treatment is applicable, and not to cases in which the epididymis is alone or principally affected.

Case 1.—*Acute Orchitis Treated by Puncture.*

James A., aged 30 years, applied to King's College Hospital on December 23, 1864, with acute orchitis. Mr. Watson punctured the tunica vaginalis with a grooved needle, letting off three drachms or half an ounce of yellow serum. The body of the testicle was not punctured. The patient expressed himself as immediately and decidedly relieved. The pain previously had been very severe. He was ordered a powder containing ten grains of Dover's powder and gr. $\frac{1}{12}$ of tartar emetic, to be taken every night at bedtime, and a mixture with twenty drops of tincture of henbane in each dose to be taken three times daily.

January 6.—The testicle is much smaller, and the pain has quite left him.

16th.—The patient complains of a great deal of pain. The cord is swollen and the back part of the testicle (probably the epididymis). Two leeches to be applied to the testicle.

27th.—The pain still continues. Strapping to be applied, and five grains of iodide of potassium three times a day.

30th.—Has been relieved since the strapping was applied. Strapping to be put on again.

Observations.—Here the case terminates, and it appears incomplete; it serves, however, to show the efficacy of a mere puncture for the relief of the acute symptoms, and at the same time the necessity of further treatment in conjunction with this plan.

Notes were taken of this case by Messrs. Renwick and Hart, the dressers of the patient.

Case 2.—*Acute Orchitis Treated by Puncture.*

A man of 25 years of age applied to Mr. Watson on December 23, 1864, with acute orchitis from an injury to the testicle. Mr. Watson punctured the tunica vaginalis with a grooved needle, with immediate relief of the pain. Ten grains of Dover's powder, with two of calomel, were ordered to be taken at bedtime, and a mixture containing tincture of henbane in camphor water to be taken three times daily.

December 28.—He was compelled to return to the Hospital on the day following the puncture on account of the return of the pain. There is now distinct fluctuation over the whole surface of the testicle, and as much pain and inflammation as before.

Observations.—This case seems to corroborate the conclusions drawn from the preceding case.

Case 3.—*Acute Orchitis Treated by Puncture.*

G. B., aged 19 years, applied on January 9, 1865, with an enlarged testicle, which he had first noticed four days before. Mr. Watson punctured the testicle with a Syme's knife, and ordered him a powder containing 10 grs. of Dover's powder and $\frac{1}{12}$ gr. of tartar emetic each night at bed time.

January 16.—The patient passed a bad night after the puncture, but felt greatly relieved the next day. The pain and swelling have nearly disappeared, and he has returned to his work as a timber sawyer; the testicle is still tender when touched.

23rd.—The patient is now almost perfectly recovered. He complains of no pain whatever, and has been at work for the last week without feeling any inconvenience from doing so.

The notes of this case were taken by Mr. Renwick, the dresser of the patient.

Case 4.—*Acute Orchitis treated by Puncture and Strapping.*

J. H., aged 20 years, applied at King's College Hospital on March 13 with gonorrhœa and acute orchitis. On March 21 the testicle was punctured, and strapped immediately afterwards.

April 17.—The strapping has been applied regularly once a week, and the testicle has gradually diminished in size. It is now nearly natural in size and shape.

Case 5.—*Acute Orchitis treated by Puncture and Strapping.*

J. H., aged 20 years, had contracted gonorrhœa in December, 1864, for which he had been treated without injections up to the early part of May, 1865.

On May 8, 1865, he presented himself at King's College Hospital with acute inflammation of his left testicle, which came on suddenly after drinking very freely the day before.

Mr. Watson punctured the testicle, and had it strapped immediately.

May 10.—The strapping again applied. The patient complained of severe pain, but said that he was able to sleep the night before. One grain of opium to be taken each night.

12th.—The testicle having become smaller, the strapping has become loose. There is no pain now. Fresh strapping to be applied.

17th.—The testicle is very little larger than natural, and is softer, and free from pain and tenderness.

Observations.—This case is, perhaps, as favourable as any that have occurred of this kind. The result was rapidly obtained, and very complete.

The notes were taken by Mr. Musgrave.

Case 6.—*Acute Orchitis treated by Puncture and Strapping.*

Robert Charles R., aged 29 years, was admitted as an out-patient at King's College Hospital, on Jan. 11, 1865, with acute inflammation of one of his testicles. The swelling had existed for about a week. Mr. Watson punctured the testicle and let out about one drachm of clear serum and about half an ounce of blood. The testicle was then strapped, and 1 grain of opium prescribed as a night-dose.

January 14.—The pain is so far relieved that he can sleep at night. There is an oozing of serum from the wound. Strapping again applied.

19th.—The testicle to be strapped again.

23rd.—Considers himself cured, as there is no tenderness nor pain in the part, and a hard lump of the size of a pea only can be felt in the epididymis.

April 24th, 1866.—Has had no trouble from the testicle since the last attendance, but within the last few days swelling of the same testicle has come on. There is no pain nor tenderness, however, and the swelling is of a soft kind and not associated with effusion into the tunica vaginalis. Hardness in the region of the epididymis, as if from old deposit, can still be felt. The site of the puncture is marked by a very faint white cicatrix in the skin of the scrotum. A mild saline mixture prescribed.

26th.—So much relieved that he is to discontinue further attendance.

Case 7.—*From Notes by Mr. C. B. Allen, Dresser of the Patient.*

C. B., aged 23, admitted as an out-patient on November 10, 1865, with gonorrhœal discharge, which was never very abundant, and generally thin. The discharge ceased about a week before admission; the swelling of the testicle commenced three days after. The swelling is not very painful on pressure, and is not of a uniform character, there being a hardness, partly in front and partly below, near the median line. Mr. Watson proposed that he should have the testicle punctured, but the patient objecting, it was strapped, and the following prescription given:—Liq. ammon. acet. ʒj.; tr. opii. ɱx.; mist. camph. ʒss.; t. d. s.

November 21.—The swelling is not reduced, and there is now distinct fluctuation in the tunica vaginalis. Mr. Watson punctured the testicle; a quantity of clear serum escaped, and then a little blood. Strapping again applied, and the same medicine and one grain of opium at bedtime prescribed.

24th.—The patient states that immediately after the puncture he felt relieved, and that he was able to walk home to Pimlico without inconvenience. He has been easier ever since.

28th.—The swelling is about the same in size, but the pain has disappeared.

December 5.—No pain nor tenderness; no hardness of the epididymis; the testicle is very slightly larger than the other. The site of the puncture is marked by a little fistulous opening, from which moisture exudes.

Observations.—The strapping and other remedies at first applied gave no relief, while the relief afforded by puncture was immediate and permanent. The existence of a fistulous opening may be regarded as an unfortunate sequel to the case; but, though no notes were taken subsequently, it is almost certain that the opening closed rapidly, as the patient continued in attendance, and did not complain of any inconvenience, nor have any other cases happened to Mr. Watson with such a complication. A patient with orchitis, in attendance about the same time (*i.e.*, from November 21 to December 27) was treated, without puncturing, by means of strapping and the same mixture as was prescribed here, and the result was equally satisfactory, but not marked by the immediate relief which was observed in the case related. In the case of C. B. there was effusion of serum into the tunica vaginalis, and the immediate relief following the puncture was probably due to the escape of this serum; in the other case there was no effusion into the tunica vaginalis, and the principal swelling was in the epididymis. Hence the difference in the plan of treatment and the equally good result in each. In other cases, the notes of which are not complete, the effect of a puncture has been less satisfactory when no serum has escaped, and when the swelling has been principally or entirely confined to the epididymis; and in all in which there has been effusion into the tunica vaginalis, the relief from puncture has been immediate, and in most of them, if not in all, the result has been successful.

Case 8.

H. M., aged 23, admitted with orchitis of the right side January 7, 1865. The swelling was accompanied with great pain, and came on in the course of gonorrhœa; it had existed three or four days before admission.

January 7. Puncture and strapping; pil opii comp. gr. v. h. s. o. every night.

14th. Strapping again applied. The swelling is much reduced; He has little or no pain.

16th. The testicle decreased in size; very little pain. Is able to sleep well at night.

19th. He has now both testicles swollen; the left being more painful than the right. The gonorrhœal discharge continues. Henbane and acetate of ammonia prescribed, and the testicles to be supported.

23rd. There is scarcely any induration in the right testicle (the one that was punctured), the left is still enlarged and painful.

Observations.—The case is incomplete, but serves to show that the treatment by puncture and strapping was successful to some extent. The attack of orchitis on the left side was, perhaps, due to the continued use of an injection during the course of treatment.

Health of Convicts.—In consequence of a representation made to the authorities by the coroner for Chatham, at the request of the jury who lately investigated the circumstances attending the death of one of the convicts at the St. Mary's Convict Prison, on which occasion the jury found a special verdict that the death of the convict was superinduced by prolonged exposure on the public works at St. Mary's Island, and insufficiency of food, and at the same time drew attention to the recent mortality among the convicts from disease of the lungs, the Government has appointed a Commission consisting of Deputy-Inspector-General J. A. Fraser, M.D., principal Medical officer at Chatham garrison, Dr. J. Balfour Cockburn, M.D., Royal Engineers, and the Governor of Milbank Convict Prison, to carry out the necessary investigation relating to this and the other deaths of convicts which have recently occurred at the Chatham Prison.

The Odontological Society held its ordinary monthly meeting on the 7th inst., at 32, Soho-square, the President in the chair. A paper was read by Mr. Ibbetson on the "Fossil Teeth of Fishes in the Paleozoic and Lower Members of the Mezozoic Rocks." Mr. Fox and other members described cases of retarded development of the teeth of unusual characters.

SATURDAY, MAY 19.

THE MEDICAL COUNCIL.

Whilst we are going to press the Parliament of the Medical Profession is beginning a new Session, and the speech from the chair, which we publish in another column, gives a clear and business-like account of the matters which will come under consideration. The subjects of general and Professional education will doubtless be carefully reviewed, and an endeavour be made to keep them up, so far as is possible, without running the risk of diminishing the number of young men able to enter the Profession, and so throwing the public into the hands of unqualified Practitioners. Regarding the visitation of examinations, the moral effect has been so good that we believe the majority of the Council will be satisfied without any publication of the details at present. The "British Pharmacopœia" is doing as well as can be expected of any book that is the product of joint authorship. A new Medical Bill has been drafted, after many delays arising from the change of Ministry consequent on Lord Palmerston's death, and the preoccupation of Government with the Cattle Plague and Reform Bill.

A plan will be proposed for deputing an adequate amount of power to a Committee of Delegates from the various Branches of the Council, whose meetings may be more frequent and less expensive than those of the whole Council. We believe we are justified in saying that, whilst the Council are desirous of protecting to the utmost the rights of the regularly qualified Medical Practitioner, they are exceedingly unwilling to draw upon themselves the suspicion of intolerance or exclusiveness as regards unqualified Practitioners, provided they do not sail under false colours, and assume titles they have no right to. It is considered extremely probable also that there will be no completed act of legislation during this Session of Parliament. Never mind. The moral effect of the Council is greater, and will increase yearly. The general education of candidates will be raised; courts of examiners will wake up; our Profession will be stocked with gentlemanly and well-informed recruits; and legislation for quacks and outsiders will be less and less necessary.

It seems from the speech of Dr. Acland, that beginning with a series of experiments on the value of Medicines, and their right to be included in the Pharmacopœia, the Council may in time become an authority on scientific matters, with functions such as those of an Academy of Medicine. Great ends have followed less beginnings than these.

DR. BENCE JONES'S LECTURES.

Professor Huxley, in his address a few days ago to the students of St. Mary's Hospital Medical School, alluded to the wicked and libellous old story in which it is said that Nature and Disease are as two men fighting, and that the Doctor is a man who comes in the dark with a big stick and hits hard, and sometimes hits the disease, and sometimes Nature. The Professor, however, bid us look forward to the time when the Physician should attain as clear a mental vision of the condition of a diseased part, and the means of relieving it, as the Surgeon has in the plainest kind of Surgery. What the Physician wants is *more light*, and that light must come from the cultivation and refinement of those sciences which furnish us with the data for deduction—the sciences of anatomy, physiology, chemistry, physics, and so forth; and the much-needed and longed-for light will come, slowly perhaps, and perhaps by unequal and intermittent increments, but come it most assuredly will while there are so many earnest, honest seekers after it as we have at the present day—men working towards the light steadfastly, laboriously. Our last week's number contained the conclusion of a remarkable course of lectures by one of the most eminent of these light-seeking students. Dr. Bence Jones has attained a very prominent position as the exponent of what we may call chemical pathology. Succeeding to the mantle of Prout, but with an immensely enlarged knowledge of organic chemistry; the disciple of, and working in the same direction and spirit with Liebig, and being the chief interpreter in this country of that eminent man's doctrines, he has ceaselessly laboured at the application of chemistry and physics to the explanation and to the repair of morbid conditions of the human body. The course of lectures which we have just published gives his latest views on the subject. They are called "Lectures on Chemical and Mechanical Diseases and their Relationship," and they are founded on the modern doctrines of the conservation and correlation of force. The key-note of the whole course will be found in the "Preface," contained in the first number of this journal in 1865, in which Dr. Bence Jones remarks:—"I shall endeavour to show, by a few striking examples, that the theory of the conservation of force opens a vast field of experimental inquiry, not only as regards the origin and connexion of the actions which constitute disease, but also as regards the actions of the remedies by which those diseases are modified or removed." Again, he says "Wherever it is possible, I shall point out how excess or deficiency of molecular action produces mechanical disease, and in my last lecture I shall rapidly prove that the converse relationship exists; for massive diseases or injuries give rise to secondary chemical diseases—that is, to excess or deficiency, or altered molecular actions, which again react on the original mechanical wrong, whereby the secondary chemical actions are exalted or depressed. I am far from thinking that all the actions that take place in the body are directly chemical or mechanical. He would be but a poor Physician who overlooked the influence of the nervous system either in the origin, the progress, or the treatment of every disease. The progress of animal electricity will probably make clear the connexion between nervous, electric, and chemical force. Then the large class of diseases which arise from the disturbances in the regulators of the chemical and mechanical actions in the body will be as clear as the errors in the chemical and mechanical actions which form the subject of this course of lectures. We are just ceasing to regard the nervous force as the origin of all the power in the body. Instead of making it a creator of force, we are beginning to regard it as the liberator and restrainer of the force in the body—in other words, as the regulator, through the blood vessels, of the extent and degree of oxidation and nutrition that occurs in the human machine."

These quotations will suffice to remind our readers of how much thought and originality these lectures contain, and to justify us in congratulating ourselves on having been the means of giving them publicity. That Dr. Bence Jones's views should in their entirety meet with even a general acceptance is not to be expected, or even, as yet, to be desired. It will be a bad day when stagnant, slavish acquiescence takes

the place of that sharp criticism, of that desire to supersede the teachings of authority, however eminent, by newer and newer doctrines which these lectures have already called forth. These lectures are eminently suggestive, and worthy of careful and thoughtful study, and will take their place in the history of Medical literature as showing how far the perverted processes of life are capable of being explained on chemical and physical principles.

THE REPORT OF THE CATTLE PLAGUE COMMISSIONERS.

The third Report of the Cattle Plague Commissioners contains a large amount of really valuable information. We have given our readers from time to time a fair share of statistical matter, and are now glad of the opportunity of presenting them with some information in reference to the more Medical and scientific aspect of Rinderpest, and the researches of the several gentlemen who were requested by the Commissioners to investigate cattle plague from special points of view. The names of the gentlemen who undertook these inquiries, and the subjects of their investigations, are—Nature, propagation, progress, and symptoms of the disease, J. B. Sanderson, M.D.; general pathology of the disease, and its relation to human diseases, C. Murchison, M.D.; chemical pathology of the disease, W. Marcet, M.D., F.R.S.; morbid anatomy of the disease, J. S. Bristowe, M.D.; microscopical researches on the disease, L. S. Beale, M.D., F.R.S.; treatment, George Varnell, M.R.C.V.S., and William Pritchard, M.R.C.V.S.; disinfection, R. Angus Smith, Ph.D., F.R.S., and W. Crookes, F.R.S.

We are told that the preparation of the third Report has devolved chiefly upon the Medical members of the Commission, who are therefore responsible for the soundness of the physiological and chemical conclusions set forth.

The following are the most important points to be noticed in the Report. In the following abstract it will be understood that we give the Commissioners' view, and that inverted commas mark quotations from their Report:—

1. *Symptoms and Course of the Disease.*—A rise of temperature precedes all other symptoms. "Within a period ranging from 36 to 48 hours after an animal has taken the cattle plague by inoculation the natural temperature rises from 102° Fah., or a little above, to 104° or even to 105½°. This occurs at a time when the animal appears to be in no way ill. It follows, therefore, that the length of the incubative period—that is, of the time when the disease is hatching in the body, is less than was supposed. The disease can be detected at least two days earlier than has been hitherto believed, and the duration assigned to the incubative period must be reduced by that time."

Two days after the first rise of temperature an eruption (epithelial desquamation) is observed about the buccal mucous membrane, and a congestive state of the vagina. These three conditions are said to be sufficient to diagnose the existence of the disease. On the fourth day "the animal for the first time shows marked symptoms of illness, and this period, which may be 110 hours after the real commencement, is usually considered by superficial observers as the beginning of the disease. After the fourth day is over the constitution is thoroughly invaded. Then ensue the urgent symptoms—the drooping head, the hanging ears, the distressed look, the failing pulse, the oppressed breathing, the discharge from the eyes, nose, and mouth, the eruption of the skin, the fœtid breath, and the other well-known signs of the disease. During the sixth day there occurs a great diminution of the contractile force of the heart and voluntary muscles, the pulse becomes very feeble and thready, the respiratory movements are modified, and the animal sometimes shows such weakness in the limbs that it has even been thought that some special paralytic affection of the spinal nerves must exist. The temperature now rapidly falls, and signs of a great diminution in the normal chemical changes in the body appear. Death usually occurs on the following or seventh day from the first perceptible elevation of temperature." Such is the progress of a typical case of Rinderpest according to the Report.

"The causes leading to the symptoms, or, in other words, the reasons why these alterations from health occur," say the Commissioners, "may be thus stated:—

"Coincident with the first elevation of temperature, and, of course, long before there is the least outward appearance of ill-health, the blood of an animal which has taken the cattle plague contains an agent which can produce the plague in another animal. In other words, the earliest fact that can be made out after infection is that the blood contains the poison of the disease, so that serum obtained from it will give the disease by inoculation. This fact, ascertained by Dr. Sanderson, is the most important pathological discovery yet made in cattle plague. It is pregnant with consequences in Medical doctrine, for though the existence of a similar fact has been long suspected in several human diseases, it has never been proved in any. So material, indeed, is it that we must dwell on it for a moment. The poison contained in a minute portion of the mucous discharge from the eyes and mouth of an animal ill with cattle plague, if placed in the blood of a healthy animal, increases so fast that in less than 48 hours, perhaps in a far shorter time, the whole mass of blood, weighing many pounds, is infected, and every small particle of that blood contains enough poison to give the disease to another animal."

In reference to the local congestions that form so prominent a feature, it is stated that "a great increase of granular matter is found to take place both within and outside of the vessels of the affected parts. The capillary vessels themselves are greatly enlarged, and the spaces between them lessened or even obliterated. At the same time a considerable nutritive alteration goes on in the mucous membrane and skin, which leads to very rapid and imperfect growth of many of the cellular elements, and this is followed by a rapid disintegration and detachment in the form of discharges."

The degree of congestion varies; it may be very superficial, and then the mucous surface may recover itself; all observers lay great stress upon the failure of the nutritive process from the loss of the epithelial lining of the digestive tract, but also it appears that "when, as sometimes happens, the mucous membrane most affected by the congestion is that of the lungs, the phenomena are not less severe; indeed, the disease is sometimes even more quickly fatal. A slight cough is soon followed by accelerated breathing, which rapidly increases, and not unfrequently the difficulty becomes so great that some of the air vesicles are broken, and the air passes into the cellular tissue between the lobules, and from this it reaches even the subcutaneous textures of the back. This is believed by Dr. Bristowe and Dr. Sanderson to be the cause of the emphysema which they fully describe."

The gravity of the disease, then, appears to be not in proportion to the degree of pyrexia, but in direct proportion to the extent of change in the mucous tracts. The true cause of this congestive condition, the Commissioners say, is still unascertained.

"The explanation which Dr. Beale gives is, that the poison itself consists of extremely minute particles of living matter, which multiply in the blood, and cause local capillary obstruction which passes on into complete stagnation. In consequence of the impeded circulation, an increased proportion of soluble nutrient matter permeates the vascular walls, and gains access to the nuclei of the vessels and adjacent tissues, which increase much in size. This change is associated with, and causes, the rise of temperature which occurs at this period of the disease.

"If regarded from a chemical point of view, it appears probable that this immediate cause resides in an increased zymotic action in the blood and in the textures, whence increased temperature, accelerated circulation, more rapid growth, congestion, obstruction, and disintegration ensue."

2. *Nature of the Disease.*—Although the cause of the disease

is contained in the discharges, the blood, and probably the textures of the diseased animal, the poison of Rinderpest cannot be separated or demonstrated either microscopically or chemically.

"Dr. Beale has examined portions of infected blood textures and mucous discharges with the highest magnifying powers that exist—namely, $\frac{1}{50}$th of an inch focal adjustment. This magnifies 2800 diameters—or, to express the magnifying power by some examples, an inch would appear to extend over 111 yards, and a child three feet tall would look as high as Mont Blanc. With such power, particles of even $\frac{1}{100000}$th of an inch in diameter having any distinct character would not be passed over. But he has found no definitely formed substance that can certainly be said to be the cause of the cattle plague. He finds a great increase of granular matter, but no new appearance decidedly characteristic of the disease. Possibly this granular matter may be the poison; possibly, again, it may exist in particles of definite form, and of a size still smaller than $\frac{1}{100000}$th of an inch, but which might be perceived if it were possible to construct instruments of still higher magnifying powers; more probably it is matter of a kind which is, and will always be, undiscoverable by the microscope. The peculiar entozoon-like bodies (Rainey's corpuscles) which are found so frequently in the muscles of animals dead with cattle plague, are not peculiar to this disease, and may be absent in it. They cannot, therefore, be the poison.

"As the microscope fails us, we turn to chemistry to detect the substance, but chemistry has not hitherto separated the poison, and no chemical test as yet exists by which it can be recognised. An examination of the air vitiated by the disease is described in the report of Dr. Angus Smith. Chemistry has as yet found in cattle plague no complex albuminoid matter in a state of rapid chemical change capable of communicating its own action to the albumen of the serum of the blood and of the textures of cattle. Hence it is only by its effects on the living body that the poison can be identified."

3. *Origin and Propagation.*—The Commissioners are entirely of opinion that the Rinderpest is an importation, and that it does not arise spontaneously. They have found no evidence of a spontaneous origin in England.

"It ought to be a matter of no surprise that we have been unable to indicate the precise channel by which the poison came into the market. From the universal ignorance of the signs of the disease at that time, and the probable slaughter of the affected animal soon after the market, evidence which might have led to the detection of it at the time would pass unnoticed and would soon be lost altogether. But, as we have since traced several introductions from the Continent, there can be little doubt that it was introduced in the same way in the first instance, and was overlooked. Moreover, in most places in England where the disease has broken out its introduction can be traced. It follows the lines of cattle traffic, and does not arise spontaneously. In the cases where no explanation can be obtained, we consider it more likely that the evidence is insufficient than that the rule proved by a multiplicity of instances should have such exceptions. In confirmation of this, we find the Austrian and Prussian veterinary Surgeons declare that, whatever may be the origin of the disease in other countries, it is always brought by diseased cattle to them.

"The way in which the disease broke out and was destroyed in the Jardin d'Acclimatation in Paris, and over and over again in Aberdeenshire, its absence from Ireland, the manner in which it has spread in England and Scotland during the summer, autumn, and winter, all these facts are conclusive evidence against the assumption of an occult atmospheric condition and in favour of its spread by multiplication in the bodies of living animals."

The poison of Rinderpest may be carried through the air a varying distance. The average is not easily defined. In an open country with a rapidly moving air it is soon oxidised and diluted so as to be powerless. The influence of soil and meteorological conditions is unimportant. Over-crowding and bad sanitary regulations act by preventing dilution of the poison and rendering animals less liable to withstand disease. It does not appear that the poison may be conveyed through the medium of drinking water, though lead water increases the fatality of the disease. The true mode of preventing the spread of cattle plague is to treat it as an "entirely contagious disease."

4. *Disinfection.*—The experiments on this point seem to have been conducted on a very large scale.

"On examining these different agents it is soon found that the number of those which can be employed with advantage is limited.

"Since the poison is constantly given off in discharges flowing from diseased surfaces, and since it may be suspended like impalpable dust in the air, it becomes necessary that any disinfectant should act continuously both on the discharges and on the air. No disinfectant can be efficacious if its action is intermittent, or if it does not act on both sources of danger.

"It is evident, indeed, that the poison ought to be destroyed at the very moment of evolution or discharge. Every minute during which it remains active increases the danger. The disinfectant must, therefore, not only be both fixed and volatile, but so cheap and easily used as to be continually in action, and it must, of course, be innocuous to cattle and men."

Out of a large number of substances, *chlorine* and the tar acids "have the advantage of being both liquid and aëriform; they can be at once added to discharges, and constantly diffused in the air." The general results, too, appear to be very encouraging.

"It is of course most desirable that no false hopes should be raised, for we have seen but too many instances in which a rude disappointment has utterly crushed what seemed reasonable expectations. But no one can peruse the account of what has been done without seeing that a fair case has been made out for a large and systematic trial of these measures. They must, however, be fairly tried; they must be used with perseverance and energy; not grudgingly or insufficiently, as has sometimes been the case, but with the determination to keep the disinfectant in presence of the poison everywhere and constantly, so that every particle of virus may be, without fail, subjected to its action."

The general use of carbolic acid in *all* cowsheds, for cleanliness' sake, is recommended.

5. *Inoculation and Vaccination.*—There is no reason to believe the Rinderpest is in any way a modified form of smallpox. "All attempts to weaken the power of the cattle plague poison or to find another agent which might make the system of the ox insusceptible to it, have entirely failed."

6. *Treatment.*—It would appear that the percentage of recoveries remains nearly the same under the most diverse plans and kinds of treatment. The influence of diet appears, however, to be important.

"But, although, as respects the value of drugs, the evidence is merely negative, this is not the case as to diet. The information obtained by the Edinburgh Cattle Plague Committee shows that by judicious feeding with soft mashes of digestible food, the proportion of recoveries has been considerably and, in some places, very largely increased. This is consistent with the pathology of the disease. In fact, out of 503 cases reported, 191 or nearly 38 per cent. recovered, and 312 or about 62 per cent. died. The result appears still more striking when the beasts are divided into two groups, according as they belonged to large or small stocks."

The sulphites have been used, but not on a sufficiently large scale to warrant us in drawing any conclusion in the matter. "No drug has been found which can be recommended as either an 'antidote' or a 'palliative.'" Inhalation of oxygen seemed to relieve the breathing; chlorine inhaled was mischievous; oxygen water as drink, useless.

7. *Future Precautions.*—After noticing the operation of stamping-out measures, the Report says:—

"With a view to the future, it is essential that the re-introduction of the disease from abroad be guarded against. In our second Report we recommended to your Majesty that foreign cattle should be slaughtered at the port of disembarkation, or, if sold for store purposes, should be placed in quarantine. We believe that the whole system of cattle transport should be revised; that good landing-places, lairs, and sheds, in which the cattle may be properly housed, tended, and inspected, should at once be constructed at the ports where cattle arrive; and that the trade in foreign cattle,

which has grown of late years to such vast proportions, should be subjected to proper regulations."

The Report ends with the expression of a very strong opinion as to the necessity for some reform in reference to slaughter-houses in large towns. The Commissioners believe—

"That it is now the time to carry out fully and permanently the changes required in the mode in which meat is supplied to our large towns. Considerable alterations have taken place already, and these have not been attended with the inconvenience which was anticipated. We would gladly see an inquiry instituted without delay, to determine whether slaughter-houses might not be transferred from all our large towns to suburban points on the lines of railway. A few large slaughter-houses, properly arranged on the best principles, and provided with pastures and sheds where the cattle could rest, would take the place of the innumerable ill-kept and ill-tended places which exist in all large towns. The change would eventually benefit alike the customer and the butcher, while the saving of pain and torture to the animals themselves would be immeasurable. The Cattle Plague has been a great calamity, but it has put a stop, for a time at least, to much that was cruel and pernicious in operation: we trust that this wholesome effect will be lasting, and that it will pave the way for more extensive reforms."

THE WEEK.

CHARING-CROSS HOSPITAL.

We observe that Dr. Tilbury Fox is candidate for the vacant post of Assistant-Physician to Charing-cross Hospital. His Professional claims to such a position are probably higher and more varied than it has fallen to the lot of most aspirants to possess. Dr. Fox is known to have taken the most distinguished position in honours in Medicine in the University of London, and few candidates for this junior office can show so much work well done, so many distinctions hardly won in the fields of intellectual contest. Of course, all of Dr. Fox's work is not of equal value, but we may mention especially as noteworthy contributions to Medical science, his work on "Parasitic Diseases of the Skin," containing the results of much original microscopic research, and which has done much to identify the various kinds of fungi and to define the part which they take in the production of disease; his philosophic essay in the *Brit. and For. Med. Chir. Rev.* towards the elucidation of the law of elementary lesions, suggested by the writings of Willan and Bateman; his studies of cholera and leprosy in the East, and his history of the puerperal fever epidemics of the General Lying-in-Hospital, recorded in the *Obstetrical Transactions*. We well remember that when Dr. Fox brought forward some observations on phlegmasia dolens at the Obstetrical Society, five or six years ago, they were very favourably received. Dr. Fox's antecedents lead us to expect a breadth of view which is much to be desired at the present epoch of English Medicine. We are too apt to take as our types the diseases met with in the one ward of the Hospital where we have studied; we want a more liberal and extended survey. Only one other candidate is mentioned — a young Physician of promise, doubtless, but who has yet to win his spurs; we cordially wish him success on the next occasion.

THE METROPOLITAN SANITARY ASSOCIATION.

A meeting of this Association was held in the Vestry Hall, Back-road, Cannon-street-road, St. George's-in-the-East, on Tuesday last, to consider the subject of the "dwellings of the working classes," the Rev. the Rector in the chair. The expectation that cholera will visit London has led the Society to invite the various Vestries to consider what steps can be taken to give more effect to the existing laws. Dr. Lankester gave a sketch of the leading influences which conduce to an unhealthy condition of the dwelling-houses of rich and poor; and in the course of a capital sanitary lecture described the ill effects of overcrowding and want of ventilation, as illustrated by the difference of mortality in town and country, and in good and bad parts of one and the same town. He spoke especially of the necessity for special air supply to crowded rooms, and particularly if gas be used. He then proceeded to discuss the question of pure water, referring particularly to the disgraceful condition in which the water butts and tanks of the houses of the poor are often found. He said that especially in cholera time surface pumps, which are apt to be impregnated with sewage and other refuse, should be shut up. Mr. Godwin, F.R.S., in supplementing Dr. Lankester's remarks, referred especially to the traps of drains; in thirty instances in one row of houses which he had examined he found every trap bad. A working man in the body of the hall discussed at some length the unsuitableness of the present style of dwellings for the poor, especially the huge block and high story "model" tenements, declaring the cottage system to be the best, being the more conducive to the independent feelings of an Englishman, and preferable in an æsthetic sense. The Rev. Mr. McGill, Mr. Hodson Pratt, and others joined in the discussion.

The Society does wisely in thus invading the East of London, which may well be called the head-quarters of the enemy.

THE "DREADNOUGHT" HOSPITAL SHIP.

It will be learnt with satisfaction by the public generally, and by those interested in the commerce of the port of London in particular, that the Committee of the Seamen's Hospital Society, with due regard to a probable visitation of cholera as the warm season advances, have already preferred an application to the Admiralty for the use of a hulk to be specially set apart for all cases of cholera that may come to the *Dreadnought*. This Hospital has, in former epidemics, received a very large number of cases of cholera. The history of these cases show in a tolerably correct way how the disease is imported into this country, and hence numerical returns from this Society have great value, in that from them can be gained the average sanitary condition of the port of London. The Committee of the Seamen's Hospital Society has shown a careful amount of foresight in making this prospective arrangement—a foresight which the Privy Council might do well to follow. The Orders in Council, issued on the 7th ult., and published in the *Times* and other journals of Tuesday last, delegate all inspecting powers as to vessels to local Boards of Health, or, if they exist not, to local corporations. This as regards the port of London is really a very loose arrangement. If there be any value in Medical inspection, it should at once be adopted systematically at Gravesend. No sort of inspection will be of the slightest avail when cholera is fairly introduced into this country, and this port with its vast import trade is at present entirely unprotected by any kind of preventive measures. The cattle plague and its ravages have surely taught us the value of being wise in time.

RUDMAN *v.* ARMSTRONG.

A Committee has been formed for the purpose of raising a fund towards defraying the legal expenses incurred by Dr. Armstrong, of Gravesend, and his son, in the late vexatious and iniquitous trial for malpraxis (Rudman *v.* Armstrong and another), in which the defendants, notwithstanding their full and righteous acquittal, have had to bear all the expenses of the trial. At the first meeting held on Saturday last, Dr. Richardson having been called to the chair, and having announced that it was expected that about £150 would meet the legal and other expenses of the trial, it was moved by Mr. Hunt, seconded by Dr. Spurrell, of Belvedere, and unanimously resolved—"1. That this meeting (with power to add to its numbers) do constitute itself into a committee to raise a fund for the above purpose." It was moved by Dr. Markham, seconded by Dr. Druitt, and carried unanimously—"2. That

*

Mr. Hunt be requested to act as Treasurer and Secretary." It was moved by Dr. Spurrell, seconded by Dr. Henry, and unanimously carried—"3. That the Profession be asked to express its sympathy with Dr. Armstrong and his son, and also its admiration of the firmness with which all offers of compromise were refused by them." It was also resolved—"4. That subscriptions of five shillings or upwards be requested to be sent to the Treasurer, No. 6, Hinde-street, Manchester-square, or to any member of the Committee, for the purpose of meeting the expenses of the trial. 5. That this Committee do meet again on Saturday, the 19th, at No. 12, Hinde-street, after which a list of subscriptions received up to that time shall be prepared for publication." Up to the present time the following gentlemen have been enrolled as members of the Committee:—W. Adams, Esq., 5, Henrietta-street, Cavendish-square; Dr. Druitt, 37, Hertford-street, Mayfair; W. Harvey, Esq., 2, Soho-square; Dr. Henry, 15, George-street, W.; T. Hunt, Esq. (Hon. Treasurer and Secretary), 6, Hinde-street, Manchester-square, W.; C. H. F. Lord, Esq., College-terrace, Hampstead; Dr. Markham, 3, Harley-street, W.; Dr. Richardson (Hon. Chairman), 12, Hinde-street, W.; Dr. Semple, 8, Torrington-square; Dr. Sedgewick, 11, Hinde-street, W.; Dr. Spurrell, Belvedere, Kent; Dr. Stewart, 75, Grosvenor-street, W.; T. Heckstall Smith, Esq., St. Mary Cray; Erasmus Wilson, Esq., F.R.S., Henrietta-street, Cavendish-square. The Committee will continue to hold its meetings until a sufficient sum is raised. We need hardly say that we wish it every success. That which will give the demonstration most force will be the collection of a large number of moderate subscriptions. The most agreeable testimony that can be awarded to Dr. Armstrong will be, in fact, that which proves to him the wide and deep-spread feeling of sympathy that is felt for him in the Profession. Subscriptions should be sent to T. Hunt, Esq., of 6, Hinde-street, London, W., the Honorary Treasurer. In reporting this trial last week we omitted to refer to Mr. Vinall, one of the witnesses called by the woman Rudman. Mr. Vinall gave some very important evidence, which gave great strength to the defence. We learn that Mr. Vinall, after attending Rudman a few times, was told he would be paid when a trial against a Doctor had come off, and at once he declined to attend longer on such terms. We also learn that he was subpœnaed without a word of consultation, and could form no idea of what would be asked him until he got into the witness-box. Then every method was adopted to extract from him damaging statements, but with no avail. He denied point blank the mercurial hypothesis; he persisted that the only symptoms he saw were those arising from inaction and bad air; and in the fairest way he could, under the circumstances, he showed how utterly disgusted he was with the whole proceeding. A more difficult position than Mr. Vinall's cannot easily be imagined, and we congratulate the Profession that in this case there was so honest, so honourable, and so independent a representative on the side of a prosecution for malpraxis. We have known a very different example.

FROM ABROAD.—DILUTION OF VACCINE LYMPH WITH GLYCERINE.

Geh. Medicinalrath Müller, director of the Berlin Vaccine Institution, has just published a communication concerning vaccine lymph which he regards as of considerable importance. After adverting to the well-known difficulty of obtaining vaccine lymph in sufficient quantity, especially when large numbers have to be speedily vaccinated or re-vaccinated during the prevalence of epidemic small-pox, he observes that it is, therefore, a matter of great importance to be in the possession of a means by which every Practitioner may preserve for himself an ample store of this precious substance. Such a means is to be found in mixing the vaccine virus with diluted glycerine. Without in anywise interfering with its efficacy, this increases its quantity and its power of keeping. Finding that the vaccine scab is best dissolved in glycerine, and impelled to seek for some adjuvatory means by the numerous applications he received from every province of Prussia, as well as from foreign parts, the author was induced to try the effect of some lymph which he had mixed with diluted glycerine, and the results were in the highest degree encouraging. While augmenting the vaccinating material ten or twenty fold, the pustules which resulted neither in their course, appearance, the amount of lymph they contained, or the reaction they gave rise to differed in any degree from the pustules produced by the purest lymph. The proportion cannot be exactly determined, because the quantity taken up by the pencil cannot be weighed or measured; but as an example it may be stated that lymph from three pustules having been mixed with diluted glycerine, served not only to vaccinate several children, but to charge about forty capillary tubes. Lymph which has been preserved in tubes can be similarly treated with the glycerine, but it will be best only to employ that which has been kept in them for a few days or weeks. How far the dilution of the lymph can be carried without damaging its efficacy is being tried. At present the results have been found uncertain when diluted more than twenty times. Diluted only ten times, they are always certain.

If these statements are admitted, as they must be, it results that the Practitioner may always be in possession of a sufficient supply of reliable lymph, which may easily be stored up, seeing that the lymph enters the tubes with greater facility than in its undiluted state, and keeps much better. With the lymph derived from a single child a whole battalion of recruits may be re-vaccinated. The vaccinator may, too, not so pressed for lymph as heretofore, exercise more caution in selecting the subjects for supplying it. On account of its greater preservability, this mixed lymph will also far better bear transmission to distant countries and tropical climates than does the ordinary free lymph. The great ease with which the tubes are filled without contact with the air, and then sealed, will much aid the employment of this diluted lymph. Dr. Müller's exact mode of procedure is as follows:—Having opened some of the pustules of a child vaccinated eight days before, he collects the lymph which issues out upon a small, new hair pencil. The pencil is then moistened upon a glass or porcelain plate by means of from ten to twenty drops of chemically pure glycerine, diluted with equal parts of water—the whole being most thoroughly mixed together by means of the pencil. With this mixture vaccination is immediately performed, or capillary tubes are filled with it and sealed for future use.

PARLIAMENTARY.—THE COALFIELDS—THE TROOPS AT HONG KONG—IRISH INFIRMARIES AND HOSPITALS—CONTAGIOUS DISEASES BILL—RINDERPEST IN IRELAND—THE CHOLERA AND QUARANTINE.

In the House of Commons on Thursday, May 10,

Sir R. Peel asked the Secretary of State for the Home Department whether it would not be desirable to instruct the Director-General of the institution charged with conducting the geological survey of Great Britain and Ireland, by which mineral statistics are annually collected and published, to collect evidence bearing on the carboniferous system of the United Kingdom, the extent of the coalfields, the thickness and quality, produce, and consumption of all beds of coal, and to report thereon; and, if so, whether the Government would issue the necessary instructions accordingly.

Sir George Grey said that Her Majesty's Government had anticipated the suggestion of the right hon. baronet, and had, even previously to the notice of the hon. member for Glamorganshire, of his intention to move for a commission on the subject, addressed a letter to Sir Roderick Murchison, who was at the head of the Geological Society, with the view of ascertaining from him whether by means of that institution certain inquiries into the extent of our coalfields could be conducted, and what would be the probable expense of such a proceeding. The answer to that letter led the Government

to hope that full information on this subject would shortly be obtained.

On Friday,

Sir J. Fergusson asked the Secretary of State for War whether the 20th Regiment (2nd battalion) had been ordered, or whether it was the intention of the Government to order it, from Japan to Hong Kong, to occupy the quarters vacated by Her Majesty's 11th Regiment, in which great mortality had lately occurred, or whether it was the intention of the Government to send native troops to that station.

The Marquis of Hartington said the 2nd Battalion of the 20th Regiment had received orders to proceed from Japan to Hong Kong, to relieve the regiment at present stationed there; but it would not be necessary that they should occupy the quarters vacated by the 11th Regiment, which had proceeded to the Cape. In March last orders were sent by telegraph to Ceylon to send four companies of native troops to Hong Kong as a temporary measure.

In answer to a question by Col. North,

The Marquis of Hartington said orders were sent that the duties at Hong Kong should be diminished by the employment of native police or watchmen, and that under no circumstances were the troops to be kept too long on duty.

The following votes were agreed to in Committee of supply: £2183 for public Infirmaries in Ireland, £15,845 for Hospitals in Dublin and the Board of Superintendence.

On Monday, in the House of Lords, the Contagious Diseases Bill passed through Committee.

On Tuesday,

Lord Granville, in reply to a question from Lord Clanricarde, stated that, in consequence of the appearance in the north of Ireland of the cattle plague, the Privy Council had authorised the Irish Government to put in force the provisions of the Act of Parliament recently passed to meet such a contingency as has now happened.

Lord Carnarvon, upon a formal motion for correspondence, called attention to the recent outbreak of cholera at Liverpool among German emigrants, and, expressing an opinion that the orders issued by the Privy Council were insufficient, recommended that measures should be taken by providing hulks for the accommodation of the emigrants arriving from Germany to isolate them from the inhabitants on shore.

Lord Granville pointed out the difficulty of establishing at once a complete system of quarantine, even supposing that such a system would be an effectual preventive to the spread of cholera. He stated the various steps that had been taken, and especially that the Government had instructed the British Consuls to make known that shipowners here would not receive German emigrants on board their ships.

The Duke of Somerset added that the number of hulks at the disposal of the Admiralty suitable for Hospital purposes was very limited, but one had been placed at Cork, another at Plymouth, and a third in the Thames.

In the House of Commons,

In answer to questions from Mr. Gregory, Lord Naas, and other Irish members, Mr. C. Fortescue said there was too much reason to believe that the cattle plague had made its appearance near Belfast, and explained the stringent measures which had been taken to stamp it out.

Mr. Sandford asked what precautionary measures had been taken by the Government against the spread of cholera.

Mr. H. A. Bruce replied that the powers possessed by the Privy Council were given by the Quarantine Act of George IV., and under it they had directed local authorities at the outports to visit all ships arriving from suspected quarters, to prohibit the landing of infected persons, and, if necessary, to take measures to isolate them, and they had also offered to place any towns which desired it under the provisions of the Diseases Prevention Act. This country, he pointed out, had never acted on the system of quarantine; we had always depended on the local authorities, and our best security must be in improved sanitary regulations, such as better supplies of water and increased ventilation and cleanliness.

NEW FELLOWS.—At a meeting of the Council of the Royal College of Surgeons of England on the 14th inst., the following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such, viz.:—Messrs. Charles Hope Buncombe, of York-place, Bow-road, and Henry Gibbs Dalton, of George Town, Demerara, their diplomas of membership having date respectively May 29, 1840, and February 19, 1841.

THE CHOLERA AT LIVERPOOL.

(From a Correspondent.)

EPIDEMICS being rather of periodical than of unusual occurrence, it might be assumed that the regulations required to prevent the spreading or to counteract the malignancy of contagious disease would be fixed, definite, practical, and prepared. Yet it does, nevertheless, seem strange that although warnings of the probable advent of cholera were duly circulated by the Government among the municipal and other local authorities of the country in the summer of last year, and again repeated within the last few weeks, and although public and special prayers have been offered up for months in all the churches of the kingdom against this "plague, with which many lands have been visited," yet when on May 4 the emigrant steamship *Helvetia* entered the Mersey as a cholera-infected vessel, she not only spread panic, but found every one unprepared to meet the difficulties of the occasion. Now why, at least in sanitary matters, are Englishmen slow to act? Why, like their Saxon prototype, do they always merit the sobriquet of "unready?" It is certainly not from any lack of either knowledge, foresight, or energy. Is it due to the complicated machinery of our governmental action, or to the jealousy and penuriousness of ratepayers, or to the privileges of our free personal action, or to the gigantic momentum of our trade and commerce which sweeps away, as impossible and impracticable, all the trammels of quarantine restrictions?

In Liverpool the local authority was not at fault. When last year the circular from the Privy Council recommended the adoption of precautionary measures, the Mayor of Liverpool, Mr. Lawrence, was able within the lapse of a few days to announce to the Government that the Select Vestry of the parish had provided a cholera Hospital. He at the same time called attention to the strange anomaly that while vessels from Africa or the West Indies whereon there had occurred fatal cases of the bilious, remittent, or yellow fever, or whereon there were still patients suffering from the effects of such sickness, the Customs' officers were directed to place the vessel under a temporary quarantine, sufficient for the inspection of the crew and passengers, yet in the event of a vessel arriving in the port with a cholera case on board, the law did not permit any interference. The Mayor asked for an Order in Council to remedy this defect, and he restricted his demand (almost *totidem verbis*) to the power given by the Order in Council of the 7th inst.—viz., permission to prevent the sick from entering the town unless conveyed, by a specially appointed vehicle, to the Hospital, and permission to authorise a Medical man to inspect the crew and passengers before being allowed to land. The only answer received to this application was an official announcement that the Government were not prepared to authorise any measure of quarantine.

Hence the panic when the *Helvetia* arrived at Liverpool on May 4. No one knew how, to what extent, or by what authority he was to act. Hence the telegraphs from the Mayor and the Collector of Customs to the Home Secretary, asking for permission to *begin to act* when, if the Government had been wise and prescient, they would have been able and prepared to act.

The Mayor, with commendable fortitude, assumed the responsibility of preventing any of the persons on board the *Helvetia* from landing until he had received the instructions of Sir G. Grey. The best arrangement, in the emergency of the moment, was also adopted, and by the 7th a vessel—the *War Cloud*—capable of accommodating some 700 persons, had given a temporary reception to 398 of the passengers who, to that time, showed no appearance of the disease. These were the British passengers, and consisted of 243 men, 89 women, and 66 children. Within a few hours later the owners of the *Helvetia* were able to engage the use of the sheds forming the emigration depôt at Birkenhead, and to them 260 of the

foreign emigrants were drafted. Another vessel—the *Jessie Munn*—was fitted up as a Hospital, and properly and liberally supplied with Medical men, nurses, medicine, and Medical comforts by the Select Vestry. As it was found impossible, on account of the suddenness and completeness of the collapse, to remove cholera cases from ship to ship at any great distance, the *Jessie Munn* was lashed to the side of the *Helvetia*, and contrivances made to remove the patients in a recumbent position. During all this time the Liverpool authorities had been most strenuous in their exertions to obtain and fit up some detached warehouse in the outskirts of the town, so as to be able to receive on shore the poor people still left on the *Helvetia*, as well as those temporarily removed to the *War Cloud*. It was felt to be not only cruel but also impolitic and physiologically wrong, to keep any person on an infected vessel; since thereby the malignancy of the disease would be intensified, and the ultimate danger to the community increased; and it was also felt that a single case occurring on board the *War Cloud* would really convert that temporary Asylum into all the frightful conditions of a plague-stricken vessel. No one who has not tried it can realise the difficulty of so far overcoming prejudice as to induce warehouse owners to let their property for the reception of cholera patients; indeed, the owner of the Birkenhead Emigration Depôt had been forced by the outcry in his township to refuse to receive any more of the passengers of the *Helvetia*. It was half-past nine on the morning of the 10th (Thursday) when arrangements were made to rent two warehouses (admirably suited for the purpose of a depôt) in Burchhall-street, near Bank Hall; orders to erect a cooking apparatus and to construct the necessary sleeping accommodation for 700 persons were given to Messrs. Holme and Nicol the same night. The borough engineer undertook all the arrangements required for water supply and for water-closets. On the morning of the 12th everything was prepared for the reception of the emigrants, who arrived about 12 o'clock. The management and feeding of the people, and the purchase of new beds and bedclothes, have been undertaken by the Vestry, and all the arrangements have, by the administrative abilities of Mr. Hagger, proved eminently successful. The people are happy, their health wonderfully improved, and only one death—that of an Irishwoman—has occurred among these emigrants since their arrival at the depôt. The present position of matters is—the *Helvetia* empty of her passengers, and undergoing the necessary purification under the inspection of the Medical emigration officers; the patients on board the *Jessie Munn* improving; the emigrants at the Birkenhead depôt under kind and considerate supervision; those at the depôt at Bank Hall well and comfortable under the circumstances of an extemporised sanatorium; while, so far as is known, no cases have occurred in the borough, except among German emigrants. I venture to believe that if last year the Government had concurred in the proposal of Mr. Lawrence, not only would the Liverpool authorities have been prepared with a cholera Hospital, but they would have recognised, in the contemplation of the practical working out of the Order of Council, the necessity of having some place prepared for the reception of those passengers and crew whom their Medical officer should consider not sick enough for Hospital, but too doubtful to be immediately transferred into the registered lodging-houses of the town. Steps are now about to be taken by the Select Vestry to provide some building where emigrants unable to find accommodation may be received as nightly lodgers at a reasonable charge, and it is expected that by this means the temptation, or, indeed, the almost necessity, of overcrowding may be removed.

I have obtained from Dr. Trench, the Medical Officer of Health, the following list of the deaths from cholera in the workhouse and on board the vessels in the river. He is not able, with any certainty, to distinguish the subdivisions of nationality among those who are registered as Germans; but he states that all the earliest cases were Dutch, and, in confirmation, has supplied me with the following names:—Johanna Schonwenberg, Evert De Boer, Peter Relfiet, Neesen Gow, Cosorlive Bosake. The passengers who, as relatives or travelling under the same broker's "contract note," were necessarily or optionally near the sick were almost always the persons attacked. Thus under the name Bosake were registered three deaths—husband, wife, and child; under that of Peterson, two brothers; under that of Relfiet, a mother and daughter. The manifest evidence that the poor Dutch were the importers of and first sufferers from the disease engendered against them an angry feeling—not only among the Irish, but also among the Prussian and other German emigrants. With Paddy the threat is that "he will have it out,"—meaning, no doubt, "in Donnybrook style;" with the Prussian and Swiss it takes the form of indignant remonstrance to their Consuls against being placed in proximity to the plague-stricken Dutch. As far as I can gather from Professional friends, nothing beyond the old treatment by opiates and external heat have been hitherto employed. The application of ice to the spine and Dr. Johnson's purgative theory have not yet found any practical adoption. All the lodging-houses of emigrants are visited daily and nightly, and in every room of the German lodging-houses purification by chlorine gas, evolved from chloride of lime and muriatic acid, is made compulsory.

QUARANTINE.

(From a Correspondent.)

As day after day passes, bringing from Liverpool fresh items of news about cholera mortality, the wretched inefficiency and practical uselessness of the feeble steps taken by the Government is but too apparent. It is now upwards of fourteen days since a formal request was preferred to the Admiralty for the loan of several hulks, to be used at Liverpool and elsewhere as receiving ships. It will be found, in another column, that the Committee of the Seamen's Hospital Society have made a similar application; but no action whatever has as yet been taken in the matter.(a) It is notorious that many fair specimens

(a) Since this article was received Government have announced that three hulks are to be lent as Hospital ships. One is to be stationed at Plymouth, one at Cork, and one in the Thames. Southampton has applied for one, but we believe the request is not to be granted.

of our wooden walls now encumber the Medway at Sheerness, and it is perfectly well known that these vessels will be used for no other purpose than to act as targets in naval gun-practice. It cannot now be denied, even by the opponents of the quarantine system, that mainly in consequence of defective arrangements the town of Liverpool bids fair to become a great focus of disease. The Registrar-General's report, a fortnight ago, showed that its recent mortality has lately been double that of London, and that this fact was due to the prevalence of typhus. The town is at present a sort of depôt for German emigrants; vast numbers of which class, having arrived lately, and being unable to proceed to the States, perforce remain, and crowd the already swarming lodging-houses of this port. But, on reviewing the whole question, it behoves us to look a little nearer home, and in so doing we may well glance with anxiety at the totally unprotected state of our own port of London. Very little labour and expense would have provided us with an inspecting staff at or near Gravesend some weeks ago, and thus avoided the great jeopardy in which the port is placed at every tide. But no restrictive regulations are carried out at Gravesend or elsewhere up or down the river, and we may fairly presume that the authorities will allow the disease to creep into our metropolis by its great water way, and then make some abortive effort to check its progress. Experiences of the recent epidemic in Europe gave so many tangible proofs of its infectious and contagious nature that we cannot now close our eyes to the benefits of isolation. A contemporary, in remarks made last week, urges that the happy examples of Greece and Sicily as to rigid quarantine are of little value, "because there is no trustworthy evidence to show that the exemption arose from the stringent quarantine maintained against infected ports." But it is a fact, and we speak from data carefully gleaned in the East last year, that the Kingdom of Greece was closed, not only against infected ports, but against many that never had cholera within their gates at all. This country was for the nonce practically isolated from the rest of Europe. It is true that commerce was, for a time, brought thereby to a dead-lock; but it is plainly our duty to deal, not with the commercial, but with the sanitary aspect of the question. There is not the shadow of an object in contending that "quarantine as practised in the Mediterranean and the Black Sea has not offered any impediment to the spread of the epidemic." We can testify from personal observation that in the ports of Turkey, Italy, and France the system of quarantine is simply a farce and utterly a delusion—that the lazarettes are in some instances placed immediately beside the walls of the town (as at Marseilles), and in others (as at Kustendjie) a community of feeling (and of course a community of disease) is established by occasional pipes and conversation interchanged between the inhabitants of the town and those of the lazarette over the (breast-high) palings of the latter. The system of isolation has never yet had (with the exception of Sicily and Greece) a fair trial in Europe. The difficulties to be encountered by its adoption in and around our shores may be insuperable; but it is clearly our duty, if we believe in the efficacy of any preventive system, to place that system before the public, and to emphasise it with all our might. Let a regular inspection be made at Gravesend of all vessels coming up the river. If any such be found to have cases of cholera on board, is it impossible to land the apparently healthy part of the passengers on the Isle of Sheppy for a limited quarantine, and then order off the vessel at once with her sick cargo to Heligoland or to the Channel Islands? Herm, one of the smallest of the latter, is now advertised for sale, and might readily be leased by Government for the purposes of a lazarette. A passage from the river to the Channel Islands is, in the summer months, by no means long, and ample accommodation could be provided for any reasonable number of patients. This scheme is after all only modified quarantine; but though it is in truth useless to attempt at any time to isolate ourselves wholly from other countries, it is imperative that some such plan as that above indicated be adopted, if we wish to save England from a repetition of the ravages that cholera has in former epidemics made among her inhabitants. We may do and dare much; but we dare not say to cholera, "Come in, and we will fight you." Until the science of Medicine can do this, we must build up a wall of some sort that the big stalking-horse will not care to jump, particularly if the prospect beyond be so unalluringly clean as to offer no inducements to his destructive tendencies.

GENERAL MEDICAL COUNCIL.

The General Medical Council commenced its annual sittings on Thursday last, at the Royal College of Physicians, Pall-Mall East. Dr. Burrows, the President, occupied the chair, and there were present the following members of the Council:—Dr. Alderson, Mr. Hawkins, Mr. Cooper, Dr. Acland, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Alexander Wood, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Thomson, Dr. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Sir D. J. Corrigan, Bart., Dr. Sharpey, Dr. Parkes, Dr. Quain, Mr. Rumsey, and Dr. Stokes.

The Registrar read a letter from Dr. Christison, in which that gentleman expressed his regret that imperative duties in Edinburgh compelled him to remain there till the end of the present week, but that it was his intention to be at the general meeting on Monday next.

The minutes of the adjourned general meeting held on April 17, 1865, were then read and confirmed.

The Registrar reported that at a meeting of the Branch Council for England of the General Council of Medical Education and Registration of the United Kingdom, held on the 8th of August last, the following official notice was read:—

"We, the Royal College of Surgeons of England, in pursuance of the power given to us by the Medical Act, do hereby appoint Mr. Cæsar Henry Hawkins, of 26, Grosvenor-street, W., to be a member of the General Council of Medical Education and Registration of the United Kingdom, for the term of five years, from the 4th of July, 1865."

The President rose and said:—

In addressing you once more from this honourable position, in which you have placed me, it is a source of gratification to me to find that public business has not compelled me to summon you to assemble at a time not generally acceptable, as unfortunately was necessary last year. Indeed, from all I can learn, our time of meeting this year meets the wishes of the members generally. (Hear, hear.)

Before we proceed to the election of our several committees and to other matters preliminary to our regular business, it appears to me that some advantages may result from a few introductory remarks from the chair in the form of a brief survey of the more important labours of the Council during the last session, of the progress of events in the interval since we last assembled in this place, of the special duties assigned to the Executive Committee and how far they have been fulfilled, as well as the labours left uncompleted when we separated, and which may be profitably resumed by the Council in the present session.

Although such a *resumé* may appear somewhat needless to those of the Council who have taken the most active part in our proceedings, and who during our long recess have directed their thoughts to our past and prospective labours, still I flatter myself that to many others it may be useful to have their memories recalled to various topics of greater or less interest to the Medical Profession, and which formed the subjects of our deliberation and discussion during the last session of Council.

The intervals between our successive sessions are so prolonged that it is almost impossible for men like ourselves, who have constant and engrossing occupation, to have before our minds, in resuming our deliberations, a clear and vivid recollection of the subjects under consideration in the previous session, and which were left undecided for various reasons, but which may now be more ripe for solution.

It will be in the recollection of the Council that a Select

Committee was appointed last year to report upon the subjects of general education to be inquired into in the preliminary examination of Medical students. That Committee made its report at a late period of the session, and the Council were of opinion that they could not then duly consider the important questions brought forward in the report of that Committee. This is a question which, I presume, the Council will think requires our immediate attention and solution, in order that the recommendations and regulations of the Council upon the subject of education of Medical students may be more complete than hitherto.

In our session of 1864 the Council directed the circulation of a document among the several licensing bodies, in which they were invited to favour the Council with observations and suggestions upon various points connected with Professional education. Many of the licensing bodies sent in last session, for the use of the Council, reports drawn up with great care, and replete with valuable suggestions. This mass of useful information has hitherto not been brought under the consideration of the Council, and certainly has not been utilised. Perhaps a committee might prepare a digest of suggestions upon points not yet settled, and which would assist the Council in deciding upon the practicability of diminishing the number of examinations where a double qualification is desired by the student, and likewise in defining the different starting points which may be recognised as the commencement of Professional study.

The next point to which I will recall your recollection is one which I think must afford unmixed satisfaction to all who are sincerely determined to carry out the provisions of the Act of Parliament which is entrusted to our administration, and who are desirous not to allow funds to remain dormant which may and ought to be exercised for the improvement of Medical education. (Hear, hear.) I allude, of course, to the visitation of the examiners of the different licensed bodies by the several branch councils. You will naturally look forward with anxiety to the reports from the branch councils, giving the results of their first visitations. What avail all our regulations and recommendations respecting Medical education if the curriculum be not completed by well-conducted and impartial examiners?

In the Session of 1864 the Council appointed a Committee to take steps for the preparation of a new edition of the British Pharmacopœia, and during the last Session the Pharmacopœia Committee made a report to the Council which was adopted. The Council afterwards thought fit to pass a resolution which may have led members of Council to suppose that a proof copy of the new edition would be in the hands of members one month before this meeting of Council, but the Pharmacopœia Committee did not pledge themselves to this effect, and the report from the Pharmacopœia Committee will no doubt give a full account of the present state of that work, and of the causes which may have interfered with the realisation of the expectations of members of Council and the Profession.

I will next allude to the duties assigned to the Executive Committee, and endeavour to explain to the Council what has been done by that body, beyond the ordinary routine work to be performed year by year.

Your Executive Committee, as far as their limited powers would permit, have endeavoured, in the interval between the past and present Session, to carry out the special business entrusted to their charge by the General Council as well as attend to communications from public bodies and private members of the Profession. A most responsible and difficult duty was last Session assigned to the Executive Committee—viz., to communicate with Government in regard to the Bill for amending the Medical Acts; it being, however, understood that no concession should be made by the Executive Committee inconsistent with the amended Bill, as proposed by the General Council.

It is but right and respectful to you that you should know what has been done in this matter.

In the latter part of the last brief Session of Parliament a communication was received from Sir George Grey, intimating that he could not undertake to introduce the Medical Acts Amendment Bill during that Session. In the autumn of last year, as you will remember, Her Gracious Majesty and her Government and people had the misfortune to be deprived of the services of the Prime Minister by the death of the octogenarian chief, Lord Palmerston. As soon as the new Government had been definitely formed, and the Ministers had returned to their official duties after the customary autumnal holiday, I brought this question under the consideration of the Executive Committee (December, 1865), and they requested your President and Registrar to seek an interview with the Home Secretary, and to urge upon his attention the wishes of the Council and Profession as to the amendment of certain clauses in the Medical Acts, 1858. Upon application, Sir George Grey favoured us with an interview, and promised to give his attention to the subject as soon as he possibly could. After the lapse of a month, and shortly before the assembling of the new Parliament, I again communicated with the Home Secretary, and brought the whole subject under his notice by letter. In reply, he courteously permitted me, in confidence, to peruse the observations of the consulting counsel to the Home Office on the proposed amendment bill, and promised to put me in personal conference with that gentleman, as soon as his most pressing occupation would permit. It must be borne in mind that at this period the Government, the Home Secretary, and the officials were oppressed by several momentous questions relating to public affairs; the cattle plague in England and Scotland, the Fenian conspiracy in Ireland, the Jamaica outbreak and inquiry, and the preparing of the promised measure on the representation of the people in Parliament, fully engrossed the time and energies of all connected with the Government, and greatly interfered with the successful progress of Medical legislation. Nevertheless, in the month of March last, I thought it my duty again to remind Sir George Grey of his promise, and of the necessity of some definite reply from the Home Office. In consequence of this renewed application, I was placed in personal conference with the counsel to the Home Office shortly before the Easter recess, and had an opportunity of perusing the draft of the Medical Acts Amendment Bill. Into this it was proposed by the Government to introduce a clause by which Medical graduates having diplomas from certain foreign and colonial universities might, under certain restrictions, be admitted into our Register rather than be compelled to practise in the ranks of irregular and unqualified Practitioners. This drafted bill, submitted to me in confidence, required careful consideration, and I found it necessary to make various suggestions in order that it might be brought more into harmony with what I believed to be the views of the General Council. I have had the advantage of further conference with the counsel to the Home Office, and the result is that the draft of the bill is completed, and I hope will be shortly submitted to you for approval.

The long interval of twelve months between our successive sessions and the limited powers conceded to the Executive Committee do, I believe, most seriously interfere with the successful transaction of the public business of the Council, and with their giving reasonable satisfaction to public bodies and private individuals who make communications to the Council. One meeting of the Council in the year, and no authoritative Executive Committee in the interval, are defects in our organisation which it would be well to remedy if practicable. It appears to me this is a subject worthy of the careful consideration of the General Council, whether they could not, by more frequent meetings or by some alteration in the constitution of the Executive Committee, render the Council more efficient as a public body empowered by Act of Parliament, capable of enforcing their own regulations and of giving satisfaction to those members of the Profession who seek advice and protection of the General Council.

The more frequent meetings of the whole of this numerous Council would entail much inconvenience upon the members, and would incur such heavy additional expenses, that such a change seems hardly feasible or desirable.

But would it be impossible to adopt the other alternative, and to alter the constitution of the present Executive Committee, to enlarge it, and make it more representative of the feelings and opinions of the whole Council by introducing a limited number of members from each of the branch Councils of Scotland and Ireland?

If the Executive Committee could ensure the attendance of any two members of each of the branch councils of Scotland and Ireland at quarterly meetings between successive sessions of the General Council, then I presume powers more extensive than can now be properly conceded to the present Executive Committee might be entrusted to this enlarged Committee, and much routine business which now occupies a large portion of the time of the General Council at each annual session might be transacted by this enlarged Executive Committee more perfectly representing the whole Council.

Our labours here would be lightened, and I think our pro-

ceedings would give more satisfaction out of doors and remove just grounds of complaint against the present unavoidable delay in answering communications made to the Council. I commend this idea to the consideration of those who are anxious to improve the efficient working of the General Medical Council.

It is out of my province, as President of the Council, to initiate measures in the course of the session, but I have not thought it beyond my proper sphere of action, at this opening of our proceedings, to recall your attention to the past, and to invite your favourable reconsideration of measures of importance incompletely decided upon in former sessions, and which appear to me not only ripe for, but also demanding a settlement. I have gone also further, and thrown out for your adoption suggestions which I believe might render the influence of the Council for the good of the Profession more uniform and continuous, and not restricted, as it now is, to the short spasmodic action of annual session.

With these prefatory remarks I conclude, congratulating the Council that so few changes have taken place in the *personnel* of the Council since we separated, and that able and distinguished members, whose period of service had expired, have been re-appointed, and are here to assist the Council with their large and varied knowledge, with their sound and independent judgment and great experience in the solution of difficult questions so frequently under discussion in the Council. (Cheers.)

The Committee was then appointed, and divided into three sections for the arrangement of the respective business matters of the Council, and a long discussion ensued as to whether two communications which the President had received from the Secretary of State relating to the new Medical Act should be read at once to the Council, or should be referred to the Committee, and also as to whether, if the letters were read, they should be published. It was first suggested that the reporters should withdraw during the reading of the letters, and then that the Council should leave it to the discretion of the reporters whether they would publish the letters or not. No resolution on the subject was passed, and the letters were ultimately read.

Dr. Acland rose to present a memorial from the Sub-section of Physiology of the British Association, adopted last year at Birmingham, and he said he only had the duty of presenting it because he was the President of the Sub-section, and therefore the duty naturally devolved upon him. The memorial presented a suggestion to the Council of a most important character, and one which had regard to one of the highest functions which they were called upon to perform. The memorial was as follows :—

"*British Association in Birmingham*, 1865.

"Having regard to the observations of the President, Professor Acland, in his inaugural address, the Committee of the Sub-section of Physiology desire respectfully to intimate their opinion of the great advantage which would accrue to physiological (and thereby to Medical) science if the General Council of Education and Registration should think fit, by pecuniary grants and the appointment of suitable persons, to undertake investigation into the physiological action of medicines. A few agents, when administered in poisonous doses, have alone been made the subjects of such research, and whilst the Medical effects of even such well-known agents as quinine have been admitted for ages, their modes of action are still unknown. Even to this moment our knowledge of the action of remedies rests only upon ordinary observations and general inferences.

"The Committee is well aware of the extreme difficulty of prosecuting exact physiological inquiries in states of disease, and above all, of the necessity for devising new modes of investigation; but bearing in mind recent researches of an analogous nature in health, they do not doubt there are Physiologists and Physicians of proved ability in such researches who would be able to devise the methods and bring the results to a satisfactory conclusion.

"The Committee also venture to suggest that no experiments should be regarded as satisfactory which (in addition to others) are not made in ordinary medicinal doses in the diseases for the relief of which the remedies are administered (as well as in other poisonous doses), and which are not performed with all the care and exactitude known in modern physiological research.

"That this resolution be signed by the President, Vice-President, and Secretaries, on the part of the Committee, and that the President be requested to present it to the Medical Council of General Education and Registration.

"Sub-Section D, Physiology.

"Signed

"Henry W. Acland,	J. Hughes Bennett,
"John Davy,	J. Vander Hoeven.
"George Rolleston,	Alexander Fleming,
"Edward Smith,	Wm. Turner."

In presenting this memorial, he would venture to make a few observations. At the meetings of the Council last year a suggestion was made by him for the appointment of a Committee for inquiring into the various ways in which the Council might justly expend its time. One of the ways which he suggested was in the consideration of scientific investigations and reports, such as were now suggested, on the effect of the remedies which, by their authority, were included in the Pharmacopœia, or which, by their authority and their power, they did not include. That Committee was not appointed, and therefore there was now no information before the Council as to whether it was in their power to make such a grant or obtain such reports. He was exceedingly anxious that a Committee should have been appointed last year for the consideration of this subject. They were now about to introduce an improved Medical Act. It was said last year that they had not the power to so expend their funds. That was a point which had to be argued, and if it turned out that they had no such powers he, for one, should be prepared to move that that power be inserted in the new Act. If it turned out that they had power to spend their funds in such a manner, it would then be a matter of opinion whether it would be desirable to exercise that power or not. Another suggestion was made to the effect that they had not sufficient funds. This was exactly one of the points raised, and he could not help thinking, although this was not the time on which he would venture to discuss that question, that they should have funds, a portion of which could be justly expended in this manner. They had expended last year £1700, as nearly as he could calculate, upon their annual meetings. The Pharmacopœia at present cost £5000. That expense was therefore over. The total invested money which they had received from the Medical Profession, which had been placed by the Government at their disposal, was more than £5000, besides their annual income. He came, therefore, to the merits of the case as to whether it was at all proper that a memorial of the kind which he presented should be entertained. The financial question he would not enter into, because he thought it would be a much better subject for the consideration of the Committee. This very argument was brought before the last meeting, when it was constantly before them. He only mentioned the fact that a large sum of money was spent by the Council, and that it had been matter of great anxiety to them that so large an amount of money should be spent on their annual meetings. He submitted on the merits of the case the proposal was a very proper proposal, to which some of their funds might be applied, and it would be impertinence on his part, speaking before men of reputation and distinction to which he could not aspire, to dilate on the subject. The Council was appointed for three distinct purposes—the registration of Practitioners, the superintendence of education, and the construction of a great Pharmacopœia. They had done with the registration—that had become a matter of routine. They were engaged in education, the expense of which in the future would probably be greater than it was in the past. The expense of registration might be considered as running its ordinary course. He regretted that Dr. Christison was not present, because when a discussion took place last year on the subject, Dr. Christison made some remarks which he should be sorry to reply to in that gentleman's absence. Dr. Christison stated that the Pharmacopœia was simply a collection of the rules and regulations for making certain preparations. The simple answer to that was that such really could not be the case, because the Council selected the articles which they introduced into the Materia Medica, or Pharmacopœia, or whatever they might call it; and in so doing they laid down the principle that those articles in the judgment of the body were the proper ones to be included. But besides that, they also excluded other articles having the same effect as those included. They included some articles and excluded others. Their authority for that arrangement seemed to him to be a simple answer to that objection. The opposition of Dr. Christison seemed to him to be untenable, and could not be sustained. The question, therefore, simply remained as to the principle

on which they made their selection. In submitting the memorial of the Sub-section on Physiology, he fully coincided with that section as to the principle that the time had come in the history of physiological science and therapeutical progress when it was a highly proper thing. He would not say it would be an improper thing to do otherwise; that a series of reports and investigations such as those suggested should be made. It was quite certain that there was nobody in the country that could make those reports and investigations more properly than that Council; and the Pharmacopœia Committee were really engaged at the present moment in carrying out the work, though he was not aware that that Committee had ever had the present proposition even suggested to it. It would not be at all becoming in him to enter into the numerous questions or illustrations which might be readily brought forward with regard to the end of the investigations, or the plan to be adopted; and, therefore, he would not waste the time of the Council by entering into those questions or illustrations; but in the event of objections being raised from its being thought inexpedient to take up the question of making such a grant as he proposed, or in the event of the matter being thought unworthy of consideration, he should of course feel it his duty to exercise his right of reply, or to take such other steps as might enable him to bring the matter forward for consideration again. Such was the view taken by the members of the Physiological Section at Birmingham, when the subject came before them, upon an address which was made by himself, in consequence of certain recent investigations which had been made. He would, therefore, conclude his brief statement in presenting the memorial by proposing the following resolution:

"That the memorial of the Physiological Section of the British Association be received and entered on the Minutes, and in conformity with the suggestion of the memorialists, that the sum of £250 be placed in the hands of a Committee to be hereafter named; and that it be the office of the Committee to expend the whole or part of that sum in obtaining investigations on the points calculated to promote the knowledge and efficacy of the remedial agents which are now assumed to be of service, or of such substances as the progress of science may point out as likely to be of avail in the prevention or the treatment of disease."

In handing in this resolution, he would only say that, should it be the pleasure of the Council to make so moderate a grant as that for which he asked, either to members of the Council or to persons outside, he could foresee a series of most important results to be obtained year after year; and he would only further add that probably no period in the history of physiological science was so exceedingly opportune for making such a proposition as that which he had brought forward as the present time.

Dr. Stokes seconded the proposition, and said he hoped the Council would fully consider the importance of the question. They had been very hardly thought of outside the Board, and were asked what they had done. He did not see why they should not make it as perfect a Pharmacopœia as the Council could produce, and he thought that this course of action disarmed those complaints, which to a certain degree were very just. The only thing was to fix it on a more scientific basis than it stood on at the present time. It was now simply empiricism. There was no scientific basis for almost any Medical proceeding, and it therefore became a very important question as to how this great objection could be removed. He conceived that the Council ought to appoint a Committee, and in his humble judgment it would be most expedient if the members of that Committee were persons external to the Council. It would not do for them to sit round that table year after year for the purpose of distributing money amongst themselves in any way, and if they called upon the scientific men outside the Council to assist them with their knowledge, of course they must pay for that assistance. He would only remind them of the large sum of money they had spent on the Pharmacopœia, and asked them to make it as perfect a Pharmacopœia as they could.

Dr. Andrew Wood said he had no difficulty in coming to a conclusion as to what was his duty in regard to this motion, and he hoped to be able to show the Council his duty was also their duty. The Medical Council had been appointed under an Act of Parliament, as Dr. Acland had truly stated, for three specific purposes—first, the registration of Medical Practitioners; secondly, the regulation of Medical education; and, thirdly, the preparation of the Pharmacopœia. These were specific and important duties of a Medical political character; but if they were going to infuse into the duties of that Council a new element, and were to carry on experiments in physiology, experiments in chemistry, and experiments in every department of Medicine, then he contended they were departing from the duties for which they were appointed; and if they expended the money which they were receiving from the Profession for performing these duties, he contended, further, they were not spending money as the Act of Parliament told them they were to spend it. He was sure that no lawyer on the face of the earth would for a moment say that they had any right to expend money in the way in which Dr. Acland proposed. Clause 13 of the Act provided that all monies payable to the respective Councils should be to the treasurers of such Councils respectively, and should be applied to defraying the expenses of carrying the Act into execution? He asked Dr. Acland to show him in what way a grant of 250*l.* for physiological experiments would carry the Act into execution. Could anything be more clear or more plain than that the money which they were entitled to raise from the Profession, they were only entitled to raise in so far as these funds were necessary in carrying the Act into execution? The 15th clause provided that every person who should be possessed of any of the qualifications named in the Act should pay a sum, amounting to from £2 to £5, and should thereupon be entitled to registration. What had the Council done? Had it found it necessary to draw from the Profession the highest amount of taxation which the Act warranted them to do? He said positively that the very moment they were able to carry the Act into proper execution they were bound to give the benefit of doing so to the Profession. He contended they were bound to reduce the tax on the Profession. That Act, he did not believe, nor any other Act, gave them the authority for taxing the Profession for carrying out an indefinite series of experiments. He would ask, Why did not the British Association carry out these experiments for themselves? Why did not they levy a tax upon their own members if they were anxious for these experiments to be carried out? But why should the General Medical Council, which was not in any degree a scientific body, and which had no right to engage in scientific investigation and appropriate their funds to the object which had been proposed? Dr. Acland had stated that a good deal had been said out of doors as to the expenses of the Council and of the annual meeting. He was not prepared to say that these expenses had not been large, but he was prepared to say that they had not been unnecessarily large, because they must take into consideration that during the last seven years the Council had been placed in positions where they had to do a vast deal of work which they would never have to do again, and he felt confident that, with a proper regulation of business, when the Council had got thoroughly under weigh, and had taken all the different subjects which they were entitled to take up into consideration and carried them out, they would be able to very largely diminish the expenses which they were now incurring; but he would state a fact, in order to show Dr. Acland how extremely wrong it would be to devote a farthing, even if they had the power to do it, which they had not, to the carrying out of scientific experiments. They had been hindered from doing the most important part of their duties in the matter of visiting examinations in a thorough and effectual way on account of the want of funds, or the want of power of applying the funds to that purpose. The Council was just now considering the most important part of their duty in superintending and regulating a proper and efficient Professional education, and if they could not do that, which was above all things essential, because they had no power to appropriate funds for that purpose, and to see that the men who went into the Profession were thoroughly posted in those subjects which were laid down as essential, he had no hesitation in saying that they were not entitled to take up the matter which was before them.

Sir D. J. Corrigan rose to a point of order, and said the question which Dr. Wood was discussing was not then before the meeting.

Dr. Andrew Wood said the question of visiting examinations was not before the meeting, but the expense of such examinations was. He thought he was entitled to show, in arguing the question, that the Council would yet have to expend a large sum of money in carrying out the objects for which they were constituted, and that they would therefore require to use their funds in a proper way, and that one of the most important ways in which they could spend their money was in this matter of visiting examinations. He held that

under the existing Medical Act the Council had not the power to grant any money for scientific experiments. (Hear, hear.) In the second place he held that, not having the power under the present Act to do this, the Council ought not to apply for power under any other Act, because it would be neither right nor fair to the Profession that they should be taxed in order that experiments should be carried out, which experiments ought to be carried out by the British Association and other similar bodies who were interested in the matter. In the last place, he held that it was their duty to reduce, as far as they possibly could, the expenses of carrying the Act into execution, with a view to reducing as soon as possible the tax now levied upon the Profession to the lowest possible point consistent with efficiency. He therefore gave Dr. Acland's proposition the direct negative.

Sir D. J. Corrigan proposed as an amendment, that the proposed investigation did not come within the province of the General Medical Council, and that they had not the power to expend the money required. He did not doubt that a vast amount of information might be obtained if the suggestion were carried out, but the point to be considered was that the whole affair was out of their province. He coincided with everything that Dr. Andrew Wood had stated, and agreed that under the Act they had no power whatever to spend a single penny for such a purpose. In addition to the clauses which Dr. Wood had read, there were others which were so strong that not only no lawyer, but no man of common sense could for a moment entertain a doubt upon the question, or could say that they had the power so to expend their money. The clauses expressly stated that the money was only to be spent in carrying the Act into execution, and nowhere did the Act give them authority to carry out such investigations as those now proposed. If the experiments should be carried out, he cordially agreed with Dr. Stokes that it should be by external persons, and not by Members of Council, for the proposition was to trace the effect of remedies when applied in poisonous doses, and he did not want that experiment carried out by any Member of the Council. (Laughter.) He thought it was quite unnecessary to argue the question that it was out of the province of the Act of Parliament.

Mr. Cooper reminded the Council that the proposed experiments were already being carried out by other bodies in their examinations in the Materia Medica and in Pharmaceutical Chemistry.

Mr. Rumsey said it had been assumed by the gentlemen who had opposed the motion that it was not one of the primary duties of the Council continuously to prepare the Pharmacopœia, but that having done it once their work was at an end. It appeared to him that in order to keep up a perfect Pharmacopœia in this country they must continuously direct their energies to that object, and he did not see how the functions of the Council could properly be performed unless some such measures were taken as were proposed in the motion now before them. He did not, perhaps, pledge himself to all the particulars of the motion, but he thought it would lead to important physiological and therapeutical inquiry. The 54th clause provided that in preparing the Pharmacopœia the Council might adopt such measures as they might think fit, and that the Pharmacopœia should be altered and republished as often as they deemed it necessary. Fresh medicines were continually being introduced, and the value of existing medicines being questioned, and he did not see how they could perform the functions which the Legislature had committed to them unless they had a continuous investigation going on. He quite agreed that the experiments ought to be carried on by persons out of their own body, and he was of opinion that no portion of their expenditure would be more heartily approved by the Profession than that which they would spend in the carrying out of this proposition. The Act certainly gave them the power to take the necessary measures to make the Pharmacopœia perfect, and therefore he held that it was quite within the power of the Council to adopt the motion before it.

Dr. Alexander Wood was not prepared to say whether the proposition made by Dr. Acland was not one the Council should accept. From the beginning of the Council they had been spending money for purposes that were analogous to it, and which perhaps were not so useful as the plan suggested by Dr. Acland. At the present moment they were paying large sums of money for making experiments in regard to the Pharmacopœia, so that they were really doing almost the same thing in another way, although perhaps not so usefully as they would be by adopting and carrying out the proposition before them. He thought a Committee might very properly consider how far some of the suggestions of Dr. Acland fell within the province of those to whom the Government had assigned the duty of dispensing the national fund; and therefore he trusted the Council would not be led away from a consideration of the subject in consequence of the legal difficulties intimated with regard to the Medical Act, but that they would look at that Act to see whether it did not give power to do something in the direction proposed by Dr. Acland.

After a few words from Mr. Hargrave,

Dr. Sharpey thought this matter had been fully discussed, but one or two points were likely to create some misapprehension. Any memorial coming from such a man as Dr. Acland deserved respectful consideration, and he thought a Committee for the purpose of the investigation suggested was one of the most important questions in Medical science. He could not agree, however, that that formed any function of this Council in any shape, to say nothing about the expenses. It had been said that they ought to take upon themselves to conduct investigations of this sort in order to maintain the character of the Pharmacopœia, but he thought that the object of the Pharmacopœia was of a far different character.

Dr. Apjohn thought if their knowledge of the action of remedies was to be extended, it would not be extended by the plan proposed. Discoveries were not generally made by bodies, but by individuals.

Dr. Aquilla Smith was firmly convinced that this Council was not a body to carry out such investigations. If they were to attempt to direct and superintend them, there would be no end to the amount of labour that might come upon them. If the proposition were carried they might be called upon to investigate the Rinderpest or any other pest that might happen in the country. He could not agree with Mr. Rumsey's view with regard to the Pharmacopœia. That gentleman had read the 54th clause, but if they referred to the context they would see that the words "All such other matters and things relating thereto" clearly referred to the list of medicines and compounds, and the manner of preparing them; and that, he believed, was the true and proper scope of the Pharmacopœia. He should vote against the proposition.

Dr. Quain said there seemed to be a double discussion going on. On the one side they were discussing the propriety of giving a portion of their funds for the purpose of carrying out physiological and therapeutical inquiries, and the other was as to their powers of doing it. He quite agreed that it was utterly beyond their province; but if the Council took the view of the Pharmacopœia that they are not only to publish the means of preparing the drugs in use, but that they are also to test the properties of drugs and to discover new ones, he felt it was an inquiry they could never efficiently carry out. (Hear, hear.) They must take what was in common use, and their duty was to follow the general means of preparing it. He thought this was not a moment when they should vote as to how the Pharmacopœia should be prepared.

Dr. Acland then rose to reply. He thanked the Council for having given so much attention to the subject, and the members individually for having spoken so calmly upon it. If the Council decided against him, he could only say such was the nature of his conviction on the question, that if he lived he should have the pleasure of seeing them side with him on a future occasion, as he was convinced of the correctness of the proposal which he had submitted. The objections taken were mainly four, and he would reply to them in order. Dr. Andrew Wood had referred to the unpopularity of the subject, and had stated that the Profession would object to their spending money collected from them in that manner. And then, secondly, he said that as soon as they could reduce the expenditure they should reduce the sum they collected from the Profession. He (Dr. Acland) entirely agreed with that proposition. They should diminish the registration fee; but the sum he proposed, £250, was a very small expenditure. With regard to the unpopularity, he had as good a right to express his opinion upon that point as any other Member of the Council, and he could say he believed it was one of the most popular things they could do. He had heard objection taken in respect to the articles which they included and excluded. Practitioners—men who had been called "routine Practitioners"—were very desirous that the Council should do something or other to clear up the precise value of the articles they included or excluded. Then, as regarded the legality, unless they took the opinion of Sir Roundell Palmer or Sir Hugh Cairns, he did not think they could decide this

point. He agreed with Mr. Rumsey and Dr. Alexander Wood that it was entirely within the province of this Council. He found in the Act that they were required to construct a Pharmacopœia, which they had done at a cost of several thousand pounds. They were also required in more than one place to "alter and amend;" therefore, this was a question of interpretation. He fell in with the view expressed by Dr. Quain, that they must distinguish between therapeutical and pharmaceutical operations. He also fully concurred in what Mr. Rumsey had said, and what, in another shape, he endeavoured to press upon the Council at the outset, that the time had come when they had to render an account of the grounds upon which they admitted a thing into the lists of medicinal agents. Dr. Quain had given an instance in the case of mercury. He would give another, and that was the iodide of potassium. He (Dr. Acland) referred to a recent article in the *Annales des Chemie* as to the mode of action of that substance, and he asked those who had read that article whether it would not have redounded to the honour of this Council to have received such a report as was therein contained? The next question—that of the funds—he would drop altogether, for they had the funds, and, as Dr. Alexander Wood had truly said, they were spending money on the Pharmacopœia at this moment. The question, therefore, was upon the merits—were they limited in their expenditure to operations of a purely pharmaceutical kind? He did not think, in their present state of knowledge, they were bound to limit themselves to the list of drugs they published or simply to the way in which they were to be prepared, but they were entitled to obtain full information, and the grounds for admitting them into or excluding them from the list. With reference to the nature of the reports, he remarked that this was not a question of necessarily elaborate investigations, to be conducted at great length. The reports of the British Association and of the Royal Society were obtained either by individuals or committees at very moderate sums, and it would be perfectly competent for this Council, and that was what he hoped they would do, to give small sums to three or four members of their own body to produce reports similar to those presented to the learned societies.

The amendment was then put, and there were 16 votes for and 5 against; it was then put as a substantive motion and carried. The original motion was therefore lost.

[The Council then proceeded to other business; but owing to the time having arrived at which we are compelled to go to press, we must reserve our further report until next week.]

(Left sitting.)

ST. MARY'S HOSPITAL.

May 1, 1866.

ADDRESS BY PROFESSOR HUXLEY.

Mr. Dean, Ladies, and Gentlemen, the pleasing part of this business, so far as I am concerned, is now over, and another portion of the entertainment begins, which I trust may be in some sense satisfactory to you, but which has its difficulties for me. When the authorities of this school were first kind enough to honour me by asking me to preside on this occasion, I did not clearly take in and apprehend, as I ought to have done, the notion, that attached to that honour there was a certain responsibility in the shape of an address; but when I found that it was proper and customary that the person who had been favoured with the privilege of awarding these testimonies of merit and desert to young men should say something on his own behoof afterwards, I cast about in my mind for some subject on which I might be able to say something that might be possibly worth hearing, or at any rate that might express my own mature conviction, and might at the same time be of some use to those who are engaged in Medical pursuits. It appeared that on the whole I could not do better than say a few words touching the relations of the physical sciences in general to Medicine and of education in physical science to Medical education; and, indeed, to make some remarks upon the whole subject of Medical education, which is now occupying so many minds and exciting so very large an interest among all the most intelligent members of the Profession,

It is an old and trite observation that Medicine is both a science and an art; and if you put what you know about Medicine into a homely phrase—I use the term "Medicine," as applying to the whole range of Physic, whether Surgical, or Medical, or what not—I say, if you endeavour to put into homely phraseology what the object of the science of Medicine is, I think you will find it to be to ascertain the nature of the disability a diseased or injured person labours under, and in the next place to have a knowledge of the means by which that disability can be removed. And if you look for a definition of the art of Medicine, it has a correlative extent—in other words, the art may be defined as the skilful use of all those means and appliances by which we ascertain what is the matter with a man, and of those further means and appliances by which the wrong thing may be set right again. Now, it hardly needs any remark upon my part to make you perfectly aware that the appliances of the art of Medicine are all of them derived from, or dependent upon, the physical sciences. I need only mention such instruments as the microscope and the ophthalmoscope, and that apparatus by which the chemical qualities of the fluids of the body are ascertained, to make it perfectly obvious that in order to make use of those great and familiar appliances of diagnosis (or finding out what is the matter with people), you must have a knowledge of chemical and of physical science. And although a knowledge of the principles of physical science, enough to enable you to use the microscope, and perhaps the ophthalmoscope, with some success may not be very great, yet if you would apply the methods of chemical analysis to the examination of the fluids of the body your knowledge of chemistry must be tolerably practical and tolerably extensive. Further than that, every liberally educated Medical man should know something about the nature of the bodies which he is constantly employing. It is, surely, not compatible with a liberal education that a Medical man should be employing quinine and not know that it is the produce of a plant and what kind of plant that is. It is hardly consistent with liberality of education that a man should employ musk and not even know that it is an animal product. And therefore I think, looking simply to the using of the appliances and means of Medical practice, it may fairly be required that a Medical man should have so much knowledge of botany and zoology as shall simply, for his own credit's sake and for the sake of his position in society, enable him to be on even terms with laymen, and that he shall know so much of botany and zoology as will enable him to give safe opinions upon matters of this kind.

On the other hand, the doctrine which I am now preaching has been pushed by some persons to a very extravagant length. I am quite prepared to admit, and, indeed, I have always had a very strong conviction, that there is something absolutely preposterous in the volume and bulk to which some of our treatises on Materia Medica extend, and the enormous quantity of irrelevant matters with which their pages are crammed. I am not one of those persons who think that because you use spermaceti you are bound to know all about the classification of the *Cetacea*. I do not clearly see the connexion between those things, nor do I think that a man is bound to be acquainted with physical optics—and I am not talking wildly now, I have a particular case in my mind,—I do not think a student should be dragged through the length and breadth of physical optics, because there are particular substances used in Medicine which affect the polarisation of light or exhibit the phenomena of fluorescence. That appears to be the Scylla we have to escape. The Charybdis we need to avoid, on the other hand, is the knowing nothing about these matters. So much for the relations of physical science to Medicine as an art—that is to say, to Medicine as the use of the implements and appliances which we employ in endeavouring to find out what is the matter with people and in removing their disabilities.

But there is a perfectly different aspect, and a very much more important one, under which physical science is related to Medicine. The relation to which I now refer is that in which Medical science—the science of Medicine as apart from the art—stands to physical science in general. And this relation is more close and more important and in every way more worthy of consideration than that other of which I spoke just now. Let us consider for a moment one of the simplest cases of disability—I want some word that shall apply both to Medical and Surgical lesions—which can be submitted to a Practitioner. Supposing that a person unable to use his arm, the humerus being dislocated, presents himself to any one for cure, and that this person is no better than what we call in the country a bone-setter. The bone-setter knows, from his experience and from the general look of the part, that the arm is out of joint, and he knows very

well, from experience also, that a particular mode of pulling that arm will probably get it to go back into its place again; whereupon he applies the pull, and, I suppose, three times out of four, the arm does go back. The fourth time, perhaps, it does not go back, and cannot be got to go back; and the fifth time, it may be, in trying to make it go back, he does something or other which makes the matter very much worse than it was to start with. Now, that is the proceeding of unscientific Medicine.

The scientific Surgeon, such as I hope all those who leave this School will be—and it certainly will not be the fault of their teachers if they are not—pursues a totally different course. The scientific Surgeon who has the same disability presented to him, in the first place calls into his mind the knowledge he has of anatomical science, and which tells him what has become of the head of that dislocated bone, where it is lying, by what obstacles its return to its place is impeded. He calls to his aid his previously acquired physiological knowledge, which tells him what influence muscular contraction is exerting in keeping that bone in its abnormal place—which teaches him to account for all sorts of symptoms—as the result of pressure on nerves, pressure on vessels, and so forth. And lastly, if necessary, he appeals to his knowledge of therapeutics, or in other words, of the influence of medicaments upon the condition of the parts of the body, and he applies them in such a manner as to diminish the obstacles which arise from the contraction of the muscles. In other words, he makes use of the information he has acquired of the physical sciences Anatomy, Physiology, and Therapeutics, to serve as the basis of a series of deductions, by the help of which the internal condition of the injured part becomes visible to the mind's eye. He knows, in virtue of these deductions, on what the bone is resting, what it is touching, what mischief it is doing, what means he ought to apply in order to bring the bone back into its primitive place, and what will be the effect of every measure which he applies for that purpose. In other words, in the case which I have selected, the scientific Surgeon knows precisely the character of the injury; and he knows precisely the kind of operation which he should perform to remedy that injury; and so far as this particular case is concerned, we may say that scientific Medicine has here attained its perfection—that is to say, the Practitioner may know the whole conditions of the lesion; and he may know exactly what he ought to do to restore the injured part to its healthy condition. And that is exactly the difference between the empiric and the scientific man—that the empiric knows in a coarse, blind sort of way—working in the dark on the doctrine of chances—that if he does certain things it is very likely certain results will follow. The scientific man, on the other hand, makes use of the data of physical science for the purpose of reasoning out the exact conditions of the case which he has before him, and for the purpose of applying the precise measures which are adapted to meet that case. I trust it is not necessary for me to use any argument to show you that it is this latter condition of mind to which the scientific Physician or Surgeon must strive, and that the labours of your teachers here are as so much lost if they have not carried you some steps towards that end.

Now, having this conception of what is meant by scientific Medicine before us, let us consider what has to be done before Medicine will reach this desirable condition. For although it may be possible to adduce instances of what I should call perfect Medical science—that is to say, where you have a complete knowledge of the lesion, and a complete knowledge of the conditions required for the repair of that lesion—yet I need not tell you that these chiefly occur in Surgical practice, and are rarely presented to the Physician; and that in the great majority of purely Medical cases we have, unfortunately, no such complete knowledge either of the lesion which has taken place, or of the steps which should be taken to restore health. In the great majority—I speak under correction here, but I do not think I shall be far wrong—in the great majority of cases the modern Physician, beneficent as his efforts are, great as his skill, and unremitting as his attention may be, yet as compared with that which is to be hoped for, and what we may fairly expect one day to attain, it must be confessed is still very much in the condition of the bone-setter. You know there is a wicked and libellous old story—I think some Frenchman invented it—in which it is said, by way of illustration of Medical practice, that in a diseased person Nature and the disease are as two men fighting; while the Doctor is a blind man, who comes with a big club and hits hard, sometimes hitting the disease, and sometimes hitting Nature. Now, there was a time when that description of Medical practice, I fear, was not libellous, but the time has long since passed by when it could have any strict application, and it is not the fault of the cultivators of Medical science if it continues to have any sort of application. But, if I might modify this story and bring it more into accordance with the present state of things, I should say that, in these days, the Physician is not blind; but, on the contrary, is remarkably sharp-sighted, acute, and painstaking; but that he finds himself in a very dim twilight, and having ascertained that the light is very uncertain and very apt to vary, he rather, as a conscientious person, abstains from using his club, and as far as possible confines himself to the position which, if I may say so without offence to the ladies here, is known as that of a "judicious bottle-holder," ready to pick up Nature whenever she gets adrift, and bring her up to time. That, I take it, is a fair description of the modern practice of Physic; a statement in the vernacular of what is meant by our *Medicine expectante*. And no doubt a beneficent change has been brought about, satisfactory to the patient and no less satisfactory to the Physician, who feels that his club is not stained by innocent blood. But, although this may be a vast improvement upon the past condition of affairs, no one who knows what physical science is, or what men of science are thinking about, will imagine for one instant that it is to be a final condition. No one can doubt that the whole purpose of philosophical Medicine and the whole striving of philosophical Physicians must be to approximate Medicine more and more to the plainest kinds of Surgery, and to enable the Physician by-and-by to ascertain as clearly what is the condition of a diseased part, and what must be done to remove that disease; to have as clear a mental picture of that as the skilful Surgeon has of the condition of a dislocated bone, and of what is to be done to remedy the dislocation.

If you come to think of the matter, all disease is, strictly speaking, a dislocation—a something out of place. In the so-called "Medical" lesions, if it is not actually bone, and muscle, and viscera, in the gross, it is the atoms of these parts, and the molecules of the fluids, and so forth, which are not what they should be and where they should be, if the patient were in a condition of health. If our senses were so fine and so delicate as to enable us to see the ultimate molecules of the human body acting and interacting, we should discern that they were out of place in every diseased part; and if we had means of reaching them directly, we could put them back again into their right order, so as to produce their right functions, in just the same way as the Surgeon replaces a bone. To do this, the Surgeon uses coarse mechanical power. He knows the bone is out of its place; his eyes give him an indication of where it is, or his hands. Touch and vision teach him what the condition of affairs is, and coarse mechanical methods are sufficient to enable him to bring matters right; but the atomic dislocation of a fever is not to be detected by touch or sight, and cannot be set straight by mechanical forces. The difference between the Surgeon and the Physician is not that they have different things to do, nor different methods of inquiry, nor that their procedure is in any way substantially different; but it is that the something which has gone wrong in Medical lesions requires special means for its discovery, and the forces which are to put that something right again cannot be applied directly and coarsely with our bodily hands, but we must send them to the dislocated atoms upon the shoulders of the atoms of those things which we call medicines, and drugs, and so forth.

To return to my old comparison,—to put the Physician into as favourable a position as the Surgeon, what he wants is simply more light. He wants a better light upon the arena of the fight, so that he may be able to remove the obstacles in the way of Nature, and may be ready, as occasion offers, to deal her opponent a severe blow without the chance of doing herself an injury. And if you will take the trouble to reflect from whence such light may be expected, you will find that there is only one possible channel, and that is from the cultivation and improvement of those sciences which furnish us with our data for deduction. I mean the abstract physical sciences of anatomy, physiology, chemistry, physics, and so forth. Just as the Surgeon's knowledge of the nature of the dislocation of a bone is a deduction from previous anatomical knowledge—as his process of cure is a deduction from other kinds of scientific knowledge—so the discernment of the nature of all morbid processes must consist of a series of deductions from an enlarged physical and anatomical and chemical knowledge, and all our attempts to

cure disease must be guided—all the light we get in that direction must be furnished to us—by a more subtle inquiry into the properties of the atoms of matter, and into the forces which they exert. Or, in other words, the whole progress of Medicine depends upon the progress of the physical sciences, from which her great principles are really deductions; and exactly in proportion as physiology, as anatomy, as pathology, as therapeutics are carefully studied and their principles better understood, so will the Physician have placed in his hands more and more powerful implements, on the one hand, for discerning the nature of disease, and, on the other hand, for meeting and conquering that disease.

This is a large subject, one which, in these curt phrases, I can hardly put before you so fully as I could wish; but I hope that you see the bearing of what I have been saying, because it is upon a clear appreciation of this that all our theories of Medical education must eventually turn. If in striving to make Medicine the noble and grand science it should be, all depends upon the perfection of certain other sciences; and if our skill in the use of the means of inquiring into disease and in using the means of cure depends upon our acquaintance with the physical sciences, it must be quite obvious to you that a thorough grounding in physical science is the basis of all Medical education. I believe that is a proposition which cannot be doubted, and which the more we inquire into it will be seen to go more and more completely into the root of the matter.

But how is such a grounding in physical science practicable? Not long ago one of the most experienced Surgeons in these islands raised his voice against the system which is at present pursued in Medical education, in throwing into the system—if I may use a Medical phrase—of a young man an enormous quantity of knowledge of all sorts of remote and theoretical kinds, to the exclusion, as he justly enough observed, of that practical information which could alone in the long run make him a skilful Surgeon. And, so far as I recollect, the argument ran somewhat in this way: —A young man leaves school; he comes to a Medical College, at which he is expected to spend three years; at the end of that time to become a Practitioner, sent forth free to kill or cure, as the case may be. He comes to you perfectly ignorant, without a scintilla of a notion of anything about science, and within that time you expect him to learn physics, or natural philosophy, chemistry, botany, zoology, with comparative anatomy, human anatomy, histology, pathology, therapeutics, Medicine, Surgery, obstetrics, jurisprudence. The thing is absurd. What you run a risk of doing is, to destroy his mental digestion, as you may destroy the physical digestion of a turkey, and make a sort of intellectual *foie gras* of him; but, as for supplying information upon all those subjects of the kind and scope which he ought to have, in that time, and with the current methods, it is out of the question. Consider for a moment: if you take only those branches of Medical study which bear directly upon practice, few persons until they come to try know how vast they are. Take human anatomy, and reflect upon the quantity of work required before a student can possess the sort of knowledge that he ought to have. And no one has a proper knowledge of human anatomy till the man who stands up before him is in a manner transparent, and all the essential organs, bones, nerves, vessels, and muscles are to the mind's eye visible in their places. Consider the knowledge of histology or the minute structure of tissue that is required. Take pathology in itself: the rudiments of it might, if they were studied thoroughly, occupy a very large share of the time. And then physiology is absolutely indispensable, and more especially that experimental physiology which is of more importance than all the rest. I say put these things together, and then superinduce upon them the practical branches of a Medical man's profession—the necessity of becoming dexterous in the use of bandages and the manipulation of instruments—and then all that a student has to learn in the way of theoretical Surgery, and Medicine, and Jurisprudence, and so forth. Why, it will be quite obvious that three years is a most scanty period to devote to all these subjects; it is as much as can be expected if in the three years, by dint of thorough teaching and zealous learning, a young man acquires a notion of the practical branches of his profession. I am not talking, of course, about the way that a man can be taught to pass an examination; anybody can be taught to pass an examination. I was almost going to say that a dog might be taught to pass an examination, or, at least, a good many of the examinations that men go through; but I speak of that kind of information which is alone worthy of being called knowledge—that information which, as I understand, your Professors here are doing their best to give you; that information which is conferred by making men go for themselves, at first hand, to the facts and see them, by leading them not to trust this teacher, or that teacher, but to work out the truth and see it as it is, and carry that away as a thing that they know of yourselves and of their own knowledge. That is the only knowledge that is to be depended upon in your future lives; and if a man is to have that kind of knowledge he cannot spare a minute out of his three years for the subjects I have been speaking of just now.

But you may turn round upon me and say, "This is excessively inconsistent; for you have been preaching to us up to this time the enormous importance of abstract physical science, and telling us we can understand nothing unless we are well grounded in the prineiples of physics, in the principles of chemistry, and in the principles of biology." No, I have been guilty of no inconsistency. I hold absolutely to that position. I hold that no man can have a proper knowledge of physiology, no man can understand what the Scotch well call the "Institutes of Medicine," unless he has gone back still further, and unless he has aequainted himself with the general laws of the physical forces and with the general powers of matter as revealed by chemistry and biology.

The fact is, that you ought to have this general knowledge of physical science before you approach the study of Medicine. I fully concur with the distinguished Surgeon to whom I refer that these are not the matters with which a man ought to be occupied when he is busy with his practical Professional education. In other words, if we could arrange things as they ought to be, all this general knowledge of physical science, all this acquaintance with the principles of physics, and chemistry, and biology, ought to have been acquired by you in the course of your ordinary education. If those who regulate education in this country had a right conception of what their duties are, or of the purpose of education and the conditions of the progress of mankind at this present time are, you would get that knowledge. And those who wish to improve Medical education must, to my mind, throw all their energies into the attempt to compel those who give us primary education to make physical science a very large constituent portion of that education. I thoroughly sympathise with those who groan over the present chaotic condition of affairs. I do not see how, for some time, we are to escape the attempt to force upon young men who come to learn Physie too much knowledge and too various knowledge. Perhaps, even, it is better they should have the kind of chaotic training they have now than that they should be altogether free from a tincture of physical science; therefore I do not in the smallest degree blame the existing system of instruction in Medical schools. I think the attempts which are being made in all the great schools of London to make physical science an integral part of Medical teaching are necessary so long as physical science is ignored in ordinary education. The effort is good; the evils which attend it must be met as best they may. But I repeat once more, the great effort of all Medical reformers must be to make such a pressure upon those who have the charge of education in the country that physical science shall be made an integral part of it. If that were the case,—if men came to their Medical studies trained not only in the facts of physical science, for that is only half the battle, but if the precious time which is now wasted in gerund grinding at school were even partially employed in accustoming them to the methods of scientific inquiry, the task of the Medical teacher would be infinitely lightened. If a knowledge of classical literature, or an appreciation of literary excellence, were really given at our schools, I should be the last person in the world to cry out against it, for I yield to no man in my respect and love for literature. But let any one of us turn back to his school-days, and let him try to call to mind what enduring result he obtained from all the Greek and Latin teaching he got at school. What was the whole effect? It was a pervading sense of nominative cases, and verbs, and so forth, to the end of the chapter. We read our Virgil, and Horace, and the rest of it, and when we had done, all that we knew was they were made up of verbs and substantives which had certain quantities and were packed together in accordance with certain rules; and as to what the whole thing meant, unless you were more fortunate than I, we had not the smallest notion of it.

It is the duty of every man to lift up his voice against this

strange waste of human time and perversion of human ability; and it is the especial duty of every one of us who has the cause of Medical education at heart to endeavour, as far as possible, to exercise such an influence upon the general education of the country as shall relieve Medical education from three-fourths of the difficulties under which it at present labours; and to bring about the great result that, when the Medical teacher begins his work, he shall not have to commence that work upon a mere *tabula rasa*, a mere raw material which has been used for no better purposes than gerund grinding. Conceive how different the case would be if the young men who come up for Medical education had been accustomed to handle physical experimental apparatus. Suppose that they had been accustomed to acquaint themselves with chemical formulæ, with chemical reactions; suppose they had learned, and there is no difficulty in learning these things, the great distinguishing characters of the different forms of life, and the great broad facts of physiology, which (I speak from experience) may be taught perfectly well to boys of from ten to fourteen years old; I say, supposing they had done this, and that they came to the study of Medicine with their minds stored with important truths, accustomed to go back to facts at first hand, and trained and disciplined in the methods of inductive and deductive reasoning, how much easier the task would be, not only for the learner, but for the teacher, and how vastly greater would be the stride made by every man towards that great goal I have already indicated—the establishment of a scientific Medicine.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

May 15.

The cholera which has appeared among the German emigrants is, I regret to say, still spreading. The authorities of Liverpool on Tuesday, the 8th inst., ordered the removal of 200 of the passengers on board the *Helvetia* to the emigration depôt at Birkenhead, and the remainder have since been transferred to the *War Cloud*. The 200 who were sent to the depôt were all in perfect health—having been passed by Dr. Buchanan and Dr. Trench, but unfortunately within a few hours after their admission a well-marked case of cholera occurred, which was followed in the course of a few days by several more. Up to the present time there have been six deaths, and there are now eleven cases under treatment. No fresh cases have been reported to-day.

The Government agent to the Emigration Commissioners intimated yesterday that the emigrants from the *Helvetia* could not be allowed to remain in the depôt, but must be at once removed, as arrangements had been made for the despatch of an emigrant ship to Brisbane at an early period, with a large number of English, Irish, and Scotch passengers, and that it was essential that the depôt should be fumigated and disinfected for their reception. Under the circumstances, it was arranged that all who could be removed should be taken to Bank Hall, preparatory to their re-embarkation on the *Helvetia*. This arrangement has not been carried out. It will be remembered that the sick from the *Helvetia* were removed to the Hospital ship—the *Jessie Munn*—which is under the charge of the parochial authorities. This vessel is provided with every requisite. Dr. Rayner, one of the Medical officers connected with the Workhouse, has been appointed to take charge of the Medical Department, and he has under him a matron and an efficient staff of nurses.

On the 11th inst. it was reported that the cholera had broken out among the emigrants that had been transferred to the *War Cloud*, but they were immediately removed to the *Jessie Munn*. It was deemed desirable, however, on Saturday, May 12, to bring the healthy emigrants on shore, and accordingly about 220 German and 450 Irish emigrants were taken to Bank Hall warehouse, a large building near Bootle, on the outskirts of the town. These premises are very commodious and well ventilated, and are sufficiently isolated from any dwelling-houses to obviate all fear of infection.

Soon after their arrival cholera again broke out, and several fresh cases have since occurred—four of these are said to have occupied adjoining beds. They have all been removed to the Workhouse Hospital.

The parish authorities have undertaken the sole charge at Bank Hall, and I understand another warehouse is about to be fitted up for the accommodation of emigrants who may not be able to obtain lodgings in the licensed houses in the town.

The influx of foreign emigrants still continues, and on the night of Monday (7th) nearly 400 arrived from Hamburgh *viâ* Hull, and in consequence of the German lodging-houses being full, much difficulty was experienced in providing them with accommodation, and some 200 of them had to be received for the night into the large waiting room of the workhouse, where they were supplied with hot coffee and bread.

Again, on Thursday night (10th) about 40 of these emigrants, finding that such difficulties had arisen in the way of their immediate embarkation, insisted upon going back to London, and from thence to Hamburgh, and these were obliged to remain all night at the Lime-street station.

On Wednesday, the 9th, about 200 German emigrants went on board a large emigrant ship bound for New York, but a number of Irishmen, who were passengers by the vessel, resisted the foreign invasion, and after some disturbance the Germans had to "skedaddle" from the ship.

The crew of the *Helvetia* addressed an urgent request to the Mayor of Liverpool for leave to come on shore, but this, of course, was refused. One of the stewards of the unfortunate steamer has died of the disease. On Friday morning, when the tender went alongside, about 40 of the crew jumped into her and came on shore—the police persuaded them, with one exception, to return to their ship.

The *Helvetia* is now cleared of passengers, and is being thoroughly cleansed and disinfected, and it is stated that she will probably sail for New York on Saturday.

In the Liverpool Workhouse Hospital there have been twelve cases of cholera admitted. Six have died. Of these, five were Germans from Rotterdam; but they were not passengers belonging to the *Helvetia*. Two of these patients had been refused admission into the Liverpool Northern Hospital, as they were suspected cases; the sixth was an Irishwoman from Bank Hall.

A German emigrant suffering from cholera was received into the Workhouse Hospital this morning from an emigrant ship about to sail from this port.

Up to the 13th, twenty deaths have taken place on board the *Jessie Munn*. Of these, sixteen were Germans, three Irish, and the twentieth was the unfortunate Surgeon of the *Helvetia*, Dr. Ross, a young man of much promise.

I have been informed that a female who keeps a small shop in Vauxhall-road died yesterday of cholera.

The Hamburg Consul stated that, according to official inquiries, there has not been a single case of cholera in the course of the present year in Hamburg.

I have thus endeavoured, briefly and with precision, to place on record the facts connected with the early stages of what may be another invasion of this country by Asiatic cholera. These facts certainly point to the conclusions that this disease is spread by contagion, and that no sufficiently vigorous and systematic efforts are being made by the authorities of this town to arrest the mischief while it may yet be practicable to do so.

The success that appears to have followed the attempts made at New York to isolate those attacked with cholera make us regret that the authorities here have not adopted the same course. The only excuse they can have may be the want of proper quarantine accommodation.

GENERAL CORRESPONDENCE.

THE TRANSITORY NATURE OF EPIDEMICS.

Letter from Dr. W. O. Markham.

[To the Editor of the Medical Times and Gazette.]

Sir,—Dr. Farr's position (as I understand it) is this:—He writes "That Rinderpest will subside spontaneously as an epidemic. The holocausts about to be offered up will, we may hope, not retard this consummation."—(*Daily News*, February 16 ult.) As an illustration of his theory of this epidemic rise and fall of the cattle plague, he quotes only one single instance—the cattle plague in Rome as described by Lancisi. "The cattle plague in Rome, he says, lasted less time than our calculation gives." It lasted, in fact, about nine months.

Now, I cannot accept this instance as an example of the epidemic rise-and-fall character of Rinderpest. I have carefully perused Lancisi, and I find, as Dr. Farr admits, that the

strictest rules as regards isolation, stoppage of movement of cattle, of rustics, and of dogs, etc., burying of the dead bodies, disinfecting stables, etc.—in other words, prevention of contagion—were rigidly laid down and practised in the Roman States, the penalty of death being attached to the disobedience of many of the orders prescribed. I find in the carrying out of these orders a sufficient explanation of the arrest of the disease in nine months.

Dr. Farr should have explained (to show the consistency of his theory) how it happened that the cattle plague ravaged other parts of Italy for many years—in fact, from 1711 to 1715. He does not explain why the supposed epidemic wave did not rise and fall in other parts of Italy. The artificial division of the States of Italy could have been no barrier to the epidemic progress of the disease. Will Dr. Farr explain on his theory why, in the Roman States alone, the disease died out in nine months, and why it ravaged the rest of Italy for four or five years?

Neither Lancisi nor Rammazini had the smallest doubt as to the disease being of a purely contagious character. Both trace its origin to that Hungarian ox, "ille fatalis bos," imported into Count Borromeo's estate, "quo momento non antea; hoc ipso loco, non alibi, incendium exarsit." Moreover, Lancisi ascribes its stamping out in the Roman States to the careful measures there carried out. He says in his preface, "That same plague which infested other Italian States for years . . . . thanks to God and the vigilance of our Prince, was here completely extinguished in nine months." Again, elsewhere he tells us, "By the month of May not a trace remained of the pestilence which had so long and cruelly punished other countries, and still existed on the other side of the Po. For this we thank the piety of the Holy Father, and his providential care."

Lancisi also gives instances where the disease had been excluded from their estates by those "qui seduli contagionis rimas omnes obstruxere." The cattle on two estates—the estates of Prince Borghese and of Prince Pamphilo,—situated in the midst of the raging pestilence, were entirely preserved from the disease. "Non aliâ plane de causâ, quam quod intentissimâ vigilantiâ prohibitus fuerit externorum corporum, in quæ cadere suspicio poterat." "In the same way have been hitherto protected the provinces of the Patrimony, Umbria, Picenum, and Flaminia. Similarly, in the Duchies of Etruria and Matina, the cattle have been preserved solely by severe laws and careful watching." So wrote Lancisi.

Will Dr. Farr tell us how severe laws and careful watching can arrest the unseen footsteps of an epidemic, and prevent it leaping the artificial barriers of a *douane?* My friend Dr. Farr must excuse me for repeating that this only one example which he adduces as proof of the epidemic character of cattle plague, seems to me to tell a tale strongly illustrative of the very reverse. I cannot think any one can impartially read Lancisi's wonderful pages without arising from them with the conviction that the cattle plague of his day at all events was spread through Italy solely by contagion; and that it was extinguished in the Roman States in nine months solely by the extraordinary measures there adopted to prevent its spread. It is true, as Dr. Farr says, that the Sacred College would not allow Lancisi to have his way with the polcaxe; but I will venture to say that the measures actually adopted by the Sacred College—of isolation, etc.,—were infinitely more stringent and more stringently carried out than any which have been yet adopted in this country.

I am, &c., W. O. Markham.

London, May 14.

P.S.—The question is a very important one. If Dr. Farr is right, the Cattle Plague Commissioners are all wrong.

MR. PROPERT AND MR. BAKER BROWN.

[To the Editor of the Medical Times and Gazette.]

Sir,—A testimonial is being got up for Mr. Baker Brown, as a kind of answer to the sober and orthodox members of our Profession who disapprove of his peculiar operation on young women. Mr. Propert is at the head of the Committee. As Mr. Propert must have had considerable experience in epilepsy during his long career of practice, may I ask whether he believes in Mr. Brown's theories of the morals of young women, and in the consequent operation? I am, &c.,

May 14, 1866. A Country Doctor.

MEDICAL NEWS.

Royal Colleges of Physicians and Surgeons, Edinburgh.—Double Qualification.—The following gentlemen passed their First Professional Examinations during the April and May sittings of the Examiners:—

Richard Voeght Clumpett, Devonshire; William Easby, Durham; Thos. Fell, Sunderland; Charles Wellis Wood, Askrigg; William M. Allan, Newfoundland; David Edgar Jones, Cardiganshire; John Anderson, Forfarshire; Douglas Donald Cameron Menzies, New Amsterdam; Samuel Brown, Jamaica; Archibald Campbell, Argyleshire; T. R. J. Woodfield, Sunderland; James Stockwell, Musselburgh; Nicholas Maker, Thurles; John F. Little, Kilkenny; Henry T. Brownrigg, Waterford; R. H. B. Wickham, Ascension; Edward Tulcott Norman, New Orleans; Robert Stevenson, Kilwinning; Jeremiah Vaughan, County Clare; Henry Brown, Belfast; Joseph T. W. Brass, Orkney; Andrew M'Master Paterson, Madras; John M'Gee M'Cormac, County Down; Lawrence J. Macnamara, County Clare; James Meehan, Limerick; J. H. Rutherford, Newcastle.

And the following gentlemen passed their Final Examinations and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh:—

William Murray, County Westmeath; Samuel Woodcock, Derbyshire; Tom Bates, Cambridgeshire; William Edward Stainton Stanley, Cumberland; Colin William MacRury, Inverness-shire; John Grindel Brayton, Whitehaven; George Myles, Limerick; Charles Robert Straton, Montrose; Aubrey Wicks, Cambridge; Charles Jones, Herefordshire; James Robinson, Lancashire; Christopher Allcock, Nottingham; James Affleck, Ayr; Richard Young, Lanarkshire; Arthur Wellesley Roche, Cork; John M'Carthy, Cork; William Dyson Wood, Wakefield; Thomas Bennett Kehoe, Cork; Joshua Hayes, Cork; Edward Godfrey Purcell, Limerick; William Henry Clarke, Birmingham; Robert Lawson Tait, Edinburgh; Daniel Bradley, Dudley; Richard Mortimer, Cork; Edgar Gailey, Annan; Robert Stewart, Perthshire; Finlay M'Dougall, Argyleshire; William Benjamin Griffith, County Mayo.

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their Final Examinations, and were admitted Licentiates of the College during the April and May sittings of the Examiners:—

James Nichol Cox, Dumfriesshire; John Wilson Moir, Musselburgh; John Rhind, Cheshire; John Antoine Palanque, Windsor; Wm. Skene, Helensburg; Hugh Brown, Lanarkshire; Robert Ayre Smith, Monkwearmouth; George Gray, Newry; Chas. M'Caskie, Edinburgh; Joseph Wood, Northumberland; Joseph Lindsay, County Antrim.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 10th inst., viz.:—

George Thomas Hawkins, L.S.A., Clapham; Arthur Eisdall Fluder, Lymington; and Alfred Harwood, Cambridge, students of Guy's Hospital. William Henry Moore, Liverpool; Edward Cleaver Maxwell, Barnstaple; and Henry Sedgwick, St. John's-street, of St. Bartholomew's Hospital. Wentworth Raynes Tindale, Peckham-rye; and James William George Farwell, St. Martins, near Liskard, of St. George's Hospital. Charles Arthur Bush, Bath; and David Edward Bernard, Bath, of Bristol. George William Mousley, Atherstone, Warwickshire; and James Sawyer, Birmingham, of Birmingham. Adam Perry Newman, M.B. Dub., Cork; and Jeremiah McCarthy, London Hospital, of Dublin. Richard Cresswell, Lewisham; and Reginald Bligh Wall, Bayswater, of St. Mary's Hospital. Richard Holt Robinson, Manchester, of King's College. John Maude Whitwell, Kendal, of the University College Hospital. Arthur Waller, Milner-square, of St. Thomas's Hospital. William M'Donald, M.D., Edinburgh; and Thomas Dealtry Atkins, Calcutta, of Edinburgh; and John Deardent Bush, Newcastle-on-Tyne.

At the same meeting of the Court of Examiners, Mr. Robert Atkinson, of H.M.S. *Prince Consort*, passed his examination for Naval Surgeon; this gentleman had previously been admitted a Member of the College, his Diploma of Membership bearing date April 17, 1854. It is stated that out of the 76 candidates who offered themselves for examination, 13 failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their Hospital studies for six months.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 15th inst., and when eligible will be admitted to the Pass Examination:—

William Jebson Stothard, George William Smith, David Owen Fountaine, and Frederick Knowles, students of Guy's Hospital. Owen Thomas Evans, John Williams Pring, and Benjamin Franklin, of Dublin. Edward Lawrie and C. H. Denny Robbs, of Edinburgh. Charles Henry Lister and Frederick Edwin Vernède, of University College. Edward Bray Pellew and J. H. Wilkie Ridley, of Newcastle. Thomas Henry Lovegrove and George Charles Coles, of St. George's Hospital. George Ridley Milles, of King's College. David Johnston, of Belfast. John James Fraser, of Manchester; and Edward Cruikshank Malloch, of M'Gill University, Toronto.

It is stated that out of the 33 candidates who offered themselves for examination, no less than 14 failed to acquit themselves to the satisfaction of the Court of Examiners, and were consequently referred back to their anatomical studies for three months. The next Pass Examination takes place this day.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 10, 1866 :—

Owen Evans, Pandy Trefrin, near Conway, N.W.; Frederick Howse, Alexander-road, Kilburn-park; Frederic Charles Mudd, West Pallant, Chichester; George Lucas, Burwell, Cambridge; Thomas Baron, Ulceby, Lincolnshire; Alfred John Leggatt, William-street, Lowndes-square.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

COUSINS, W. J., M.D., has been appointed one of the Medical Officers for the Royal Portsmouth Hospital.

ELLIOTT, ERNEST, M.D.Aber., M.R.C.S.E., has been appointed one of the Honorary Medical Officers to the Royal Portsmouth, Gosport, and Portsea Hospital.

HARDIN, W., L.Q.C.P.I., has been appointed one of the Medical Officers of the Royal Portsmouth Hospital.

POLLOCK, A. J., M.D., has been appointed Physician to the Foundling Hospital.

SHUTTLEWORTH, G. E., B.A.Lond., M.R.C.S.E., has been elected Resident Medical Officer to the Kilburn, Maida-vale, and St. John's Wood Dispensary.

SMITH, W., M.R.C.S.E., has been appointed House-Surgeon to the West London Hospital.

BIRTHS.

BEITH.—On May 10, at the Royal Naval Hospital, Plymouth, the wife of R. Beith, M.D., Deputy Inspector-General of Hospitals, of a son.

CREGEEN.—On May 15, at Upper Brent Cottage, Blackheath-hill, the wife of J. J. Cregeen, M.D., of a daughter.

FEGEN.—On May 7, at 20, Tamar-terrace, Stoke, Devonport, the wife of W. B. Fegen, Staff-Surgeon R.N., H.M.S. *Impregnable*, of a son, stillborn.

MCBRIDGE.—On April 22, at Newry, the wife of Dr. A. McBridge, of a son.

MUNRO.—On May 11, at Kinross, the wife of R. Munro, L.F.P.S.Glas., of a daughter.

MURRAY.—On the 4th inst., at Newgate-street, Newcastle, the wife of John C. Murray, of a daughter.

STAINSTREET.—On May 13, at 3, St. James's-terrace, Malahide, the wife of R. Stainstreet, M.D., of a son.

WOAD.—On May 9, at Ashton-under-Lyne, the wife of Herbert Woad, M.R.C.S., of a son.

YELF.—On May 12, at Moreton-in-Marsh, the wife of L. K. Yelf, of a son.

MARRIAGES.

WATSON—BEWLEY.—On April 26, at Monkstown Church, W. T. Watson, M.R.C.S.L., to Isabella, second daughter of W. Bewley, Esq., of Illerton Killiney, Co. Dublin.

DEATHS.

ALLANSON, J., M.R.C.S., at Watford, on May 4, aged 63.

ALEXANDER, J. T., M.R.C.S.Edin., at 2, Church-hill, Morningside, Edinburgh, on May 13.

BRABANT, R. H., M.D., at Marlborough-buildings, Bath, on May 13, aged 85.

HARVEY, W. H., M.D., at Torquay (Professor of Botany in the University, Dublin), on May 15, aged 55.

PIM, T., M.D., of Castledermot, Co. Kildare, on April 14, aged 60.

SMITH, S., M.R.C.S.E., at Ardres, France (formerly Surgeon to the Forces of His Majesty George III.), on May 15, in the 92nd year of his age.

STEVENS, J., L.R.C.P.Edin., at 26, Bloomsbury-square, on May 16, in the 47th year of his age.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Croydon Union.—Mr. Albert has resigned the Fourth District; area 2130; population 13,200; salary £100 per annum.

Hastings Union.—Mr. Henry E. Herbert has resigned the Third District; area 8144; population 1552; salary £40 per annum.

Knaresborough Union.—Mr. Joseph Frobisher has resigned the Harrogate District; area 13,069; population 6669; salary £35 per annum.

Warwick Union.—Mr. H. Blenkinsop has resigned the Workhouse; salary £64 per annum.

APPOINTMENTS.

Bosmere and Claydon Union.—Henry O. Rowland, M.R.C.S.E., L.S.A., L.M., to the Claydon District.

Driffield Union.—Samuel N. Harrison, L.R.C.P.Edin., M.R.C.S.E., to the Kilham District.

Godstone Union.—Charles R. Thompson, M.R.C.S.E., L.S.A., to the Eastern District.

Haslingden Union.—William J. Stott, L.R.C.P.Edin., M.R.C.S.E., L.M., to the Haslingden District and the Workhouse.

Thirsk Union.—John C. Robinson, L.R.C.P.Edin., M.R.C.S.E., L.M., to the Kilburn District.

Weymouth Union.—Joseph Carruthers, M.R.C.S.E., L.S.A., L.R.C.Edin., to the Portland District.

THE LEVÉE.—At a levée held on Saturday at St. James's Palace, by his Royal Highness the Prince of Wales on behalf of Her Majesty, the following presentations took place :—Dr. Arbuckle, Inspector-General of Hospitals, Her Majesty's Bombay Army, by Secretary of State for India; Surgeon-Major W. C. Coles, M.D., by the Secretary of State for India; Staff-Assistant-Surgeon J. d'Altera, by the Adjutant-General; Dr. Mouat, Inspector-General of Prisons, Bengal, by the Secretary of State for India; Surgeon J. B. Scriven, Bengal Army, by the Secretary of State for India. The following gentlemen attended the Levée :—Drs. J. R. L. Dickson, Langdon Down, Watson, Scott, John Forbes, J. Balfour Cockburn, R.E., George Owen Rees, Ruttledge, Baines, and Alexander Marsden; Deputy-Inspector-General Graves; Messrs. Spencer Wells, Haynes Walton, Oscar Clayton, Cæsar Hawkins, and James Paget.

THE cholera in the quarantine at New York is said to have assumed a mild form, and to be gradually disappearing.

CHARLOTTE WINSOR, the child murderess, has had her sentence commuted to penal servitude for life.

THE Acclimatisation Society of Great Britain and the Ornithological Society of London have amalgamated. The first general meeting of the united Societies was held on Monday, in the council room of the Royal Horticultural Society, South Kensington.

THE PHARMACEUTICAL SOCIETY gave a most admirable *conversazione* on Tuesday evening, at their house in Bloomsbury-square. The guests were received by the venerable President, Mr. Morson, and Mr. Hills, representative of the chief founder of the Society, and then were ushered into spacious apartments filled with all that is new and wonderful in chemical and physical apparatus and natural history specimens. Amongst the last we must speak in terms of admiration of the collection of exotic plants, and still more of the herbaria, and especially the collections of ferns and seaweeds exhibited on the walls. A lecture by Dr. Thudichum on Parasitic Diseases of Animals gave a practical finish to a very agreeable evening's hospitality.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending May 5.	Week ending April 28.	Week ending April 21.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

Note.—11 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Cambridge, 1; Chester, 3; Huntingdon, 1; Leicester, 1; Middlesex (extra Metropolis), 1; Norfolk, 1; Nottingham, 1; North Riding of York, 1; and the Metropolis, 1. These inspectors returned 80 cases last week.

REMARKABLE SUICIDE(?).—Mr. Humphreys, the Middlesex Coroner, held an inquiry on Thursday, May 10, touching the death of a woman whose name is unknown. Inspector W. H. Maskell said that the deceased had fastened a piece of string round her neck. She had evidently held with her left hand the end of the twine against the left side of her neck, while with her right hand she had wound the twine eighteen times round her neck. Every time that she had twisted the string round her throat she had pulled it tight. When found, the remains of the ball of twine were in her right hand. On the ground near her lay a black velvet bonnet, which she had evidently taken off in order that it might not be in the way. The deceased was about 35 years of age. Mr. George Yarrow, M.R.C.S., deposed that he found on the body of the deceased various marks of violence. The jury returned a verdict—"That the deceased woman unknown was found dead, and

that the cause of her death was strangulation; but how, or under what circumstances she became strangled, there is no evidence to show."—*Express.*

Criminal Abortion.—At Clerkenwell, on Saturday, May 12, Helen Forester, described as a nurse, and her daughter, Caroline Forester, were placed at the bar before Mr. D'Eyncourt, on remand, on the charge of having caused the death of Mrs. Henry Slowman, aged 35, by means of abortion. Dr. Brown said that since the last examination Mrs. Slowman had died. Before her death she made a statement to him and Dr. Walker, in which she described what had taken place. Evidence having been given that the cause of death was the attempt to procure abortion, Mr. D'Eyncourt committed the elder prisoner, who is about 60 years of age, to take her trial for wilful murder, and the younger prisoner as an accessory after the fact.

New Surrey County Hospital at Guildford.—The building stands on a terrace on the eastern slope of the Hog's Back, overlooking the town, from which it is distant little more than a furlong; it covers, together with out-buildings, a plot of two acres, enclosed in a low wall, and consists of a centre block and two wings facing N. and S., and running parallel to the high road to Farnham. It is built of Bargate stone with red brick dressings, and has a plain unpretending front. The general arrangement is on the Pavilion principle. The ground floor is designed for the "administration" and out-patients' departments only, and is an exact copy of the new Hospital at Aylesbury. The matron's and House-Surgeons' rooms, porter's room, store rooms, and board room fill the centre and left wing; the consulting rooms, dispensary, and out-patients' waiting room, with bath room, occupy the right wing. There is a small hall and spacious staircase in the centre, with corridors leading to the offices above-mentioned. The kitchen department is placed in a building in the rear of the centre block, with which it communicates by a corridor, and consists of the kitchen, scullery, bread room, servants' dining room, pantry, larder, etc. The stores for coal, beer, and wine are in the basement under the centre block. The first floor is devoted entirely to the in-patients, and is arranged in strict accordance with the plans laid down for small Hospitals by Miss Nightingale. There are two large wards, each occupying the whole of one wing, with small wards in the centre block, and the nurse's rooms placed between the large and small ward on each side, so as to command both. The large wards are 92 feet by 26 feet, and are 16 feet high, with opposite windows, five on each side, filling one-fourth of the wall space, and a large end window opening on to a balcony with a smaller one on each side of it. The number of beds in each is 21. At the further end of each long ward are two projections, or wings, one containing a lavatory and bath room, the other having a row of three water-closets with a lobby ventilated by opposite windows. These wards have fire-proof floors. At the entrance of each long ward is the nurse's room, with windows looking into ward on each side; opposite to it is the ward scullery, also having a window overlooking the ward. Two small wards on the north side of the corridor are intended for eye cases. There is another small ward which may be used as a recreation room, with a long window opening on to a balcony. A third corridor leads from the staircase to the floor over the kitchen department, in which is a small operating room, lighted by a skylight and two windows in the north wall, and on each side of it is a small ward with nurse's room. On the same corridor are the lift for raising coals from the basement, a closet with a shoot for dirty linen, a store closet, a scullery for the use of the operation wards and a watercloset. On the second floor, which is only over the centre block, are the sleeping rooms for nurses and servants. The roof of the long wards has an inner roof of deal, which was put in at the wish of Lord Onslow, who paid the cost of it, as well as giving the site for the building. The warming of the long wards is effected by three open fire-places in each ward, aided by air flues which are heated by the fire-places and discharge the warm air through openings on each side of the fires. The ventilation of these wards is chiefly dependent on the windows, but there are three large apertures in the ceiling over the gas burners which light the ward, leading into air shafts which are carried up by the side of the chimney flues, so that the heat thus communicated gives an ascensional force to the air within. The laundry is in a detached building in the rear, as far removed from the Hospital as the space would admit of. It consists of a ground floor, where the washing is performed with the assistance of the modern machines for washing and wringing, and of an upper storey where there is a drying-room and a mangle. A stable with one stall is built against the laundry. The dead house is also in the rear, and at an opposite corner of the enclosure. It contains a small receiving room and a post-mortem room, with the usual conveniences. Among the various gifts should be noticed that of Mr. G. Curling, of Cullum-street, City, who gave the drugs, all the dispensing appliances and fittings, in sufficient quantities for making a fair start. The architect is Mr. E. W. Lower, of Guildford.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The review of Trousseau's Lectures shall be inserted next week.

The remarks of Dr. Bushnan on Medical education and the functions of the Medical Council in the *Temple Bar* magazine for January are so good that we commend them heartily to our readers. We have had them for a long time "in the printer's hands" for publication, and we hope to make room for them next week.

G. Chaplin, 14, Poland-street, Oxford-street, manufactures the extension splints used at the Middlesex Hospital. The cost is from 8s. to 10s.

Bath.—Mr. Parkes will oblige us by sending an account of the means he employed in curing the 111 cases he mentions.

A Candidate.—The new regulations for the Fellowship of the College will not be published for a fortnight. Write to the Secretary.

Mr. Chattaway's successful case of operation for inguinal hernia performed with the aid of Dr. Richardson's anæsthetic spray, shall have early insertion.

Testimonial to Mr. Griffin.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—May I ask for a prominent place in your journal for the annexed circular, which has been forwarded to every known subscriber to the Griffin Testimonial Fund? I am, &c.

145, Bishopsgate Without, May 12. Robert Fowler, M.D.

"*Griffin Testimonial.*

"Dear Sir,—The design for the above being nearly completed, I am desirous to receive from every individual subscriber to the fund a written intimation, as to whether it would be consistent with his desire and convenience to attend a banquet in London (say about 3 p.m. in the day) whereat to publicly present the Testimonial to Mr. Griffin.

"I would also respectfully ask each subscriber to forward me, at his earliest convenience, his *carte de visite*, having his designation, professional title, and (if a Poor-law Medical officer) the name of his Union plainly written on the back.

"I have reason to believe that it would be most agreeable to Mr. Griffin to additionally receive an appropriate album containing the photographs of his friends and admirers.

"Prompt attention to the above will greatly oblige.—Yours faithfully,

"Robert Fowler, Treasurer and Hon. Sec.

"145, Bishopsgate-street Without, London, May, 1866."

Mr. Baker Brown on Epilepsy.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I believe I am only expressing the feeling of a vast majority of the Profession when I thank you for the review of Mr. Baker Brown's book in your number of the 5th instant. If the literature of which Dr. Marion Sims with his ethereal coitus, and Mr. Baker Brown with his declitorisation, have published typical specimens, grows fast, we may be sure that the admission of a Medical man to family confidence will be jealously guarded.

Putting moral considerations aside, I believe Mr. Brown's recommendations to be based on mistake. When the practices he alludes to prevail, the initial movement begins, not in the clitoris, but in the brain. History tells freely of the lust of eunuchs, who cannot be much subject to "peripheral irritation" when the emasculation has been, as it often is, complete. Mr. Brown's theory and practice would indicate excision of the tongue as the treatment in cases of voracious appetite.

Doubtless vicious habits exist among girls, and I fear to a greater extent than your reviewer seems to think; but they are to be conquered, when conquest is possible, by moral treatment, by watchfulness, by providing incessant occupation and amusement.

I can only say that I should be easily tempted to chastise any Medical man who ventured to catechise a daughter or a sister of mine on such a subject, and I venture to say that any jury would excite considerable "peripheral irritation" in the hero of the operation which has been gibbeted by Dr. West. I am, &c. M.D.

May 9.

Erratum.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Observing in the *Times* of Saturday that my name, in the pass list of the College of Surgeons, is put down as being of the London Hospital, I beg to say it should be of St. Mary's Hospital. Would you kindly have it so inserted in your impression of next Saturday? It would thus run:—Wall, Reginald Bligh, Bayswater, St. Mary's Hospital.

I am, &c.

4, Bishop's-road, Bayswater, May 14. R. B

Doctors' Cards.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—It is not uncommon for a Physician or Surgeon to give a card to a patient, in order to obtain for him admission to a Hospital, or to give a Hospital patient the address of some other doctor. I have done this many times. It has now and then dimly occurred to me that an improper use might be made of these cards, however innocently they might be given. A few days ago a Medical friend told me that a patient to whom he had given his card for some such purpose as I have just mentioned had used it in order to get a pair of boots. I was selfishly amused at this incident, but my friend—who, by the way, never shows a very great sense of the humorous—thought it no joke; nor was he sufficiently temperate to feel grateful to the rogue for being modestly satisfied with a pair of boots. I am quite sure the fellow might, with a little management and plausibility, have lived for weeks on the highly-respectable introduction the card of so reputable a householder as my esteemed friend is would give him. I had almost forgotten this little incident, which combines so much instruction and amusement, when this morning it was brought to my mind in a rather disagreeable way. I called on an "interesting case" of recovery from paralysis, which I had been permitted to see, with a Medical friend, in order to get a specimen of the patient's urine for examination. After thanking me very elaborately for what he was good enough to call my kindness to him during his illness, the man said that his sister, a lady's-maid in a family at the West-end, had given my card to her master, who was, he added significantly, a wealthy man. My card had been given to this patient merely to ensure the safe delivery of a bottle of urine. I then wished very heartily that, so far as the loss to myself would be in question, that he had used my card to get himself a pair of boots on my credit, instead of sending it out to spread my reputation. A thing like this is liable to cause much misunderstanding among Medical men. I dare say a good many would run the slight risk of misunderstanding rather than be obliged to pay for a pair of boots; I would rather lose the boots, for, from what I have seen of Medical squabbles, the disputes arise, not so much from mistakes, errors, and inadvertencies, as from the distortions and magnifyings that foolish and uncharitable people give to them. Nevertheless, as I am far from anxious to supply even the most interesting of my cases with boots on a large scale, and as I am more anxious still that my private card should not be carried by ladies'-maids with warm praises to their masters, I shall try to make less use of my cards; and I ask insertion of this letter as a warning to those who are in the habit of giving cards to patients. I am, &c.,

Cardiac Murmur.

The Effects of Public Executions.

It appears to me that the framers of the new bill touching capital punishments have made a cardinal mistake in that clause of the proposed measure which recommends the execution of criminals within the walls of a prison, only to be witnessed by a select number of persons, who are to certify to the hanging. I have smoked a pipe with criminals who have been hanged in front of the old debtors' door of Newgate—boozed with them—congratulated Calcraft on his appearance, good health, and the like, among them all, including divers and sundry other characters; and I know that the fear—or dread, which is the same thing, I suppose—of appearing on the scaffold, and seeing the great multitude of people, and hearing the hum of many voices, strikes more terror into the mind of the criminal than the horror of strangulation. I have seen poor creatures—I won't say cajoled, but spoken kindly to by Sheriffs of London—spoken to by the reverend ordinary of the gaol in brotherly love, and then shaking hands all round—why, the doomed man was never in all his life in such gentle company before, and he looked happy, delighted. Fact! But when the cold bleak wind whistled down by St. Sepulchre's, with her doleful bell striking on the ear, in a minute or two to be shut for ever, the dramatic illusion of the "press-room," the sheriffs in their gold chains and "clear starched" ruffles, all disappeared—the culprits shiver and weep. A public execution is dreaded by these persons; and I write from personal observation in the prison, and on the gallows. The Earl of Malmesbury seems to hold the same opinion; he has been ill for some time now, but he came down to the House the night of the second reading, and strongly opposed the clause of the Bill referred to. His Lordship considered that a public and infamous death was highly calculated to have a deterrent influence on any one inclined to heinous crimes; and you are right, my noble Lord. To my utter surprise, Samuel Wilberforce, Bishop of Oxford—as knowing a Bishop as ever wore lawn sleeves, expressed himself as believing that private executions were regarded with greater horror and dread by the criminal classes than public ones. I am sure that this is a great mistake, and I have had more experience in that line than most "honest men."—*London Correspondent of the Perthshire Journal.*

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·777 in. The atmospheric pressure increased to 30·11 in. on Monday, and declined to 29·43 in. on Saturday.
The general direction of the wind was S.W. and W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 42·5°.

APPOINTMENTS FOR THE WEEK.

May 19. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.
Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

21. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

22. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.
Ethnological Society of London, 4 p.m. Anniversary.
Royal Medical and Chirurgical Society, 8½ p.m. Mr. Gaskoin, "On Continued Syphilitic Inoculation."

23. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m. Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

24. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

25. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

GENERAL MEDICAL COUNCIL.

First Day, Thursday, May 17—*Continued.*

Dr. Alexander Wood rose to move, in pursuance of notice, "That when the sittings of the Council shall extend over a Saturday, the Council shall on that day assemble at 10 a.m. and adjourn at 1 p.m." He said the object of this proposal was sufficiently obvious. There was a certain portion of the Council who lived within a reasonable distance of London, and on the breaking up of their meeting on a Saturday could reach their homes and spend the evening with their families; but there were others who lived at a greater distance who were unable, in consequence of the lateness of the hour at which the Council rose to enjoy this privilege, and were obliged to remain in London over the Sunday. Seeing that the arrangement he proposed would let them free earlier in the day, and would not inconvenience those who resided in or near London, it would be a great boon to the members who lived at a distance from London. Under these circumstances, he did not think the Council would stand in the way of the proposal being carried out.

Dr. Parkes seconded the resolution.

Sir D. J. Corrigan, Bart., supported the motion.

Mr. Cæsar H. Hawkins said he intended to move an amendment, because he felt that Dr. Alexander Wood and the other gentlemen coming from the country could not be aware of the effect of the resolution. The Council were asked to sacrifice three of the most valuable hours of the whole twenty-four; and though he was sure the members living in London would gladly accommodate the country members as much as possible, still he did not think they were justified in giving up their Saturday sittings, for the proposition virtually amounted to that. They must consider that committees were appointed upon different questions, and those committees had to meet in the morning and prepare their reports for the general assembly, but they could not possibly do this and be prepared to meet the Council so early as 10 o'clock. He thought, therefore, he should be quite justified in proposing an amendment, which he trusted Dr. Alexander Wood would take as a kind of compliment, to show they were really desirous of meeting the views of those who came from the country. His amendment was, "That the hour of meeting of the Council shall be 1 p.m., and of adjournment 4 p.m., when the meetings shall take place on Saturdays."

Dr. Quain seconded this amendment.

Mr. Syme thought there were only three members who would be affected by the motion. He should be sorry to advocate any measure which would be inconvenient to any member of the Council, but considering that not a few—the majority—submitted to great inconvenience and pecuniary loss by coming to London, he did not think the proposition was unreasonable.

Dr. A. Smith called attention to the 3rd Section of the Standing Orders and Regulations, which provided that the Council should meet each day at 2 p.m. and sit till 6 p.m.

The President said he felt it his duty, as their President and as a defender of the public interests, to put before them what must necessarily be the consequences of this motion if it were carried. They ought to consider they were not a private club, or engaged in any private business for themselves, but they were really trustees for the Profession and the public, and were engaged on public business. They had representatives present of great interests, who had particular duties to perform; and therefore he did not think any alteration should be made in their mode of procedure or the time of meeting that would materially interfere with the performance of their public duties. He should not only oppose the resolution on personal grounds, but he thought it was his duty to oppose it in every way he possibly could—by argument, solicitation, and vote—and to beg that the Council would not accede to it. What would be the consequences of such a motion as this? In the first place, they had standing orders and regulations, which had been framed after very careful consideration, and which the Council hitherto had always been tenacious of adhering to. When it had sometimes happened that, through pressure of business, a member had been unable to bring forward a motion of which he had given notice, he had solicited the Council to have the meeting prolonged from 6 to 7 o'clock, or to meet at an earlier hour on the next day, but almost invariably the Council had determined they would not depart from the regular order of business. It was of the utmost importance that they should adhere to their stated hours of meeting and breaking up. It was of importance because it would ensure a more regular attendance of members of the Council. He could not at all agree with the observations which had fallen from Sir J. D. Corrigan, that the principal part of their work was confined to the two hours from 4 to 6. Any member of the Council must know that some of the most valuable and some of the hardest work—the work that was most highly appreciated—was done in Committee. It would often happen that the Council would not be able to go on with its business if the committees appointed had not met and brought forward their reports. In the business of that very day it had been proposed that a Committee should meet on the following day at 12 o'clock upon the subject of the Medical Amendment Act. It was impossible that Committee could get through their work in one day. If this measure were carried, the consequence would be that even the Committee which was to meet on the next day would not be able to meet again till Monday, and as the result of that this important question must be put on one side; for if the Council were to meet at 10 o'clock, how could the Committee prepare a report for their consideration? The result of the motion would be not merely to curtail the Council meeting one hour, but entirely to put aside all committees on a Saturday, as it was unreasonable to suppose a Committee would meet before 10 o'clock or after the Council had met. In the latter case it would be putting the cart before the horse, because the Committees were required to precede and not follow the Council. Therefore he begged them to seriously consider the question before they made up their mind to spend a half holiday on the Saturday. Moreover, it had been said that their present arrangement was a hardship, but he really did not think it could be regarded in that light. Whenever the Council had been assembled, if any member of it had had any pressing business, either private or public, there had never been any difficulty in his absenting himself on any particular day. If any one of them wished to go away in the course of the afternoon, he was entitled to ask permission of the President, and that permission was always freely granted. As their President, he felt bound to put these facts before them. Then he was reminded by the Registrar that if they were to have important business transacted on a Friday, and have that business carried on up to six o'clock, they could not get the Minutes printed and ready for the use of the Council by ten o'clock on the following morning. He protested against the motion, which would, in fact, so far from shortening, add one day to their session. A great deal had been said about the inconvenience to those who would like to go away from London on the Saturday; but when they had public business to transact they should not look to making half-holidays, and he did not think that was a reason which should be urged upon them to induce them to adopt this course. It had been said, and properly, that those members who came from a great distance had, no doubt, willingly accepted their appointment, and would accept the responsibilities. He had followed his predecessor's example in endeavouring to meet the wishes of the members who resided away from London. It was practically impossible those who resided in London could meet at the hour proposed. Out of the twenty-four hours there were three in which it was absolutely incumbent upon them to attend to practice in their own homes, and those three were from ten to one o'clock. Patients travelled by railway long journeys to consult their Professional Medical advisers in London between those hours, and therefore he did not think the convenience of the resident members ought to be disregarded, as it would be if the proposition were agreed to. He, therefore, recommended the Council to accept the compromise of Mr. Cæsar H. Hawkins to meet at one o'clock and separate at four, which would still enable the members who were anxious to go away to leave London earlier.

Dr. Alexander Wood, in reply, said he felt himself placed in an awkward position. He was sure that nothing but a perfect sense of duty would have compelled their President to take part in this discussion; at the same time, he (the President) must excuse him if he dealt with him the same as he should deal with any other member sitting round that table. He thought the latter part of the President's speech was an answer to the commencement. He first laid down most strictly that they were engaged in the performance of great

publie duties, with the discharge of which no private considerations should interfere—that they were present to discharge those duties to the Profession and the country to the best of their ability, and that none of them had a right to come there and plead his private convenience and interests as an argument for interfering with the arrangement which had been laid down to regulate their proceedings; and yet what appeared to him to be the most powerful part of the President's speech was when, in conclusion, he appealed to them not to drag away the metropolitan Practitioners from their private duties in order that they might attend to their public duties. Their being continually present at the Council had such an effect upon them as to render it practically impossible for them to discharge their labours properly towards the end of the sittings. Many of them suffered from the constant and incessant sedentary occupation, and from breathing an atmosphere they were not accustomed to, when their sessions extended over a Saturday; and he simply proposed that they should have an opportunity of leaving London until Monday, when they would meet again. He did not think that was too much to ask. If his proposal were carried out, it would be a great boon to those who lived within a short distance of London, such as the representatives of Oxford and Cambridge. It was, of course, a painful thing to interfere with the Professional duties of any class, but he wished to ask whether two hours in one day, or two at the most, during the session was too much for their friends in London to sacrifice for the convenience of those living at a distance? The House of Commons, for example, did not sit in perpetual session from Monday to Saturday. With reference to the compromise proposed, he did not think that was sufficient. He would rather go on with the existing system, for if they were to sit till four o'clock the boon was not worth their acceptanee. The President had told them that in case of imperative duties necessitating their absence they might go to him, and ask for leave of absence; but he, for one, should not like to ask him, and he did not think any member of the Council would do so. As regarded the committees not being able to meet, he thought there should be one day in which their labours might cease, inasmuch as the constant working from ten in the morning till six at night had a very bad effect upon them, and it would be very much to their advantage if they had one day in the week in which no committee sat.

The amendment was then put and carried by 11 to 6. It was accordingly put as a substantive motion and agreed to.

Dr. Storrar moved "That the motion which has been just carried be inserted in the standing orders."

The motion was seconded by Dr. Embleton and agreed to.

The next business was with respect to the reports from the Branch Councils for the visitation of examinations.

Dr. Paget said that with respect to these visitations of examinations, he should like to draw attention to the fact that since the last meeting of the General Council, reports had been made by certain licensing bodies in accordance with the resolution passed on April 12, 1865, which required that those licensing bodies which had not already done so, should be requested to furnish a statement of the dates of their examination—whether they were written, oral, or practical examinations, and the length of time the candidate was under examination in all these ways; and that the Registrar should transmit these reports to the members of the Council, in order that they might be taken into consideration at the next meeting of the several Branch Councils. Accordingly, these reports had been got in by the Registrar and printed; but they did not appear in any way upon the Minutes. He would ask the Council whether it would not be proper that these reports should be entered on the minutes, or put in some form, so that they could be cited?

The Registrar: We have them all printed except two, which came in since; all could be printed if desired.

Dr. Stokes wished to know whether the reports from the English, Irish, and Scottish Branch Bodies respecting the examinations would be read now or not?

Dr. Sharpey thought they had better be printed and circulated amongst the members.

The Registrar said the report from Scotland had already been printed for the use of the members.

The President: It will be desirable that the Registrar read the resolution of the General Council of last year; there seems to be some misunderstanding as to the special and general reports.

The Registrar read the resolution as follows:—"That each of the Branch Councils, or such of the members as may be deputed by their Councils, shall from time to time visit the examinations, preliminary as well as special, conducted by a qualified body in the respective divisions of the United Kingdom, and report the result of their observations to the General Council."

The President: Now, we have to request the several Branch Councils to communicate to this Council the result of their examination. Some one must move that the Branch Councils be asked to do this.

Dr. Alexander Wood called attention to a resolution (page 293 of 3rd volume of Minutes) of April 16, 1865, which required the Councils either to visit the examinations themselves or depute certain of the members to do it. But to whom was the Report to be made? He thought that if the Branch Councils paid a visit of examination they had to report to the General Council, and if the Branch Councils deputed certain members to do it, then these members stood in place of the Branch Councils, and these members must make the Report. He did not think that the Branch Councils had any power whatever to intervene between the members they deputed to visit and the General Council, but the Report must be made direct by those visitors.

The President: The Council must decide that question—that is not the interpretation put upon it by the Executive Committee of the English Branch Council.

Dr. Alexander Wood: I should like some of those who take this view to read an extract which in the slightest degree warrants such a view. The resolution is in page 293 of the 3rd volume of Minutes.

The Registrar: The original resolution is in page 165.

Dr. Sharpey said it was a small matter. It was competent for a Branch Council to originate any report respecting these general Reports. The object was to have them sent on. The Branch Councils could hand in any Reports of their own.

Dr. Alexander Wood did not suppose that this Council would object to receive any Report from any English Branch Council; but what they were insisting upon was, that they should receive direct the reports of those gentlemen deputed by the English Branch Councils to visit the examinations.

After one or two further observations,

The President said: We have a matter before us, which is, "That the Reports be entered on the Minutes which have been received from the licensing bodies, in accordance with the resolution of the General Council, passed on April 12, 1865, viz.: That those licensing bodies which have not already done so be requested to furnish a statement of the dates of their examinations and of the mode in which such examinations are conducted—whether by written, oral, or practical examination; and of the length of time a candidate is under examination in each or all of these ways; and that the Registrar transmit these Reports to the members of the Council, in order that they may be taken into consideration at the next meeting of the several Branch Councils." (Minutes General Council, vol. 3, p. 237).

This motion was then moved by Dr. A. Smith, seconded by Dr. Paget, and agreed to.

The President: I have this motion handed in by Dr. Alexander Wood, and seconded by Mr. Hargrave,—"That the reports from the Branch Councils, and from the members of those Branch Councils deputed by them for the visitation of examinations, be printed and circulated; and that the business Committee be instructed to set apart an early day for their consideration."

Dr. Acland said he resolved to make a remark upon one matter on which he thought a little misapprehension existed. When the English Council were called together it was a distinct understanding (at least, he understood it so), that these reports should not be made public, but they would be handed in to the Branch Councils, and the Branch Councils would hand them in as they thought fit. Whether that was a good or a bad plan was another question, but certainly that was the understanding; and one of the reasons assigned for it was that there was a great want of uniformity in the reports which were drawn up—some were elaborated and some short.

Dr. Alexander Wood said that at the last meeting a committee was appointed; that committee made a report and the report was agreed to; and if any one wanted the reports to be private, that was the proper time to suggest it. He did not think any Branch Councils had power to come to such an understanding upon the question. He did not think that any Branch Council could say there was anything to be kept back The General Council had issued definite instructions and they ought to be obeyed.

Dr. Storrar understood that the Branch Councils were to make reports to the General Council. The reports from the Branch Councils would be presented, and by all means let the Council have the original reports; but he entreated Dr. Wood not to bring anything in the way of a charge against the Branch Councils of a desire to omit anything they ought to do.

Dr. Alexander Wood assured Dr. Storrar that he did not, in any degree, mean to bring any charge.

The motion was put to the meeting and agreed to.

The Council then adjourned.

Second Day.—Friday, May 18.

The Council met at 2 o'clock.

The names of the members having been called, the minutes of proceedings at the meeting on the preceding day were read by the Registrar (Dr. Francis Hawkins) and confirmed.

The President said the first business on the programme was the consideration of the Report of the Committee on the subjects of General Education deferred from last session. (Minutes of General Council for April 15, 1865, vol. 3, pp. 285-6.) He thought it would be better if that Report were read first of all.

The Registrar read the Report, which was as follows:—"The Committee on the subjects of General Education having duly considered the subject remitted to them, resolve to recommend to the Council—That after the year 1867 the examinations in subjects of general education be left entirely to the National Educational Bodies recognised by the Medical Council—the Council confining its regulations on general education to publishing a list of the examinations which may from time to time be approved of by them; it being understood that no certificate which does not affirm the proficiency of the candidate in Latin, and also his knowledge of the elements of geometry, and of the elements of mechanics and hydrostatics, be accepted.—W. Stokes, Chairman."

Dr. Stokes suggested whether it would not be advisable to defer the consideration of this Report for a day or two. When the reports of the visitants of examinations were before them they would be in a better position to discuss it.

Dr. Andrew Wood said he rose to make a motion upon this subject, which was brought before them on the last day of the last meeting of the Council. The motion which had been made, by which this Committee was constituted, was for a most important purpose, that purpose being no other than the laying down of some curriculum of subjects, in which all candidates for diplomas or degrees should be examined before the commencement of Professional study. He must confess, and re-state what he stated last year, that he was greatly disappointed by the Report which was presented to them on a subject so important and extensive, and the more so because, as Dr. Stokes had said, the preliminary education of those that were to enter upon the Medical Profession was, if anything, of more consequence to be regulated by the action of this Council than even the Professional education.

Dr. Stokes rose to a point of order. He did not know there was any question before the Chair.

Dr. Andrew Wood said he was going to move that this Report be recommitted. He thought he was quite in order in doing that.

The President remarked that he thought it better the Report should be read to the Council before it was considered by them. It had been read; and having been read, he asked the Council if any member had any motion to make upon the subject.

Dr. Stokes said he thought it better the consideration of the Report should be postponed till the following day.

Dr. Andrew Wood rose and said he had a motion to make in reference to it; and, of course, that being the case, they must hear what he had to say.

Dr. Stokes said that if Dr. Andrew Wood moved the consideration of the Report be deferred, he should move an amendment upon it.

It was arranged that Dr. Stokes should move first in the matter, and he accordingly proposed, and Dr. Paget seconded —"That the Report of the Committee on General Education be considered on Saturday, May 19."

Dr. Andrew Wood said he would then move an amendment, which was to the effect that the Report of this Committee be recommitted to the Committee, with instructions to them to take under their consideration the very important document which had been prepared, as was stated yesterday by the Registrar in this Council, entitled "Preliminary Examinations in Arts," with replies, in which were given, in a most admirable form, all the different examinations which were now recognised by the General Medical Council. His reason for moving this was that he thought that they were entitled to a full report upon this most important question before discussing it. He held that in this matter they had done very much like putting the cart before the horse. They had first recognised the examinations of some eighteen different national bodies as preliminary examinations. They seemed to be taken at random, because, when he looked at the requirements of these different examinations, he found they differed very much both in their matter and in their quantity. What would have appeared to him a much more rational mode of proceeding would have been for them to have laid down what they considered the proper minimum curriculum of preliminary education, and then, looking at the different bodies presented to them and claiming admission. to have said, "All those that come up to that, or go beyond it, shall be recognised by this Council." He made bold to say, and he recollected his friend Dr. Paget saying the same thing last year, that there were some of the examinations which were recognised at this moment by the Medical Council as examinations by national educational bodies which came infinitely short of the requirements they considered necessary for their Profession—which came infinitely short also of those instituted by many of the licensing bodies who were held to be only capable in a secondary measure to superintend this important matter. When he looked at the examination required by the body which he had the honour to represent, he found that the examination was much fuller than the examinations conducted by these National Educational Bodies whose examinations had been so highly lauded and recommended to them to supersede their own examinations. He, for one, did not think they would be prepared, as a body, to part with the power of examining in preliminary education until the bodies that were recognised as National Educational Bodies had gone beyond their requirements, or at least come up to them. Now, it appeared to him it would be greatly for the edification and the good of the Council if this report should be sent back to the Committee, that the Committee should take into their consideration this most important and circumstantial document, and then that they should come forward with such a report as should enable the Council to discuss the several questions, one question being whether they should lay down any minimum curriculum of examination for Medical students; and the second question would be whether, having laid down that curriculum and seen exactly what bodies came up to it, they might not greatly amend the list they had at present. They might be met with the proposition that this matter should be left entirely to the National Educational Bodies. (Hear, hear.) He was quite prepared to leave it to those National Educational Bodies when they should have so improved that they came up to the full requirements of that Council for the Medical Profession, but not till then; and therefore he trusted the Council would agree to the amendment he now submitted, that the matter be recommitted, and that the document entitled "Preliminary Examinations in Arts recognised by the General Medical Council" be placed before them, and then the Committee would be in a position to give them a full and circumstantial report upon this matter, and then they would be able to discuss, and he hoped to settle, this important question. They had been going on for some years, and they had never yet laid down this curriculum of Professional study; but it was quite time they should do so, and if they were to begin to do it they should begin at the beginning—the preliminary educational examination of those who were to enter into the Profession. He then moved an amendment in the following terms:—"That the report of the Committee on General Education be recommitted, and that the Committee be instructed to take into consideration and report upon the examinations in general education at present conducted by the various National Educational and other Bodies recognised by the General Medical Council"

Dr. Parkes seconded the amendment.

Dr. Storrar said he hardly thought this was an amendment upon Dr. Stokes's motion. He could support both, and he thought the Council might support them both with very great advantage. Dr. Stokes had contemplated what he was not previously aware of,—that certain of the reports upon education would contain information as to the perfect or imperfect manner in which the present system of Arts examinations were conducted. If so, then such reports would be

most proper to come under the consideration of the preliminary or Arts Education Committee. He looked with considerable favour upon Dr. Andrew Wood's amendment. He thought the time had come when this Council might very properly lay down more precise expressions of opinion as to the importance of subjects which should constitute the Arts curriculum of men entering the Medical Profession. In the year 1859 Dr. Andrew Wood and himself held very strong views upon this subject. They felt it was highly desirable they should mark down with some degree of precision the various subjects, whether compulsory or optional, on which the preliminary attainments of students entering the Profession should be tested. A very strong pressure was put upon them by Dr. Acland, who at that time was very much engaged, and he must say meritoriously engaged, in presenting the scheme which had been adopted by the Universities of Oxford and Cambridge for the purpose of testing the general education of the Profession. The line taken up by himself and friends was this,—"Do not let us do anything which will indicate an interference with the general education of young men in the country; let us fairly accept the tests that have been prescribed by the existing bodies. The Universities will not be content with this; let us not prescribe any special or particular subject, but let us be satisfied to receive from young men desiring to enter our Profession a certificate of having passed the examination of one of those public bodies." That was the view they propounded at that time. He felt that now, in 1866, after a lapse of seven years, they might fairly advance a step further. He did not think that all the arrangements for preliminary examinations had been carried out with the vigour or rigour which he thought the importance of the Medical Profession required; at the same time, it must be admitted that upon the whole they had made some progress, and that the importance of preliminary education was now largely acknowledged, and acknowledged, in fact, to that extent that he believed the prevailing opinion was that if they were confined to the pointing out of one single blot, to the exclusion of all others, the effacing of which blot would be most important for the improvement of Medical education, that blot would be the insufficiency of the examinations. Now, entertaining these views very strongly, he would invite the members of the Council to join him in supporting Dr. Andrew Wood's amendment, which simply amounted to this, —that the time had arrived, after a lapse of seven years, when they might fairly take the whole machinery into consideration, and judge whether they had not arrived at that point when they might come to some decision upon the subject.

Dr. Alexander Wood thought it was incorrect to suppose the Committee existed at the present time.

The President said he was quite aware of that, and he had communicated his opinion to Dr. Stokes, that at the present moment no Committee existed. If Dr. Andrew Wood's amendment were adopted, they would have to appoint a committee.

Dr. Paget said his only objection to Dr. Andrew Wood's amendment was, that it seemed likely to defer the full consideration of this matter to a late day in the session, and if Dr. Andrew Wood had named an early day for the full discussion of it, he should gladly have voted for his proposal; but, as last year the matter was referred over to the following year because it was before them late in the session, it might happen again this year, and that, he thought, should not be the case. Dr. Andrew Wood had mentioned that it was brought forward on the last day of the last session. That was not quite correct; it was the last day but two; but on that day even they were told it was too late to consider so important a question. Now, if this were to be referred to a committee, and the committee did not make their report very early indeed, they might be told again that as the day for its consideration might be likely to be the last but two, it would be too late this session. All he wished was an early day for its discussion; and if an early day for the consideration of it were fixed, he should certainly vote for the appointment of a committee. With regard to the report of last year, he did not think it was justly disparaged at all. The Committee consisted of Dr. Stokes (the Chairman), Mr. Arnott, Dr. Acland, Dr. Storrar, Dr. Thomson, Dr. Apjohn, and Dr. Quain; and that Committee, consisting of persons very well qualified to consider this matter, was unanimous in its report, and it was unanimous for one reason, because the members of it wished to make a moderate report—a report so moderate in its requirements that it could be carried into effect without any violent opposition. It was substantially in two parts; and Dr. Stokes moved the adoption of the first part in order that it might be considered independently, and the second part was not discussed generally by the Council; but Dr. Acland made some remarks disparaging the latter part of the report, which was this: "It being understood that any certificate which testified to affirm the proficiency of the candidate in Latin, and also his knowledge of the elements of geometry, and the elements of mechanics and hydrostatics, be accepted;" subjects without which the examination could not be considered satisfactory. He remembered that when Dr. Andrew Wood disparaged that, he did make a remark which he (Dr. Wood) had referred to, though not quite correctly. What he said on that occasion was, that there was not sufficient ground for disparaging this part of the report; because one at least of the examinations which the Council already recognised, was inferior in its requirements to what the Committee recommended in their report. He did not use any words so eloquent as "infinitely short." He said it fell short of the requirements; nor did he use any such expression as that it fell infinitely short of what was required by the preliminary examinations for conducting preliminary education by the licensing body; and for a good reason he did not make that remark, because he didn't think—and he believed the Council generally did not know—what the examinations of this licensing body were. (Hear, hear.) If he had known, he might have added one or two to the list of examinations, which had fallen actually short of what was represented by the Committee, and which was disparaged by Dr. Andrew Wood.

Dr. Stokes expressed his willingness to accept the amendment, provided an early day was appointed for the discussion of the subject.

Dr. Andrew Wood said that would depend upon the Committee. If they would be ready by Monday, he should be willing to consider the report then. Would that do?

Dr. Stokes then withdrew his motion, and the proposition of Dr. Andrew Wood stood as the original motion.

Dr. Acland wished to say a few words in reference to what fell from Dr. Storrar. He referred to the history of this matter. It was hardly worth while to go into the history of it, but at the same time there were several members of the Council who did not join in the discussion which took place, extending over five days, and ending in a unanimous vote, with one exception, of the Council, to refer the educational examinations to the National Educational bodies, that being the real fact of the case. He would venture to draw the attention of the Council to that, because he was sure Dr. Storrar would agree with him that not one word said by him (Dr. Acland) at that elaborate discussion, advocated in any way the interest of the Universities or middle class or local examinations, or any other sort. He, amongst others, said that the wisest thing to do at the commencement of the institution of this body was to take the verdict of those gentlemen, but what was it he did afterwards? If they would refer to page 99 of the Minutes, vol. iii., May 7, 1864, they would find, he then ventured to say, that the time had come when the principle of *quis custodiet custodes* might be very properly inquired into; and he then moved that a committee of this Council be appointed to draw up a report to the Council in the ensuing year, giving them ample time for their work, as to what were the subjects of examinations which should be required by all students prior to their prescribed course of Professional study, because they would see it might be a very proper thing that they should form their own judgment upon these systems, and see whether they agreed in their judgment or not. Now, he believed, though he was not quite sure, that Dr. Andrew Wood was in the majority which drew up that recommendation. He (Dr. Acland) did not think it could have been more completely done, as he then proposed a committee be appointed to draw up a report, seriously and considerately, during the interval between the two Councils, but this was then considered to be an obstructive movement, whereas it turned out it was a movement just the reverse, because if it had been carried out in the last year they would have had an elaborate report—eight months being allowed to the Committee to draw it up in, and they would not only have had this list, but a full discussion of the whole question of the Professional course of study. Most of them had given their attention to this matter. There was a great difference in the opinions which persons held as to what subjects would be required in a preliminary Arts examination, and what should be referred to the second, and so forth. He therefore, having proposed this very matter two years ago, was quite ready to join heartily in it now. It was of the utmost consequence that this should be done without delay, but he had great

doubts whether a report such as would be satisfactory to the Council could really be drawn up in two or three days during the session. It would be exceedingly facilitated by the documents presented by the Registrar. He should support Dr. Andrew Wood's proposal, on the understanding that it came forward at once, and that all could be done during the two or three days should be done. As to the extreme value of the question, he entertained no more doubt now than he did two years ago.

Mr. Rumsey said he should be sorry to appear an obstructive in any way on this occasion, although some of the considerations thrown out by Dr. Acland were of such great importance that he could not avoid pressing them upon the Council again. He did not see how such an important question as the determination of the subjects for the curriculum for pre-Professional education could possibly be settled by a committee appointed in the continuance of a session, and acting and reporting during that session. It seemed to him to be a work of such gravity, involving so many questions of deep interest in regard to the training of the human mind in those branches of education which were required to enable persons to belong to this learned Profession, that he hoped before they proceeded to the appointment of a committee, which was to report in a day or two, the Council would fairly consider whether any such report was likely to be worth their receiving. He would not underrate the great power of mind possessed by the majority of the members of the Council, but he conceived a subject so vast would be sufficient to appal men to have committed to them to decide and report upon in a few days. He confessed his entire disbelief in the possibility of framing a report worthy of their reception within that period, and therefore he asked that before any such report be presented a long and full examination of this question be granted, that a comparison of the various subjects to be included, and the amount of qualification on each, might be fairly considered.

The President reminded Mr. Rumsey that they were considering the Report at the present moment. The Report from the Committee of last year was to be re-committed.

Mr. Rumsey wished to say that he did not believe any report returned by this Council within the present session could be such as they would act upon. He contended that this ought to be the work of a small body of thoroughly qualified men acting within the interval between the sessions, and on that ground he supported the principle laid down by Dr. Acland in 1864, though he would not make any motion to that effect at the present time.

Dr. Alexander Wood was astonished, he said, at this time of day to hear such remarks as those just expressed. There were three courses open to the Council in reference to the matter before them. The first was that the Council itself should take up the subject and deal with it; the second, that the Council should appoint a committee to deal with it; and the third, that the Council should take up the Report of the committee already existing, and deal with that. The natural course of proceeding would be to take up the Report of the Committee previously appointed. Dr. Andrew Wood very properly remonstrated with them against pursuing that course, because the Report itself was of so meagre a character, intimating that from the information that had since come into their possession it was impossible for them to do full justice to the subject by taking up that Report; and accordingly he proposed that the said Committee, in whom the Council had perfect confidence, with their increased means of information, should reconsider the question, and bring before them an amended and full report; and he indicated very generally the nature of the report that might be expected. If that impression should prevail universally in the Council, what would be the result of it? This was the twelfth meeting of the General Council, and they had never yet faced the subject of what preliminary education should be; and there were many gentlemen sitting at that table who would come forward now and ask them again to postpone the consideration of it. And why, forsooth? That it might be considered by a Committee during the interval between the sessions. Had they any faith in a Committee doing that? Did they not know what the lamentable proceedings of such Committees generally were? Having plenty of time before them, postponement after postponement took place, till the Council meeting was close at hand, and then there was perhaps a hurried meeting and a report, which very likely would not be so well digested as one considered by a Committee during the sitting of the Council. This was the first time he had heard that the Committee, which had been constantly in the habit of preparing very important business for the Council, had not done their duty. It was the first time he had heard the Committee told they could not digest the business sufficiently for discussion in this Council. They had been sitting for little purpose during the previous sessions of the Council if those Committees which they had from time to time been in the habit of appointing had not properly considered and discussed the business. The fact was, the real business was done in the Committees. It was in the Committees that the subjects were thoroughly sifted or digested for discussion in the Council, and there was no reason to doubt these Committees. There was no special difficulty about the subject of preliminary education which would require them to deal with it in a different manner from that in which they dealt with any one of the grave questions that had come before them since the Council commenced its sessions. He thought it was a subject which they had all been considering for years; and if they had not been considering it for years they had no right to sit at that table. (Hear, hear.) He held there was not a single man upon the Council who was not disposed to bring his mind to bear upon this subject in Committee, and therefore he did not think it would take long to bring up a first report—a report which would be subject to revision at every meeting of the Council. For this reason, he opposed the obstructive proceeding which would stave this matter off till another session, and gave his cordial support to the proposition.

Mr. Cæsar Hawkins said the Report before them contained two points, one of which was very important, and would, he thought, require a great deal more consideration than could be given to it in the short time proposed. The second point, as to what should be the proper subject for the preliminary examination, seemed more easy. That was one thing for this Council to determine, but the other was much more important. If the Council would allow him, he would draw their attention to one subject which he thought had not received sufficient attention from them—namely, the difficulty of determining what body should be recognised by this Council for the preliminary examination. It appeared to him they had not sufficiently called to their assistance the different licensing bodies, as they might be termed. Long before this Council had formed any list of examinations, the body he belonged to had drawn up a resolution, that, after a certain date, every candidate should go through a preliminary examination. They said that in the latter part of 1858, and the moment this Council was appointed they felt this would be one of the first subjects they would have to take up, and the body to which he belonged immediately formed that resolution. Of course, as soon as they did that, it was necessary for them to communicate with all those schools and bodies throughout the world with which they were in communication, and inquire of them what means they had for instituting examinations to satisfy the College of Surgeons of England that they were sufficient for this purpose. And when the recommendation of this Council was first sent round, this was the answer the body he belonged to sent, that they had agreed to receive, as sufficient evidence of the preliminary examinations of those bodies, testimonials of all the educational bodies enumerated in the third recommendation of the Council; but they had also recognised testimonials from several bodies not enumerated in the recommendations, and this list was sent to this Council, and they also said that they had some other applications, chiefly from the colonies, which were under the consideration of the College. Their recognitions included twelve additional bodies, which were not put down in the list of this Council; but this was no want of respect to the Council, because it was begun before they sent out their recommendations, and they were willing to unite in assisting this Council in forming proper rules that might be recognised. The College of Physicians of England had done something of the same kind. He found on the Minutes that on one occasion three educational bodies were sent to this Council as having been recognised by the College of Physicians, but he could not find that any attention had ever been paid to that subject, although he had searched the Minutes for that purpose. He thought, therefore, that when the Committee were endeavouring to settle the subject they should form the minimum of education, they should also take into consideration the examinations of the bodies which were in their own list, and not put down in the *resumé* drawn up by the Registrar; and they should inquire into the examinations recognised by the different licensing bodies to see if these examinations were equivalent to what they required by their own recommendations. It was of importance to get uniformity between the

list of this Council and the lists of the different educational bodies, that they might all agree not only as to the subjects of examination, but also as to the bodies that should be recognised. He thought the Committee should take that into consideration, and inquire of the different licensing bodies what educational bodies had been recognised by them.

Mr. Rumsey rose to protest against two accusations that had been made against him. The first was to the effect that he wished to obstruct the business of the Council. He believed the suggestions he made were ——

The President said he could not permit Mr. Rumsey to argue the point. He might explain.

Mr. Rumsey then remarked that the second point was that the Committee would not meet to discuss the subject until just before the Council met. That was a matter of opinion, and he had a precedent for proposing such a course of action in the Pharmacopœia Committee, which sat during the intervals of the session.

Dr. Parkes thought the Report should be referred back to a committee, as all the bodies enumerated on page 297 were not alluded to in this paper on the Preliminary Examinations in Arts. If the Committee had time to do so, he thought it would be desirable to have before them the examinations of other bodies not enumerated on page 297, to see if the list could not be extended. With regard to the minimum which had been laid down by the Committee, he thought it virtually excluded several of the bodies referred to in the list, and therefore it would be necessary for the Committee seriously to consider whether they could enforce that minimum, or what should be the exact standard laid down. The Royal College of Surgeons of Edinburgh demanded a really good preliminary examination in general education, although under the head of "compulsory," there were only three subjects, but two of the "optional" subjects were really compulsory.

Sir D. J. Corrigan said that before the resolution was put he wished to move an amendment. He had been acting on the Committee of Education for many years, and he thought that the Council, after having passed twelve sittings, had come back to the point from which they started, without the slightest prospect, in his mind, of coming to a conclusion. What he was about to propose might perhaps be embodied in the resolution, or, if that were rejected, he should propose it as a distinct amendment. In the original report by Dr. Stokes there was one element of discord which must come out and occupy them for days—namely, that the different licensing bodies in the Profession should altogether give up their right to preliminary examinations. Therefore, in recommitting the Report, there would be an element of discord which would again, in his mind, revive a discussion which would not terminate at the end of this Session. They had been for eight years upon this subject; and he cordially agreed with Dr. Andrew Wood that the time had now come when they should lay down what they conceived to be the minimum of education. There was not a member of the Council who would come there on Monday, Tuesday, or Wednesday with one atom of knowledge more than he possessed at the present moment. He had no objection to the subject being referred back to a committee; but he wished there should be an expression of opinion from the Council as to what they expected that committee to recommend. Dr. Alexander Wood had said that the Committees laboured. He (Sir D. J. Corrigan) knew that as well as most men on the Board. But how did they get on after they had laboured for three years? They recommended certificates of examination to be received as a guarantee of the proficiency of a student desirous of entering their Profession without that examination including Latin and Greek. Were they to go back to that? He said plainly, the time had come for giving an expression of opinion on the part of this Council as to what ought to be the minimum; and with that view he begged to propose an amendment, or, if Dr. Andrew Wood coincided, it could be embodied in his resolution, that this Report on the subject of preliminary examination be referred to a committee. His amendment was this:—"That, after the year 1867, no certificate of examination in subjects of general education be recognised which does not include Latin and Greek, also a knowledge of the elements of geometry, and of the elements of mechanics and hydrostatics; and that a list of the examining national educational bodies authorised to conduct such examinations, and recognised by the General Medical Council, be published from year to year." Now, he should take the sense of the General Medical Council as to this amendment. The only thing he had put in, in addition to the recommendation of Dr. Stokes, was simply Greek; and he must say that, although he had been beaten two or three times on this point, he thought a student who came into their Profession without a knowledge of Greek was utterly incompetent. Were they to continue to get such answers from students as they got now? He remembered on one occasion a candidate being asked what physiology was; and after some hesitation he said he thought it was a fungus. (Laughter.) Could any student take up an English book on almost any subject, or go into botany and zoology, without a knowledge of Greek? And yet it stood in the face of this Council that they did not think it necessary for students to know Greek.

Dr. Leet seconded the amendment.

Dr. Andrew Wood said he had no objection to incorporate Sir D. J. Corrigan's proposal with his resolution. It was hardly an amendment to the motion.

Dr. Alexander Wood said it was a sort of ὕστερου πρότερον, if he might quote Greek on this occasion, after the remarks of Sir D. J. Corrigan.

Dr. Paget thought the essence of what Sir D. J. Corrigan proposed was that Greek should be one of the subjects, and he sincerely hoped the time would come when it would be possible for the Council to insist upon that; and if he were a member of the Council at that time he would heartily support it. But he believed that at the present time it was not possible to insist upon a knowledge of Greek before entering upon the Medical Profession. To give Sir J. D. Corrigan some information on this point, he found in the Report of the Board of Examiners on the examinations of candidates for Medical commissions in the Royal Navy in 1860, page 160, paragraph 6, the examiners said, "We regret to have to report that in a very large number of cases indeed the candidates displayed a lamentable ignorance of Latin." Therefore he thought at the present time what the Council had to insist upon was, first, a knowledge of Latin, which was generally regarded as a stepping-stone to Greek. And he might just call attention to the fact that amongst the candidates at the examination to which he had referred there was one who had the double qualification of Licentiate of the Royal College of Surgeons of Ireland, and Licentiate of the Apothecaries' Hall, Dublin, and that gentleman was utterly ignorant of Latin grammar; so that he thought it would be better for them to insist upon Latin before Greek, though he quite agreed that Greek was a very desirable thing for students to be acquainted with.

Dr. Alexander Wood thought a committee should be appointed to quietly and calmly consider the subject, and report to the Council three or four days hence. The first question for them to consider was not whether they were to insist upon Greek, but whether the matter was to be digested by a committee and then brought before the Council. If he voted against Sir D. J. Corrigan's amendment, he protested against being held to be averse to teaching Greek.

Dr. Apjohn supported the amendment.

Dr. Storrar wished before the resolution was put to guard himself against its being supposed that if he voted against the amendment he was putting his veto upon Greek. For the last fifteen months he had been engaged on a commission of inquiry into the state of the public schools in this country, and there was one conclusion he had arrived at, which was this, that the amount of bad education in the country was infinitely greater than he had the least conception of when he ventured to hold up his hand in favour of certain subjects of general education. And from that he concluded that if they, in 1867, required that which was utterly impossible to get, they would not only not get Greek, but they would not get other things. What they wanted to institute was sound education. (Hear, hear.) If it were really necessary, let them begin with English alone, and then proceed from that to Latin. English and Latin, he thought, they could get, and also the elements of mathematics. It was a question in his mind whether, considering the great importance of French to Professional men, that might not be more important than Greek, particularly when they came to consider that at the present time they had a chance of getting French when they had no chance of getting Greek. Therefore, he earnestly desired that Sir D. J. Corrigan would not press his view now, but leave the subject to the consideration of the Committee; and then, should their report be insufficient to satisfy Sir D. Corrigan, he might bring forward his proposition. The Committee might report that, after a certain date, they found it expedient to admit Greek; and if it did not contain that expression, it would then be time for Sir D. J. Corrigan to bring forward his motion.

Mr. Rumsey also suggested that Sir D. J. Corrigan should defer his motion till the Committee made their report.

Sir D. J. Corrigan said he had no objection to withdraw his amendment, with the understanding that he could bring it forward again if he thought proper after the Committee had brought up their report.

The amendment was accordingly withdrawn, and the original motion was put and agreed to.

The following committee was then appointed:—Dr. Stokes (chairman), Mr. Hawkins, Dr. Acland, Dr. Paget, Dr. Storrar, Dr. Fleming, Dr. Thompson, Dr. Apjohn, Sir D. J. Corrigan, Dr. Quain, and Dr. Parkes.

Mr. Cæsar Hawkins moved, "That it be an instruction to the Committee to extend their inquiry to the various examinations which are recognised in the several licensing bodies as sufficient for the examination of Medical students, and which are not included in the list of the Medical Council."

Dr. Stokes opposed this motion. All that the Council had to do was to express an opinion as to what ought to be the minimum of education required. They had nothing to do with the character of any body whatever. If they adopted the motion, it would be quite impossible to get through the work of the session.

Sir D. J. Corrigan concurred in what Dr. Stokes had said, that if this instruction were given to the Committee it would be impossible to get through the work of the session. There was recognised by the Royal College of Surgeons in London the preliminary examination of the College in Ireland. As a member of the Branch Council in Ireland, he had for the last three months been endeavouring to find out what that preliminary examination was, but had never been able to do so nor to tell what the subjects were; and yet that examination was recognised by the College of Surgeons of England, although it was not one of the bodies recognised by the General Medical Council. He thought this ought to be stopped, and that candidates for examination ought not to receive a certificate of efficiency unless the examination was recognised by the General Medical Council. They knew nothing about the examination, nor had they been able to obtain any information. If that information were supplied to them they would be most happy to receive it, but he thought that the motion now before the meeting would stop the whole proceedings.

Mr. Hawkins said that the College of Belfast was established in 1861, before the list was established by the Medical Council. All the Universities, such as at Glasgow, St. Andrews, Aberdeen, and the various Canadian and Indian Universities satisfied the College of Surgeons that their examinations were equal to those of the minimum of the Council.

The motion made by Mr. C. Hawkins was not seconded, and therefore was not put; and Sir D. J. Corrigan's amendment having been withdrawn, the original motion was put to the vote and carried.

The Registrar next stated that, in compliance with a resolution of the Council, he had addressed a communication to the Director-General of the Army Medical Department, thanking him for the returns with which he had favoured them of the results of the examinations held in 1864 of candidates for Medical commissions in the army, accompanied by a copy of the regulations for the admission of candidates, and a list of the questions proposed by the examiners. At the same time he applied for similar returns with regard to the Indian service, and requested that in future return columns might be attached similar to those in the returns relative to the examination of candidates for Medical commissions in the Royal Navy, so as to specify in similar detail the number of candidates, and the heads under which the candidates failed to answer. To that communication he had received the following reply:—

"Army Medical Department, November 21, 1865.

"Sir,—In reply to your letter of the 20th April last, requesting to be furnished with a return, on the form which you enclosed, showing the different licenses of the candidates for commissions in the Army Medical Department, and the subjects in which the unsuccessful ones were deficient, I am directed by the Secretary of State for War to inform you, for the information of the Council, that, as a return made on the form required, would have the effect of allowing the unsuccessful candidates to be identified, and thereby bringing upon them individually a stigma which they never supposed, on presenting themselves for examination, they would be called upon to incur, the request contained in the last paragraph of your letter cannot be complied with.

"I am to add that the usual returns hitherto furnished will be continued.

"I have the honour to be, Sir, your obedient servant,

"J. B. Gibson, Director-General."

Sir D. J. Corrigan thought the returns, as they were furnished, were worthless, inasmuch as they did not give the necessary information. He would not like to do anything that would be at all disrespectful to the Director-General, but for all their purposes the returns were quite insufficient. No information was given as to the licensing bodies, or the bodies who rejected the students.

Dr. Parkes moved—"That the communications from the Director-General of the Army Medical Department be entered on the Minutes, and that the Registrar be directed to apply to the Director-General for the returns promised in these letters." It was not for him to defend the Secretary of State or the Director-General for having decided that it would be undesirable to furnish the information which had been applied for, but he would observe that the Director-General had furnished the returns precisely as they were originally asked for, and as they were then considered to be satisfactory by Dr. Apjohn, he thought they might still be taken to be so.

Dr. A. Smith said the additions which the Navy had made to their returns had never been anticipated by the Council. The Director-General of the Army Department had not departed from the original form suggested by Dr. Apjohn, and it appeared that the Navy Board were wrong in giving that general information.

Dr. Andrew Wood seconded the motion for placing the correspondence on the Minutes. He thought it very desirable indeed that the public should know precisely what they had applied for to the Director-General of the Army Medical Department, and also the reason why those returns were not furnished. The Council had done all they could in getting information, and he thought that the communication ought to appear upon the Minutes, for the sake of giving publicity to what the Council wished. He also hoped that application would at once be made to the Director-General, so that the information might be presented to them and placed upon the Minutes immediately.

The motion was carried unanimously.

The Registrar then read a communication from the Director-General of the Medical Department of the Navy containing information as to the candidates who had presented themselves during 1865 for examination. The number of candidates was twenty-one, of whom twelve were successful, and of these, five passed good, two moderately good, and five indifferent examinations. The majority of those rejected were utterly ignorant of the Latin language, two failed altogether in anatomy and Surgery, and two more were so ignorant of Materia Medica that it would have been dangerous to have passed them as qualified. The inspectors regretted that so much ignorance of Latin should have been displayed by a large proportion of candidates, and expressed their sorrow that many of the manuscripts sent in had given evidence of such an ignorance of orthography and of the most ordinary rules of English grammar and composition as could hardly have been credited in members of a liberal Profession.

Dr. Paget moved, Dr. Stokes seconded, the following resolution, which was carried unanimously:—"That the thanks of the Council be returned to the Director-General of the Medical Department of the Navy, for his valuable communication relative to the examinations of candidates for Medical commissions in the Navy."

The Registrar read a communication from the Under-Secretary of State for War, relating to a resolution passed by the Medical Council, to the effect that they were of opinion that initials indicating the several Medical qualifications which Army Surgeons possessed should be inserted after their names, without distinction or preference to one degree or licence over another, each Surgeon, when he possessed more than one Medical qualification, having only one appended to his name. The Secretary of State wished to know the opinion of the Council as to the particular initials which should be used to designate the several Medical qualifications described in the table appended to the Medical Act, and for which abbreviations were therein laid down.

On the motion of Sir D. J. Corrigan, seconded by Dr. Sharpey, the following resolution was, after a few remarks, unanimously carried:—"That the communication from the Under-Secretary of State for War be entered on the minutes, and that it be referred for consideration to a Committee, con-

sisting of the following :—Sir D. J. Corrigan (Chairman), Dr. Alexander Wood, and Dr. Embleton."

A letter addressed to the Registrar by Dr. Mackesy, President of the Irish Medical Association, was next read, and also a resolution adopted at a Medical meeting held at the Limerick Junction, stating that in the opinion of the Association the Medical Council had not properly performed all its functions with reference to preliminary education.

Dr. Paget proposed and Dr. Urjohn seconded, the following resolution :—"That the letter from Dr. Mackesy, and the resolution of the meeting of Medical Practitioners at Limerick Junction, be entered on the Minutes and referred to the Committee on General Education."

Mr. Syme objected to the letter being entered on the Minutes.

Dr. Alexander Wood said that if the gentleman who wrote the letter and the gentleman who sent the resolution were respectable members of the Profession, they could not refuse to enter the letter and the resolution on their Minutes, and he thought the least they could do would be to refer it to the Committee.

Mr. Rumsey thought that Dr. Mackesy's communication was entitled to their most respectful attention. He was the President of the Royal College of Surgeons of Ireland, and was a man who was looked up to by that learned body as their President; therefore he had every reason to be treated with all due respect by the Council. The resolution accompanying the letter had been passed after very careful deliberation by the body assembled, who considered that the Council had not fulfilled the functions which it was intended to fulfil. They did not take the matter up in an impertinent spirit, but in a spirit of free inquiry; and he therefore hoped that every consideration would be bestowed upon the memorial. He thought the matter did not touch the question of preliminary education, and he thought, therefore, that it should be referred to the Committee on Medical Education.

Dr. Sharpey suggested that it should be stated on the Minutes that a letter was received and read, and that then the resolution should be added.

Sir D. J. Corrigan said the resolution gave only a one-sided view of the question, and if they did it in that way they would only be adopting the resolution of the Irish Association; and by the putting it on the Minutes without Dr. Mackesy's letter, they would be pleading guilty to the charges brought against them. The quotation in Dr. Mackesy's letter was from a letter of his (Sir D. J. Corrigan's) which he wrote in defence of the Council. A charge was brought against the Council, which was altogether unfounded. Dr. Mackesy's letter explained how this arose; and having found his error, and that the Council had not the power to do what the meeting thought they had, he now suggested that they should go to Parliament to get that power. A man who had acted in that way, and who had apologised for having led the Association into error, was entitled to their consideration and attention, and he therefore suggested that both the memorial and the letter should be inserted in the Minutes.

Dr. Andrew Wood said he thought that the Irish Medical Association had acted hardly respectfully to the Council in sending such a resolution. He recollected that the Medical Council was soundly rated and abused for their interpretation of the Medical Act. He had read the address which Dr. Mackesy delivered to the Association, and, as he thought they were entitled to receive the benefit of the advice which a man of high standing and position in the sister island gave them, he would read a brief passage from it. Dr. Mackesy said :—"The subject first in order, and most interesting to the Profession generally of the United Kingdom, has reference to the working of the Medical Act and the Medical Council, and it is with much reluctance and with deep regret I have to say that the Medical Profession have been sadly disappointed in the practical results of the enactments. I think I give expression to the general feeling of the Profession when I attribute our disappointment to the want of unanimity, action, and firmness on the part of the Medical Council in not having as yet, after the lapse of seven years, made due provision for the preliminary education of students intended for the Medical Profession. If Medicine is to maintain its claim to be ranked as one of the learned professions, and its professors are to hold that social status and position they should do, it is all important that young men, before they enter upon their Professional studies, should be well acquainted with general literature and well grounded in the classics. We have reason to complain, also, that the Council has not drawn up and enforced on the different Medical bodies empowered under their respective charters to examine and to grant licences and diplomas in Medicine and Surgery a uniform system of examination for the United Kingdom, that would accurately test the acquirements, the scientific and practical knowledge of the candidates, and thus prevent uneducated and incompetent persons from being legally qualified to practise Medicine and Surgery. That uneducated and incompetent persons have, unfortunately for the public and the Profession, obtained such qualifications, from the want of a stringent examination, has been abundantly proved by the examination of candidates for commissions in the Medical Department of the Army. All candidates must have a diploma in Medicine and a diploma in Surgery before being admitted to examination, and yet one-third of those competing, who were legally qualified in Medicine and Surgery, failed to obtain the minimum number of marks required in the preliminary examination to qualify them for admission into the service. The examination of candidates for the Medical Department of the Navy was still more discreditable, for some of those competing, also holding legal qualifications in Medicine and Surgery, were so ignorant of the Latin language that they could scarcely translate the Pharmacopœia from which they were expected to prescribe for their patients. Now, all this is anything but creditable to us as a learned body, and must tend to bring the Profession into public disrepute; and its explanation, I presume, is only to be found in the sharp competition that exists amongst the numerous licensing corporations for the fees paid on the diplomas of those they admit to Medical or Surgical practice; and the obvious course to be pursued in order to remedy such incompetency is to adopt a uniform curriculum and course of study by each and all of those bodies granting licenses or degrees, which should be fully enforced by the Medical Council, and, if required, by the Privy Council. A high standard of education in our Profession is the more required at the present time, when it is admitted that the application of Medical science to the health of the community is a matter of primary importance in the prevention of disease, by the removal or diminution of the causes tending to shorten the duration of human life." He hoped he had not tired the Council by reading this extract, but he thought the matter was one of great importance. Dr. Mackesy appeared to be a man of high education, who had a high standard of his own Profession, and he did trust that before the session closed they would be in a position to say that they had the means to prevent effectually illiterate students from entering the Profession by laying down, as they ought to have done long ago, a minimum curriculum of study in regard to preliminary education and by taking measures to see that that was carried out. He felt much indebted to Dr. Mackesy for the kind and gentlemanly manner in which he had written on the subject, but he could not help expressing his regret that the members of a liberal Profession meeting together as they did in Ireland should have spoken of the Council in a manner which was disrespectful to the Council and not creditable to themselves.

Dr. Parkes moved as an amendment, "That the Council pass on to the order of the day."

Mr. Syme seconded the amendment.

Sir D. J. Corrigan asked if this was a course consistent with the claims which the gentleman who sent the resolution had upon them. The resolution was passed at a meeting of 217 members of the Profession, who showed their great anxiety upon the matter by being present from all parts of the country. It certainly expressed, perhaps in strong language, what they felt; but he held that a letter coming from the President of one of the largest Associations in the United Kingdom, gathered from every part of Ireland, was entitled to some consideration.

Mr. Hargrave said the Association were perfectly justified in using strong language in expressing their anxiety upon this important matter, which was well worthy of the consideration of the Council.

The President said that a member of the Council had acknowledged himself to be the writer of a quotation which appeared in Dr. Mackesy's letter, and he certainly was surprised that any member of the Council, whatever might be his private opinion with regard to the Council in general, should have expressed such a strong opinion and to have published it to the world at large. It seemed to him to be a very strong expression of opinion with regard to the conduct of the Council and with regard to the conduct of the several licensing bodies which were represented in the Council. Although he thought that the opinion of Dr. Mackesy and

other Practitioners was entitled to consideration, yet he thought it would not be right for it to be entered on the Minutes. The letter was a very severe criticism, but it was altogether incorrect. The Council had not done as much as they wished to do, nor as much as they ought to have done. They might properly refer the matter to the Committee of General Education, but he thought it would be improper for them to place it upon the Minutes.

Dr. Alexander Wood said he was utterly at a loss to understand the conduct of a member of the Council who had acted in the way in which Sir D. J. Corrigan said he had done. It was a very serious business when a gentleman sitting at the table furnished the materials for an attack upon the Council, but he felt sure it must have been done in ignorance. He did not speak in an unfriendly way of Sir D. Corrigan, for they would be very good friends as soon as they got to the door. He hoped the Council would always do what they thought to be right, and not care what was said about them out of doors; but it was a very different thing when a member of the Council, sitting at the table, and taking part in the discussions, dared to attribute motives to the members of the Council sitting round the table which were totally unworthy of them as gentlemen and as members of the bodies which they represented. He utterly disclaimed any selfish consideration on the part of any members of the Council, but they met there year after year simply to discharge their duty to their Profession, and he would appeal to every gentleman present how little selfish considerations for the bodies they represented had weighed with them when they were considering the interests of the Profession at large. He felt that the author of the quotation in the letter was bound to apologise to them, first for having written the letter, and secondly for having characterised it, as he had just done, as a defence of the Council.

Sir D. J. Corrigan said he believed that whenever in the course of a debate in the House of Commons any member was personally attacked he had the right to reply, and he claimed the same right now. His simple reply was that he endorsed every opinion, every syllable, and every letter of the quotation which had been read, and that those opinions had been repeated over and over again in the Council, and had gone out to the world through the public press. He had often alluded to the state of Medical competition, and there was nothing in the letter which he had not said over and over again at the meetings of the Council. He still adhered to everything which he had said, and he was quite surprised that the gentleman opposite should speak as he had done, especially as he was the representative of a body (the Royal College of Physicians of Edinburgh) who, just before that Council was called into existence, granted their licences without examination at ten guineas each.

Dr. Wood rose to order, but was overruled by the President.

Sir D. J. Corrigan repeated what he had stated, and said it would be within the recollection of every member of the the Council, and that students were entitled to registration without any examination at all. No one could contradict him in this. It really did occur, and he brought forward a resolution on the subject that no licences which were granted without examinations should be entered on the Register, but it was met at the time by an *ad misericordiam* argument by the man who now came forward and charged him with imputing wrong motives. Was there a man at the table who would not endorse what he said? He had a case in which he refused to give a certificate of recommendation for the Edinburgh licence to an incompetent man, and he was driven into a corner to give a reason why he acted so. He called the whole thing a battle of the shops, and he had not said so much in the letter as he had said there at the Council. He had no hope of a better state of things so long as the present disgraceful competition existed. He still affirmed that the letter was his.

Mr. Syme rose to move a vote of censure on Sir D. Corrigan, but the President said he could not then take another amendment.

Sir D. J. Corrigan hoped that no such insult would be offered to Dr. Mackesy, of the Association, as was involved in the carrying out of the amendment.

Dr. Parkes did not consider that the amendment could be regarded as an insult to Dr. Mackesy, inasmuch as the resolution would not have been passed by the Association had they been in possession of all the information.

Dr. Quain said he should be glad if the matter could be referred to the Committee.

Dr. Storrar said that even supposing the resolution was unsound, he thought that any person who would take the trouble to look into the matter would acknowledge that the Council was guiltless of neglect to the extent which the Association had attributed to it. There could be no doubt that the proper position of the Profession could best be maintained by raising the standard of education, and he should be glad for the resolution to appear upon the Minutes and be published, so that the members of the Profession might know what the real state of the case was.

Dr. Paget said he could not consent to the passing of the amendment that the Council should proceed to the order of the day, though he would willingly acquiesce in the letter and the resolution being referred to the Committee without being entered on the Minutes. It would not be respectful either to Dr. Mackesy or to the Irish Medical Association to pass the amendment.

The amendment was then put and negatived.

Dr. Acland moved, and Dr. Andrew Wood seconded, the following amendment:—"That the letter from Dr. Mackesy and the resolution of the meeting of Medical Practitioners at Limerick Junction be referred to the Committee on General Education."

Dr. Alexander Wood again objected to the conduct of Sir D. J. Corrigan, which he said was injurious both to the Council and to himself.

Sir D. J. Corrigan protested against a second attack being made upon him.

The amendment was put and carried by a majority of five, and was then carried as a substantive resolution.

The Council adjourned at six o'clock.

Third Day.—Saturday, May 19.

The Council re-assembled to-day at 1 o'clock, in accordance with the resolution passed on Thursday.

The minutes of the preceding meeting having been read and confirmed,

The Registrar said he had to request the Council to direct that the name of William Adams be restored to the Register, it having been omitted through an erroneous report of his death. The fact was his name appeared in the obituary of the *Lancet*, and the report of his death was, for some time, uncontradicted. A letter was sent to his address in accordance with the 14th section of the Medical Act, and no answer being returned for six months or more, and there being no suspicion of his being other than dead, his name was omitted from the Register. It seems he left the St. Ives where he had been residing, and nobody knew where he had gone to. Upon making inquiries it was discovered that he had been living in Stirling, and was now in the army. They had had his signature at the Royal College of Surgeons, so that there could be no reason why he should not be restored to the Register, if the Council would give direction to that effect.

Mr. Hargrave moved, and Mr. Cooper seconded—"That the name of William Adams be restored to the Register," which was agreed to.

The next business was to consider a petition from Mr. Richard Organ (received at the close of the last session).

It appeared that the name of Mr. Richard Organ had been erased from the Register in consequence of his misconduct. From the minutes of June 18th, 1860, which were read, it seemed that the petitioner and his solicitor were called before the Council, and the Chairman stated the charge against him in the following words:—"It is charged against you that you are not possessed of any qualification entitling you to registration under the Medical Act of 1858; that certain of the representations contained in your memorial to this Council, dated 12th January, 1859, are untrue; and that your name has been incorrectly placed on the Register; and, further, that you have been guilty of conduct infamous in a Professional respect, in attempting to obtain by fraudulent means a diploma from the Royal College of Physicians of Edinburgh." Resolutions in accordance with these charges were agreed to, and on June 19th, 1860, it was moved by Mr. Teale, and seconded by Dr. Alexander Wood, "That it having been proved to the satisfaction of the General Council that the entry of the name of Richard Organ has been fraudulently and incorrectly made on the Register, the General Council do by this order in writing direct that his name be erased from the Register."

The Minutes of the 18th June, 1860, also contained a letter from Mr. James Fluker, Mr. Organ's solicitor, addressed to the Registrar, which contained the following paragraph:—It

is right I should also give notice that if his name should be wrongfully erased from the Register he will look to the Council for compensation for any damages which he may sustain therefrom, and take such proceedings for this purpose as he may be advised."

At the General Council on the 25th April, 1864, a letter was read from Mr. Organ desiring to be restored to the Register, when the Council declined to accede to his request.

In the present petition, dated April 15th, 1865, Mr. Richard Organ expressed contrition for past misconduct, and hoped the Council would take a merciful view of his case.

This petition with the various minutes of proceedings on the question having been read,

Dr. Alexander Wood moved that the petition be dismissed. He regretted exceedingly that the gentleman who originally moved that the name of Richard Organ be erased from the Register was not now a member of the Council, inasmuch as he was thoroughly familiar with the state of feeling which existed in regard to Mr. Organ in the district where he resided. He (Dr. Wood) did not propose this motion on personal grounds, but because he sat at that table representing the body against whom the fraud was committed, and for which Richard Organ deservedly suffered. If the offence had been a mere technical offence like Valentine's, a mere stating his age to be different from what it was, though he did not look upon that as a light offence, he should have been prepared to pardon it; but looking at the case as it was when it first came before this Council, he should be surprised indeed if a majority of those around that table should think the name of Richard Organ should ever be restored to the Register. Richard Organ wrote to the Royal College of Physicians of Edinburgh, requesting that he might be taken on examination for their diploma. A correspondence took place and a gentleman who called himself Mr. Richard Organ presented himself for examination. After coming to Edinburgh he was taken ill, and attended by the then Secretary or Registrar of the College of Physicians through a dangerous attack of pleurisy. He came up for examination in a very indifferent state of health, and was rejected. A short time afterwards a letter of inquiry was addressed to the Registrar of the College of Physicians as to whether he was sure it was really Richard Organ who presented himself, because the "Richard Organ" who was examined was in the habit of writing letters and posting them to a Richard Organ still resident in Yorkshire. This letter was put into the hands of the Procurator Fiscal, the Public Prosecutor for Scotland, who inquired into the case; and, having done so, told them that if they had passed this man he could have prosecuted both, but as it was, no prosecution could lie. It was discovered that Richard Organ had sent a man to personate him at the examination. More inquiry was then made into his Professional history, and it was found he had already stood a trial for forgery at the York Assizes, and that from a technical error on the part of the prosecution the case was not proved against him. His whole previous character was anything but respectable. Under these circumstances the case came before this Council; and he (Dr. Wood) would recall to the attention of those who were present at the time, how a solicitor appeared at the Council with Richard Organ and bearded and insulted them, and told them what their duty was in this matter. He then dragged them before the Court of Queen's Bench, and did his utmost to assert his legal right and put them in the wrong, and though they gained the case, it put them to a great expense. After that he immediately associated himself with a partner in order that he might practise legally, this man being put forward as his stalking-horse; and he continued to practise, as far as he knew, till this day in the place where he originally settled. This was a question which ought not to be decided by certificates or testimonials, but upon its merits. In the next few days they would be engaged in laying down regulations for Medical education; but if this Council failed in keeping the Register as free as it could from names of dishonest men they could do but very little towards improving Medical education. He, therefore, begged to move that the petition be dismissed.

It was suggested by Dr. Storrar and Sir D. J. Corrigan whether Dr. Alexander Wood would not propose his resolution in this shape, "That on a review of the case of Richard Organ, the Council declines to accede to his petition."

Dr. Alexander Wood said he had no objection, and the resolution in this form was then put and agreed to.

A letter was then read from Dr. Steele, Registrar of the Branch Council for Ireland.

The President called attention to the fact that, according to their regulations, the applicant ought to apply to the Branch Council of Ireland, which had power to register students.

Dr. Aquilla Smith put the Council in possession of the facts of the case, but his remarks were inaudible to our reporter.

Sir D. J. Corrigan thought this question was a very difficult one, and directed the attention of the Council to the proceedings of the Scottish Branch of General Council of Medical Education and Registration of January 12, 1866, No. 37, paragraph 5, in which it was said, "The Registrar (Dr. Robertson) produced a register of Medical students, prepared in accordance with the recommendations of the General Medical Council, and with the instructions received from the Branch Council. He stated that only 68 students had made such applications as entitled them to registration, but that a large number of exceptional claims had been made, including the whole of the Medical students who, in November, 1865, had commenced their Professional studies in the Universities of Glasgow and Aberdeen." And in No. 38 of the proceedings of the Scottish Branch Council, January 26, 1866, a letter was read from the University of Glasgow, dated January 12, 1866, and signed "Thomas Moir, registrar," in which he said, "In transmitting to you the accompanying list, I am directed to state that as, according to the present regulations of the University of Glasgow, Medical students are in certain cases admitted to enter upon their Professional studies previously to their having passed an examination in general education, it has been thought expedient not to adopt the plan of registration recommended by the General Medical Council, and for which you sent the required printed forms, but in the meantime to transmit an authentic list of Medical students who have commenced their Professional studies at this University, and are in the first year of their attendance, with a statement as to whether or not they have passed an examination in general education."

Dr. Andrew Wood was extremely obliged to Sir Dominic Corrigan for bringing this matter forward, and he thought his colleagues on the Branch Council of Scotland would bear him out in saying that when this happened he raised his protest against it. He stated in strong words that he felt this ordinance of the Glasgow University was practically in defiance of the Medical Act and the Medical Council, and that unless some means could be taken for getting quit of such an ordinance, he for his part did not care how long he remained a member of the Council or how long the Medical Act remained in existence. But he did not think they were to sit down calmly and deliberately and say that they could do nothing and would do nothing. With regard to the University of Edinburgh, the Council had already done good there; and if they persevered and used the influence they ought to have, and which he trusted they should have, they would succeed in other quarters. He did justice to the Edinburgh University the more because it had been his fate to speak, not against the University itself, but against what he thought was impolitic in that University. He might mention that the University of Edinburgh—and Professor Syme would corroborate him—had applied to the Privy Council for power to put out some of their ordinances, that the Privy Council had granted them the power, and that, in that University at least, whatever might be done elsewhere, for the future no man would be allowed to commence his Professional studies until he had passed his preliminary examination. He was convinced that the influence exercised by the debates which had taken place in this Council had been the means of effecting this change. Now they were bound to go on. And if he held an opinion, as he did hold it—although it would not come well from him—with regard to what the Glasgow University had done on this occasion, he should feel himself bound—and he thought Sir Dominic Corrigan would feel himself bound—to move some resolution condemnatory of what had been done in that University, and condemnatory of what might be done in like manner in any other body whatsoever. He could come here with clean hands, and report that everything the Council had desired had been for some time carried out in the Edinburgh University, and they admitted no man for registration as a Medical student until he had passed his full and not a partial examination upon the subjects of general education. His great desire was to remove any stigma from Scotland, to render it utterly impossible that in any future meeting of this Council it should be truly stated there was anything done in Scotland which would savour in the slightest degree of any endeavour being made to wile away a student from any part of the kingdom by not enforcing regulations

which were held to be paramount by other bodies in the country. He trusted Sir D. J. Corrigan would follow up his observations—in which he entirely concurred—with some resolution which would lead the Glasgow and Aberdeen Universities to adopt the same honourable step which had been adopted by the Edinburgh University, and bring themselves under the control of the Council, loyally and truly, as the other bodies had been doing of late years.

After a few words from Mr. Syme,

Mr. Hawkins said he viewed the report from the Scottish Branch Council with great astonishment, when he saw there were twenty-four different persons—eleven at Edinburgh, ten at Glasgow, and three at Aberdeen—who had not passed their preliminary examination, and were registered as if it had been quite in accordance with the rules of the Council. He was glad to hear that was no longer the case in the University of Edinburgh. The Royal College of Surgeons of England had, since 1861, fully carried out the instructions of this Council, and no one was now admitted to Professional study who had not previously passed his preliminary examination; but they had occasionally been subjected to this difficulty, that persons wished to be registered with them who passed their preliminary examination at other places, and amongst them were some who had come from Scotland. He did not know whether it applied only to the three Universities in Scotland or throughout England, that they divided their preliminary examination into different parts, and allowed a student to pass a portion at one time and a portion at another; and when he had passed a portion he was permitted to register as if he had done the whole. A great number had done so. Persons had come to them for registration of their preliminary examination, and the Secretary of the Royal College of Surgeons of England had been obliged to refuse them because their certificate only applied to a portion of the examination. He did not think there would be any difficulty with regard to the Irish Branch Council's application. It appeared that the student referred to has nothing to call upon this Council for. He passed the preliminary examination in the latter part of January, and, therefore, his entry for the Professional examination must be strictly in the beginning of February.

Dr. Alexander Wood said it was important the Council should be in possession of the true facts of the case, which were peculiar. At the same time that the Medical Act passed the Scotch Universities' Act passed, which placed the whole of the Universities under the management of a Commission, which issued from time to time ordinances under which they were compelled to act. Now, one of those Ordinances, which had been frequently referred to in their discussions, stated that it was desirable, "as far as possible," the preliminary education should precede the commencement of Medical study. Those words, "as far as possible," were intended to give some latitude at the commencement of the working of the Act to students who might find a difficulty in accommodating themselves to the changes and expressed stringency of the Medical education. He was bound to correct what Professor Syme had said. He (Dr. Wood) believed the Universities of Edinburgh did, as far as possible, insist upon preliminary education before the commencement of Medical studies. Now, what he wanted particularly to call the attention of the Council to was, that this Commission, in the Report which they presented to her Majesty, embodied all the Ordinances, and they further stated that it was not expedient that any of those Ordinances should be altered by any one University without communication with the other Universities in Scotland. The Ordinances could only be altered—first, by coming before the Senatus Academicus; secondly, by coming before the University Court; and thirdly, a petition for an alteration must be signed by the Chancellor of the University, and then come before her Majesty's Council, who must then decide as to whether the alteration should be effected or not. When the Senatus Academicus took the preliminary step for petitioning that these words, "as far as possible," should be struck out, and of having certain other valuable alterations made, the University Court, before whom it next came, ordered copies of the proposed alteration to be sent to all the other Scottish Universities, and it was made matter of discussion at that Court whether it was fair that a University of Edinburgh should go on with this amendment unless the other Scottish Universities concurred. He was sorry to say that the other Scottish Universities did not concur; but, nevertheless, the Edinburgh University took the unselfish and high course of coming forward irrespective of any personal or pecuniary advantage which it might possess, and wiped away what had always been felt to be a reproach to their fame; and he might also add, from some knowledge of the preliminary examinations which took place in the University, that they were of a very high character indeed, and if a fault could be found with them, it was that, in the present state of the Medical Profession, they were a shade higher than they could expect many of the pupils to attain to.

Dr. Storrar said he had been considering how the question, which was a serious one, could be most practically dealt with; and he begged to draw attention to a notice of motion by Dr. Smith, "That a Committee be appointed to consider and to report upon the working of the system of Registration of Medical students, adopted by the General Council last year." Now, he proposed that this Registration Committee should be appointed first, and then the next step would be to refer this question to that Committee, and with that view he had drawn up a resolution in this way, "That the case of students admitted to Registration who have not passed any examination in Arts, or only a portion of such examination, be referred to the Committee on Registration to consider and report upon." By adopting this course they would have a brief analysis of all these cases, and all that could be said in their favour, and when they had such a Report before this Council they would be in a better condition to determine what was to be done than they were at the present moment. Dr. Storrar then alluded with regret to the accidental absence of Dr. Thomson, and hoped nothing would be finally settled in this matter till that gentleman was again at the Council. He suggested, in conclusion, that Dr. Smith should at once move the appointment of the Committee.

There being no objection to this suggestion,

Dr. Smith proposed the resolution of which he had given notice of motion, "That a Committee be appointed to consider and to report upon the working of the system of Registration of Medical Students adopted by the General Council last year."

Dr. Storrar seconded the resolution.

Dr. Andrew Wood thought the Committee proposed was much called for, as he believed that the order instituted for the Registration of Medical students required amendment. The Medical students had been with great difficulty instructed in the method of making application for Registration, and indeed many of them had altogether refused to do it. The fact was, the machinery was cumbrous, and he thought this might be remedied. Suggestions should be obtained from the Registrars themselves. He knew the Registrar of Scotland had made some excellent suggestions with regard to the improvement of Medical Registration, and he hoped before the session closed the Council would so amend the system of Registration as to make it not only easy of application, but efficient.

The resolution for the appointment of a Committee was then agreed to.

Sir Dominic Corrigan having been proposed as one of the Committee, the honourable Baronet gave his reasons for declining to act. He said that as the University of Glasgow had declared they would not carry out the recommendations of the Council as to registration, he had no hope whatever that anything they did would produce any effect upon them. If there had been the least chance, that chance was totally removed by the information which Dr. Andrew Wood had given them,—namely, that when the University of Edinburgh applied to the Privy Council for a regulation which would enable them to refuse any student who presented himself for examination without undergoing a preliminary examination, the University of Glasgow said "No." If he turned to Ireland, he found that a student had a right to go to Trinity College under Act of Parliament and matriculate himself, and that College could not refuse his entering upon his Medical studies without any examination whatever. If he turned home to the Queen's Colleges, as the representative of the Queen's University in Ireland, he knew they received students without their having passed a matriculation examination. The Belfast College, finding that the matriculation examination was too hard for Medical students, instituted a little private examination of their own, of which the College had no cognisance whatever. Dr. Andrew Wood had asked him to propose a resolution condemnatory of the Glasgow University, and if he thought any such proceeding would solve this question he would do it; but he considered their labours in this matter would be useless, and therefore he must respectfully decline to do so, or to act on the Committee.

The following Committee was then appointed:—Dr.

*

Embleton (Chairman), Mr. Hawkins, Dr. Storrar, Dr. Fleming, Dr. Thomson, Dr. A. Smith, Dr. Andrew Wood, Dr. Sharpey, and Mr. Hargrave.

It was then moved by Dr. Storrar, and seconded by Dr. A. Smith, and agreed to:—"That the cases of students admitted to registration who have not passed the Examination in Arts, or only a portion of such examination, be referred to the Committee on the registration of Medical students to consider and report upon."

Sir D. J. Corrigan suggested that Dr. Steele's application with regard to the registration of a student should be refused.

The President reminded the honourable Baronet that Dr. Steele's letter was merely a request for a student to be registered who had passed his preliminary examination. They were bound to register him, and the only question was, whether he should be admitted from the day of the application, which was February 1, or three months afterwards.

Dr. Storrar proposed, "That the letter from Dr. Steele, with an application from a student to be registered, be referred to the Committee just appointed."

Sir D. J. Corrigan seconded the resolution, which was at once agreed to.

The next business before the Council was a notice of motion, by Dr. Fleming, of the following additions to the standing orders and regulations:—

"1. That a Business Committee be elected every session, to act from the close of that session till the close of the next. The election to take place by ballot, by means of marked lists.

"2. That the Committee consist of five members, exclusive of the President.

"3. That the constitution of the Committee and the mode of election be as follows:—Two members to be first chosen from the whole body of the Council, and then one member from the English, the Scottish, and the Irish Branches of the Council respectively.

"4. That the members of the Committee meet before the close of the session during which they have been elected, and appoint one of their number as chairman.

"5. That the chairman summon the Committee to meet previous to the commencement of the sessions of the General Medical Council, in order to prepare and arrange, as far as practicable, a programme of the business which they consider should be submitted to the Council during its sittings; in addition to which, during the sessions of the Council, programmes of subjects to be brought forward and of notices of motions be prepared by the Committee and distributed as often as they may consider necessary. In all programmes, business brought forward by the Committee to be distinguished from business introduced by individual members.

"6. That the Committee have full power to regulate the order of business, and to fix what days, or part of days, be appropriated to business introduced either by themselves or by individual members.

"7. That the remuneration to the members of the Committee while engaged in preparing and arranging the business previous to the meetings of the Council, be on the same scale as for attending the meetings of the General Council."

He said his motion was simply to endeavour to expedite the mode of conducting the business of the Council, and if it were carried out it would save a great deal of valuable time, and prevent much unnecessary discussion. At its institution this Council had great difficulties to contend with, and although he was not a member at the outset, he could quite appreciate the trouble which must have been experienced in putting a very imperfect and complicated Act of Parliament in motion. (Hear, hear.) It could not have been expected that a body of 24 gentlemen from different parts of the United Kingdom, who were comparatively unknown to each other, with conflicting opinions and representing various interests, would at once settle down to business in that methodical way which facilitated the proceedings of similar bodies of much older constitution. If, however, any man whose name was on their Register could only look back to a few years before this Council was in existence, and remember how the Profession was agitated from one end of the kingdom to the other because there was no central body, when the licensing bodies were in antagonism one with another, and now thought of the harmony that existed, he must be satisfied the General Council had done a great amount of good. (Hear, hear.) It was only by experience they came to approve of systems by which their proceedings could be carried on in the best way; and he thought they ought to avail themselves of such experience as they had acquired, and see whether by adopting the additions he proposed, or similar ones, they would not greatly facilitate the conduct of public business. He then went through the proposed additions *seriatim*, and explained what he conceived would be their advantage in bringing about the desired result.

Dr. Embleton seconded the proposition, remarking that he believed if it were adopted it would tend to shorten the sittings of the Council by two or three days each session.

Dr. Smith thought the proposition did not propose to do anything more than could be done at the present time by the Executive Committee. He considered it would be very objectionable to introduce extra machinery into the Council. They should be very cautious in complicating matters by a Business Committee, which would have power during the long interval between one session and another.

Dr. Andrew Wood said he thought at first there was something of greater importance in the proposed additions than now appeared to be the case. A very large amount of the business of the Council was not known till they had been assembled two or three days, when it cropped up in the course of other business. His idea was, that it was the duty of the Executive Committee during the intervals of the sessions to watch the progress of events, especially the Branch Council Minutes, and it was clearly their duty to meet a day or two before the assembling of the General Council and act as a Business Committee, in order that they might put in shape enough business to occupy them the first day or two; so that if the Executive Committee would only do what he conceived to be their duty, the proposed committee would be unnecessary. He hoped Dr. Fleming would withdraw his proposition.

Dr. Alexander Wood said that at the commencement of the session he suggested what had been found of so much advantage: of allowing the Executive Committee greater latitude, and he thought nothing more was required. If Dr. Fleming's resolution became law, there would be a little danger of creating an *imperium in imperio*. It was impossible to arrange the business in the methodical way indicated.

Mr. Syme was understood to say that the duties assigned the Executive Committee did not embrace what was contemplated by the motion, and therefore it would be necessary to enlarge their powers if Dr. Fleming withdrew his resolution.

Dr. Fleming said that as the feeling of the meeting seemed against his proposition, he would withdraw it if the Council would enlarge the powers of the Executive Committee.

The resolution was accordingly withdrawn.

The Registrar next read a copy of the agreement with Messrs. Spottiswoode for printing and binding a new edition of the British Pharmacopœia.

Sir D. J. Corrigan complained that he had never seen a proof copy of the Pharmacopœia, so as to give him an opportunity of making suggestions. Would the work be sent to press without being submitted to the members, in accordance with a resolution of the Council to that effect?

The President: Certainly not. The Pharmacopœia Committee are prepared to make a report and give the Council an account of the state of progress of the work, and the Council may act upon that report as they think proper. The Pharmacopœia Committee have no idea of publishing the work without complying with the order of the Council.

Dr. Quain, chairman of the Pharmacopœia Committee, said the work was not ready, but he had no doubt it would be before the close of another year.

The President thought the consideration of this subject should be deferred till the Pharmacopœia Committee brought up their report.

The subject then dropped.

Dr. Stokes laid upon the table the report of the Committee on General Education, which he hoped they would be able to discuss on Monday.

Dr. Andrew Wood moved, and Dr. Acland seconded,—"That the report of the Committee on General Education be received and entered on the Minutes," which was agreed to.

It being now four o'clock, the Council adjourned till Monday.

Fourth Day.—Monday, May 21.

The Council re-assembled at 2 o'clock on Monday, the President in the chair.

The Registrar read the Minutes of the last meeting, which, after a few corrections had been made, were confirmed.

The following report from the Committee on General Education was then presented:—

"REPORT ON GENERAL EDUCATION.

"The Committee have given their best attention to the resolution of the Council of May 18, wherein they were 'instructed to take into consideration and report upon the examinations in general education at present conducted by the various National Educational and other bodies recognised by the General Medical Council.' The Committee, having had before them the digest, prepared by the Registrar, of the preliminary examinations in Arts recognised by the General Medical Council, are of opinion that any further analysis of those documents already before the Council would be unnecessary. The Committee are of this opinion, inasmuch as they are prepared to state to the Council what appears to them to be the smallest list of subjects for examination through which a qualifying body can ascertain whether a youth has attained the accurate mental training necessary for entering with advantage upon Professional studies. The subjects of examination that the Committee recommend are as follow:—*Compulsory.*—1. English language, including grammar and composition. 2. Arithmetic, including vulgar and decimal fractions; algebra, including simple equations. 3. Geometry: first two books of Euclid. 4. Latin. *Optional.*—One of the following: Greek, as far as Xenophon or Lucian; French; German; natural philosophy (mechanics, hydrostatics, pneumatics). The Committee recommend that certificates of proficiency be received from all the chartered educational and licensing bodies in Great Britain and Ireland which bear evidence that the candidates have been examined and approved in the above subjects. In the case of certificates received from similar educational and licensing bodies in other parts of the empire and foreign countries, satisfactory evidence must be given to the Medical Council (or Branch Councils) that such certificates are equivalent to those given in the United Kingdom. The Education Committee, having considered the letter and resolution of the Irish Medical Association forwarded by Dr. Mackesy, and referred to them, recommend that the resolution be entered on the Minutes. The Committee further recommend the forwarding this resolution to Dr. Mackesy. "W. STOKES, Chairman."

Dr. QUAIN proposed, and Mr. HARGRAVE seconded, that the report should be considered paragraph by paragraph. This resolution was carried, and the first paragraph was, after some discussion, adopted. Certain amendments and alterations were introduced in the second and third paragraphs, after which they read as follows:—

"The Committee, having had before them a digest, prepared by the Registrar, of the preliminary examinations in Arts recognised by the General Medical Council, consider that an analysis of this document would be unnecessary."

"The Committee beg to suggest to the Council what appears to them to be the minimum amount of subjects for examination through which a qualifying body can ascertain whether a student has undergone the mental training necessary for entering with advantage upon Professional studies."

On the fourth paragraph, relating to the subjects of examinations recommended by the Committee,

Sir D. J. CORRIGAN proposed the following amendment:—"That Greek be included in the compulsory subjects of examination after the year 1869." He believed Dr. Stokes, who was chairman of the Committee, would not object to his stating that they had a very long discussion on this matter at the Committee, and that different views were then taken of the subject. He had undertaken, as a member of the Committee, to convey the opinion of some at least of the members of that Committee to the Council. For his own part, he should have preferred altogether omitting the list of optional subjects, so as to have confined themselves simply to the subjects which they thought absolutely necessary, leaving it to the students to offer themselves for examination in any other subjects if they pleased. The general opinion, however, was in favour of including the optional subjects upon the list, and therefore it only remained for them to include Greek among the optional subjects. He had a strong opinion upon the matter, and was very much supported in it by several of his fellow members on the Committee. He had prepared an amendment to move on Friday last, providing that Greek should be included among the compulsory subjects after 1867, but in conversation he found that several members of the Committee were prepared to support that amendment on condition that he altered the date from 1867 to 1869, which he had now done, in order to give students a fuller opportunity of learning Greek. He held very strongly to the opinion that Greek ought to be included, and he thought that two years of preparation for it would be quite sufficient. With regard to the importance of the language, he did not think it necessary to say one word. He did not at all desire that a man on presenting himself for a preliminary examination should profess to be an accomplished classical scholar, or that he should be capable of being examined in the merits of erudite criticisms upon high Greek authors; but he thought it highly important that he should have such a fair knowledge of Greek as to be at once capable of understanding the names which were made use of in the practice of the Profession, or of taking down a lexicon and finding out what they were, and of being able to meet learned men in their own rank of life. The only question was as to the time which should be allowed. From the very useful and valuable analysis which had been made by Dr. Hawkins, he had ascertained that the number of licensing bodies granting certificates was twenty, and that of these nine at the present moment required Greek, while eleven did not. It was plain, therefore, that those who required it and those who did not were pretty nearly equally divided; and he thought that if the Council ignored Greek, as they did last year, they would be really, though not intentionally, allying themselves with those bodies who adopted the lowest standard of requirements. If nine of the licensing bodies required Greek as compulsory, he considered that the Council ought to lean to that side, which was really the side of better education. The Apothecaries' Hall of Ireland had required Greek for nearly the last sixty years, and if they now ignored it they would be doing a very injudicious thing. If it were not asked for by any bodies, the Council might say that it was not required, and that it did not become them to introduce any new element into the examinations; but when nine out of twenty did require it, it was their bounden duty to stand by their side, and not to lower the standard which had existed in some of the bodies for nearly half a century.

Dr. STOKES suggested that the amendment might be embodied in the Report by stating that after 1869 Greek would be compulsory.

Dr. CHRISTISON said his objection to the amendment was that the Committee had made a very proper selection of subjects, but if they once began to alter the list the difficulty was to know where to stop, because it really was difficult to decide which of the optional subjects was the most important. The next subjects in the list were French and German. There were two reasons why they required these subjects to be studied. One was for the purposes of general cultivation in life. He hoped that no one would seek to overrate the importance of Greek in this respect, but no one could say that the cultivation of French, and especially of German, was equally suitable, whilst, if they come back to the simple object of preparing a student for the cultivation of his Profession, both as a student and as a Practitioner, there could be no doubt that, practically, French was of far greater importance. The next subject was that of natural philosophy, and as a means of general cultivation he did not think that any man who had tried this in his youth could fairly say that it was not necessary, and when they considered the importance of it to students in studying their Profession, no one could say that it was immaterial. As a teacher, he had far more pleasure in seeing students coming up to be examined in natural philosophy than in other subjects, and he thought that Sir D. J. Corrigan ought to be satisfied with having got Greek on the optional list, especially as in Edinburgh and in other places at the present time there was a much larger number of students acquiring a knowledge of Greek than at any former period.

Mr. HARGRAVE urged the necessity of a knowledge of Greek, and supported the amendment.

Dr. ALEXANDER WOOD said it was quite true that the Council had before it what the various examining bodies required from the students for examination, but they had not before them another very important set of documents, which, in discharging part of the functions of the Medical Council, he had recently had occasion to examine—namely, the results of those requirements. (Hear, hear.) They had not the returns to the requisitions before them, and they were not, perhaps, in a position fully to understand how little of what was professed to be required of them the students were able at present to perform. He confessed that while he would be the very last to undervalue any mental discipline, or any subject that was essential to a Medical student, he should be

satisfied at present, till he had some further experience, with less profession, if he could get a great deal more practice. He should like to know what sort of papers in English and in arithmetic those bodies got which required Greek. He had lately had occasion to examine some of the examination papers of a body which required Greek, and he found those papers were sadly defective in English grammar, and even of English spelling. He had frequently revised such papers himself, and all he could say was that, if the students had cultivated the Greek language, they certainly had not the English. He thought that their great object—sitting at that table—was not to elevate the standard too high, if they could not secure that standard being reached, but to insist for the next few years on a proper examination in those branches in which they had some chance of getting a perfect and thoroughly efficient examination. For these reasons he was perfectly satisfied with the Report of the Committee, and he should be very glad indeed if they could get the subjects which were down in the compulsory list properly examined in, and the students properly qualified in them. If they could do that, those who succeeded them at that Council in after years might insist on Greek and other languages; but he did not want them to attempt more than at present they could perform; and, above all, he did not want them to deceive the public by holding out to them that they insisted on Greek when they knew that they could not even get English.

Dr. Storrar seconded the amendment, and said he hoped it would not be considered that the gentlemen who were in favour of it were trying to practise on the credulity of the public. They were just as anxious to have the education of gentlemen entering the Profession improved as any others could be, but their opinion was that in the year 1869 Greek might safely be included in the compulsory subjects, and they put this out as an intimation to all the schoolmasters in the kingdom that the Medical Council did consider Greek to be an important element of Professional education. He had seen a great deal of examinations during the last few years, and had remarked that there appeared at the present time to be a great spirit of competition among boys in the various schools to go in for some kind of examination. To such an extent did this spirit of competition prevail amongst British schoolboys at the present time that if they required Greek in 1869 he felt sure they would get it. He quite agreed in the opinion that if they wanted it at the present time they would not be able to get it, or if they did it would be in such a disgraceful form that it would not be worth having, and would be a bad precedent to set; but in the year 1869 he felt that they might very safely ask for it. He would particularly call attention to the great efforts which had recently been made in other professions to improve education. This was especially the case with the law, and so anxious was the Association of Solicitors in London to encourage the advance of preliminary studies that they offered a special advantage to every man who was able to appear in the first division of matriculation examination of the University of London. They did not ask the Council to require Greek at the present moment, but to give the schoolboys and schoolmasters notice that they should ask for it in 1869. Dr. Christison had referred to natural philosophy, and he (Dr. Storrar) fully felt the importance of that branch of study, and would not give it up, but what he said was, that natural philosophy, although most valuable, was not such a school study as Greek. He wanted them to go to school till they were seventeen years of age, and if they went to effective schools, and took advantage of them, they would have no difficulty in the way of providing either Greek or natural philosophy. He recollected it was stated last year in the report that the Council viewed with satisfaction the fact that many of the students had made a great advance in such studies between the period of their preliminary examination and the time of their entering on their more Professional studies. There could be no doubt that Greek could be taught much more effectually at schools than natural philosophy could, and what they wanted was to give the students the power, inasmuch as several of the names came from the Greek, and which they could not otherwise understand, of picking words to pieces and seeing what they were made of. Another thing which had weighed upon his mind, though it had not been pressed before the Council, was that by the system of indifference to general education which prevailed in the Profession, they not only got young men of good abilities coming into the Profession insufficiently prepared for Professional study, but they also got all the waste of the schools. Boys who were worth nothing at school were often turned into the Medical Profession, because there a classical education was not necessary. This was no fiction, but he had seen such cases over and over again, where men put their first son, who had taken his degrees at the university, into the profession of the law; while the other, who was a puzzle to his father to know what to do with him, was turned into the Medical Profession, though he knew but very little Latin, and certainly no Greek at all. He thought it would raise the character of the Medical Profession, and certainly it would raise the character of the young men who came to study in it, if they demanded a real and substantial advance in their education, and on this ground he cordially seconded the amendment.

Dr. Andrew Wood was not disposed to yield to any man in the high opinion he held of a liberal education, carried out to the utmost in the way of preliminary studies, for young men, but there were two considerations, as it appeared to him, which they ought to keep in view in that discussion. It was a very good thing to have men highly trained in a large number of subjects of general education, men who by the training which they had been enabled to go through had fitted themselves for the higher qualifications of the Profession, such as taking degrees at the Universities and other high positions; but there was another consideration, and they must take care that, whatever their individual opinions upon the importance of general education might be, they did not pitch their requirements so high that either they would not be carried out in practice or that the public would be deprived of a sufficient supply of Practitioners of Medicine and Surgery. Far was it from him to say that any illiterate man should enter the Profession, and he said this with more boldness, because he felt proud to be able to vindicate the College which he represented, and to state that it was one of the first bodies which did establish a preliminary education examination long before the Medical Act was passed, but it did appear to him that they were going in a wrong direction when they reduced to such a minimum the number of optional subjects. He believed that even in the competitive examinations for the Civil Service of India, and also, if he was not mistaken, in the examinations for the Army and Navy there are several subjects that were left optional, and, as he thought, for a very good reason—namely, that the minds of young men were not all framed in the same mould nor bent in the same direction. He had seen men of the greatest ability, who would have done honour to the Profession in any point of view, who had great difficulty in compassing geometry and algebra; and yet, if they were taken in Greek and some other subjects, it would be found that they would make most magnificent scholars. They ought not to make a kind of bed of Procrustes and put every man down to the same level, but should carry out some means by which the classical man should be enabled to choose classics to a certain extent, and the geometrical man geometry to a certain extent. Even at Oxford and Cambridge there were men of the most brilliant abilities in geometry and the sciences akin to it, but who in the classics made no great appearance, while on the other hand, there were some of the most brilliant classical scholars who were unable to solve even a simple problem in Euclid. It did appear to him that it was wrong for them to lay down too stringently the subjects in which they would have candidates examined. He did not wish to reduce the amount, but he thought it would be far better to make more of the subjects optional, so that men might choose exactly those subjects which they were able by their abilities to compass, and then they would not exclude from the Profession many men who would be a great honour to it, but who, if they adopted one common standard, and applied it to everybody, would not be able to enter it with any credit to themselves. The object of their examination in general education was not to ascertain whether a man knew the meaning of a particular word, but to ascertain whether he had had a liberal education, whether his mind had been trained in such a way as would enable him, when he entered the Profession, to grapple with its difficulties, and if a man could give him a certificate that he knew a certain number of the subjects on the list, leaving the rest to his option, he should be quite satisfied that the man had received such a liberal training as fitted him for entering the Profession. He would stand up for Greek as much as any man, because it was a language that he loved, and always had loved; but to tell students that Greek was compulsory was, in the present state of education, entirely out of the question. He agreed with what Dr. Alexander

Wood had said, that they ought first to make sure that their students were acquainted with their own language. He did not know how it was on other Boards, but he was not ashamed to say that a great many students came forward to the examinations with which he was mixed up who were so utterly ignorant of their own language that they could not even spell it, and his friend Dr. Parkes would corroborate him to a great extent in this. If they threw upon the students at this time of day too many subjects, and made those subjects compulsory, there was a risk that the students might neglect the more simple matters of English and arithmetic and Latin in their desire to make an appearance in Greek. He was happy to say, for Sir D. J. Corrigan's information, that in Scotland many of the students were now including Greek in their examinations, but he did say that if now, or even two years hence, they introduced this bed of Procrustes, they would be depriving the Profession of many most useful Practitioners who, apart from such high attainments as were now sought to be required, were well calculated to supply the wants of the country. Looking at the miserable returns which many members of the Profession received in country parts, in Scotland at least, if not in England, he thought it would be extremely difficult for those parts of the country to be properly attended by Medical men if they pitched their preliminary requirements too high; and yet during the last 15 or 20 years, and he believed Dr. Christison and Mr. Syme would bear him out in this, many of the men supplying those country districts had been able to vie, as members of the Profession, with many of their metropolitan brethren. He would, therefore, caution the Council against pitching their requirements so high as to keep such men out, inasmuch as there were many men who were not Greek scholars, but who would make most excellent Physicians and Surgeons. He felt very strongly upon this subject, and he only wished the Council to keep the observation in view that they might fail in obtaining the end they desired if they endeavoured to fix their requirements too high.

Mr. Cooper said he could not give a silent vote on the occasion. There was much good sense in what had fallen from Dr. Andrew Wood, and he also entirely fell in with what was said by Sir D. J. Corrigan as to the great importance of the Greek language to any gentleman who wished to have a competent knowledge of their art. All their terms were derived from the Greek, and they could not get a clear and comprehensive knowledge of those terms unless they knew something of that language. He knew it had cost him a deal of time and trouble at a period when he might have been studying his Profession, and, therefore, he should like to see the students come up for examination with a very fair knowledge of Greek, inasmuch as it would greatly help them in the acquirements which they might afterwards attain. If, however, there were already so many failures in the subjects for examination, where could they find men for the country districts, and for the army and navy and volunteers, if they increased the number of compulsory subjects?

Dr. Leet said he had had some difficulty in adopting that portion of the Report of the Committee, because if they adopted the educational system proposed they would seriously interfere with what the Council was anxious to have carried out. The Apothecaries' Hall of Ireland had demanded Greek for 50 years, and the Edinburgh College of Surgeons also required it, and hence there was a serious objection to exclude Greek from the papers.

Dr. Apjohn considered that a certain amount of Greek was indispensable, but he thought that a small amount of it would suffice, and that what we wanted could easily be acquired. In several recent examinations the appearance of the students in Greek had been of the most satisfactory kind. He thought it was perfectly practicable to state, if Greek were made compulsory, what amount of it would be required. On the Committee, he proposed that a certain book should be selected, and he suggested one of the gospels, but that was objected to. He thought that a proper test ought to be established.

Dr. Parkes said that it had occurred to him that they should be in a much better position to judge of this subject two or three years hence than they were now, and he therefore thought that it would be undesirable to take any action in the matter at the present time. In two or three years they would see the results of the present examinations, and would then be able to decide more fully whether Greek might be included with advantage. He would, therefore, suggest that the deiberation on this question should be deferred for three years, and that no motion should be made till they had before them the reports of the examinations in preliminary education.

Mr. Rumsey said this was a subject on which he had previously addressed the Council. He regretted that a report should have been issued from so learned a body as the Committee on general education, containing certain decisions on very important subjects, without stating their grounds for those decisions. (Hear, hear.) He should like to be informed as to the grounds on which certain subjects were included and others excluded from the preliminary education of Medical men, and on which some were made compulsory and others optional. He admitted that there was not sufficient time to enter so fully and satisfactorily into these subjects as might have been wished, and he would, therefore, attribute the meagreness of the report in that respect to want of time on the part of the Committee, who were most competent to give their reasons for what they had done. He should also like to know the bearing of preliminary education upon Professional duties and social relations, which was a most important matter for the Council to consider, and they needed a report on this subject to satisfy the learned part of the public as well as the Profession. The Universities and other learned bodies in the country wanted to know why they had adopted certain subjects and why they had omitted certain others. He confessed that he had always supported the insertion of Greek as a compulsory subject, and he was supported in this view not only by the arguments which had been adduced by others, but also by his own observation in the matter. They must have men educated fully equal to the clergy of this country if the Profession was to maintain anything like an equality with other professions. He had known two or three instances of what had been already referred to, where boys of inferior abilities had been put into the Profession, and in one case a boy who, though very clever, was the greatest scamp, and had learned nothing, was selected to go into the Medical Profession, because it was said that he could do so without knowing Greek or Latin. As to the importance of Greek, he hoped the Council would not consider it an impertinence if he read an extract from one of the greatest authorities on Medical education on the Continent. Lancisi, who wrote at the beginning of the last century, said, in his "De Recta Medicorum Studiorum Ratione Instituenda," Dissertatio 1:—"Non moror earum linguarum necesitatem quibus Ars ipsa principium debet; Græcæ imprimis, et Latinæ; Græca sunt enim omnium fere corporis partium, naturæ operum et morborum, atque harbarum, et medicamentorum nomina, *quorum qui significationes tenet, earundem quoque rerum adumbratas habet definitiones.* Græcus est preterea Principum medicorum sermo, e quibus aphorismorum oracula, observationes certas, et Pharmacorum exploratam vim, medendique methodum haurire debemus." A modern writer, too, in the *Saturday Review*, in speaking of the education of the liberal professions, instanced the Medical Profession as one which particularly required the study of Greek as a preparation for its practice. When a journal like the *Saturday Review*, which represented the intellect of the country, spoke in this way, they ought not to run counter to such a suggestion, coming from outside the Profession. It was a demand of the public rather than of the Profession that they should be supplied with learned and thoughtful men. He did not admit the validity of the argument that because a certain number of Medical men in the country must always be badly remunerated, they were not therefore to be well educated. They had an instance of the very reverse in the curates in the country parishes, many of whom had taken their first and second class degrees at the Universities, and all of whom had reached a standard far higher than any which had ever been demanded of a Medical student. He asked them to give Medical men such an education as would enable them to associate with curates who got £80 a-year. He believed that the difficulty of obtaining students who knew Greek had been greatly overrated. He had conversed with the head masters of some of the principal schools in the country, and they assured him that if the Medical Council required Greek in three or four years' time, they would be able to have an abundance of it, and that they only had to create a demand, and a supply would soon be found. Since Sir D. J. Corrigan had altered his motion, he could now support it, though he could not have done so as it originally stood.

Dr. Aquilla Smith supported the amendment. He did not believe that a high standard was at all necessary, but he considered a moderate knowledge of Greek to be of the highest importance.

After some remarks by Mr. Syme,

Dr. Paget said he had very great difficulty indeed in forming a judgment upon this matter, and that difficulty was very much increased by the way in which the Committee had put both Greek and natural philosophy as optional subjects. His own opinion was, that natural philosophy ought, at some period or other in the course of study to be made compulsory upon Medical students. Dr. Christison's argument was a very weighty and unanswerable one, that comparing the two subjects natural philosophy was of more importance to the Medical student than Greek. He did not agree with Dr. Andrew Wood's remarks about differently constituted minds. At Cambridge there was no difficulty whatever in getting a classical man to pass his examination in mathematics, and *vice versa;* in fact, a classical man was not allowed to show his brilliancy until he had a considerable knowledge of mathematics, and there was no doubt that a man was better educated, and his mind better balanced by taking the two things. The argument as to the low remuneration of Medical men might be met in this way. If the Medical Council required such qualification as that the number of men would be decreased, the remuneration would be at once increased, and this was strikingly proved years ago in Paris, where, after a higher standard of requirements was introduced, the number of Medical students decreased from 3800 to 800. The public would also benefit by it, because the worst men would be excluded. Dr. Storrar's remark was a weighty one, and he hoped would receive due attention, as to Medical students remaining longer at school.

Sir D. J. Corrigan said he thought the discussion had cleared the ground to a very great extent. He would remind the Council that the report of the Committee referred only to school days and school education, and however anxious they might be to insert natural philosophy, they thought that that could not be so well included in school studies, but had better be left to the time of Medical studentship. Another thing was, that they did not want to enforce Greek at the present moment, but were only proposing to make it compulsory at the end of three years; and if there was any man who, between 1866 and 1869, could not get as much Greek as they wanted, the sooner he left the Profession the better. No books had been named in which students were to be examined, because it was thought best to leave that matter entirely to the various examining bodies themselves. He believed that he agreed with Dr. Christison in principle; but he also believed that the object of securing a good education could be best attained by supporting his amendment. Dr. Alexander Wood had stated that the students who came up in Greek were very bad English scholars, and he implied that if they had not studied Greek they would not have neglected English. He at once turned to the reports of the deputation, of which Dr. Alex. Wood was a leading member, but he could not find there any report on any preliminary examination, which was all that they were now dealing with. He did not agree with Dr. Andrew Wood's observations about different minds being differently constituted, because their object was not to open a door for every variety of mind, but to qualify their students to pass their examinations as Physicians and Surgeons. The former examinations were not found by the Government authorities to be high enough, and therefore the Army and Navy Medical Departments had been obliged to take them into their own hands, and he thought that by raising the standard they would be doing the greatest service in the world, both to the social status of the Profession and to the men themselves. Dr. Parkes and Dr. Paget had suggested that action in this matter should be postponed for the present, as they did not know how it would work; but he would remind them that it had already been demanded in some bodies for fifty years, and that nine bodies out of twenty had now pronounced in its favour. He quite agreed that natural philosophy was of immense importance, and should be made compulsory at some time or other; and when they came to deal with Professional education he intended moving that it should be made compulsory; but he did not think they ought to enforce it on a boy of 17. He had taken up this matter in all seriousness, and he earnestly commended it to the Council. If an advanced education was now required of solicitors, why should it not also be required of Medical men? Sir D. J. Corrigan then altered his amendment as follows:—"That Greek be transferred to the list of compulsory subjects after the year 1869."

The amendment was put, and carried by 14 against 9. The President was about to put it as a substantive motion, when

Dr. Andrew Wood said he had an amendment to propose upon it. With regard to not taking any notice of preliminary examinations by visitation of the Universities and Colleges, he was not responsible for what might have been done by others; but if Sir D. J. Corrigan had glanced at page 30 of the Reports of Deputations, he would have found not only that preliminary examinations had been most particularly, but that they had been most circumstantially attended to. On page 31, they would find that, on April 4, 137 students appeared for examination. There seemed to have been examined in English 77, of whom 52 passed, and 15 were rejected; in Latin 74, and of these 55 passed, and 19 were rejected. Then came a curious fact as showing something of the genius of the Scottish mind—in arithmetic there were examined 69, and of these only 3 were rejected. In Mathematics 69 were examined and only 7 rejected. In Greek 45 were examined, and of these, 22 passed and 23 were rejected. In French there were 48 examined, of whom 29 passed and 19 were rejected. In German 6 were examined, of whom 3 passed and 3 were rejected; in the higher mathematics 6 were examined, of whom 5 passed and 1 was rejected; in natural philosophy 27 were examined, and of these 23 passed and only 4 were rejected; in logic the number examined was 52, of whom 31 passed and 21 were rejected; and in moral philosophy 25 were examined, of whom 15 passed and 10 were rejected. This showed that Sir D. J. Corrigan was wrong in supposing no attention had been paid to preliminary examination in Scotland. He thought there was room for improvement in the curriculum which they had laid down for their students, and that there should be compulsory and optional subjects, and he believed that natural philosophy should be taken completely out of the category of preliminary education, and made compulsory as one of the subjects of Professional education. (Hear, hear.) That was the case in the College of Surgeons long before the Medical Act was brought into operation, and they had no difficulty at the age of twenty-one, when young men came up for examination in Professional subjects, of getting from them a certain amount of knowledge of natural philosophy. He would therefore move that natural philosophy be removed from the preliminary education altogether, and that it be transferred to the Professional education. No man could learn physiology properly without a knowledge of natural philosophy, and on that ground he thought no student should be allowed to enter the Profession who had not been educated and tested in that subject. He was anxious that English, geometry, and Latin should be compulsory.

The President: Do you leave out algebra?

Dr. Andrew Wood said he would not leave it out, but put it amongst the optional subjects. By what he proposed he was not reducing the amount of general knowledge, but rather a modification of the way in which it was demanded, and he believed it would be found to work well, and give that scope to differently constituted minds which, in spite of what Sir D. J. Corrigan had said, he still believed in. In conclusion, he moved as an amendment, "That the curriculum for preliminary education shall be as follows:—First, compulsory, English language, including grammar and composition; arithmetic, including vulgar and decimal fractions; geometry, first two books of Euclid; and Latin. And that two of the following subjects be optional by the student:—First, algebra; second, Greek; third, French; and fourth, German." He did not, he said, want to get rid of natural philosophy, but would afterwards move that it be taken at a later period.

Dr. Acland said that if the Council attempted to lay down a rigid rule with regard to ante-Professional education it could only do so safely, he respectfully submitted, simultaneously with its consideration of what it meant to require in the Professional studies. This was a real difficulty, and one to which he did all in his power to draw the attention of the Council in 1864. Speaking generally, he believed that the Medical student ought to be educated in the same way as any other English gentleman. He said nearly 20 years ago at Oxford, and he would say the same now, that it was desirable that every person passing an Arts examination should also pass in some subject of physical science, but he made an exception in the case of a Medical student. If they eliminated from their optional list natural philosophy, it would only be on the distinct understanding that it was to come into and form part of the Professional studies. If Dr. Andrew Wood was to eliminate algebra the Council ought to have some understanding that it was to be required at a later period.

Dr. Storrar thought Dr. Andrew Wood appeared to shunt

Greek altogether. The resolution was that Greek should be admitted in 1869, and, therefore, Dr. Wood should bring forward a proposition touching that question, unmixed with anything else.

The PRESIDENT ruled that Dr. Andrew Wood's amendment was quite in order.

Dr. ACLAND suggested that they should take each subject on the list separately.

Dr. ANDREW WOOD said he had no objection, and proposed "That each item of the proposed plan of the Committee as to the subjects of general education be put separately to the Counell."

Dr. PARKES seconded the resolution, which was carried *nem. con.*

Dr. ANDREW WOOD then moved, and Dr. PARKES seconded, —"That the first of the compulsory subjects be English language, including grammar and composition," which was agreed to.

Dr. STORRAR next proposed, and Dr. THOMSON seconded,— "That the Committee's recommendation that arithmetic, including vulgar and decimal fractions, algebra, including simple equations, stand as one of the compulsory subjects, be adopted."

Dr. FLEMING remarked that, as a member of the Committee who had this subject under discussion, when he commenced the consideration of it he was inclined to make the optional subjeets more numerous, but he saw reason to alter that opinion. There were two points to be borne in mind,—the first was, they must educate a student in particular subjects pertaining to the Profession; and the second, discipline his mind so as to render him able to grapple with the various difficult subjects which would come before him in the study of Medicine.

Dr. ANDREW WOOD moved, as an amendment,—"That the words 'Algebra, including simple equations,' be omitted." By putting algebra amongst the optional subjects, it would enable a man, if he chose, to take Greek or French. He proposed this amendment with the view of afterwards moving that algebra be included amongst the optional subjects.

Dr. ACLAND seconded the amendment *pro formâ*.

As the feeling of the Council seemed to be against the amendment, it was withdrawn, and the resolution was agreed to.

On the motion of Dr. STORRAR, seconded by Dr. SHORTER, the third compulsory subject—"Geometry, first two books of Euclid"—was agreed to.

Dr. SHORTER moved, and Sir D. J. CORRIGAN seconded,— "That Latin be one of the compulsory subjects."

Dr. ANDREW WOOD eonsidered an examination in Latin a perfeet sham unless the student was examined in the construction of the language. In English they included "Grammar and Composition," but now they proposed simply "Latin;" and the consequence would be students would come up for examination, thinking they had nothing to do but translate a sentence, and in most cases they could do that, and yet be entirely ignorant of the construction of the language.

Dr. STORRAR quite agreed with Dr. Andrew Wood. He had over and over again lifted up his voice against the way in which Latin examinations had been conducted. In bygone times he had been considered violent in his denunciation of the Royal College of Surgeons in this respect, for they kept Cæsar's Commentaries staring the students in the face from year to year. He thought when they put down simply "Latin" they might leave it to the public educational bodies to determine what should be the degree of Latin required, and what form the examination should take, and he still thought that was sufficient.

Mr. HAWKINS explained that the Royal College of Surgeons did not always examine in the same Latin book. They each year issued a subject for the following year. In one year it might be a passage from Cæsar's "De Gallico Bello," and another from something else.

Dr. STORRAR said he did not object to Cæsar's "Commentary," but to the fact that the examination always seemed to be in the first book.

Dr. SHARPEY assured the Council that, from what he had seen, if they restricted Latin to mere translations from books, it would be no test whatever of the student's proficiency.

After some further discussion,

It was proposed by Dr. STORRAR, and seconded by Sir D. J. CORRIGAN, "That the fourth recommendation of the Committee should stand thus—'Latin, translation, and grammar.'"

And as an amendment, Dr. FLEMING proposed, and Dr. ALEXANDER WOOD seconded, "That the recommendation should stand thus:—'Latin, including translation and parsing.'"

The amendment having been put and carried, was put as a substantive motion, and agreed to.

It was then agreed that Greek should be one of the optional subjects.

Sir D. J. CORRIGAN moved what had already passed as an amendment as a substantive resolution, namely, "That Greek be included in the list of compulsory subjects after 1869."

After the amendment had been seconded,

Dr. ALEXANDER WOOD asked whether it was competent for them to accept the resolution. He thought it should be an instruction to the Council of 1869 to take it into consideration.

Dr. THOMSON rose to propose an amendment. He acknowledged that he attached great value to Greek as a means of training in connexion both with general and scientific education, and he hoped at no very distant date to see Greek introduced into the list of compulsory subjects, but he did not think they were in a position to decide at present even for 1869. In Scotland very great progress had been made. While some six or eight years ago they could not have ventured upon this subject, they might now do so with safety in several of the institutions that granted degrees. It would be more easy for the Council to take a middle course, and therefore he proposed, as an amendment, "That the Medical Council, while fully aware of the importance of a knowledge of the Greek language as a means of training in connection with general and scientific education, and most desirous of seeing it included in the list of preliminary subjects for examination for a Medical qualification, are of opinion that it is expedient to defer for the present the introduction of Greek into the compulsory part of the curriculum."

Dr. ANDREW WOOD seconded.

Sir D. J. CORRIGAN thought this could not be received as an amendment. It said it was not expedient to introduce Greek into the curriculum at present, and his resolution did not say it was.

Dr. ANDREW WOOD said Sir Dominic Corrigan's motion tied down the Council to a course of action three years hence; but Dr. Thomson's proposition left the matter open, so that it might be discussed next year or the year after. He did not think the Council should pledge themselves to anything that was to happen three years hence.

Dr. ACLAND thought it would be a dangerous thing for this Council to issue any declarations which were at all likely to be withdrawn. Nothing could be more unfortunate for them than to endeavour to enforce that which it was very doubtful they would ever get thoroughly accomplished. Some years ago he collected opinions from experienced masters on this point; and one of the most experienced that he knew said that the necessary consequence of their forcing Greek upon every member of the Medical Profession would be that they would have an inefficient and discreditable examination, because it was impossible out of the average mass of any profession to compel the students in the present state of knowledge to acquire Greek. Sir D. J. Corrigan's motion was an instant injunction to schoolmasters who were preparing young men for the examinations that they must teach Greek. But it so happened that one of the points upon which the ablest and best schoolmasters had been most pressed was to give up a great deal of classical work in order that they might press into the average mind other subjects; and were these poor men to have both their ears boxed at once? He knew a young schoolmaster who had lately taken one of the higher classes of grammar schools; he was an accomplished scientific man, and was bending his whole energies to a high class of education for the upper middle classes; and if his opinion were asked upon this subject, he would say by all means let Greek be optional, because he was doing his utmost to train the mind in the most fundamental manner he could in the pursuit of scientific study. Therefore he (Dr. Acland) thought that unless they were prepared to compel all the schoolmasters immediately to turn their attention in an opposite direction to that in which it had been turned for the last few years, they had better wait another year or two before pressing Greek.

Dr. STORRAR wished to reply to Dr. Acland, who had said that some of the schoolmasters in the country, and some of the most valuable of them, were giving up Greek——

Dr ACLAND: No; I must not have saddled upon me what I did not say.

Dr. Storrar asked to be allowed to complete the sentence —were giving up the use of Greek as a means of training the average mind.

Dr. Acland: That is not what I stated.

Dr. Storrar was most anxiously desirous of not misrepresenting Dr. Acland or any other gentleman. He was ready to admit there was a certain section of the middle classes —that section of young men who were going into merchants' offices or various other pursuits in civil life—amongst whom it was becoming the practice to give up the study of Greek, and to put in its place German, French, or mathematics, or some of those educational subjects which, while they served the purpose of intellectual discipline, could be brought more usefully to bear upon their future pursuits in life than Greek. If that was what Dr. Acland intended to say he perfectly agreed with him. But what he wished to represent to the Council was this—that according to the schemes they had hitherto published they had contemplated detaining young men at school until they were 17 years of age, and they laid down that it was of the greatest importance for the comprehension of physiology, and many of the scientific terms—anatomy, chemistry, natural history, in fact, all the circle of the sciences, that some knowledge of Greek should be acquired. They were, therefore, of opinion that before the age of 17, assuming a boy to be gifted with average mental powers, and subjected to ordinarily good means of training, that it was possible for him to acquire a knowledge of Greek.

Sir D. J. Corrigan remarked, with reference to what Dr. Acland had said about his motion binding the Council, that it was only following a practice that had always obtained in the Council in regard to preliminary and Professional education. If it were found injudicious to press it in 1869, then it would be in the power of the Council of that year to rescind it, and it was much better it should come out now as a warning.

The amendment was then put, and there were for, 9; against, 11. It was, therefore, lost. The resolution, that after the year 1869 Greek should be one of the compulsory subjects, was put, and carried by 12 against 7.

It was proposed by Dr. Parkes, and seconded by Dr. Storrar, and resolved, "That French be one of the optional subjects."

German, as one of the optional subjects, was also agreed to.

It being now nearly six o'clock,

The President said that as the other recommendations were likely to meet with some discussion, he thought it better to adjourn the consideration of the Committee's Report.

Dr. Andrew Wood then laid upon the table the Report of the Committee on the Draft of the Medical Acts Amendment Bill, and moved that it be received and entered on the Minutes. As this subject was the order of the day for to-morrow, he said it would take precedence of the adjourned debate on the subject of general education.

Sir D. J. Corrigan referred to Standing Order No. 5, which distinctly stated that the adjourned business should have the precedence.

After some discussion, Dr. Andrew Wood moved that the Standing Order be suspended, which was seconded by Dr. Parkes, and agreed to.

The Council adjourned at the usual hour.

The Admiralty have, during the last week, granted to the Seaman's Hospital Society the *Belleisle*, to be used as a floating Hospital for the reception of any cases of cholera that may apply for admission on board the *Dreadnought*. The *Belleisle* was fitted for a Hospital ship in the late war, and was sent to the Baltic. She is, therefore, in every respect well suited for this purpose, and the *Dreadnought* Committee may be congratulated in that so good a ship is placed at their disposal.

ORIGINAL COMMUNICATIONS.

ON THE NATURE OF VITAL FORCE.

By W. MOXON, M.D. Lond.,
Pathologist and Curator of Museum to Guy's Hospital.

The controversy between Drs. Odling and Beale is in such able hands that it would be presumption in a third person to interfere. But the question mooted, which concerns the nature of vital force, is of such paramount importance that now it is under agitation it may be allowable to introduce a phase of it which appears to me not yet to have received the notice that is due to it.

When Dr. Odling affirms that the powers at work in the living organism are correlated with the physical forces, he affirms that which with the widest meaning of the term "physical force" is probably true; and it seems to me that Dr. Beale in no way invalidates his opponent's position when he shows that the mechanical arrangements by which the chemist on the one hand and living substance on the other respectively produce a given result are most widely different; for, even if the powers acting in living matter be never so unlike physical forces in manner of action and in the nature of their external manifestations, yet they may be as much correlated with heat as heat with mechanical motion, or as light with sound,—for what can be more different than the key of C major and the solar spectrum?

Let it be, then, as Dr. Beale graphically shows, that the proceedings in living matter are conducted in a manner whose simplicity contrasts very strikingly with the complexity of the chemists' procedures; and let it be that these differences in the methods argue like differences in the causes governing those methods; yet all this will only show the vital force to be another phase of manifestation of the general store of physical forces equivalent to heat, or light, or chemical attraction, and differing from each of these after the same manner in which each of these differs from the other.

On the other hand, Dr. Odling, in regarding the powers evidenced in the phenomena of living structures as only varieties of general physical force, or physico-chemical force, appears to me not to yield sufficient importance to the peculiar characters of certain forces now included amongst these, and brought with them under the dominion of the law of "correlation and conservation of physical forces."

Dr. Carpenter has shown, by reasonings of the same nature with, and as conclusive as, those adduced by the exponents of the law of correlation of the physical forces, that the same law must be extended to the nervous force, concerning which he says:—"But in animals we find an additional power, termed nervous agency, nothing analogous to which exists in plants. This power, related on the one hand to the conscious mind, to which it communicates impressions derived from the external world, is also related in a very remarkable manner to the vital endowments of the organism in general, particularly to the contractile tissues" (*Phil. Trans.*, 1849, p. 736), and "nerve force thus generated" (by the agency of nerve-cells) "is not merely *expended in arousing mental activity on the one hand*, or in exciting muscular contraction on the other, but it has an intimate relationship (there can be no doubt) with all the *other* manifestations of vital force which the animal organism exhibits." (*Loc. Cit.*, p. 740. The italics are mine.)

If, then, mental activity is to be classed under manifestations of nerve-force, as a correlative of the physical forces, there should be fair account made of the importance of this member of that group. I do not think it too much to claim on its behalf that the title "conservation of physical forces" should be raised to that of "conservation of psychico-physical forces." And, allowing its due weight to the psychical element, we may consider that, on the whole, Dr. Odling casts no slight on the dignity of the vital force by limiting its efficiency to the exertion of psychico-physical powers. Since all he advances may equally be applied to mental activity, along with the rest of the phases of the vital force, and, indeed, in saying that vital force is but a correlate of physico-chemical force, he is saying what is consistent with the belief that vital force is of the nature of consciousness or mind.

In truth, if we consider the wonderful phenomena of development and growth, and compare them, as effects, with mechanico-chemical causes on the one hand, and with rational causes on the other, (by the term "rational cause" I mean a

cause endowed with reason, such a cause as man is,) does it not appear certain that the phenomena of development are not such as to result from causes simply mechanico-chemical, but rather that they evince the effects of rational causes? For if, with an able author, we explain the steps of the growth of leaf-buds by external pressure, we have then to show how that pressure itself always takes such and such definite determinations; and, having come to regard the leaf as cast in a mould, we yet want to know how the mould came to be made. This must be as complex as the object moulded, and we gain nothing by passing our consideration from the one to the other.

One step in the recent progress of philosophy appears in this part of the argument to be of great importance as tending to bridge over the bottomless abyss which now separates mental from physical science. I allude to the urging by Mr. Mill ("Examination of the Philosophy of Sir W. Hamilton," p. 215) of the distinct relations borne by the subject and object of a sensation to the sensation itself, so that "the immediate correlatives are not the pair subject-object, but the two pairs subject-sensation subjectively considered and object-sensation objectively considered." That the mind should dwell on this distinction between the sensation in relation to the subject and the sensation in relation to the object will, I believe, ultimately lead to a union of the sciences of physiology and psychology much closer than at present seems probable, for when we have come to regard the object and objective sensation as separate from the subject and subjective sensation, we shall, I think, find plenty of evidence that objective sensations do exist apart from subjective sensations to an extent wholly beyond our present capacity for belief. I know how difficult it is to conceive objective without subjective sensations when we appeal only to our own minds, in which the operations of consciousness always include both the relation to the object felt and that to the subject we call self; for the constancy of this association of subject and object, *whenever we are conscious of our sensations*, naturally grows up into a sense as of their necessary connexion—a sense so abiding that nothing is more difficult than to conceive a sensation unfelt.

And yet this very difficulty is itself as surprising even as it is constant, when we reflect that in any night's sleep we experience sensations of which we are not subjectively conscious, and that in young infants we get evidence of objective consciousness long before any subjective consciousness is displayed. Further, the manifestations of sensation, and even of some approach to reason, which are shown by very low creatures, such as infusoria and rotatoria—as, for instance, their discrimination between substances fit and unfit for their food, the knowledge they show of the neighbourhood of their own species, and the like; all these things, if we can overcome the usual ignoration of them, bear well a construction which regards them as purely objective sensations.

Suppose, then, that we should have to conclude that objective consciousness is no more peculiar to the nervous centres than is heat or mechanical motion to the body, and that the consciousness which is centred and manifested in an animal's brain is in its relation to force at large comparable with the heat which is set free in his body; the essential similitude being obscured by the fact that heat is a manifestation which causes within human control can readily educe, and which we at once recognise by simple sensation; whilst, on the other hand, consciousness cannot be educed by any mechanism we can ourselves build up, and can only be found out by inference, and not by simple sensation, an intermediate relation being held to those extremes of heat and consciousness by galvanism, which we have now become able to call forth by means of appliances we well know.

In the phenomena of growth and development, such an astounding adaptation of means to ends is shown, and all so utterly beyond the province of physical and chemical forces as elsewhere experienced—only imitable in the faintest degree when the reasoning mind of the chemist guides the process—that it seems not unreasonable to attribute the causation of those phenomena to something rather akin to consciousness—such an objective consciousness as those above alluded to, as evidenced in dreams, in infants, in worms; yet simpler, and yet more remote from subjective consciousness; so that the choice of one combination of composition or shape is due, not to such a preference as leads sulphuric acid to soda, but to such a preference as leads a vorticella to swallow one microscopic particle rather than another, this being an excessively low manifestation of the preference which operates as motive in higher beings.

This is not so very absurd as it seems at first sight: any one who will take the pains to sit and watch a group of infusoria, and think how much he can make out of the half-conscious, half-mechanical phenomena they show, will be prepared to deal with the conception of separate objective consciousness as a by no means fanciful but very real thing.

However, it is far from my wish to urge such a theory of vital causes; my intention is only to advance it in the hope of showing that the subject which Drs. Beale and Odling are discussing is wider than at first appears, and that the affirmation of Dr. Odling, that vital force is one of the correlatives of the physical forces, is not contradictory of Dr. Beale's view of the paramount importance of the living thing as a transformer, seeing that its correlation with the physical forces does not show that it is not a thing so paramount as mental activity.

SATURDAY, MAY 26.

GENERAL MEDICAL COUNCIL.

The admirable address delivered from the chair at the opening of the present session of the General Medical Council is not only, as we have already termed it, clear and businesslike, but it is also highly suggestive, and suggestive in some directions that were, we suspect, hardly intended. In the latter part of it practical suggestions were put forth "for the improvement of the efficient working" of the Council, which well deserve, and will doubtless receive, very careful consideration; but the earlier part of the address reads, to our mind, very like a delicate satire on the proceedings of the last year's session. It would, perhaps, be scarcely respectful to suspect the President of an intention—"not to put too fine a point on it"—to "chaff" the Council about the magnificent amount of work they had accomplished; and yet, on reading his "brief survey of the more important labours of the Council during the last session," such a suspicion is all but irresistible, for what does his *resumé* amount to? "A Select Committee was appointed to report upon the subjects of general education to be inquired into in the preliminary examination of Medical students," and it made a report, but at so late a period of the session that "the Council were of opinion that they could not then consider the important questions brought forward in the report." In 1864 the Council had invited the several licensing bodies to favour them with observations and suggestions upon various points connected with Professional education, and many reports, "drawn up with great care and replete with valuable suggestions," were last session sent in for the use of the Council; but "this mass of useful information has hitherto not been brought under the consideration of the Council, and certainly has not been utilised." The visitation of the examinations of the different licensing bodies by the several branch councils was agreed upon, a report was received from the Committee appointed to take steps for the preparation of a new edition of the "British Pharmacopœia," and "the

Council afterwards thought fit to pass a resolution which may have led members of the Council" and the Profession to suppose that a proof copy of the new edition would be in the hands of the members one month before this meeting of the Council; but that was an error; the work was not to be got through with so fast as that.

And that was all!—all that seemed worthy of being included in a *resumé* of "the more important labours" achieved by the Council last year—the seventh year, be it remembered, of their costly existence. Perhaps, however, we ought rightly to include in the list of labours the special "duty assigned to the Executive Committee" of communicating with the Government in regard to the Bill for amending the Medical Acts, inasmuch as that duty devolved on the Committee in consequence of insuperable obstacles having intervened to defeat the efforts of the Council to effect the work for which they had been so early brought together—viz., the passing of an Amended Medical Acts Bill last year. If we get one this year, we shall owe it to the energy and persistence of the President of the Council in urging the subject on the attention of the Government. Looking at the business already before Parliament, it is indeed difficult to discover grounds for even a faint hope that we may get an Act passed: still, "hope springs eternal in the human breast," so let us hope for success on this point, as also that the present session of the Council may be more fruitful of what is generally understood by the phrase of "work done."

A considerable part of the first day's sitting was consumed, it would be rude to say wasted, in discussing a motion of Dr. Acland's founded on a memorial from the Sub-section of Physiology of the British Association, suggesting that the Council should, "by pecuniary grants and the appointment of suitable persons, undertake investigation into the physiological action of medicines." Sir D. J. Corrigan carried by a very large majority an amendment to the effect that such investigations did not come within the province of the General Medical Council, and that they had no power to expend money on such objects. Dr. Acland means to bring the matter again before the Council by a motion to refer the question to their solicitor for a legal opinion. It seems a pity that he could not have in some other way ascertained the general feeling among his colleagues, and so have saved the time occupied by the first discussion.

An attempt made by Dr. Alexander Wood to get a Saturday half-holiday for the Council at the expense of the mornings of the London members, was met by a kind of half-way compromise, a resolution being passed that on Saturdays the Council should meet at one and rise at four. This will allow the country members who, according to Dr. Alexander Wood, "suffer from breathing an air they were not accustomed to, when their sessions extended over a Saturday," to escape from the mephitic and oppressive atmosphere of the West End, and breathe some pure country air till the Monday, when they may return to their labours with renewed vigour—not of lungs, we hope, but of thought.

On Friday the report of the Committee on the subjects of general education, deferred from last Session, was received, and was ordered to be re-committed, with an instruction to the Committee "to take into consideration and report upon the examinations in general education at present conducted by the various national and other bodies recognised by the General Medical Council." The result we shall report further on. The Council then proceeded to consider communications from the Medical Departments of the Army and the Navy. An application had been made by the Council to the Director-General of the Army Medical Department in April, 1865, for returns of the results of examinations, held in 1865, for Medical commissions in the army and in Her Majesty's Indian Service, and the request was made that the returns might, like the returns received from the Navy Department, "specify in similar detail the number of the candidates, and the heads under which the candidates failed to answer." In May the Director-General returned a reply promising the information asked for, but in November he informed the Council that the Secretary of State for War objected to furnish "a return, showing the different licences of the candidates for commissions in the Army Medical Department, and the subjects in which the unsuccessful ones were deficient," on the ground that such a return "would have the effect of allowing the unsuccessful candidates to be identified, and thereby bringing upon them individually a stigma" which they had never supposed they could receive. It would be difficult, perhaps, to avoid this risk if the list of candidates were a very small one, but in such a list as the Army Medical Department has to present it would surely be easy so to arrange it as to make it impossible for any one outside the Examining Body to spot any of the individual candidates, and the information sought for is of such special value in showing the weak points in education, and in the present system of examinations for diplomas, that we greatly regret it should be withheld. The return from the Director-General of the Naval Medical Department tells a most pitiful story,—twenty-one candidates presented themselves for examination in the year, only twelve of whom were successful, five passing good, two moderately good, and five indifferent examinations; "the majority of those rejected were utterly ignorant of the Latin language, two failed altogether in Anatomy and Surgery, and two were so ignorant of Materia Medica that it would have been dangerous to have passed them as qualified;" and the Examiners add that "many of the manuscripts sent in by the candidates have given evidence of such an ignorance of orthography and of the most ordinary rules of English grammar and composition as could hardly have been credited in members of a liberal Profession." It is difficult to remember while reading such a return that every one of the candidates held a diploma; the great majority, indeed, held two, one (rejected deficient in Anatomy, Surgery, and Latin; manuscript indifferent) held three different licences; and one, who "passed an indifferent examination," was possessed of four, including the licence of the London College of Physicians and an M.D. degree. That a gentleman who possessed only the licence of the Royal College of Surgeons of England should be rejected as "deficient in chemistry, Materia Medica, Midwifery, and botany" is not to be wondered at, as the College does not stoop to those subjects; but it is sad to find that when he succeeded, on a second trial, he should have passed "a good examination in all branches *excepting Surgery*, which was fair." Now, no one will take this list as anything like a fair specimen of the average kind of men who succeed every year in entering our Profession; what the return most forcibly evidences is the deplorable state of the Navy Medical Department. These candidates are all it can show for a whole year, and of these five only pass a good examination; no words can more powerfully depict the unpopularity of the service. But the return should also be a valuable lesson to teachers and to examiners; it is most lamentable, to use a mild expression, to find that men so ignorant of all that they ought to know, as were some of those diplomaed candidates, could have gained admittance to the Profession through any portal whatever.

In 1865, the Council sent to the Secretary for War a recommendation that in the Army List "initials, indicating the several Medical qualifications of Army Surgeons, should be inserted after their names, without distinction or preference to one degree or licence over another," and that each Surgeon should be allowed to display only one Medical qualification. Lord De Grey now very naturally asks for a list of *initials*—what *initials* are, for instance, to be used to indicate a "Licentiate of the King and Queen's College of Physicians of Ireland?" and "suppose, for illustration, a Licentiate of the King and Queen's College of Physicians, Dublin, is also an M.D. of Edinburgh or a Member of the London College of

Physicians, or a Licentiate of the Society of Apothecaries, which of these Medical qualifications is to have the precedence, and by whom is this to be decided?" A Committee was appointed to consider the matter; we do not envy them the task of working out the initials. Will they rank the qualifications according to a principle of seniority, or will they leave the choice in the hands of the happy owner of a multiplicity?

A letter from Dr. Mackesy, President of the Royal College of Surgeons of Ireland, and of the Irish Medical Association, enclosing a resolution adopted at a very large meeting of the latter body, stating that in the opinion of the Association the Medical Council had not properly performed all its functions with reference to preliminary education, gave rise to a very warm discussion. Some members of the Council thought the letter and the resolution very important, and wished that both should be entered on the Minutes; others found them very impertinent, and desired that the Council should pass on to the order of the day; and others, again, would enter only the resolution on the Minutes. The conduct of one of the members of the Council was very freely commented on, and the tails of an Irish coat were most defiantly trailed across the floor of the Council chamber. Eventually, the letter and resolution were referred to the Committee on General Education, which, when reporting on the matter at a later date, recommended that the resolution should be entered on the Minutes. It was hardly worth while making such a disturbance about the matter, for even the President in defending the Council could only say that they "had not done as much as they wished to do, nor as much as they ought to have done;" and we strongly suspect that outside the Council the verdict will be in favour of the peccant resolution, and pithily expressed against the Council in the old phrase of "served them right." Besides, as the Council have now agreed on what shall be the minimum amount of subjects required in the preliminary examination, they may feel that they have an excellent answer to any criticisms on their former proceedings, or non-proceedings, in the matter, and can afford to receive them with entire composure.

The Report of the Committee on the subjects of general education was taken into consideration on Monday, and much of it adopted. For the details we must refer our readers to the published Minutes, and content ourselves with stating here what subjects the Council had determined on as part of the "minimum amount," when the debate was adjourned. "*Compulsory.*—1. English language, including grammar and composition. 2. Arithmetic, including vulgar and decimal fractions; algebra, including simple equations. 3. Geometry, first two books of Euclid. 4. Latin, including translation and parsing; and 5. One of the following *Optional subjects*—Greek—French—German."

On the motion of Sir D. J. Corrigan, seconded by Dr. Storrar, it was also resolved, "That after the year 1869, Greek shall be one of the compulsory subjects."

The debate was then adjourned, there remaining for discussion the position that Natural Philosophy should occupy in the Educational scheme—whether it should rank among the optional subjects of the preliminary or the compulsory subjects of the Professional examination. We shall reserve our remarks on the whole subject till we can place the completed scheme before our readers, but we must congratulate Sir D. J. Corrigan on his success with the Greek question; he has fought it with courage, perseverance, and skill. We do not think that any amount of teaching in Greek—or in anything else—could make anything but a blockhead of his young gentleman who "hesitatingly thought Physiology was a kind of fungus," but we do think that it is not too much to require some knowledge of Greek from every student who wished to be entered for one of the learned and liberal Professions. To those who really fear that in the middle of the 19th century this is demanding too high a degree of education, we recommend a study of the speeches of Sir D. J. Corrigan and Dr. Storrar on the subject.

The proceedings of the Council during Saturday's sittings do not demand much notice here. A very important question came before them as to how they should deal with the fact of students having been permitted to commence their Professional education at Glasgow before passing the preliminary examination, but as the whole matter was referred to a Committee to examine and report upon, it will come before us again.

A Mr. William Adams, once of St. Ives, and now in the army, prayed that his name might be restored to the Register, its having been omitted through an erroneous report of his death. His prayer was of course granted.

A rather pathetic petition from Mr. Richard Organ to be allowed to present himself at one of the Examining Boards, was peremptorily, and we think rightly, rejected.

Tuesday's and Wednesday's sittings were occupied almost entirely by the discussion on the Medical Acts Amendment Bill, but it will be impossible for us to give the Minutes or the speeches of those days till next week.

THE LONDON SURGICAL HOME AND THE TESTIMONIAL TO ITS FOUNDER.

Reports of Medical charities are not usually amusing reading, but there are exceptions, and we have recently lighted upon one. We have lately seen a series of these papers having reference to a certain special Surgical institution at the West-end of London, which are certainly as good in their way as that racy chapter of "Martin Chuzzlewit," in which the Lady Interest and the Gentlemanly Interest vie with each other in doing homage to the talents and virtues and disinterested benevolence of the great Mr. Pecksniff. The chapter referred to may be entitled the Pecksniffian Apotheosis, the reports to which we invite attention, the Brunonian. The hero of the latter, however, takes a much more active part in the proceedings they detail than did the celebrated architect on the occasion of laying the foundation-stone of the grammar school. That great genius could only reply to the cheers which greeted him by telling the crowd how much he was affected, and by paternally blessing them; but the founder and Surgeon of the institution we write of eclipses Mr. Pecksniff—at least, in self-composure and presence of mind. Like lesser persons, he has a taste for adulation, but he far surpasses the vulgar herd in his capacity for it. He is one of those representative men in whom no bashfulness limits the power of swallowing; no misgiving disturbs digestion. The greasiest and most rancid butter seems to sit easily upon his placid stomach. His mental organisation may be compared to that of a self-supplying patent digester, for when other people have exhausted themselves in praising him, he immediately takes up the parable and begins to praise himself.

Are our readers sceptical on the subject of disinterested philanthropy? do they need convincing that the genius and intelligence of the present era of Surgery are equal to the cure of any and every disease? do they want to know where the best skill our Profession can give is to be found? and are they curious as to the department of Medicine which is specially under the Divine guidance, and as to who may be its chief apostle? then verily let them procure the Reports and Proceedings published by the London Surgical Home during the last half-a-dozen years, when all their doubts will be settled and all their inquiries answered.

These and many more wonderful things the benighted outside Profession will find in these pages; but it was not for us that the speeches were made and these mysteries revealed. Fair faces hung on the lips of the speakers, and doubtless in many a boudoir their touching appeals and the singularly unvarnished reports which illustrate them, have stimulated alike the curiosity and compassion of the gentle occupants. This, we think, is a new feature in the machinery of Medical charity. Medicine used to be a reticent science. There was a time when

the goddess was veiled to all but her immediate worshippers, when her mysteries were reserved for the initiated, and the infirmities of poor humanity were safe in her keeping. But a new era has dawned. Surgical Homes and Brunonian discoveries have changed all this. The goddess is not only unveiled but unpetticoated. Lady patronesses are presented with printed reports in which lists of female maladies, from rupture of the perinæum to hypertrophy of the clitoris, are paraded as piquant excitants to almsgiving; and the benevolence of the wives and daughters of Westbournia, like the Protestant horror of martyrdom in Lord Macaulay's country rector, is kept at a white heat by the very natural reflection of—

"How very bad it must feel."

It were unfair to deprive our readers of the topics for amusement and reflection which these Reports have afforded ourselves: we therefore offer them a few extracts. We select a pamphlet entitled "Proceedings at the Third Annual Meeting of the London Surgical Home for Diseases of Women." This *brochure* contains the Annual Report of the Committee, and a short-hand writer's transcript of the speeches made by various orators who addressed the meeting. The Report of the Committee is of a highly cheerful and congratulatory character; it informs the world that the "reputation" of the Institution "increases day by day, and all the Medical journals now include the London Surgical Home amongst the recognised Medical Institutions of the metropolis." A few lines further on, we are told that "many delicate and difficult operations have been performed, in cases which required an extraordinary combination of Medical skill with the most careful nursing." We then read that of sixty-nine cases of cure enumerated, twelve were cases of patients "who suffered from one of the most distressing and annoying diseases to which the sex is liable;" and a little further on "The extraordinary instances of complete restoration to health after years of hopeless suffering, which the past year has witnessed, must be attributed, under God, in the first instance, to the skilful treatment and careful attention of the Medical officers." The Report is followed by a tabular statement of patients admitted, arranged according to their diseases; of these there are six-and-twenty specified, nearly all being affections of the pelvic viscera, and most of them of the reproductive organs. We pass over the speeches of the reverend gentleman who occupied the chair, and of another minister who spoke on the occasion. In whatever cause religious motives are appealed to, they at least demand our respect, and although religion degenerated into pietism has forfeited much of its claims, there is more than enough worth extracting in the remaining speeches to fill our allotted space. Mr. J. F. Clarke rose to move the congratulations of the meeting to the founder of the Institution on its continued prosperity, and to offer its best thanks to him for his constant and invaluable services in promoting the efficiency of the Institution. The speaker thought that the "thanks of the Profession" to which he belonged "were deeply due to the distinguished Surgeon." He went on to say "that the cases which have been received into this Home, and which have been cured and relieved, were cases that were turned from the doors of "the great and magnificent" London "Hospitals." "All honour to the man who has devoted himself to the cure and relief of a class of diseases most lamentable, most distressing, and most difficult of cure," with much more in the same exalted strain. Then followed a Mr. Holt, who professed to represent the general public on the occasion. He was certain that "the success which has attended the London Surgical Home is due to Mr. Brown." "Mr. Brown's friends are all well acquainted with his Professional skill, his kindness, and the success which has always attended his operations."

Then came the speech of the day. Most men, under the circumstances, would have disclaimed thanks, but the founder, with charming honesty, confessed that he looked forward to being thanked with pleasure. He said he found the toils of his Profession and the gratitude of his patients together "almost too much for his buoyant disposition and for the natural elasticity of constitution which God, in his mercy, had given him." He then tells his audience that the great problem he is engaged in working out is "that all that is considered incurable shall, by God's blessing, be cast away from our scientific Profession, that there shall be no such thing as incurability, but that every case that comes before us shall receive the blessed antidote by the skill and science of man, guided and directed by God." Further on he informed them that 168 perfect cures had been made in the year. "Now recollect," he says, "that a very large majority of the number were considered perfectly incurable, and would not have been cured if we had not this Institution or some similar one to receive them." The patients "meet with the best skill which our Profession can give them." Even the nurses turned out by the Surgical Home are superior to all others. "We train them up in a way in which they can be trained nowhere else." The great point, however, in the speech is the foreshadowing of some sublime discovery which, although its nature is not absolutely specified, we take to be none other than that of the new operation for epilepsy. Our readers will bear in mind that "the founder" is addressing an audience described by one of the clerical speakers as "dear Christian ladies." . . . . "We can say in this Institution we take the most difficult problem in the world to solve, and we do solve it here. We are glad and thankful, therefore, to be able to rank as high as other people who are working in the great field of progressive work. During the last few weeks a fact has come to my own knowledge of such vast extent that I shall not even allude to it here. But another year I shall be able, I believe, firmly to say that such an astounding fact has come before me, and has been demonstrated, as will startle mankind when they hear it. A great scientific fact, calculated to benefit thousands and thousands of those who are affected with the most distressing sufferings that can possibly be brought before us—sufferers who are in their separate Asylums, cut off and excluded from the face of man and every loved one. I believe we shall see that even these come under the scientific skill of the Surgeon, and that God will bless and cure them." The modest oration ends thus:—"Allow me to say that as long as God gives me health and strength I will devote myself as earnestly as I have done, *and more so I cannot*, to the elucidation of truth, to the establishment of health, and to the benefit of every one who comes into this Home under my care."

We can only mention a speech of the Physician to the Institution, who told the "dear Christian ladies" that he had frequently seen disastrous failures in operations undertaken by others which Mr. Brown performed with such great success, and further dilated on "Mr. Brown's admirable skill and dexterity;" but there is one quotation from an after-speech by the latter gentleman which is really too good to omit, as, with what has preceded, it may give a sceptical Profession some idea of the great mental effort required to have evolved the operation for epilepsy from the inward consciousness of "its discoverer," and the scarcely inferior effort which it and similar proceedings need for their performance:—"Thursday is our operating day. . . . Every one's brain is stretched almost beyond the power of endurance, and the exertions of every one are almost superhuman." The proceedings terminated by the reverend Chairman pronouncing the Benediction. We hope we shall not be deemed irreverent if we suggest the following quotation from Sheridan's *Critic* as a form of prayer to be used on future occasions for the staff whose brains are thus "stretched:"—

"Assist them to accomplish all their ends,
And sanctify whatever means they use to gain them."

We do not feel ourselves called on to pronounce on any grave question of morality. We are only censors of good taste and Professional propriety. There are certain unwritten

laws current in our Profession which have hitherto had the effect of keeping desire for notoriety within due bounds amongst its members. But it would now seem that to laud one's own Surgical talents, to boast of cures of diseases, boldly stating them to have been incurable by other members of the Profession, to publish lists of disgusting diseases for the perusal of innocent women—as long as all this be done under the form of a Report of a self-originated Hospital, and with an unctuous reference to the Divine blessing, is a certain passport to Professional fame and a claim on Professional gratitude. It may be so. The age is a progressive one, and old-fashioned ideas of good taste and of the responsibilities and duties which the Profession of Medicine imposes on its followers may be as behind the time as are living within one's income and being contented with three per cent. But surely these Reports are a sufficient testimonial to the virtues, talents, and public services of the founder of the Surgical Home without the Profession being called on to furnish any other. What in the way of laudation can any testimonial express which has not been testified by the clerical and Medical orators who have met to do honour to the "distinguished Surgeon," or which the "distinguished Surgeon" has not testified of himself? Can the force of puffing any further go? For ourselves, if the Profession respond to the appeal that has been made to them and fill the subscription list of the founder of the London Surgical Home, we shall be tempted to accept the views held by the Rev. Dr. Cumming, for we remember that a sign of the latter day is to be that for brass men shall bring gold.

THE WEEK.

PARLIAMENTARY.—THE CATTLE PLAGUE IN IRELAND—THE NUISANCES REMOVAL BILL—METROPOLITAN WORKHOUSE INFIRMARIES—THE CHOLERA AT LIVERPOOL.

On Thursday, May 17, in the House of Lords the Contagious Diseases Bill was read a third time and passed.

Mr. Herbert asked the Chief Secretary for Ireland whether he had been informed that the cattle plague had been introduced into Ireland by a drover from England, and, if so, whether the Government was prepared to forbid English drovers entering Ireland during the continuance of the plague in this country.

Mr. C. Fortescue could afford the House no further information respecting the cattle plague in Ireland. The hon. gentleman might be sure that the Government would put in force the full powers granted to them by law, but he could not for the moment give any definite answer to the question of the hon. gentleman.

Mr. Knatchbull-Hugessen obtained leave to bring in a Bill to amend the Nuisances Removal Act.

On Friday, in the House of Lords, in answer to a question by the Earl of Carnarvon, Earl Granville said that some of the Reports as to the condition of the Metropolitan Workhouse Infirmaries, ordered by the President of the Poor-law Board, had already been furnished to that Board, and it would be the duty of the Government to lay them before Parliament.

In the House of Commons, in answer to some questions by Mr. Laird, as to the removal of 200 emigrants from the *Helvetia*, a ship infected with cholera, to the Government Emigration Depôt at the Birkenhead Docks,

Mr. Bruce said that the Government was informed by an officer in the employ of the Emigration Commissioners that the emigrants in the *Helvetia* were removed to the Birkenhead Depôt by order of the Mayor of Liverpool. The depôt was not the property of the Government, but was occasionally used by them for their emigrants. It consisted of a large dormitory upstairs capable of holding 400, and of a mess-room downstairs. Four hundred emigrants, who were to sail on the 9th, were confined to the dormitories, and the 200 emigrants from the *Helvetia* were placed for the night in the mess-room. He was unable to say whether the Birkenhead authorities were communicated with. The cholera broke out among the passengers of the *Helvetia* soon after their arrival at the depôt; but he had no reason to think that any of the 400 emigrants who left the depôt on the 9th had suffered. He was happy to say that no new cases were reported since yesterday, and that no case had occurred among the inhabitants of Birkenhead. The Government have no intention of using the depôt for a considerable time. Their emigrants would be shipped from other ports.

THE CHOLERA AT LIVERPOOL.

(From a Correspondent.)

Deaths in the Town.

When and where died.	Sex. M.	Sex. F.	Age.	Profession.	Cause of Death.
May 14; 152, Vauxhall-road	—	F.	(?)	Shopkeeper ..	Asiatic cholera.

Referring to this last case, the Medical Officer stated at the Health Committee that immediately after receiving intelligence of the circumstance he visited the residence of the deceased, and saw her daughter and the doctor who attended her. He found from the statements of the daughter that her mother had been for years subject to periodical attacks of very severe purging; that about a year since she suffered from a fall and injury of the skull, which at the time endangered her life, and afterwards left her a weakly invalid; that the symptoms of purging and the appearance of the evacuations were in no respect different in the last than in the former attacks of sickness, and that the evacuations were coloured, and not like rice-water. The Surgeon stated that he had not seen any of the evacuations; he had found her sinking on his visit; she had had no purging for eight hours before death—that is, from 2 a.m. to 10 a.m. Dr. Trench mentioned to the Committee that he did not consider the case one of decided Asiatic cholera, although he directed the necessary purification of the house and clothes to be adopted.

During this meeting of the Health Committee the Medical Officer was asked about the death of a priest from cholera, as mentioned in the *Times*. He stated that he had not heard anything which could have given rise to the rumour. He did not believe the truth of the report.

KILLED BY A GAME COCK.—An inquest was held last Saturday, by the Coroner for Middlesex, on the body of Charles Winter, aged three years, who died from the attack of a game cock. He was attacked by the bird, which pecked him severely about the face and head on Tuesday, and he died on the following Monday. Mr. R. Meldola, M.R.C.S., said that the deceased died from effusion of serum on the brain caused by the shock to the system, arising from the attack and pecks of the game cock, as well as from the fright.

REVIEWS.

Symptoms and Treatment of the Cattle Plague, with a Sketch of its History and Progress. By Arthur Wynne Foot, M.D. Pp. 69. Dublin: McGlashan. London: Longmans.

Dr. Wynne Foot adapted his book for "the instruction of the landowners, graziers, and cattle dealers of Ireland," but without any sacrifice of scientific diction or detail. His description of the early symptoms of Rinderpest is quite a word picture: the dismal shake the diseased animal gives to its head, and the cattle inspector listening for the periodic rattle of the stall head chains, is quite a touch of art. We quote a few of his remarks. In Rinderpest the inspiration is jerky and expiration ends in a *groan*, not a *grunt*, as in pleuro-pneumonia. "It is, in fact, most distressing to hear the *groaning* of a number of plague-struck cattle." Along the spine especially there is subcutaneous emphysema, the air rushing out with a "*fizz*" when the skin is punctured, a mode of relief which is only temporary. One Norfolk farmer thinks he cured a cow by long scored incisions upon the back. Dr. Wynne Foot describes the skin eruption as dirty yellow scabs, which, being raised, show on their under surface and the corresponding surface of the skin a white, pulpy, sodden appearance, in which he could observe no true formation of pus; this spot is not depressed, and he does not think it characteristic of cattle plague; neither is it necessarily a bad symptom. He passes on to the incubation of the disease; the symptoms in sheep and goats; the "modifying circumstances," which are but *two*, viz., "calves take the Rinderpest sooner than older animals, and Dutch cows are more amenable to treatment and succumb less readily than English cows." With these exceptions, neither age, nor sex, nor breed, nor mode of feeding seems to make any difference." It is curious that, as in the early epidemics of cholera people thought the wells were poisoned, so when this plague broke out in Mrs. Nichols' dairy on July 4, 1865, the same impression prevailed, and portions of the viscera and specimens of the water were sent to the Royal Veterinary College for analysis, when Professor Simmonds at once said there was no other poison in the case than that of a new cattle disease which had come into the country. "No carnivorous animal has been affected with the disease." "A pregnant cow does not necessarily slip her calf," and "a four months' calf taken from a Rinderpest dead cow showed no signs of the disease." On the skeleton map of England and Scotland, kept in the Privy Council Office, there were, when Dr. Wynne Foot examined it, 12,000 *red marks*, indicating the centres of infection; these showed that the Rinderpest has no tendency to follow the courses of rivers; and as to atmospheric conditions, it is worse in cold and wet, and better in warm and dry weather.

The author gives a clear description of the morbid changes of tissue, taking each organ by itself. He then describes the treatment and preventive measures in the various countries which have been attacked, also inoculation, vaccination, and how to perform them; he quotes Dr. Ballard's papers on the Predisposing Causes of Rinderpest, gives a history of the disease, and winds up with what is "unpleasantly true, that as a general rule treatment is worse than useless." However that may be at present, we would hope that some rational and scientific treatment (we do not believe in "*cures*") of Rinderpest will be arrived at in time, after such acute observers as Dr. Wynne Foot have further considered the subject.

GENERAL CORRESPONDENCE.

THE FEE FOR CLITOROTOMY.

[To the Editor of the Medical Times and Gazette.]

Sir,—A patient of mine was induced by perusing the last report of the London Surgical Home to apply for admission. She was informed by the Surgeon that the Home was intended only for those unable to pay for Medical advice, and recommended to come to London to have her clitoris removed.

Some time after the operation she asked the fee, and was more surprised than pleased to find that she was expected to pay one hundred guineas. This seems a large sum for such an operation, and it is to be regretted that the patient was not previously told the amount.

I am, &c., F.R.C.S.

MR. BAKER BROWN'S OPERATION.

Letter from Dr. Charles West.

[To the Editor of the Medical Times and Gazette.]

Sir,—I beg leave to state that the Surgeon who performed the operation for the removal of the clitoris in the circumstances related at p. 663 of my "Lectures on Diseases of Women," and to which you refer in your review for May 5 of a work on "The Curability of Certain Forms of Insanity, Epilepsy, etc.," was Mr. Isaac Baker Brown.

I saw the lady whose history I have detailed for the first time on Sunday, February 2, 1862, in consultation with Mr. Paget, of St. Bartholomew's Hospital, and Mr. Barnes, of King's-road, Chelsea.

I refer to those gentlemen in corroboration of the truth of my statement. I am, &c.

61, Wimpole-street, May 22. Charles West.

P.S.—I did not see the review until the latter part of last week, or should have forwarded this statement in time for the *Medical Times and Gazette* of May 18.

NEW INVENTIONS.

MAGNETO-ELECTRIC APPARATUS BY MESSRS. WALLS AND CLOSE.

We have tried the magneto-electric apparatus of Messrs. Walls and Close, of Bow-lane, and find it a remarkably compact, cheap, and efficient instrument. It is supplied with handles for administering the currents conveniently to any part of the body. Practitioners who are not within reach of Dr. Althaus or Mr. Harry Lobb should possess one of these machines for restoring limbs that have been paralysed by disease of the nervous apparatus or by the inaction consequent on compound fracture, etc.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 22nd inst., viz.:—

Richard Morgan, Aberdare, S. Wales; Thomas Franklin Lloyd, L.S.A., Finsbury-circus; George Birch, L.S.A., Kingsland; George Jesse Barnabas Stevens, Southgate-road; and Charles Handasyde Carver, L.S.A., Nottingham, students of Guy's Hospital. Alfred Hutchison Smee, Finsbury-circus; John Horsfall, B.A. Oxon., Leeds; Julius Lawrence Levy, Westbourne-terrace; Michael Perry, Haswell, Berks; and John Charles Galton, M.A. Oxon., Exeter, of St. Bartholomew's Hospital. David Roberts Pughe, L.S.A., Aberdovey; and Edward John Adams, Charlton, Kent, of St. Thomas's Hospital. Campbell Fair, Outerrard, Co. Galway; and Gordon Archdall, Bundoran, Co. Donegal, of the Dublin School. John Rees James, Llanelly, Carmarthen, of the Middlesex Hospital. Berkeley Murray, Barbadoes, of King's College. Georg Friedrich Julius Schott, M.D., Göttingen, Frankfort-on-the-Main. Thomas Lansome, Birmingham; and David Johnston, Magherafelt, Co. Derry.

The following gentlemen were admitted Members on the 23rd inst, viz.:—

Edward Cruikshank Malloch, M.D. McGill College, Montreal, Ottawa, Canada West; Julian Augustus Michael Evans, Pinner, of University College; and Leander Van Ess Parker, M.D. New York, Nova Scotia.

At the same meeting of the Court, Dr. James Middleton, L.R.C.S. and M.D. Edin., of the Royal Hospital, Greenwich; and Dr. George Russell Pickthorne, M.D. Aberdeen, of H.M.S. *Challenger*, Sheerness, passed their examinations for full Surgeons in the Royal Navy.

It is stated that out of the twenty-eight candidates who offered themselves for examination for the Diploma of Membership, seven failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their Hospital studies for six months.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 17, 1866:—

Alderson Newsam, Totnes, Devon; Thomas Silvester Gell, Stafford; Arthur Griffith Evans, Narborth, Pembrokeshire; Edward Roberts Smith, Dudley; John Dearden Bush, Newcastle-on-Tyne; James Campbell Macaulay, Leicester; James Milward, Cardiff.

The following gentleman also on the same day passed his First Examination:—

Richard Careless Sanders, London Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Bryan, E., has been appointed Assistant House-Surgeon to the Public Hospital, Sheffield.

Ellis, Edward, M.D., has been appointed a Physician for Out-Patients to the Samaritan Free Hospital for Women and Children.

Fogge, H. W., M.R.C.S.E., has been appointed House-Surgeon to the Royal Free Hospital.

Kealy, John Robert, M.D., M.R.C.S., has been appointed a Medical Officer of the Portsmouth, Portsea, and Gosport Hospital.

Leared, A., M.D., M.R.C.P., has been appointed Honorary Physician to St. Mark's Hospital for Fistula and other Diseases of the Rectum.

Wilkinson, J. S., F.R.C.S.E., has been appointed an Assistant-Surgeon to the Central London Ophthalmic Hospital.

Workman, Charles J., M.D., has been appointed one of the Visiting Physicians to the Infirmary for Consumption and Diseases of the Chest, Margaret-street, Cavendish-square.

BIRTHS.

Ashenden.—On May 16, at 41, High-street, Hastings, the wife of C. Ashenden, M.R.C.S., of a son.

Ashley.—On May 21, at 28, Labroke-square, the wife of W. H. Ashley, M.D., of a daughter.

Burke.—On May 13, at Bighi, Malta, the wife of Dr. John Page Burke, F.R.C.S. Eng., of a daughter.

Craigie.—On May 14, at Doddington, Kent, the wife of J. Craigie, M.R.C.S., of a son.

Kelson.—On May 16, at 130, St. Paul's-road, Camden-square, the wife of G. Kelson, M.R.C.S., of a daughter.

Longmore.—On May 20, at Hamble Netley, the wife of Deputy-Inspector-Longmore, Army Medical Staff, of a daughter.

Phelan.—On May 19, at Kilmagamny, Co. Kilkenny, the wife of W. B. Phelan, L.R.C.P., of a daughter.

Seccombe.—On May 18, at Terrington, King's Lynn, the wife of J. T. Seccombe, M.D., of a son.

Smith.—On May 22, at 9, Finsbury-pavement, the wife of Abbotts Smith, M.D., of a daughter.

Sumner.—On May 18, at 15, Wellington-terrace, St. John's-wood, the wife of W. A. Sumner, M.R.C.S., of a son.

MARRIAGES.

Fotherby—Engshöm.—On May 22, at Allhallows Church, Tottenham, H. J. Fotherby, M.B., 40, Trinity-square, Tower, and Louth, Lincolnshire, to Louisa Mary, only child of Charles F. Engshöm, Esq., Her Britannic Majesty's Consul at Gottenburg, Sweden.

Leathem—Newman.—On May 12, at All Souls, Langham-place, James Leathem, M.D., to Mary Matilda, daughter of A. Newman, Esq., Mortimer-street.

DEATHS.

Cannon, A., M.D., at 15, Cambray-place, Cheltenham, on May 15, aged 79.

Harday, R., M.R.C.S., L.S.A. (Vice-President of the London Obstetrical Society), at Hull, on May 12, aged 63.

Hare, H. C., M.R.C.S., at Cawood, Yorkshire, on May 15, aged 39.

Rose, Thomas Fraser, on May 12, on board the steam-ship *Helvetia*, in the Sloyne, Liverpool, from cholera, aged 34.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Lincoln Union.—Mr. R. S. Harvey has resigned the Eleventh District; area 9528; population 1821; salary £20 per annum.

Williton Union.—Mr. Wright has resigned the Williton District; area 16,602; population 5670; salary £79 per annum. Also the Workhouse; salary £35 per annum.

APPOINTMENTS.

Edmonton Union.—Ernest Ringrose, M.D. St. And., M.R.C.S.E., L.S.A., to the Cooper's-lane District.

Ellesmere Union.—Alfred Eyton, L.F.P. & S. Glas., L.R.C.P. Edin., to the Overton District.

Isle of Thanet Union.—George R. Lawrence, M.R.C.S.E., L.S.A., to the Minster District and the Workhouse.

Leigh Union.—William Hoyle, M.R.C.S.E., L.S.A., to the Atherton District.

Tenterden Union.—Nathaniel E. Creswell, M.D. St. And., M.R.C.S.E., L.S.A., to the Biddenden District.

Wincanton Union.—James J. Luce, M.D. St. And., L.R.C.P. Edin., M.R.C.S.E., L.S.A., to the Wincanton East District and the Workhouse.

Worksop Union.—Alfred Beckett, M.R.C.S.E., L.S.A., to the Blyth District.

Cambridge.—At a Congregation held on May 17, the following degree was conferred: —*Ad eundem:* William Daniel Moore, M.D., Dublin.

Dr. Barnes has been elected an Honorary Member of the University of Charkow, in Russia.

Dr. William H. Harvey, F.R.S., Professor of Botany in Trinity College, Dublin, and Keeper of the University Herbarium, who had long been ill, died of phthisis on the 15th inst. at Torquay.

The cholera has shown itself at Nantes. On the 19th inst. twelve cases were reported. The disease, however, seems not to have taken great hold, and to be already on the decline.

The British Association.—At a meeting of the Nottingham Town Council on Thursday, it was unanimously resolved, on the motion of Dr. Tindal Robertson, to invite their Royal Highnesses the Prince and Princess of Wales to honour the town with their presence on the occasion of the visit of the British Association. A deputation, consisting of the Mayor, Town Clerk, and Dr. Robertson, were appointed to wait upon their Royal Highnesses.

Testimonial—Mr. Frederick Haze Watts on being obliged to resign his appointment of Resident Medical Officer of Middlesex Hospital from ill health, received from a quarterly court of the governors on their accepting his resignation, an unanimous vote of thanks for his services, and was presented by his colleagues, past and present, with a handsome silver ewer, from Lambert's, Coventry-street, of the value of twenty guineas, with the inscription engraved—"To Fred. H. Watts, Esq., from friends and colleagues on leaving Middlesex Hospital May, 1866," as a recognition of his uniform kindness and courtesy to them, and as a mark of their friendship and esteem.

Chipping Norton, Oxfordshire.—A testimonial was presented to J. Farwell, Esq., F.R.C.S., of Chipping Norton, on the 8th of May, by eighty-two of his patients residing in the neighbourhood of Chipping Norton, consisting of a miniature brougham and fittings complete, a pair of horses, with double and single harness. Mr. Farwell's attendance on his out-town patients being interrupted last winter by a long and severe illness, they took this opportunity of showing their appreciation of his kind and unremitting attention and skill during a practice extending over a period of more than thirty years. The total amount subscribed was £258 5s.

The Mecca Pilgrims.—From information received by the Board of Health of Alexandria, it appears that the sanitary condition of Mecca has not this year been at all affected by the arrival of pilgrims in that city, and that a party of devotees were about to return to Suez on the 7th inst., perfectly free from cholera. The pilgrims were subjected to examination upon their embarkation at Djeddah, and up to the present time their general state of health has been completely satisfactory.

The London Sick Poor.—The Guardians of St. George's, Hanover-square, are calling a conference of all the London guardians at St. James's Hall, "with a view to procure the fullest information necessary to determine the proper action to be taken in relation to the resolutions submitted to the Right Hon. C. P. Villiers, the President of the Poor-law Board, by Lord Carnarvon and others, members of an Association for the Improvement of Workhouse Infirmaries." The resolution to be submitted to this meeting is as follows:—"That the removal of paupers from the control of parochial management, and placing them under a central or Imperial authority, would be subversive of the principles of local self-government, and that the collecting together of the sick paupers in large Hospitals containing 1000 beds each would not be conducive either to the cure or the well-being of the inmates."

The Scottish Universities.—The Vice-Chancellor and Professors of the University of Edinburgh have transmitted a petition to Sir William Stirling Maxwell for presentation to the House of Commons, praying that two members may be granted to the Scottish Universities instead of one, as proposed in the Redistribution of Seats Bill. The petition sets forth that the constituency which would be entitled to vote in the election would be above 4000, independent of the stimulus to registration which the grant of representation would give. The constituency of London University, to which it was proposed to give one member, was about 1800, and that of the Queen's University in Ireland, which to get another, was probably not half so many. To group Edinburgh University with St. Andrew's would give a constituency of 2700, while Glasgow with Aberdeen would furnish a constituency of 1600. On these grounds, and considering that Oxford, Cambridge, and Trinity College had each two members, the petitioners solicit that the Universities of Scotland should have two. A similar petition has been sent by the Principal and Professors of St. Andrew's University. The proposed constituency are the resident graduates, a body organised for the first time by the Universities Act of 1858,

and forming a General Council in each University, which meets twice a year to discuss questions concerning the government and general interests of the University.

INFANTICIDE.—At the meeting of the Harveian Society, held on May 17th, it was proposed by Mr. Curgenven, and seconded by Dr. Hare, "That a Committee be formed consisting of the following members:—Dr. Tyler Smith, the President; Mr. J. Brendon Curgenven, and Dr. Charles Drysdale, the Honorary Secretaries; Dr. Hardwicke, Deputy-Coroner; Mr. Ernest Hart; Dr. Sanderson, Medical Officer of Health for Paddington; Mr. Benson Baker, and Mr. Sedgwick; with whom will be associated Dr. Lankester, the Coroner for Central Middlesex, to draw up a report on infanticide, with the object of suggesting the best means of checking the crime; and to report on the causes of death of young children, the best means for preventing excessive infant mortality, and to suggest some plan for the care and rearing of illegitimate children other than the present workhouse system." Communications on these subjects are solicited by the Committee, and should be addressed to Mr. Curgenven, 11, Craven-hill-gardens, W.

ARMY MEDICAL DEPARTMENT.—The annual general meetings of the Army Medical Officers' Friendly and Benevolent Societies were held at the Ship Hotel, Charing-cross, on Saturday, the 19th inst. The Friendly Society was established in 1816 by the late Sir James McGrigor, Director-General of the Army Medical Department. It is strictly a reversionary annuity society, and intended to secure annuities to the widows of Medical officers by the payment of a small annual subscription. At the present time there are 105 widows receiving annually £22 or £44, according to the class to which their husbands subscribed. The funds are in a very flourishing condition, the capital of the Society being upwards of £78,000, and according to the quinquennial examination just completed, it is confidently believed that there is a considerable surplus of assets over liabilities. Notwithstanding this success, it is much to be regretted that in spite of every effort of the Committee, very few of the young Medical officers of the present day join the Society, for it is felt that it was intended for the benefit of the whole Department, and not merely a few of its members. The Benevolent Society was also established by Sir James McGrigor in 1820, and is quite distinct from the Friendly Society. It is essentially a charitable institution for the purpose of granting pecuniary aid towards educating those orphans of Medical officers left unhappily in distressed circumstances, and it supported chiefly by donations and subscriptions from members of the Medical Department. The Society now possesses a capital of upwards of £16,000, the interest of which, together with subscriptions, is annually distributed among cases that require assistance. At the present distribution the sum of £565 was voted in various sums between twenty-five families, and it must be gratifying to the Department to know that so much real good is annually effected towards relieving the necessitous condition of the orphans of their deceased brother officers.

THE following are the last week's Cattle Plague Returns.

Note.—9 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Buckingham, 1; Chester, 1; Durham, 1; Essex, 1; Lincoln, 1; Worcester, 1; York, 2; and for Scotland, 1. These inspectors returned 32 cases last week.

CATTLE PLAGUE IN IRELAND.—The cattle plague, which was thought to have been "stamped out" at Drennan, has reappeared beyond the "cordon," which is now to be extended so as to include the entire county of Down. The disease is supposed to have been introduced by the clothes of some graziers who had returned from England. The disease is reported to have made its appearance in the counties of Sligo and Waterford. The counties of Down, Antrim, and Armagh have been proclaimed by Privy Council under cattle plague regulations. No further cases are reported in the county Down, and rumours of the appearance of the disease elsewhere are unfounded. We have heard on good authority that two deaths occurred on last Saturday in Dublin under most anomalous circumstances. In one case death resulted in twelve, in the other in twenty hours, the only symptoms being rapid prostration, failure of circulation, and the pouring out of great effusions of blood in and under the skin. The cases bore great resemblance to that of a Medical student whose death we recorded some six weeks ago. We understand that the features of the disease were so unusual that the Physician who attended one of the cases could only compare it to the "Black Death" of the sixteenth century. We hope in our next to be able to place before our readers a full report on the subject.—*Dublin Medical Press.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Ab Initio.—Write to the American Minister.

To C. G. L., High-street, Coventry.—We believe the person referred to is a great rascal.

Bolton, Wilberfoss, York.—It is not the function of a Medical journal to give advice gratis on Medical or Surgical cases. If the patient has been duped and plundered by quacks, let him lay his case before the most eminent Medical man in his neighbourhood, and do implicitly what he advises.

A New Use of Chloroform.—The *Cleveland Herald* describes how a condemned murderer, who behaved with such violence that the sheriffs could not approach him, was conquered. Two large syringes were procured and filled with chloroform, and the contents of one of them discharged into the cell. The prisoner was somewhat taken aback by this novel procedure, and told them to come on with their doctors' stuff, but they would never subdue him in that manner. A second discharge of the chloroform-laden syringe, however, did the work. In little less than four minutes from the time of the first injection of the chloroform, the raging man was quiet, and sank down on the floor perfectly helpless.

B. B., Wolverhampton.—Before despairing of a cure for *prurigo senilis*, get Dr. Balmanno Squire's Series of Photographs of Skin Diseases; you will there find a definite and perfectly reasonable theory of the disease, viz., that it depends on the *pediculus corporis*. Now, this is either true or not true. If true, it gives you at once a guide to the successful treatment. If not true, you will have lost one happy illusion, and you can but try some more of those "fortuitous compounds of brimstone, quicksilver, iodine, arsenic, sarsaparilla, corrosive sublimate, glycerine, vitriol, cod-liver oil, carmine, and rose water," wherewith, as you allege, some skin doctors charm away the local and constitutional symptoms of their patients.

Erratum.—*Med. Times and Gazette*, May 12, 1866, p. 507, *for* "Ovid's Metamorphoses" (lib. xx.), *read* ("lib xv.")

THE OPERATION FOR THE CURE OF EPILEPSY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Please to publish the following *bon-mot* relative to the proposed mutilation of our nymphs:—"Abraham circumcised his males; but Isaac says, Go to, let us circumcise our women."

I am, &c., FREDERICK J. BROWN, M.D.

Rochester, May 22, 1866.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been further received on behalf of the above fund:—W. B. Irving, Esq., Newark (second), 1s.; Thos. Robinson, Esq., Alton (second), 5s.; H. J. Mathew, Esq., Horsham, 10s. Amount previously announced, £136 6s. 3d. Received at *Lancet* Office, £13 11s. 6d.

I am, &c.,

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, May 23, 1866.

POOR-LAW MEDICAL REFORM AND VACCINATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged by your giving insertion to the annexed letter, addressed to the Poor-law Board, but to which I have not as yet received a reply.

I have been in correspondence with members of the Select Committee on Vaccination, and have forwarded my opinion on the Government Bill to the Committee. Mr. Bruce, the chairman, has written to a Member of Parliament as follows:—"Should the Committee on the Vaccination Bill decide upon taking evidence, I will not fail to bear in mind your desire that Mr. Griffin should be examined."

Since the last list of subscriptions was published, I have received the following:—Eaton, F., Grantham, 10s.; Hulme, J. D., Blaby, 5s.; Garlick, F. S., Halifax, 20s.; Crowther, T., Halifax, 10s.; Nowell, W., Halifax, 10s; Mackinder, D., Gainsborough, 5s. I am, &c.,

RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, May 21, 1866.

"12, Royal-terrace, Weymouth, May 17, 1866.

"My Lords and Gentlemen,—On February 3 last I forwarded to your honourable Board the draft of a proposed Bill 'for the better regulation of Medical relief to the poorer classes in England and Wales,' which was acknowledged in these words:—'I am to inform you that the provisions contained in the Bill shall receive the considerations of this Board.'

"My object in now writing is to ask you to do the Poor-law Medical officers the favour to receive a deputation from them in order that they may urge upon your honourable Board the desirableness of sanctioning some, at least, of the propositions named by them in their proposed Bill, and that you will recommend them to Parliament for adoption, either as a distinct bill or as part of the intended Poor-law Continuance Bill. Any day after next Saturday week that the Board may fix to receive a deputation will give time for me to communicate the fact to the Poor-law Medical officers through the medium of the Medical journals, provided the reply be received on or before next Tuesday; otherwise I must ask for the postponement of the deputation until the following week.

"I have the honour to be,
"My Lords and Gentlemen,
"Your obedient servant,
"RICHARD GRIFFIN,
"Chairman of the Poor-law Medical Reform Association.
"The Poor-law Board."

THE ARMSTRONG TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Several Medical men in this neighbourhood have subscribed to the fund now being raised for the purpose of defraying the expenses incurred by Dr. Armstrong in the late trial of Rudman *v.* Armstrong. I enclose you a cheque for £5 5s., the amount of the subscriptions, and shall be much obliged by your inserting the names of the subscribers, as annexed, in the *Medical Times and Gazette*:—

Dr. Parker, 10s. 6d.; Dr. Vinen, 10s. 6d.; Dr. Cuolahan, 10s. 6d.; Dr. Dixon, 10s. 6d.; Dr. Lucey, 10s. 6d.; H. H. Button, Esq., 10s. 6d.; Chas. White, Esq., 10s. 6d.; Thos. Blakeley, Esq., 10s. 6d.; N. F. Hall, Esq., 10s. 6d.; E. Phillipps, Esq., 10s. 6d.

I am, &c., H. CUOLAHAN.

9, Grange-road, Bermondsey, May 23, 1866.

The following subscriptions have also been received:—Joseph Toynbee, F.R.S., £1 1s.; Dr. Andrew Clark, 10s.

RECOMMENDATIONS OF COMMITTEE ON ARMY AND NAVY MEDICAL OFFICERS AND THE DUKE OF CAMBRIDGE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It has been stated on reliable authority that the long-hoped-for Warrant has been deferred to the Greek kalends, or, as His Royal Highness the Duke of Cambridge expresses it, to this day twelve months. The lively interest His Royal Highness takes in the well-being of the Medical Departments of the public service must be particularly gratifying to the gentlemen who succeeded in obtaining Medical commissions at the last Chelsea examinations, and the course he advises the Government to pursue with reference to the recommendations of the Committee must be as satisfactory to them as it will be encouraging to others. Jesting apart, I dearly love economy, and admire it vastly in public functionaries, and as a Royal marriage is a matter of less public importance than the efficiency of a great public service, I should be glad to know if His Royal Highness recommends, on economic grounds, that the payment of the dowry of his sister be deferred "to this day twelve months." I am, &c.

London, May 21. VIGILANS.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 30·070 in. The mean daily reading was above 30 in. on every day after Sunday. The pressure of the atmosphere was 29·70 in. on the morning of Sunday, and it rose to 30·25 in. on Wednesday.

The general direction of the wind was variable.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 51·7°.

APPOINTMENTS FOR THE WEEK.

May 26. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

28. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

29. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Professor Austed, "On the Application of Physical Geography and Geology to the Fine Arts."

30. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m. Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

HUNTERIAN SOCIETY (Council, 7½ p.m.), 8 p.m. Dr. Barlow, "The Pathology of Cholera."

31. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

ROYAL INSTITUTION, 3 p.m. Professor Huxley, "On Ethnology."

June 1. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. Professor Roscoe, F.R.S., "On Opaleseence of the Atmosphere."

WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Annual Meeting. Dr. Blandford, "Some Cases of General Paralysis of the Insane."

GENERAL MEDICAL COUNCIL.

Fifth Day.—Tuesday, May 22.

The Council again assembled at 2 o'clock.

The minutes of the preceding day were read and confirmed.

Mr. Hargrave moved, and Mr. Cooper seconded, "That the Report of the Committee on the draft of the Medical Acts Amendment Bill, transmitted from the Home Office, be read."

The Bill and Report were then read.

REPORT.

"The Committee according to the resolution of the Council have carefully considered the Medical Acts Amendment Bill as drafted at the Home Office, which is to the following effect:—

"MEDICAL ACTS AMENDMENT BILL.

Draft of a Bill to Amend the Acts relating to Practitioners in Medicine and Surgery.

"Be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

Preliminary.

"I. The Acts described in the schedule to this Act, and this Act shall be construed together as one Act; and for that purpose the expression 'this Act,' when used in the Medical Act (of the Session of 1858), shall include the present Act; and the Acts described in the schedule to this Act and this Act may be cited together as 'the Medical Acts,' and are comprised in that expression when hereafter used in this Act; and this Act may be cited separately as the Medical Acts Amendment Act, 1866.

"*Members of Council.*

"II. Section 7 of the Medical Act (1858) shall be read and have effect as if the words 'qualified to be' were omitted therefrom.

"*Registration.*

"III. Where, under the authority of the Medical Acts, the General Council or any Branch Council direct the erasure of the name of any person from any Register, the name of that person shall not be again registered in any Register except by direction of the Council which directed the erasure, or by order of a Court of competent jurisdiction.

"IV. If the General Council think fit in any case they may direct any Registrar to restore to his Register any name erased from him therefrom, and the Registrar shall restore the same accordingly.

"V. Section 14 of the Medical Act (1858) is hereby repealed, but this repeal shall not affect the past operation of that Section, or anything already done under it, or invalidate any existing Register, order, or regulation kept or made under it, or affect any proceeding or thing commenced under it, or the power of the General Council to make any order in relation thereto; and every such proceeding or thing may be carried on and done as if the said section had not been repealed.

"VI. Each Registrar shall keep his Register correct in accordance with the provisions of the Medical Acts and the general regulations and special directions of the General Council (whether made or given before or after the passing of this Act).

"VII. Each Registrar shall erase from his Register the name of any person deceased.

"VIII. Each Registrar shall from time to time insert in his Register any alteration in the address or qualification of any person registered.

"IX. In the execution of the aforesaid duties, each Registrar shall act on such evidence as in each case appears to him sufficient, subject to any regulations of the General Council.

"X. Each Registrar may erase from his Register the name of any person who has ceased to practise; and in order to the better execution of that duty, each Registrar may send by post to any person registered in his Register a registered letter, addressed to that person according to his registered address, inquiring whether or not he has ceased to practise, and if the Registrar does not, within three months after sending such as letter, receive any answer thereto from the person to whom it is sent, he may, within fourteen days after the expiration of the said period of three months, send by post to that person another registered letter, addressed to him according to his registered address, referring to the first letter and stating that any answer thereto has not been received by the Registrar, and if the Registrar does not within three months after sending such second letter receive any answer thereto from the person to whom it is sent, that person shall, for the purpose of the present section, be deemed to have ceased to practise; and the name of any person shall not (without his consent) be removed from the Register on the ground of his having ceased to practise, except in pursuance of the provisions of the present section. Provided that a person whose name has been erased from the Register with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this section by reason of his being engaged gratuitously in the cure or treatment of any disease or injury.

"XI. Every person shall be entitled to be registered under the 'Medical Act, 1858,' who is qualified as follows:—

"*First.* Is at the time at which he applies to be so registered legally possessed either of one of the qualifications described in Schedule (B) (a) of this Act, or of some other Foreign or Colonial Diploma, obtained in the opinion of the General Council after such course of study and such examination as guarantee to their satisfaction the possession by the applicant of sufficient knowledge and skill for the efficient practice of Medicine and Surgery.

"*Secondly.* Has resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application.

"*Thirdly.* Has not been guilty of any offence which, according to the laws of the country to which he belongs, would disentitle him to practise Medicine and Surgery, or which, according to the 'Medical Act, 1858,' would enable the General Council to strike his name off the Register.

"XII. If it appears to the Privy Council, on the representation of the General Council, that any qualification other than those described in Schedule (A) to the 'Medical Act, 1858,' and in Schedule (B) to this Act is granted by any University, College, or Body in the United Kingdom or elsewhere, after such a course of study and such examination as guarantee to the satisfaction of the General Council and Privy Council that any person to whom such qualification has been granted possesses the requisite knowledge and skill for the efficient practice of Medicine and Surgery, it shall be lawful for the Privy Council (in the case of any qualification granted by any University, College, or Body in the United Kingdom) to direct by order that every person holding such qualification shall be entitled to be registered under the 'Medical Act, 1858,' in the same manner and with the like effect as if the qualification were described in the Schedule (A) to the 'Medical Act, 1858,' and (in the case of any qualification granted by any University, College, or Body elsewhere than in the United Kingdom) to direct by order that every person holding such qualification shall be entitled to be registered under the 'Medical Act, 1858,' in the same manner and with the like effect as if the qualification were described in the Schedule (B) to this Act.

"XIII. The provisions contained in sections 20, 21, and 22 of the 'Medical Act, 1858,' shall apply to any qualification which, in pursuance of this Act, entitles persons to be registered under the 'Medical Act, 1858.'

"XIV. The degree of Bachelor of Surgery conferred by the University of London shall, for the purpose of enabling any person to be registered under the 'Medical Act, 1858,' be deemed to be one of the qualifications described in Schedule (A) of that Act.

"*Unregistered Persons.*

"XV. Section 40 of the Medical Act (1858) is hereby repealed; but this repeal shall not apply to or in respect of any offence committed before the passing of this Act, or affect any proceeding pending at the passing of this Act.

"XVI. If any person practising Medicine or Surgery, or engaged in the cure or treatment of diseases or injuries, not being registered under the Medical Acts, takes or uses any of the designations enumerated in Schedule (A) to the Medical Act (1858), as amended by Schedule (B) to this Act, or by any other of the Medical Acts, or the designation of Physician, Surgeon, Doctor of Medicine, or Apothecary, or any other designation used by or used to distinguish duly qualified Practitioners of Medicine or Surgery, or any class thereof, or the designation of Professor of Medicine or of Professor of Surgery, he shall for every such offence be liable, on summary conviction, to a penalty not exceeding twenty pounds.

"*Saving.*

"XVII. Nothing in this Act shall prejudicially affect any occupation, trade, or business, rights, privileges, or employment expressly saved from the operation of the Medical Act (1858), or affect the rights or interest of any person or class of persons expressly exempted or protected by any provision of any of the Acts described in the schedule to this Act.'

[*** We omit the Report, as the purport of it will be gathered from the discussion, and an amended version will be found at the end of the debate of May 23.]

Dr. Andrew Wood said he need hardly recal to the attention of the Council the fact that during the last session they discussed at great length the proposed Bill for amending the Medical Acts which the Council themselves drew up. During those discussions there were several subjects incidentally introduced which he trusted would not be introduced on the present occasion. The clause to which he particularly referred was that for giving the Medical Council larger powers in regard to the great question of education. It might be in the recollection of the Council that this subject was discussed again and again, and the final conclusion of a considerable majority of the Council was, that it was better their powers with regard to it should be allowed to stand as hitherto. It might also be recollected that one great object—*the* great object, he might say—of going to Parliament at all for an amended Bill was that of amending clause 40, which had proved notoriously inefficient in its power. They had also a long discussion upon that clause. Various amendments were suggested, but the conclusion at which, by a large majority, the Council arrived was to prepare the clause which stood now in the proposed draft Bill with very little modification as No. 16. He need not read the clause itself, but the Home Office had made one important alteration by the introduction of the words "Doctor of Medicine," instead of "Doctor," as in the Council's draft Bill. If the Bill should be passed with this alteration, he saw ample means of all unqualified men continuing to practise as hitherto, without incurring the penalties of the Act. Before turning to the new matter, which formed the important part for discussion, he would allude cursorily to the registration clause. The Home Office Bill, as the Committee mentioned, adopted the registration clause, drawn up for the purpose of facilitating registration, substantially, with only two modifications. The first of these modifications was that in clause 3 of the preliminary Bill the words "or by order of a court of competent jurisdiction," had been added. He believed those words were put in in order to remove all doubt, and that this addition would be taking no power from the Council; and even if it did he did not think they would have any objection to be relieved so far from the great responsibility which they incurred in erasing a name from the Register from a feeling that there was no power of appeal to the courts of justice. Then, the only other alteration that had been made in the registration clause was with reference to the notice to be sent to persons whose address could not be found. Instead of sending two letters, as the Council's clause suggested, within six months, at intervals of three months, the Home Office clause enacted that if within three months after sending the first letter the Registrar did not receive any answer thereto,...

(a) Schedule (B) includes the Diplomas of certain eminent Foreign and Colonial Schools of Medicine.

he should send a second letter within fourteen days of the expiration of the three months, and if at the end of six months no answer was received, the person's name should be erased. There was another point before coming to the new matter, which was that the preamble introduced by the Council had been left out in the Home Office Bill. There might have been valid reasons for doing so, but if there were no such valid reasons it appeared to him they would be able to justify their application for the insertion of the following words:—"Whereas the Medical Act, 1858, has been found ineffectual to enable persons requiring Medical aid to ascertain who are qualified Practitioners," etc. If this was not put in, it did not give Parliament or the public the means of knowing why it was, after the lapse of eight years, they were going again for an amendment of the Act. The new matters introduced might be reduced to two. The first was that the degree of Bachelor of Surgery of the University of London was to be included in Schedule (A) of the Medical Act. Last year, they might recollect, they had a division upon this point, and it was decided that the degree of Bachelor of Surgery should not be placed in Schedule (A). He thought it due to himself to explain why he voted against that proposition, which was simply this, that he did not think the Council had the legal power to make additions to Schedule (A), and he was more than ever confirmed in his opinion that that was the proper legal interpretation. He still held that in refusing to put new qualifications in the Medical Act he was acting in a legal manner. But now the thing had been legally affirmed, he could not see on what ground he could refuse the registration of Bachelor of Surgery of the University of London, which he believed was granted after a full education and a full examination, when all other Universities in the kingdom had been allowed to register a similar qualification. He now came to the most new and, as the Council he had no doubt would consider, the most important introduction in the Bill—he meant the introduction of the power in the Council of registering foreign and colonial diplomas and degrees. It was thought necessary when the Medical Act was first introduced that, with a view of obviating hardship, power should be placed in the Council of registering those colonial and foreign degrees which had been obtained previously to the passing of the Medical Act, provided the Council were satisfied that these degrees and diplomas had been properly obtained. But there the power of the Council ceased, as regarded such qualification, because it was also provided that in the case of any diplomas and degrees granted by foreign and colonial bodies after the passing of the Medical Act, the Medical Council should have no power. Now, he did not think this Council *proprio motu* would have moved in this direction, but from the statement made by the President in his very able address at the commencement of this session, and from various papers which had appeared from time to time in the Minutes of the Executive Committee, it appeared that under strong pressure the Home Office felt that they were not at liberty to deny to foreign and colonial qualifications all right of being registered as Medical Practitioners in this country. And he must honestly confess that he had come to the conclusion that there was an injustice as regarded our great colonies in the fact that all those who had obtained qualifications in Great Britain, and had registered under the Imperial Act, were entitled when they went to the colonies to practise there without being submitted to colonial legislation. He thought when such was the case that there certainly should be, at least, some degree of reciprocity in this matter. If it were the case that there were not the means of educating and testing duly qualified men in our colonies, then he thought it would be necessary for this Council to oppose any attempt to introduce such qualification into the Medical Act. But they knew that in the colonies—Canada, for example—there were several first-rate Universities—Universities which, to the best of their knowledge (and they had looked into the matter), had ample staffs of teachers, and had instituted preliminary and Professional examinations which appeared, at all events, to come up to the minimum which they had established in this country. And therefore he thought it was a graceful and proper act that they should as much as possible get every facility from the Home Office of registering degrees and diplomas from Canada. There was another part of our great empire in which Universities had started within the last few years,—he alluded particularly to Calcutta, Madras, and Bombay,—which Universities, young as they were, had already obtained very high repute, had been established, and from them many men highly qualified in every respect came here year by year in order to take the British qualification, but who, in consequence of the charters which had been conferred upon those Universities, might be able to obtain high degrees and high diplomas there, and therefore ought, according to the law of reciprocity, to be entitled to be registered without further examination when they arrived in this country; so that, as regarded Canada and India, it seemed to him there was no difficulty. Then, with respect to Australia, it was well known that Universities were rising both in Melbourne and Sydney; that very splendid buildings had been erected for the purpose of Universities, and he believed that gradually staffs of teachers were being formed, if they had not been already completely formed. The Committee would have been inclined to have recommended that the recognitions of degrees and diplomas granted there should also have been carried out, but they had found on inquiry no means of testing whether they were deserving of recognition. But, supposing the Council agreed to the introduction of colonial degrees and diplomas, it was quite evident that leaving them out at present would be no material injustice, because clauses in the Bill enabled the Council from time to time, if they saw fit, to make representation that those diplomas and degrees should be recognised if they could obtain the consent of the Privy Council. Then, in regard to foreign diplomas and degrees, perhaps there might be more difficulty in coming to a resolution to register them, for this reason—that those Universities and degrees were altogether beyond British control, and that they had no means by visitation, supervision, or otherwise, of ascertaining exactly how far those were qualifications they ought to recognise. But they could not ignore that there were some Universities and schools abroad of such high repute that they knew for a fact that the qualifications granted there were quite as high, if not higher, than many of those that were granted in Great Britain; and in all of those they would be inclined to recognise the qualifications which at all events were higher than their own. Such Universities as those of Paris, Berlin, Vienna, Copenhagen, which was very high, and Stockholm, they had had no difficulty in specifying; but there was another class of foreign Universities and bodies—those in the United States—regarding which the information of the Committee was hardly so full as they could wish. At the same time, it was quite clear that if they adopted the principle at all of recognising foreign diplomas and degrees, they might almost afford a *casus belli* to the United States if they were to exclude them from the recognition which they gave to other nations. Now, he trusted the Council would be inclined to entertain the proposition of the Home Office, and adopt the principle of recognising such foreign and colonial degrees and diplomas as approved themselves to the Council as worthy of recognition, because it was quite evident, from what was stated by the President on the first day of this session, that if they refused to adopt that principle they thereby stated that they refused the Bill. He understood that the Home Office would not support the amendment of the Medical Act unless they introduced into that Bill clauses recognising, to the extent to which they might see fit, and which they might approve of, foreign and colonial degrees.

The President thought Dr. Wood should qualify this statement somewhat, because they had upon their Minutes a letter from Sir George Grey, expressing his opinion exactly as he intended it to be expressed.

Dr. Andrew Wood proceeded to say that in regard to foreign and colonial degrees and diplomas, the Home Office had requested this Council to prepare a Schedule (B), which was to include those diplomas and degrees, foreign and colonial, which they deemed worthy of recognition. He could say for the Committee and himself that to be called upon within a short time to go over all the qualifications in in the world, and to be able to say which were worthy of recognition and which were not, was a peculiar task for which they held themselves very little qualified; and they doubted very much whether it was desirable to have a Schedule (B), because if they once put any bodies, foreign and colonial, in a Schedule (B) it was quite obvious that it would be an extremely difficult thing afterwards to remove them in case the Council should see reason to do so. But the Committee had advanced an alternative which he thought they felt disposed to recommend the Council to adopt—namely, that without fixing definitively Schedule (B), the Council should be empowered or commanded annually to prepare and publish in the *Medical Register* and in the *Gazette* a list of those bodies, foreign and colonial, which, with the consent of the Privy Council, they considered ought to be recognised. If this

were done, it was evident that every year it would be one of the duties of the General Council to revise this list; to add to it at times those rising universities and bodies in our colonies, and others, perhaps, abroad, who might make application and satisfy them that they deserved to be recognised; or it might be to recommend that any of those bodies, because they had not been found to keep up the requirements which they might have had when the Council originally recognised them, be represented to the Privy Council with the view of having their names taken off the list or the registration suspended. It now remained for them to determine whether they would support the Bill of the Home Office in its present shape, whether they would have a Bill at all, or whether they would amend it so as to bring it into conformity with their own views. What appeared to him to be the best plan of putting it in proper shape would be to read the Bill clause by clause, and at the same time that a particular clause of the Bill was read to read that clause in the Report which commented upon it, and then it would be competent to move the adoption, amendment, or rejection of any particular clause. He then moved—"That the draft Bill be now read clause by clause with the corresponding clause in the Report of the Committee."

Dr. CHRISTISON seconded the motion, which was agreed to.

The PRESIDENT remarked that, with reference to the omission of the preamble adopted by the Council last year, he did not think it had been intentionally left out by the Home Office, but that it was a mistake.

Dr. ANDREW WOOD proposed, and Dr. PARKES seconded—"That it is desirable that the preamble clause of the draft Bill of the Council, which is as follows: 'Whereas the Medical Act, 1858, has been found ineffectual to enable persons requiring Medical aid to ascertain who are qualified Practitioners, etc.,' be inserted before the words, 'Be it enacted.'"

Sir D. J. CORRIGAN considered the preamble proposed to be inserted by Dr. Andrew Wood one of the most objectionable parts of the Bill, because it gave to unqualified Practitioners what they never possessed until the Medical Act was introduced, a statutory right to practise. He thought it desirable to have the preamble omitted.

After some discussion, the resolution was carried, by 8 votes against 7, with the words, "if there be no legal objection," added.

Clause 1 was then read, and on the motion of Dr. ANDREW WOOD, seconded by Dr. PARKES, was agreed to, as also was clause 2.

Clause 3 was read in connection with paragraph 1 of the Committee's Report, and adopted on the motion of Dr. ANDREW WOOD, seconded by Dr. PARKES.

Clauses 4, 5, 6, 7, 8, and 9 were also adopted, the latter in conjunction with the second paragraph of the Committee's Report.

With regard to clause 10, as to the erasure of a person's name from the Register, there was some slight discussion, and it was resolved, on the motion of Dr. ANDREW WOOD, "That the consideration of clause 10 be postponed, and that Mr. Ouvry be consulted in regard to it."

Clauses 11, 12, and 13 were taken together.

On the motion for the adoption of clause 11, which was proposed by Dr. ANDREW WOOD and seconded by Dr. PARKES,

Mr. CÆSAR HAWKINS moved, "That the nomination clause inserted in Schedule (B) be postponed till after the remaining clauses of the Bill have been considered."

Dr. ALEXANDER WOOD said that no separate motion was required.

Sir D. J. CORRIGAN thought there were serious objections to the clause as it stood. He had no objection to gentlemen within our own empire being recognised, but he did feel that they were going very far when they proposed to admit foreign or colonial diplomas. If an Englishman took a degree at one of the highest Universities in England and then went abroad, that degree was not recognised, and he thought they were going too far in taking diplomas from all foreign countries, without any reciprocity. He therefore moved, as an amendment, that the word "foreign" be omitted from the clause.

Dr. A. SMITH seconded the amendment.

Dr. ALEXANDER WOOD said he was very much disposed to support the amendment on account of the experience he had when he was Chairman of the Committee on Foreign Communications. There were certain universities and colleges abroad about the teachings and examinations at which there could be no doubt whatever, but there were certain others—and he referred particularly to America, where universities sprang up like mushrooms—in which the course of study was such that they could have no security whatever that the persons who went through it and received degrees were properly educated. But they were placed in a very peculiar position, and it was in view of that peculiar position that he was led to support the original motion rather than the amendment. The original Bill, as drafted by the Council last year, contained no provision of this kind whatever; that Bill was sent to the Home Office and had now come back from the Home Office with these clauses most elaborately prepared and introduced, and he thought they might make up their minds, from all that they could gather from the course which the Committee had taken, that if they did not accept some clauses of that sort they would get no Bill at all. The only question, therefore, was whether they would accept the clauses or whether they would give up the Bill altogether, and have no Bill at all. He did not believe, however, that they were placed in such very dangerous circumstances as Sir D. J. Corrigan would lead them to believe, because they would only admit diplomas from certain bodies who were mentioned in Schedule (B). But, better than this, the Committee, at his instance, had that morning suggested that there should be no schedule at all, because while the schedule was going through the House of Commons and the House of Lords it would be quite competent for any member of either House to propose some other body—such as the Homœopathic University of Ohio, and unless they were prepared to checkmate such a movement as that, they might find a very heterogenous mass of bodies thrust into the schedule. But if they could get the Home Office to consent that instead of a schedule being appended to the Act the Medical Council, in communication with the Privy Council, and by the authority of the Privy Council, should annually prepare a list of such bodies as, so far as they could judge from their printed regulations and the knowledge they could get of them, were fit to be recognised, he did not see why they should refuse to agree to that if it was to be the price which they were to pay for getting a Bill. He did not think they need trouble themselves much about reciprocity or free trade. If England had waited to institute the free trade movement till other countries initiated it, they would have had nothing of the kind even up to the present time, and in this movement he thought the best plan was to show a liberal disposition, and to trust that foreign countries and Universities would follow their example. He did not attach much weight to the argument, but he thought that if the alternative plan suggested by the Committee were adopted by the Council and assented to by the Home Secretary, there would be no difficulty whatever in so regulating the clause that they would not be in danger of having admitted to their Register unqualified persons.

Dr. PARKES suggested that the clause should read,—"Is at the time at which he applies to be so registered legally possessed of a foreign or colonial diploma."

Dr. CHRISTISON though it would be advisable to separate altogether the colonial qualifications from the foreign ones. He was afraid the effect would be to introduce a large number of foreign diplomas.

Mr. SYME said it seemed that the Bill would not be accepted by the Government if they made these alterations, and he believed this was in consequence of certain applications which had been made to the Government.

Dr. QUAIN said he knew from his own personal knowledge that these views were entertained by the Government a very long time ago, and long before what was referred to by Mr. Syme.

Dr. ANDREW WOOD thought there would be some weight in Dr. Christison's suggestion if it were not for the conditions contained in the clause. They could not form a clause with less stringent conditions, and he did not know that they required more stringent ones, especially if Dr. Parkes's suggestion were carried out. When they came to the next clause Dr. Christison could object to registering any large number of foreign diplomas, because none of them expected to do that; but he felt satisfied that if they excluded the word "foreign" from the Bill altogether they would not get any Bill whatsoever. What Dr. Quain had stated was very important, that the Government had long been impressed with the opinion that there ought to be reserved a power, whether exercised or not, of registering foreign and colonial degrees and diplomas; and that the Government must have had some such feeling was quite clear from the fact that in the original Act provision was made for registering these foreign and colonial degrees and diplomas which had been acknowledged previous to the passing of the Act. He did not care, there-

fore, whether it had been pressed upon the Government from certain quarters or not, but he looked to the justice of the case, and to what was the policy of the Council. When they were offered a Bill which they believed was calculated to do good service to the Profession, should they refuse to take it because they had been asked to register foreign and colonial degrees and diplomas, provided they were fully satisfied with them in every respect? The Council were to intimate the names of the bodies whose degrees they would register, and there was a guarantee that the thing would be done completely in the fact that, although the Council would intimate those names they would also have to receive the sanction of the Privy Council. It was so fenced and guarded that he did not think they would run any risk, because he had no doubt that the Council, whenever a foreign qualification was presented to it for registration, would exercise the greatest jealousy in registering it, and then they would not register unless they were perfectly satisfied that they could do it justly and properly towards the Profession at home. If he imagined that they were going to enable a man who could not get a qualification in this country to go abroad to some foreign University and there obtain a qualification on easier terms and come back and demand registration, he would rather give up the Bill altogether; but it was their duty to see, in recognising foreign diplomas, that the conditions for obtaining those diplomas were up to their minimum, and even above it. So fenced and guarded, and with the consent of the Privy Council being necessary, he did not think they ran any very great risk in adopting the clause.

Dr. Christison said he would withdraw his suggestion, as he thought it would be an unfortunate thing for the Government to suppose that the Council were adverse to recognising all foreign qualifications whatever.

Dr. Paget reminded the Council that in some countries a diploma did not give the right to practise.

Dr. Christison said that was the case in Prussia, where, before a man was entitled to practise, he had to undergo another examination besides that at the University.

Mr. Rumsey said that both in France and Germany the license to practise was a different thing altogether from the qualification for a diploma, and the body which conferred the diploma was not the body which gave the license.

Dr. Paget said the clause only mentioned "foreign diploma," and though a person who applied might have a diploma, he might not have a license to practise.

Dr. Alexander Wood said it sometimes happened in foreign countries that there were political reasons why a man who was properly qualified did not apply to the State for a license to practice, but he did not see why they should refuse him if in other respects he was properly qualified.

Mr. Cæsar Hawkins said the clause applied equally to all colonial degrees. Although their registration nominally gave them a right to practise in all parts of her Majesty's dominions, it was not so in fact, but they must also be registered in the several parts of those dominions. In Canada a law had twice been attempted to be brought in, providing that diplomas granted in England should not exempt persons holding them from a second examination in Canada, and he had got this law altered by the Secretary of State, but they still retained the right to require fresh registration.

The President thought the Council was attaching more importance to the clause than it merited. The Government were anxious to remedy a defect in the present Medical Act, which had been pointed out by many members of the Council—namely, that they no longer possessed the power they once had of admitting to their Register the graduates of foreign and colonial Universities and Colleges. It was the opinion of her Majesty's Government and of many members of the Council, that there should be some power created in the Medical Council of admitting to the Register distinguished foreigners and colonial graduates who might reside within the United Kingdom. The only question was how that power should be exercised. If the Council were to express an opinion that they coincided with her Majesty's Government in that view, he thought there could not be much difficulty in carrying the matter out in connexion with the wishes of the Council. For his own part, he certainly thought that the suggestion made by the Committee in their report was a far preferable mode of carrying out the object to the clause as drawn up by the Home Office. It would be much better if they had power from year to year to name and revise the list of the foreign or colonial bodies whom they deemed entitled to the distinction. He thought it was never intended by the Government that the privilege proposed should be accorded largely as had been supposed. He thought the Council might adopt the clause with safety, reserving, of course, the power to fill up Schedule (B), and taking care to insert in that schedule no foreign or colonial Universities or Colleges of whose respectability and character they were not fully satisfied. If the Council admitted the principle, he thought the Government would be content with the insertion of a small number of bodies, and that nothing would be forced upon them.

Sir D. J. Corrigan said he had listened very attentively to this discussion on his amendment, to which amendment he still adhered. Dr. Alexander Wood said they ought not to adopt that amendment because the Government had stated that unless this clause were accepted they would not pass the Bill. He thought the subject of such consequence that if it were before them in that way, that if they did not consent to this clause they would get no Bill, they ought to reply that they would have no Bill rather than have one which contained that clause. He was persuaded that nothing could be more ruinous, and that they would be flooded with applications from the holders of foreign diplomas, and then they would be placed in a very difficult position. A single member of the Council, acting under certain influence which might be brought to bear upon him, and which probably would, might propose that certain persons be admitted to registration on a foreign diploma, and then the Council would have to prove, what it would be hardly possible to prove—namely, that the examination of those persons had not been sufficient. In other words, the Council would be called upon to prove a negative, or to show a reason why they refused the application. The case with regard to Practitioners before 1858 was not at all analogous, and therefore did not apply to this case. The President had said that the only object was to admit distinguished foreigners, and if he were sure of this he would at once withdraw his amendment; but if that were the only reason the clause was not necessary for it, because at the present time there was not a body in this country who would not admit a distinguished foreigner. He did not believe that any distinguished foreigner would ever come here to enter the arena of practice, but under this clause they would be opening the door to a band of adventurers, and he did not know where they would stop. In Belgium the Government were not satisfied with the examinations of the Universities, but themselves examined all the holders of degrees before they allowed them to practise, and yet under this clause the holder of a degree may obtain registration here when he had failed to acquire the right to practise in his own country. There was no hardship upon such men at present, for they only had to attend a College for twelve months, and if they wanted degrees to be at a University for six months, and they might at once present themselves for examination. For all these reasons he thought they were opening the door too wide, and he therefore pressed his amendment.

Dr. Andrew Wood said they only wanted to provide for the registration of foreigners who proved themselves to be properly qualified, and no man would be able to apply unless he had obtained a diploma from one of the bodies which the Council named. The first step was for the Council to decide, after mature deliberation and investigation, what degrees and diplomas were worthy of recognition, and having decided, a man who came with one of those diplomas would be admitted.

The amendment was put and lost, and the original motion was carried by 14 to 5.

Dr. Alexander Wood proposed the adoption of clause 12, omitting all reference to Schedule (B), and adding—"The General Medical Council shall annually submit to the Privy Council for approval a list of the foreign and colonial qualifications which from time to time the General Medical Council may consider worthy of recognition, such list to be published in the *Gazette* and in the Medical Register for the year."

Dr. Rumsey seconded the motion.

Dr. Acland moved, and Dr. Sharpey seconded, as an amendment, that the clause as it stood should be adopted, omitting any reference to Schedule (B).

After a long and desultory discussion the debate on the motion of Sir D. J. Corrigan, seconded by Dr. Embleton, was adjourned.

Sixth Day.—Wednesday, May 23.

The Council reassembled at the usual hour, and confirmed the Minutes of yesterday's proceedings, which were read by the Registrar.

On the motion of Sir D. J. Corrigan, the Council resolved itself into a committee in order to consider further the report of the Medical Amendment Act Committee.

Mr. Ouvry, the solicitor of the Council, read, at the request of the President, the form in which he considered clause 10 ought to be drafted :—

"Each Registrar may erase from his Register the name of any person who, having ceased to practise, shall desire to have his name removed from the Register; and each Registrar may send by post to any person registered in his Register a registered letter, addressed to that person according to his registered address, inquiring whether or not he has ceased to practise, and whether he desires his name to be retained on the Register; and if the Registrar does not, within three months after sending such a letter, receive any answer thereto from the person to whom it is sent, he may, within fourteen days after the expiration of the said period of three months, send by post to that person another registered letter, addressed to him according to his registered address, referring to the first letter, and stating that any answer thereto has not been received by the Registrar; and if the Registrar does not, within three months after sending such second letter, receive any answer thereto from the person to whom it is sent, that person shall, for the purpose of the present section, be deemed to have ceased to practise and not desire to have his name retained on the Register. And the name of any person shall not (without his consent) be removed from the Register on the ground of his having ceased to practise, except in pursuance of the provisions of the present section. Provided that a person whose name has been erased from the Register with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this section by reason of his being engaged gratuitously in the cure or treatment of any disease or injury."

The clause was then adopted as amended.

Sir D. J. Corrigan rose to propose an alteration in the clause, but the President decided that he was out of order in doing so, but that he could propose the alteration when the whole Bill came before the Council.

On the adjourned debate on clause 12 being resumed,

Dr. Andrew Wood said he had a communication of some importance to make with reference to what had taken place with regard to the debate since its adjournment. A great deal of time had been spent yesterday in discussing the clause, but he believed that Dr. Christison, after giving to the matter the attention of his very practical mind, had now put things in such a condition as would greatly aid the deliberations of the Council.

The President ruled that Dr. Andrew Wood was out of order, and must reserve his remarks till he had put the amendment to the Committee.

Dr. Acland withdrew the amendment which he moved yesterday, and the President said the question now before the meeting was the resolution proposed by Dr. Alexander Wood and seconded by Mr. Rumsey, that clause 12 should be adopted as amended.

Dr. Christison said that as the result of his consideration of the matter, the clause had been placed before Mr. Ouvry, who had made certain corrections in it more clear, distinct, and conformable to what was right. After reading the clauses attentively, he found that they were very much mixed up together, and there was also involved in them a most important privilege which nobody had adverted to in the course of yesterday's discussion—namely, a privilege given to the Council to determine, with the sanction of the Privy Council, that any new titles which might be given in the United Kingdom should be registered in like manner as if those titles had existed originally. This was a privilege which had not been mentioned, but he thought it was one of the most important items in the clause, and it appeared to him that to the extraordinary mixing up of different things in the clause was owing part of the confusion which existed yesterday and the difficulty of getting out of it. On looking over the clauses referring to colonial and foreign degrees and diplomas, he had come to the conclusion that they might make the whole thing very plain by separating the one entirely from the other. The matter had been submitted to Mr. Ouvry, and a little correction would be required. Among the corrections which he proposed was one by which colonial and foreign diplomas were only to be recognised if they conferred the right to practise in the country or colony where they were obtained, and this seemed to be according to the general opinion of the Council. Another correction was with regard to the privilege of recognising new titles, and provided a condition that such new titles should only be recognised if they were granted by bodies which were legally entitled to grant them, because by a strange omission in the clause as it stood, any Medical body in the United Kingdom might grant a new title, and the Council would be entitled to take it up. No lawyer could have intended to introduce by a side-wind such a privilege, which was never intended to be granted at all. Another correction referred to the latter part of clause 11, which provided that any person should be entitled to registration who had not been guilty of any offence which, according to the laws of the country to which he belonged would disentitle him to practise Medicine and Surgery.

The President said he could not accept any amendment on clause 11, which had been fully discussed yesterday and passed, and had now been entered on the Minutes and approved by the Council.

Dr. Christison said they must go back to clause 11, because there was an important omission, inasmuch as there was no allusion to the Privy Council, and they were quite sure that they would not get the approbation of the Government unless they included the sanction of the Privy Council.

Dr. Andrew Wood believed there was nothing in Dr. Christison's amendment which was at all inconsistent with what they did yesterday. It only confirmed and carried it out and put it into a practicable and legal shape. The solicitor had now prepared the clauses in the form in which they could be legally carried out and adopted by the Council and approved by the Government. In a matter of so much importance, it would never do merely on a point of form to go to the Home Office with a Bill which did not contain the mind of the Council.

Dr. Alexander Wood withdrew the motion which he had made yesterday, and stated his reasons for doing so. He had made his motion for the purpose of providing against what appeared to him to be a very great evil to which they might be subjected if the Government Bill became law. Under the New Medical Act Schedule (B) was to be appended containing the names, inserted by the Council, of certain bodies whose diplomas they considered to be of equal rank with those mentioned in Schedule (A). It did occur to him, knowing a little of the temper of the House of Commons, and of certain individual members of that house, that it might be quite possible while the schedule was passing through the House that certain members might move, without the consideration which they would wish given to it, that certain Universities might be added to the schedule which it would be no credit to the Council to be associated with, and whose licentiates or graduates they would not wish to admit upon the Register. That was his first difficulty; and the second was, that in the schedule the names would be fixed, and the schedule would be like the laws of the Medes and Persians. New Universities might rise abroad which they would wish to have associated with them; but they would not be able to do so without going to Parliament for the power. Under these circumstances, he proposed that, instead of the Schedule (B.), they should annually present a list of bodies to the Privy Council, and, with their approval, enter diplomas from those bodies upon the Register. This was highly approved by the Committee, and when the clause came before the Council he proposed the motion now before them for the sake of bringing out that view. He did not profess to be a lawyer, and therefore was not able to prepare the draft of a Bill; and, when he found that Dr. Christison, with his clear and logical understanding, and the Chairman of the Business Committee had gone to the solicitor, and that the solicitor had prepared clauses which fully and efficiently carried out the object he had in view, he saw no reason whatever for pressing his motion, which, with the permission of the Council, he now begged to withdraw.

Dr. Christison moved that there should be substituted for clause 12 the clauses prepared by the Solicitor.

Dr. Quain seconded the motion.

Mr. Ouvry then read the clauses he had prepared as follows :—

"1. Every person who has resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application shall be entitled to be registered under the 'Medical Act, 1858,' who legally possesses a colonial or foreign diploma from a University, College, or other body qualifying him to practise Medicine or Surgery in the colony or foreign country where such diploma was obtained. Provided such diploma shall have been granted by a University, College, or other body recognised in a list of such qualifications, as shall from time to time appear to the General Medical Council as proper to be included in a list to be annually prepared by such Council, which list shall be submitted to Her Majesty in Council for approval, and shall thereupon be published in the *London Gazette*.

"2. If it appear to the Privy Council, on representation by the General Medical Council, that any qualification, other than those described in Schedule (A) to the 'Medical Act, 1858,' as amended by this or any other of the Medical Acts, is granted by any University, College, or body in the United Kingdom, legally entitled to grant the same, after such a course of study and such examination as guarantee to the satisfaction of the General Medical Council that any person to whom such qualification has been granted possesses the requisite skill and knowledge for the efficient practice of Medicine and Surgery, it shall be lawful for Her Majesty in Council to direct by order that every person holding such qualification shall be entitled to be registered under the 'Medical Act, 1858,' in the

same manner and with the like effect as if the qualification were inserted in the Schedule (A) to the Medical Act, 1858."

Dr. Andrew Wood said that by this clause they would constitute their Registrar a judge in a very important matter, which he had not been before. The question as to whether a man had been guilty of an offence was one for the Council to decide rather than the Registrar, and he did not think it right to impose such a duty upon the Registrar. It was introducing a very new principle indeed to make the Registrar the judge of a man's moral character.

The President said the Registrar had already a discretionary power, and if he had any doubt about any applicant, he was at liberty to hesitate before he placed him upon the Register. Such a case had recently occurred.

Dr. Andrew Wood thought that if that were so under the Medical Act he saw no reason why it should not be continued.

Mr. Ouvry said the Registrar had the power to do so, and if he did he was bound to take the responsibility.

The President said it was a very important matter. If a man of immoral character in Paris was given up by his colleagues, and obliged to flee from the country, was the Council bound, if he made application, to put him on the Register? By requiring him to live in the country for twelve months before he applied, they certainly had a safeguard.

Mr. Cæsar Hawkins thought they should have the same power in this respect over foreigners as they had over their own countrymen.

Dr. Andrew Wood suggested that the consideration of clause 12 should be deferred until the bringing up of the Report.

The President said they were now sitting in Committee, and could not rescind a former resolution of the Council.

Dr. Alexander Wood proposed that they should settle clause 12, and then when the Report was brought up pass a resolution that clause 11 was unnecessary in consequence of what followed.

Dr. Christison moved that, instead of clause 12, the clauses prepared by the Solicitor should be substituted.

Dr. Alexander Wood seconded the motion, which was carried unanimously.

Clause 13 was adopted.

Dr. Andrew Wood proposed, and Dr. Parkes seconded, the adoption of clause 14.

Dr. Paget thought the clause might be adopted without any harm but for the remarks with which it was introduced by the Chairman of the Medical Acts Amendment Bill Committee, who spoke of it as a matter of justice to the London University, inasmuch as all other Universities in the United Kingdom were allowed to register a similar degree. The matter was made still worse by the explanation which that gentleman gave of his vote against the same proposition last year—namely, that he was under a misconception as to the legality of it. It seemed to him that the whole thing was a mistake, and a very unfortunate one, since it placed the Council in the disagreeable position of having done injustice last year. If all other Universities were allowed the power, there was no doubt that a great injustice had been done to the University of London, but the facts showed that such was not the case. The first fact was that no other University in Great Britain had the power of registering the degree of Bachelor of Surgery, and the next fact was that the University of London had the power of registering any degree in Surgery which was granted by any other University in Great Britain. The original Act granted the privilege of registering one degree in Surgery—namely, the Mastership—to all the Universities in the United Kingdom without any exception, the University of London being, of course, included. The only other qualification in Surgery possessed by any University in the United Kingdom having the right of registration was that of Licentiate of Surgery granted by either of the Irish Universities—the Dublin University and the Queen's College in Dublin—so that, under the Acts as they existed, there were two qualifications in Surgery which had the privilege of being registered, and no University whatever possessed the power of registering the degree of Bachelor of Surgery, which was an entirely new degree. He was by no means prepared to oppose the measure. The question was a large one, which might well be discussed; but if advisable at all, he did not see why the privilege should be confined to the University of London, and this opinion seemed to be entertained by the gentleman who had made the marginal title, for there there was no allusion to the University of London at all, but simply said "degree of Bachelor of Surgery to be a qualification." If it were right to grant the privilege to one University, it was right to grant it to all, and he said this without entering into the general question, which involved principles worthy of discussion, and if it were proposed in his own University he should oppose it. He would propose that the words "University of London" should be substituted by "any University in the United Kingdom."

Mr. Hargrave seconded the amendment.

Sir D. J. Corrigan approved of the principle, and suggested the introduction of the words, "Any University in the United Kingdom legally authorised to grant the same."

Dr. Paget said some Universities not now authorised might in future become authorised, and they ought to provide for that.

Dr. Storrar asked to be allowed to make one remark in justice to himself and the University he represented. When he proposed last year that the Degree of Bachelor of Surgery of the University of London should be registered, his motion was rejected, and the University of London then took the only course open to them. They appealed to the Secretary of State to insert the clause in the Bill; but they were not bound to ask the same for every other University in the Kingdom. Had they done so, they would have gone beyond their duty, because some Universities might not desire it. They therefore only asked the privilege for themselves.

Dr. Apjohn inquired what the qualifications in Arts were.

Dr. Storrar replied that they were the same as those for a Bachelor of Medicine.

The amendment was then put and carried as follows:—"The Degree of Bachelor of Surgery conferred by any University in the United Kingdom, which now is, or hereafter shall be, legally entitled to confer the same, shall, for the purpose of enabling any person to be registered under the 'Medical Act, 1858,' be deemed to be one of the qualifications described in the Schedule (A) of the Act."

The amendment was afterwards carried as a substantive motion.

Dr. Andrew Wood proposed the adoption of Clauses 15 and 16, after omitting the words "of Medicine" in Clause 16.

Dr. Parkes seconded the motion.

Dr. Christison said in any case of the kind anticipated by this clause the prosecutor would have to prove the practice, on the part of the person offending, which was always a very difficult thing to do. Another objection was that if they omitted the words "of Medicine," they would prevent any man from using the title of "Doctor," though he might really be entitled to it, being a Doctor of science, philosophy, or music. In order to conciliate the Government in that respect, they might require proof of the practice of Medicine and Surgery in that particular instance, but he did not think they would be able to conciliate the Government by merely striking out the words "of Medicine." The important point was how to include the phrase "Doctor" in the list of prohibited titles not to be used by unlicensed Practitioners. It was very odd that every other title which was usually given to a man practising Medicine should be forbidden by the Act, while the English title of all that was known was not so forbidden, because this was what the clause amounted to as it stood at present.

Sir D. J. Corrigan said he had seen written on a door in the Strand "Dr. Donovan, Practitioner and Teacher of Phrenology." How was such a case as that to be met?

Dr. Alexander Wood: Was he a Practitioner in Medicine?

Sir D. J. Corrigan said he left that to those who went to him to decide. He quite concurred with Dr. Christison in the objections he had expressed, and thought the words must be left in.

Dr. Andrew Wood was sorry that they were going into the same debate that they had last year. If the Home Office had introduced into the clause anything different from what the Council agreed to last year, there might fairly be a discussion, but as they had debated the clause last year and made several amendments, and as the Home Office had adopted the clause with only the objectionable words "of Medicine" introduced into it, he thought it was a great pity to raise the discussion again. The clause in the Medical Act had proved inefficient because the offence for which the penalty was imposed was not that of practising Medicine, but of taking a title implying that the person was placed upon the Register; and he believed that some audacious individuals actually dared to put on their plates "Mr. So-and-so, Practitioner in Medicine, not registered," and so escaped the infliction of the penalties. After a large amount of discussion last year they had arrived at this clause, which he believed had given great satisfaction throughout the Medical Profession, who would be greatly disappointed if it were left out. The new matter that was intro-

duced then was, "That no man shall practise Medicine under any Medical title who is not registered under this Act." It would not be more difficult to prove practice now, but easier, because if they found a man practising Medicine under any such title they would refer at once to the Medical Register, and if his name was not there the penalty could easily be enforced. If the Council should fall back upon their former position they would subject themselves to a great amount of odium outside, and would show a vacillation which was not creditable to them. The question was, were they prepared to enforce registration, and if they were prepared to do so last year, why not this year? He hoped the Council would not take such a retrograde step, which would be disrespectful to the Home Office and bring odium upon themselves.

The President was obliged at this point to leave the meeting, and the chair was taken by Dr. Stokes.

Dr. Paget objected to the way in which the question was put by Dr. Andrew Wood. The question was not as to the imperfections of the old Act, for on that they were all agreed. It was not correct to say that the clause was the one they agreed upon last year. If it were, it would be vacillation to discuss it again; but the clause as it had come back from the Home Office was so altered, though only by a few words, that it seemed to him to be actually worthless. If the words "of Medicine" were omitted, any quack might with perfect impunity call himself "Doctor," practise Medicine, and not be amenable to the law at all, and thus the public would continue to suffer as they had suffered. The only persons who would be amenable to the law, according to the Home Office clause, would be those, with whom he did not entirely sympathise, but many of whom were most respectable, but who, though legally qualified to register, did not do so. He thought they were wrong in not registering, but he was sure the Council would not wish gentlemen such as many of them were to be prosecuted and fined.

Dr. Alexander Wood said the clause was not the one they agreed to last year. Dr. Christison had proposed an ingenious plan for making the clause effective and to carry out the design of the Council in a manner which would be least offensive to the gentlemen who influenced the Home Office in the matter. If they went back again with the clause of last year it would not be respectful to the Home Office. There were other Doctors besides Doctors of Medicine, and why should these be disfranchised? It was suggested that they should modify the clause so as to satisfy the Home Office as to their reasons for leaving out the words "of Medicine," and also guard against the necessity of being obliged to prove practice. There were difficulties in the way of framing such a phrase, but he had no doubt it would be done, and that the Council would adopt it.

Dr. Christison said that at the first it would perhaps have been wrong to compel every man practising Medicine to register, but he thought they were compelled to do so now. If his suggestion was adopted, they would make the prosecutions as easy as possible.

Dr. Sharpey said there were a great number of persons who had the degree of Doctor of Medicine who were not engaged in practice.

Mr. Rumsey mentioned that last year a clause was agreed to commencing with the words, "Any person practising Medicine or Surgery, or being engaged in the treatment of diseases or injuries," etc., and he thought with that general proviso Dr. Christison's object would be fully obtained, without weakening the application of the proviso to the other titles. He hoped the same general clause as the Council agreed to last year would be now insisted upon.

Sir D. J. Corrigan said that if the words "Any person engaged in the cure or treatment of diseases or injuries" were used, it would have to be proved that the person was so engaged. If a man adopted the title of Accoucheur he would be absolutely liable to the penalties of the Act.

Dr. Andrew Wood wished, before making further remarks, that Mr. Ouvry would state what he thought would be the effect of these two clauses, because from what took place last year he (Dr. Wood) believed the clause proposed by Dr. Christison would answer no purpose whatever. He also had a strong idea that the Home Office were not particularly wedded to the words "Doctor of Medicine."

Mr. Ouvry did not agree that the words "engaged in the cure or treatment of diseases or injuries" would be introducing a new difficulty. He thought they were necessary because they implied the offence. No doubt in many cases there would be difficulty in proving it, but he did not see how they could avoid that difficulty in any way. With regard to the title of "Doctor of Medicine," as put in by the Home Office, that was simply absurd, because it was already prohibited in the former part of the clause, inasmuch as it was one of the designations specified in the schedule of 1858. The Home Office had not considered that the clause was really limited by the first words, "any person practising Medicine or Surgery." He should think, with reference to what Sir D. J. Corrigan had said, that a person following the Profession of an Accoucheur would be engaged in "practising Medicine or Surgery."

Sir D. J. Corrigan said that under the Charter of the London College a man might practise as an Accoucheur without any qualification whatever.

Mr. Hawkins pointed out the words, "or any other designation used by or used to distinguish duly qualified Practitioners of Medicine or Surgery, or any class thereof," and remarked that surely midwifery was one of the class.

Dr. Acland imagined that this clause would allow persons registered under one title to use another. Was it intended to do so?

Mr. Ouvry said it had nothing to do with registered Practitioners, but applied only to unregistered.

Dr. Andrew Wood then moved, and Dr. Parkes seconded, "That clauses 15 and 16, as to unregistered persons, be adopted, with the omission of the words 'Schedule (B) to,' and of the words 'of Medicine,' after 'Doctor.'"

Dr. Christison asked Dr. Wood whether he retained the words, "or engaged in the cure or treatment of diseases or injury? He thought it would be a dangerous thing to do so.

Dr. Andrew Wood said they considered the effect of that last year, and it was only after very great deliberation that those words were put in. He hoped Dr. Christison would allow them to stand.

The clause was then adopted with the omission proposed.

Dr. Andrew Wood next moved, and Dr. Parkes seconded, "That clause 17 be adopted."

Dr. Acland rose *pro forma* to move an amendment. He said they were aware that notice of motion had been given, and would come on this session, with regard to the legality of what he proposed on the first day of the session, concerning grants for particular purposes. He did not at all desire that any clause should be inserted in the Amendment Act to give them powers which he believed they at present possessed, but he conceived he was obliged to take this opportunity of offering the clause, inasmuch as the Council had voted that they had not the power to make grants for particular purposes. The clause he would propose would, if accepted, stand as No. 17, and the only difference would be that clause 17, as it at present stood, would be 18. He then proposed, "Notwithstanding anything in the Medical Act to the contrary, such expenditure as from time to time may be deemed by the General Council necessary for the improvement of the list of Materia Medica shall be deemed to be authorised by the Act." Though he brought this clause forward he did not think it was necessary, as he maintained they had the power, but if they had not, they ought to have it.

Mr. Rumsey said that, as a matter of form, he would second the amendment of Dr. Acland.

Mr. Sharpey thought this amendment was quite unnecessary. There could not be a doubt as to the power of the Council to spend money for making scientific inquiries, but he objected to Dr. Acland's proposition on the first day, because he did not think the inquiry proposed was necessary or expedient.

After some further remarks, Dr. Acland withdrew his amendment, and clause 17 was agreed to.

Dr. Alexander Wood rose to propose a resolution to the effect that the Report of the Committee be referred back to be adjusted in accordance with the alterations in the clauses of the draft Bill, when

Sir D. J. Corrigan interposed by observing that the Committee's Report had not been adopted.

Mr. Hargrave then moved, and Mr. Rumsey seconded, "That the Committee's Report be read paragraph by paragraph."

Dr. Alexander Wood said the Committee's Report was simply an explanation of the Bill, and, having settled the clauses of the Bill, that they should now proceed to settle the Committee's ideas upon it, seemed to him one of those ways of wasting time for which this Council was peculiarly felicitous. He therefore moved as an amendment, "That the Council do now resume."

Dr. Acland seconded the amendment, remarking that as the Report had been received and entered on the Minutes any further discussion upon it was unnecessary.

Sir D. J. Corrigan rose to a point of order. There was a great difference between receiving a Report and adopting it. They had received reports over and over again, and they had undergone great alteration before being adopted. There were passages in the Committee's Report to which he had a strong objection, one of which was this—"The Committee, on the whole, would recommend that—the objections stated notwithstanding—under the conditions contained in the Home Office clauses, the Council should accept these clauses, especially as they are given to understand that the insertion of them is a *sine quâ non* to the support of the Bill by the Government." Now, he objected altogether to adopt a paragraph which told them that it was an understanding on the part of the Committee that unless they put their hands under the feet of the Government and accepted a Bill they did not approve of, they might get no Bill at all. Therefore he should support the resolution that the Report be read paragraph by paragraph.

Dr. Andrew Wood thought Sir D. J. Corrigan was perfectly in order. They went through the analogous Report brought up last year in a similar way. It was necessary, along with the draft Bill, to take the comments of the Council upon it, as it would help the Home Office to understand what they proposed.

Dr. Alexander Wood then withdrew his amendment, and the resolution "That the Report be read paragraph by paragraph" was carried.

The Registrar then read the preamble paragraph in the Committee's Report.

Sir D. J. Corrigan proposed, and Dr. A. Smith seconded, —"That the first part of the Report be amended as follows :—

"The Committee having fully considered the Bill, and compared it with that which was drafted during the last session of the General Medical Council, beg leave to submit the following Report :—

"The Bill of the Home Office embraces substantially the Bill of the Council, with, however, some important additions and alterations which require specific notice.

"*The Preamble.*—The Council's draft Bill commenced with the following Preamble :—'Whereas the "Medical Act, 1858," has been found ineffectual to enable persons requiring Medical aid to ascertain who are qualified Practitioners, etc.' This Preamble the Home Office draft leaves out.

"The Committee are of opinion that, if there be no valid reasons against its being retained, it would be desirable that it should be restored as part of the proposed Bill."

Dr. Alexander Wood thought the proper way of proceeding would be to send the Report back to the Committee, in order that they might amend it in accordance with the resolutions of the Council on the draft Bill, and then this amended Report could take precedence of all other business to-morrow (Thursday). If Sir D. J. Corrigan was not satisfied when the Report came up, he would still be at liberty to object to any paragraph. He moved a resolution to this effect.

Dr. Acland seconded this proposition, remarking that, whether they were acting on precedent or not in considering the Report paragraph by paragraph, it seemed they were doing a very irrational thing.

Sir D. J. Corrigan rose to a point of order. A resolution had been passed that the Report be read paragraph by paragraph, and having got through two paragraphs he considered a new motion on the subject a proceeding not to be tolerated. If the course he proposed was irrational, it was the course that had been pursued on every occasion on which a report had come up.

Dr. Alexander Wood again hoped the Report would be remitted to the Committee, as it would save a great deal of valuable time.

Dr. Andrew Wood was in favour of the Report being considered paragraph by paragraph.

The Chairman was about to put the motion that the Council do now resume, when

Sir D. J. Corrigan again rose, and protested against it. This was a point of immense importance. A resolution had been carried that the Report be read paragraph by paragraph, and he put it whether, that resolution having been carried, it was not altogether out of order, in the middle of this discussion, to propose an amendment which would abrogate the original resolution.

The Chairman ruled that it was irregular, and therefore he declined to put it.

Mr. Hawkins thought they would get into inexplicable confusion if they went on in this way. The Report had been considered in conjunction with the corresponding clauses of the Bill, and therefore the only common-sense plan would be to appoint a Committee to bring up another Report upon what they had done, so that it might be sent to the Home Office with the Bill as amended.

Mr. Syme said the Report before them was simply the Report of a Committee; what they wanted to send to the Home Office was a report of the whole Council, and therefore he considered they had decided upon a right course.

The Chairman thought that under the circumstances they could not avoid going through the Report paragraph by paragraph. The whole object of that Report was to assist the Government in giving them a proper Bill, and it was of the utmost importance to them that it should go to the Government, not from a Committee, but from the whole Council.

Sir D. J. Corrigan's motion was then put and carried.

The next paragraph of the Report having been read,

It was moved by Sir D. J. Corrigan, and seconded by Dr. Andrew Wood, and agreed to,—"That Section II. of the Report be amended, as follows :—

"2. *The Registration Clause.*—The object of the clause as to registration, proposed in the Council's draft Bill, was to facilitate the duty of the Registrars in keeping their Registers correct; to enable persons who, having ceased to practise, may desire it, to have their names erased from the Register; to render it imperative on the Registrar to address to any registered Medical Practitioner (instead of one letter within six months, as in the 'Medical Act, 1858') two letters within six months, at an interval of three months, inquiring as to change of residence, before erasing his name from the Register, and to prevent any person who has been once erased from the Register from being re-registered without the instruction of the General or Branch Councils.

"In the Home Office Bill this clause has been substantially adopted, though the phraseology has been somewhat varied, and the clause has been subdivided for convenience into eight clauses. The Home Office Bill contains, however, two additions requiring mention, viz. :—

"I. The Council's draft Bill provided that when the name of any person shall have been erased from the Register by the General Council or any Branch Council, it shall not again be registered in any Register, except by direction of the Council which directed the erasure. The Home Office Bill adds the words, 'or by order of a Court of competent jurisdiction.' The Committee see no objection to this addition.

"II. The Council, in their clause, had provided that the Registrar should address to any registered Medical Practitioner two letters within six months, at intervals of three months, inquiring as to whether he had ceased to practise, or had changed his residence, before erasing his name from the Register. The Home Office clause diminishes still further the chance of any mistake by providing that the letters to be addressed by the Registrar shall be registered letters; and that the second letter shall be addressed within fourteen days after the expiration of the first three months."

It was moved by Sir D. J. Corrigan, seconded by Dr. Andrew Wood, and agreed to :—"That section 3 of the Report be amended as follows :—

"3. *New Clauses as to Registration of Foreign and Colonial Practitioners.*—The Home Office Bill embraces three new clauses (11, 12, 13), which provide for the registration of foreign and colonial Practitioners, under certain conditions, these conditions being—(1) That only those foreign and colonial diplomas and degrees shall be registered which have received the sanction of the General Medical Council, and shall be included in a new schedule entitled Schedule (B), which the General Council have been requested by the Home Office to prepare. (2) That the provisions contained in sections 20, 21, 22 of the 'Medical Act, 1858,' shall apply to all qualifications contained in the schedules to the proposed Bill—that is to say, that the Council, if they do not consider the course of study and examinations to be gone through in order to obtain any such qualifications sufficient, shall be entitled to represent the same to the Privy Council, who shall have power to suspend the right of registration. (3) That no qualification, whether British, foreign, or colonial, other than those included in Schedules (A) and (B) in the proposed Bill, shall be entitled to registration unless by order of the Privy Council, on the representation of the General Medical Council. (4) That no person shall be registered upon any foreign or colonial diploma or degree who has not resided in the United Kingdom for a period of not less than twelve months immediately previous to his making his application for registration.

"The Council are aware that, though there was power in the Council to register, if they saw fit, persons holding only foreign or colonial diplomas and degrees—provided they had obtained them previously to the passing of the Medical Act, 1858—yet that they had no power to register any such diplomas and degrees obtained after the passing of that Act. The Committee consider it fair and right that some provision should be made for the registration of foreign and colonial diplomas and degrees (especially if registration be rendered indispensable for practice under recognised Medical titles), as it would be a harsh measure to deny the privilege of registration in this country to persons who may come from abroad or from the colonies holding foreign or colonial diplomas or degrees, provided these qualify for practice in the countries where they have been granted, and are deemed deserving of recognition by the General Medical Council, as implying education and examination not inferior to the minimum required in the case of qualifications granted in the United Kingdom.

"In the Home Office Bill a new Schedule (B) is proposed to be introduced, for the purpose of including those foreign and colonial degrees and diplomas which are to qualify for registration. The duty of preparing this schedule has, as already stated, been committed to the Council by the Home Office.

"Whilst the Committee have done their utmost to meet the wishes of the Government in framing a Schedule (B), they have found the difficulty of the task to be so great that they consider it preferable to make a provision in clause 12 of the proposed Bill, by virtue of which it shall be lawful for the General Medical Council annually to prepare and submit to the Privy Council, for approval, a list of those foreign and colonial qualifications which, from time to time, the General Medical Council may consider worthy of recognition—this list to be published in the *London Gazette*.

The fourth section of the Committee's Report was then read.

Sir D. J. CORRIGAN moved, and Dr. ALEXANDER WOOD seconded, "That section 4 be amended as follows :—

"4. *Registration of the Degree of Bachelor of Surgery.*—The Committee see no reason why the degree of Bachelor of Surgery, conferred by any University in the United Kingdom, which now is, or hereafter shall be, legally entitled to confer the same, should not be included in Schedule (A)."

The fifth section was then read.

Sir D. J. CORRIGAN said that if he stood alone he should be inclined to vote against this paragraph, especially this sentence—"The Committee believe that the Home Office Bill, with the amendments suggested by them to be adopted by the Council, would prove a salutary amendment of the Medical Act, one calculated to benefit the Medical Profession, but especially the public for whose protection from unqualified Practitioners it makes more efficient provision." If they put it in this way, it seemed as if they looked after themselves and the public, while they took no steps in this Bill for improving the education of men engaged in the Profession.

Dr. ANDREW WOOD said the reason for putting this sentence in the Report was that there was a very general impression abroad, and in Parliament especially, that these Medical Bills were made alone for the good of the Medical Profession. That was a doctrine he utterly repudiated. If the Medical Profession had an interest in having a Medical Act, the public had a ten times greater interest, because it was to give them the means of knowing who were the men to whom they could trust their healths and their lives. It was no use going to Parliament without stating in strict terms what was actually the case—that the public were largely interested in having a Medical Bill that they might be wrested from Medical quacks. He did not see why Sir Dominic should object to that sentence. He (Dr. Wood) quite agreed they ought to have good education for those who entered the Profession, and that they were endeavouring to obtain. At all events, let the Profession and the public know that they were endeavouring in every way, so far as they could, to guard the public against being imposed upon by Practitioners, either out of the Profession or in it, who were not qualified.

It was then proposed by Sir D. J. CORRIGAN, seconded by Dr. ANDREW WOOD, and agreed to—"That the remaining portion of the Report be amended as follows :—

"5. *The Penalty Clause.*—This important clause, as framed by the General Council last year, has been substantially adopted in the Home Office Bill. There is only one important point requiring notice, viz., that instead of the word 'Doctor,' as in the Council's draft Bill, the words 'Doctor of Medicine' have been used in the Home Office draft Bill. The Committee believe that the effect of this alteration is materially to weaken the clause; as, if it be retained, unqualified persons will continue as now to practise Medicine, calling themselves 'Doctors,' but not 'Doctors of Medicine,' and will thus evade the penalties. It might be said that by using the word 'Doctor' only you include all Doctors, whether of Philosophy, Law, etc. The answer to this is, that it is only those who, not being registered, are 'practising Medicine under the title of Doctor' who are affected by the clause. The Committee would advise the Council to represent this matter very specially to the Home Office.

"The Committee believe that the Home Office Bill, with the amendments suggested by them to be adopted by the Council, would prove a desirable amendment of the Medical Act, one calculated to benefit the Medical Profession, and the public, for whose protection from unqualified Practitioners it makes more efficient provision. They therefore trust that the Council will adopt it, and will, before the conclusion of the present session, send a deputation to the Home Office to state the views of the Council regarding the Bill; and further, to urge on the Government the expediency of the Bill being introduced as a Government measure."

It was next resolved, on the motion of Dr. ALEXANDER WOOD, seconded by Dr. EMBLETON—"That the Chairman of the Committee do now report progress, and that the Council resume."

It was further proposed by Dr. ALEXANDER WOOD, and seconded by Dr. EMBLETON, "That it be remitted to the Medical Acts Amendment Committee to prepare and bring up the Bill, as now amended in Committee of the whole Council. That the Report of this Committee take precedence of all other business to-morrow."

This resolution having been put to the meeting and agreed to, the Council adjourned.

SEVENTH DAY.—THURSDAY, MAY 24.

The Council met at 2 o'clock, the President in the chair. The minutes of yesterday's meeting having been read and confirmed,

Dr. ANDREW WOOD brought up the Report of the Medical Amendment Acts Committee as amended, and with the following additional recommendations :—

The Committee have carefully gone over, with Mr. Ouvry, the draft Bill, with the alterations adopted by the Committee of the whole Council. They beg leave to make the following suggestions in reference to the Bill as it now stands :—

"1. The Committee recommend, that as clause 11, as originally adopted by the Council, is inconsistent with clauses 11 and 12, as subsequently agreed to by the Committee of the whole Council, the first mentioned clause 11 be omitted from the draft Bill."

"2. The Committee recommend, with a view of simplifying the language of the clause adopted in place of clause 11 by the Committee of the whole Council, that these words should be erased—viz., 'of such qualifications as shall from time to time appear to the General Medical Council as proper to be included in the list;' and that the words 'General Medical Council' should be substituted for 'such Council.'

"3. The Committee recommend, that in lieu of the third division of clause 11 of the Home Office draft Bill, it be provided in clause 13 that sections 29 and 39 of the Medical Act of 1858 be added, so as to bring persons registered under foreign and colonial qualifications under the same liability of removal from the Register, for offences as those registered under Schedule (A) to the Medical Acts."

The Committee would further recommend that, instead of communicating to the Home Office the Report of the Medical Act Amendments Committee, as finally adjusted by the Committee of the whole Council, the Council should transmit a succinct statement, prepared by their solicitor, Mr. Ouvry, of the reasons for such alterations in the Government draft Bill as may be adopted by the Council. Finally, the Committee recommend that a letter be, without loss of time, addressed by the President to Sir G. Grey, requesting that he will receive a deputation from the Council in reference to the Bill, on as early a day as he can conveniently appoint.

Dr. ANDREW WOOD then moved, and Dr. EMBLETON seconded,—"That the Report of the Committee on the Medical Acts Amendment Bill be received, and that the recommendations contained in it be considered seriatim."

This motion was carried, and the report adopted to the end of the 9th clause.

On the motion for adopting the 10th clause,

Sir D. J. CORRIGAN moved the following amendment :—"That in clause 10 the four last lines, viz. :—'Provided that a person whose name has been erased from the Register with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this Section, by reason of his being engaged gratuitously in the cure or treatment of any disease or injury,'—be omitted. He thought that the clause, as it stood in the Bill, would read very badly to a stranger, and in the House of Commons, because it would be impossible to understand the motive which induced them to include those words. It would read as though they did not care whether a man went out of the Profession or not, or whether he practised as an amateur (in which case the patient would be much better without his treatment than with it), provided he did not take a shilling for it. The object was said to be that clergymen or very humane persons who had studied the Profession and had been registered, might desire their names to be taken off the Register, but might still wish to practise gratuitously among the poor. He was perfectly sure the poor would be very much better without such men than with them. They sought to be Practitioners, though their names were not on the Register, and he objected to saying that they would allow that, provided they practised gratuitously, for money could be got from the poor in many ways.

Mr. SYME seconded the amendment.

Mr. OUVRY said the proviso had been put in by the Home Office, and it did not seem desirable to meddle with it. He did not think the proviso would have any material effect.

Sir DOMINIC CORRIGAN said that after the statement of the solicitor he objected to the clause a thousandfold, and he would rather have the whole Bill thrown out than have those lines inserted. It was very easy to see the object of those who introduced them, and how there would be a scrambling of certain persons to get on the Register—persons who had no status, and who could get on the Register with scarcely any examination at all.

The PRESIDENT disclaimed using any influence in getting the words inserted, and said it was well known that the Legislature was very unwilling to grant them the power of imposing pains and penalties.

The amendment was put, and nine members voted for and nine against it. The President gave a casting vote against the amendment, which was therefore lost, and the original motion carried.

Dr. ANDREW WOOD moved, and Dr. PARKES seconded, the following motion, which was agreed to :—"That in lieu of clause 11, adopted by the Council; and in lieu of the clause 11, subsequently adopted by the Committee of the whole Council, the following clause be substituted,—viz. :—

"Every person who has resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application, who legally possesses a colonial or foreign diploma from a University, College, or other Body qualifying him to practise Medicine or Surgery in

the colony or foreign country where such diploma was obtained, shall be entitled to be registered under the Medical Act, 1858. Provided such diploma shall have been granted by a University, College, or other Body recognised in a list to be annually prepared by the General Medical Council, which list shall be submitted to Her Majesty in Council for approval, and shall thereupon be published in the *London Gazette*."

On clause 12 the following resolution was, after some discussion, moved by Mr. HAWKINS, and seconded by Dr. PAGET:—"That a new clause be drawn up, or some words added by Mr. Ouvry, to a clause like clause 29 of the Act of 1858, which shall apply to persons registered under clause 12 of the draft Act on foreign or colonial qualifications, for crimes and offences committed in their own countries, of the same nature as those referred to in clause 29 of the Act (1858), when committed in England, Scotland, or Ireland, by persons registered under the Act of 1858."

This motion was lost, and the following, proposed by Dr. ANDREW WOOD, and seconded by Dr. PARKES, carried instead:—"That clause 13, which is as follows,—viz., 'The provisions contained in sections 20, 21, and 29 of the Medical Act, 1858,' shall apply to any qualification, which in pursuance of this Act entitles persons to be registered under the Medical Act, 1858,—be amended, by inserting after '22' the words '29 and 39,' and by striking out the word 'and' between 21 and 22.

The two following resolutions were adopted unanimously on the motion of Dr. ANDREW WOOD, seconded by Dr. PARKES:—"That Mr. Ouvry be requested to prepare a succinct statement of the reasons for the alterations made in the Government Bill by the Council (based on the Report of the Medical Acts Amendment Committee, as finally adjusted by the Committee of the whole Council) for transmission to the Home Office." "That a letter be addressed, without loss of time, by the President to Sir G. Grey, requesting that he will receive a deputation from the Council in reference to the Bill, at as early a day as he can conveniently appoint."

Dr. ANDREW WOOD proposed, and Dr. PARKES seconded,—"That the Report of the Medical Acts Amendment Committee be adopted as amended by the Council."

Sir D. J. CORRIGAN said he rose for the purpose of moving an amendment and of expressing his conviction, which might or might not be shared in by other members of the Council, that a more mischievous Bill than that which was now before them, or one which would be more useless to the Profession, could not be devised. Not only did he feel a great objection to the Bill on its own merits, but he very much objected to going forward with it under the circumstances in which they were placed with regard to the Government, and which connected them with the Government, or rather which disconnected them from them. In order to prevent any mistake or misconception, he would at once propose the following amendment:—"That the Secretary of State be requested to take the necessary steps to procure the issuing of a Royal Commission to inquire into the working of the Medical Acts, and to examine the members of the Medical Council, and such other persons as they may see fit, with the view of framing a report that may lay the ground for a Medical Bill that will ensure the better education of candidates for the practice of the Medical Profession, and better protection for the rights of qualified Practitioners, than the present Medical Act affords." In supporting this amendment, he would first express his obligation to the President for putting the whole case in a nutshell by saying that the full scope of the Bill was the hope that the Government would enable them to introduce the word "Doctor" instead of "Doctor of Medicine." The President also put the question, as far as he understood, and he hoped he was not misrepresenting, whether it would not be right, in consideration of obtaining that great boon, to submit to a great many things from which they dissented. They were now going to Parliament with a Bill which gave them no redress; but if they looked into it they would find it repealed a most important clause contained in the Act of 1858, to which he would draw their attention. That clause was—"That, after the first day of January, 1859, the words 'legally qualified Medical Practitioner,' or 'duly qualified Medical Practitioner,' or any words importing a person recognised by law as a Medical Practitioner, or member of the Medical Profession, when used in any Act of Parliament, shall be construed to mean a person registered under this Act." They were now going to repeal this Act, which was the whole foundation of the protection of the Profession, for it had been carried by a majority—a small one, it was true, but still a majority—that a person might obtain the placing of his name on the Register by any means whatever, no matter what they were; that once on the Register he could withdraw his name from it; that he could still continue to practise, and would be a legally qualified Practitioner, though his name was not on the Register. In other words, the Bill provided that persons over whom they had no control, and who got their qualifications as they best could, could get their names on the Register, and then withdraw them, but still continue to practise and be recognised by law as qualified Medical Practitioners provided they practised gratuitously. They could commit any crime or any felony they pleased, and turn round and laugh at them and say, "We are qualified Medical Practitioners, though not on the Register, and you cannot convict or punish us unless you prove that we have taken money for practising." So much for the protection of the Profession! Was it a great boon that, as the Home Office had provided, a man was not subject to penalties unless he wrote "Doctor of Medicine" or received money from his patients? Then the Committee in their Report had proposed a list of at least 17 foreign Universities, many of them having 13 or 14 Colleges, whose diplomas at one fell swoop should be recognised; and yet this was called protecting the Profession in the United Kingdom! No matter how they guarded it, there would be men come to them whose social status abroad was of the lowest description, and the Profession would be inundated by a horde of unwashed foreigners who possessed no status in their own country, and who lived in a way that would be a disgrace to them; and not only that, but when once on the Register, it was very doubtful whether they could be legally ever taken off. Was this protecting the Profession?

The PRESIDENT said the Council had not given their sanction to this being done.

Sir D. J. CORRIGAN said the Committee had admitted these 17 Bodies in their report, and with the colonies the number would amount to 40. It was not at all probable that the number would be confined to that, but that it would increase.

Dr. ALEXANDER WOOD rose to a point of order. The Council had already settled by vote that the clause should stand as part of the Bill, and he wanted to know whether these discussions could be reopened again and again in that way. Sir D. J. Corrigan had bestowed a great deal of time and attention upon the matter, for which the Council felt indebted to him. For the best part of two days the Council had been engaged in considering the Bill, which they had now amended, and had passed a resolution to send it to the Home Office, and yet after that Sir Dominic Corrigan came foward and made a speech directed against the Bill. There surely must be some irregularity in such a course, and the Council was being led into that irregularity.

Sir D. J. CORRIGAN said the only irregularity about the matter was the interruption by Dr. Alexander Wood. The question now before the Council was not that they should send a Bill to the Home Office, but that the report of the Committee be adopted; and he held that he had the right to move the amendment unless the Chair decided that he had not.

The PRESIDENT ruled that Sir Dominic Corrigan was quite right in moving an amendment upon the motion, which was that the report of the Medical Amendment Act Committee be adopted. As Dr. Alexander Wood had stated, they had agreed upon the amendments to the Bill, and that the Bill should be sent to the Home Office, and also that it should be accompanied by a succinct statement by the solicitor of the reasons why they thought the changes necessary. The only thing he was not quite satisfied about was that Sir Dominic Corrigan seemed in his speech to charge the Council with having sanctioned the recognition of seventeen foreign Universities.

Sir D. J. CORRIGAN said he did not say the Council had sanctioned it, but the Committee.

Dr. SHARPEY considered that Sir D. J. Corrigan's remarks did not apply, because this matter was not contained in the Report at all.

Sir D. J. CORRIGAN said he had only stated what he begged the liberty to repeat, that the recommendation of the original Report was for seventeen foreign Universities and their Colleges. When that recommendation came before the Council he had strong fears as to what the effect of it would be, and in submitting his amendment he held that he was perfectly at liberty to introduce any argument which in his opinion justified the amendment he had proposed.

The PRESIDENT said the Council and Sir Dominic Corrigan were of the same opinion with reference to the recognition of those seventeen bodies, and they had declined to recognise them.

Sir Dominic J. Corrigan said he must again repeat what he had stated before, that the Committee originally recommended seventeen foreign Universities whose diplomas should be recognised. Here he would leave this subject and go on to another; but before he went further, he would say at once that even to the manner in which the Bill was to be proposed or brought forward he most strongly objected. The Secretary of State for the Home Department had declined to have any hand in the Bill. They were now a public department of the State, and what did the Secretary of State say to them? He recommended them to put the Bill into the hands of some person in the House of Lords or some person in the House of Commons, but he recommended the House of Lords. Was that a proper position for the Council to be placed in? Was it a proper thing for the President to have to go down to the lobby of the House, and wait, hat in hand, and with

"Bated breath and whispering humbleness,"

till he could find some one who would take charge of the Bill? He asked in all sober seriousness whether this was a proper position in which to place the Council. Even if he cordially approved of the Bill, he would not go either to the House of Commons or the House of Lords, and stand, hat in hand, and ask private Members to take it up. They would be met by a whole host of opposition, by homœopaths and quacks, and all kinds of people. Who was to invite the discussion? Who was to stand with a soap-boiler or a respectable man in some other trade, who understood his own trade very well but knew nothing of the Medical Profession, and with a homœopathist on the other side, and bring forward the Bill? The Government had shelved them, and he suggested that a letter should be written to Sir George Grey, stating that as he had declined to take up the Bill of a public department of the State, they, under those circumstances, declined to go forward with the Bill, and would let the onus rest upon him of refusing to introduce a Bill which concerned both the public and the Profession. He did strongly object to go to the House of Commons or the House of Lords in the manner which Sir George Grey suggested.

Dr. Christison asked if the Council were really placed in that position, because if it was he thought every member of the Council would object to it.

Sir D. J. Corrigan said they applied to Sir George Grey to undertake the charge of the Bill, and he would read Sir George Grey's answer:—". . . . I am directed by Sir George Grey to say . . . Some member of the House of Commons might be found by you who would take charge of it. It would be better, if possible, that it should be brought in in the Lords with a view to its progress." Were they prepared to act upon that, that "some private member might be found by you who would take charge of it?" He now came to his reasons for adopting the course which he had proposed, and, to have recourse to a very common expression, but one that had a great deal of truth in it, he would say he thought that they were putting the cart before the horse. What were they doing? They were about to state, as the reason for the course which they wished to adopt, that qualified Practitioners required to be protected from unqualified or ignorant men. This was all very well, and he did not object to it. If a member of Parliament were asked to take the Bill up, it would be on the ground that qualified Practitioners ought to be protected. But what would that member say when he was met in the House, as he would be, by a reference to an authority which could not be disputed—namely, the returns from the Navy Board, and which showed that last year, 1865, that Board reported on the gross ignorance of a great number of the candidates sent from the licensing bodies, the representatives of which sat around that table. The blame of that rested with those bodies, for the candidates had gone from nearly every one of them. It might be said that this was in 1865. Then he would come to 1866, and the report in 1866 from gentlemen whose word could not be doubted, was—he would quote the exact words by-and-by—they begged to express their surprise that members of a liberal Profession should be found who were incompetent to spell and write the commonest English composition, while some of them were so ignorant of therapeutics or the basis of Medicine, that it would be unsafe to let them pass. Now, would not any sensible member of the House of Commons say—"I do not see what is the object of this Bill, nor why I should support it, for according to the evidence in the Minutes of the Council it is clear that the registered Practitioners are just as bad as the unregistered, and the unregistered just as good as the registered. I do not see how it makes the least difference to the public whether the man who does not know how to prescribe is registered or not; in other words, the one is just as bad as the other." He had said that they were putting the cart before the horse, and he contended that their first step should have been to have asked for powers which would enable them to enforce such rules upon the licensing bodies as would prevent them exhibiting them in such a painful and humiliating position before the world. If they had done this—if they had been able to enforce a good education, and to say that no men were let loose upon the public but such as were to be trusted, then they might fairly go forward and ask for protection; but they must not ask for protection, nor was there any chance of getting it if they did, till they had first taken some steps to enforce a proper education. In the present state of things the men who were turned out from the Navy Board were, with their diplomas, let loose upon the public. If they adopted the course he proposed, and asked for a Royal Commission, they would then set themselves right both with the Legislature and with the public, for they could say that if these evils had arisen they had done their best to prevent them; whereas, to go and ask for the Bill at present would be to lay themselves open to misconstruction, and, in his opinion, to put the wrong foot foremost. If they applied for the Royal Commission,—and if his amendment should be carried he should at once move that the Royal Commission be applied for,—they could state to that Royal Commission the objects they had in view, but that there were insuperable difficulties in their way. They did not want to say they were not defective, but they wanted to show where they were defective. What the constitution of the Royal Commission should be would be best left to the Secretary of State; but let the Commission be applied for and appointed; let it examine every member of the Council; let it examine those without and those within; let them confess their failings before it, whatever they might have been, and then that Royal Commission would frame a report to the Government upon the whole matter. But, even supposing the Government threw overboard the Royal Commission, they would then be in a better position than they were before, for they would have been able to say that they had done everything in their power, and that if the Government had not thought proper to aid them in amending the defects which existed, the Council had nothing to look back upon; but if they went forward with what the President had truly called "this wretched Bill," ("Hear, hear," and loud cheers) they would be in a worse position, in the opinion of the public, than they were before. With regard to the Register, he should, if a Royal Commission were granted, indicate an alteration from the present form, which he held would be an improvement upon it. If he took up the *Almanach de Médicine* he did not find the Practitioner of Leicester-square, who prescribed for the organ-grinders—and he knew one or two of them under peculiar circumstances—set side by side with the highest men in the Profession. (Hear, hear.) Even with regard to the Register, he would propose an improvement and suggest that they should do what was done in the *Almanach de Médicine*, where those who possessed high qualifications were placed by themselves in one class, and all the names arranged according to the various qualifications. The two great objects they had to gain were the better education of Practitioners and a protection for themselves. He would read a resolution passed by the Cork Medical Association, which he believed expressed in plain words what they all felt:—"That convinced as we are by increasing experience of the paramount importance of securing to the country competent Practitioners in Medicine and Surgery, we desire to record our anxious wish to see the Medical Council so modified, both as to its constitution and powers, that it will enforce a high uniform standard of education, both preliminary and Professional, on all licensing bodies throughout the United Kingdom." He believed that this embodied what was thought by a great many of them. Up to the present hour there was not a single licensing body which had concurred with their recommendation, except by accident. It did happen that the Dublin University, to its great credit, would not permit any man to commence his Medical studies without he had undergone a thoroughly sifting examination in preliminary education. Some others did the same, but how were they circumstanced at the present moment? In the Report from the Scottish Branch Council, they found that a large number of exceptional claims had been made, including the whole of the students who, since November, 1865, had commenced their studies in the Universities of Glasgow and Aberdeen, and who had been allowed to commence their Professional studies without a preliminary

examination. Added to this, they had a communication from the University of Glasgow to the effect that that body thought it not expedient to adopt the plan of registration recommended by the Council. That letter said—"In transmitting to you the accompanying list, I am directed to state that as, according to the present regulation of the University of Glasgow, Medical students are, in certain cases, admitted to enter upon their Professional studies previously to their having passed an examination in general education, it has been thought expedient not to adopt the plan of registration recommended by the General Medical Council, and for which you sent the required printed forms, but in the meantime to transmit an authentic list of Medical students who have commenced their Professional studies at this University, and are in the first year of their attendance, with a statement as to whether or not they have passed an examination in general education." At the end of eight or nine years they found, not one body, but several bodies, who did not pay the least attention to the regulations of the Council. The University which he represented was exactly in the same predicament, and was just as bad as any other. The Queen's University in Ireland did not comply with the recommendations of the Council, nor pay the least attention to it. They all differed from the Council as to the time when Professional study should commence. He did not attach blame to any of them for this. He did not say that they should attend to the regulations of the Council, and hoped he should not be understood as passing a censure upon any of them; but he was simply showing that they were in a position in which they were utterly powerless to enforce good education or good examinations, and that their first step ought to have been to have gone before Parliament for powers to enable them to do that, and then, after that, to ask for protection for the Profession. It was no use leaving the conduct of examinations to those bodies who had an interest in the matter on account of the fees by the students. The London University had no interest of that kind. In a letter which he had written to Dr. Mackesy, the President of the Medical Association in Cork, he pointed out that the Council had no power to enforce any course of study or examination, but that the several corporations could do as they liked; and in that letter he said—"The Medical Council has no power to enforce any course of study or examination. They tried it with the University of Edinburgh in the second year of their existence, and were beaten. The several corporations may do as they like, and in the present state of free trade and underselling each other for the profit of the diplomas, I see no hope of any amendment." But, supposing when the matter came before the House of Commons, legal opinion was taken, and it was held that they had the power, then the next question they would be asked would be what they had done with it. (Hear, hear.) They would be told that they had the power to protect the Profession from unqualified persons entering into competition with those who were qualified, and yet at the end of eight years they were not able to put their hands upon a single instance in which they had attempted to exercise that power, and that they now came and asked for protective laws when their own conduct showed that they did not care a straw about them. He promised to read to them the Report of the Naval Board in 1865, and he would do so:—"The majority of those rejected were utterly ignorant of the Latin language; two failed altogether in Anatomy and Surgery, and two were so ignorant of Materia Medica that it would have been dangerous to pass them as qualified." It might be supposed that there had been some improvement since then, but, unfortunately for that supposition, the Report for 1866 was still worse, for it said,—"In renewing our expressions of regret, that so much ignorance of the Latin language should be displayed by a large proportion of the candidates who submit themselves for examination, we are sorry to have to add that many of the manuscripts sent in by the candidates have given evidence of such an ignorance of orthography and of the most ordinary rules of English grammar and composition as could hardly have been credited in members of a liberal Profession." This was the improvement between 1865 and 1866, and yet in the face of this they came forward and asked the House of Commons to protect them from unqualified Practitioners, when on their own Minutes they had the evidence that such were the men who at the present moment were let loose to practice upon the lives of Her Majesty's subjects. His conclusion was that they were in a dilemma,—either that they had not the power to enforce education, or, if they had the power, that for eight years they had been doing nothing for the public safety in that respect. If they went before the House of Lords or the House of Commons with the Bill in its present condition, they would be placed, as a public department of the State, in a humiliating position; but if they applied for a Royal Commission they would be putting themselves in the high position of doing justice to all, concealing nothing, and showing that they were disposed to do what was right, either by Act of Parliament or by themselves. If they went on as they were going, he very much feared that a contingency would arise which would come upon some of the licensing bodies, and perhaps all of them, like a thunderbolt; and that was that as the Army and Navy Boards, seeing the lamentable state of ignorance in which the Council let them loose upon the public, had ordered certain examinations of their own, under examiners of their own, and would not recognise a single examination of the Council's, so the Poor-law Commissioners of England and Ireland would do the same. He did not know the powers of the Poor-law Board in England, but in Ireland they had the power of examining for themselves the qualifications of any man who held office under them, and he certainly should not be surprised if to-morrow an order were to come out referring to the communication from the Navy Board and saying,—"We do not feel justified in entrusting the care of our poor to the licentiates of any one of your licensing bodies, but we will ourselves appoint a body of examiners to test the ability of those who take charge of the poor under our supervision." If this were the case, what a lamentable position they would be in. If they asked for a Royal Commission they would be able to say that they had voluntarily offered every information to the public, that they wanted a new Bill, that they wanted an amended Bill, and that they would expose the weaknesses of the licensing bodies and the defects of the present Bill. It now only remained for him to apologise for the time which he had taken up in bringing this matter forward. He felt deeply and sincerely that they had come to a most painful crisis and turning-point in the existence of the Council. It was a matter of such importance that he felt it to be his duty to give expression to his feelings and opinions upon it. If he had made use of a single observation which might have offended any person or any licensing body, he hoped they would recollect that he had not spared his own body, and in bringing his amendment before them he believed he was only discharging a public duty.

Mr. Rumsey, in seconding the amendment, trusted the Council would kindly listen to the few remarks he had to make, and if he should say anything at all disagreeable, either to any of the Council as a body or to the institutions which they represented, he hoped they would excuse it on the gravity of the question which this amendment brought before them. He did not support the amendment on quite the same grounds as the mover did; he supported it without opposing the Report of the Committee on the Medical Acts Amendment Bill. He was perfectly ready to support the amendment proposed by the Council, not because he thought that was the best way of settling the question, but because he believed it would be a very useful and valuable alternative in the event of Sir Dominic's amendment being defeated. It was impossible and unwise for them to ignore the dissatisfaction which existed in the Profession at large as to the results of legislation in 1858, the working of the Medical Acts, and the present state of the Medical law. The dissatisfaction was not that of uninformed and unthinking persons, but of thoroughly accomplished and highly educated minds. If he might be permitted, he would read six lines from a letter addressed by one of the most distinguished members of this Profession to another very distinguished member of it in this country. It was unnecessary for him to give the name of the writer.

The President reminded Mr. Rumsey that it would have more weight if the name was given.

Mr. Rumsey said he could not do that. The writer said, "I only share in a common opinion that if the Medical Council were to adjourn its sittings for a very long period the loss to the Profession would be extremely small." (Laughter, cries of "Oh, oh!" and "Name.") He was happy to assure them that he did not endorse the opinion he had read. (Hear, hear.) He granted them that the present demands of a large portion of the Profession had been, and were still to some extent unreasonable; but that was no reason whatever why the grounds of this complaint should not be fairly considered. He granted this also, that no legislation could establish all the so-called rights and abolish all the supposed wrongs of thei

body; but the question was whether all had been done that might have been effected under a better law, or which might have been effected under their own Amendment Bill. Now, he came to certain defects in the Act of 1858—defects in principle, which were not touched by the Amendment Bill before the Council. The preamble, they would be so good as to observe, was not repealed; a preamble most objectionable, most unsatisfactory, and most partial. To register under the Act of 1858 must be confessed to be a very imperfect means of distinguishing qualified Practitioners, and when made even more perfect than it was, it by no means became the sole or main object of Medical legislation. The Amendment Act would still be so framed as to place all degrees, grades, and qualifications in one dead-level category. It would do away with the necessity for full and complete qualification for the high and important duties of a public official character, and it would lead administrative bodies to be content with a lower standard of qualification than they might otherwise have thought it right to demand. With regard to education, probably as much had been done by the Council as was possible under the conflict of opinions and the absence of compulsory powers which so remarkably characterised this Council. He confessed his surprise that so much had been accomplished; nor was he one who would at all ask for compulsory powers. He thought it most fortunate that the Council, in its present constitution, had not such compulsory powers, and it was very beneficial to the public that they should not be so empowered with their present constitution. Then, with regard to the third department of the duties entrusted to them under the Act, the Pharmacopœia, he trusted the Council would render a good account of that next year; yet let it be recollected that the bulk of the labour devoted to that great work had been done out of the Council, and in the intervals of the session. So much for what had been done. Now, he would ask permission to draw attention to questions of great importance which might come before a Royal Commission. One was whether the machinery constituted by the Act was the best that could be devised to attain the objects of that Act; whether it was the most suited to meet the rational and moderate wishes of the Profession, and the obvious needs of the public; whether, in fact, this peculiar combination of representative and executive functions was a successful experiment? He admitted, as much as any member of this Council could admit, the importance of full representation in a deliberative body; but he affirmed that just in proportion as the representation of all interests, Professional and educational, was perfect, so the body represented became unfitted for ministerial and administrative duties. This was not seen by those who clamoured for Medical Reform before 1858. They fancied Parliament would not only constitute a representative Council, but would invest it with large summary and administrative powers. But Parliament did no such thing, nor would it ever do anything of the kind. Were practising Physicians and Surgeons throughout the kingdom adequately represented, as the Colleges were so overpowering in this Council, then, however perfect for deliberative purposes, this Council would become more remarkably unfitted for the execution of the Medical measures which resulted from its deliberations. On the other hand, were the executive powers of this body strengthened by Parliament, it would be probably on condition that its representative constitution was modified and subordinated. There might perhaps be two bodies—one a large consultative body, and the other a small executive body. Another question which might come before a Royal Commission would be this, whether a General Medical Council so constituted, and combining representatives from the three divisions of the United Kingdom, could or ought to be expected to settle in a mandatory way all details of registration and education on precisely the same principles and by the same methods and details for the whole kingdom. There were, he need not say, already existing firmly established differences of practice in the three kingdoms—differences which depended on national character, each system appearing to be suited more or less to its own people, and hence had originated that wide difference of opinion between the three nationalities which they had observed in this Council. Many of those differences seemed to him perfectly irreconcileable; there was enormous difficulty in smoothing angularities to obtain a mere specious surface of uniformity. Nor did he admit that such superficial uniformity was desirable, because he believed if it were carried it would be unreal. Far better that each Branch Council should regulate independently the Medical education of its own division, the registration of its students, the order and even the curriculum of study, at its own discretion, in conformity with its national habits and characteristics, only provided always that the standard of qualification be suitable for all, and the reciprocity of privilege complete. By such an arrangement the Royal Commission might report that the duties and the cost of the General Council would be greatly diminished. A few questions would always remain of material bearing, and these might be referred to short annual meetings of the whole Council; or it was quite possible the Royal Commission might recommend—and Parliament might decide upon their recommendation—that such matters be referred to a Committee or a small body directly responsible to the Government. To such a body would more fitly belong the framing of Medical laws, and the carrying on of what Mr. John Stuart Mill called the "legisfactive" function, as distinguished from the "legislative," which he did not think they performed in the best possible manner; while the approving, amending, and vetoing powers would still belong to the large representative body, or bodies into which the Council might resolve itself, or be transformed. He did not state these simply as his own views; they were views held by many persons of great political experience and esteem—men who had thought upon this question all their lives; and whether right or wrong he submitted that they ought not to be tabooed by this Council. In conclusion, Mr. Rumsey expressed his approval of even the small measure of amendment indicated by the Amendment Bill; and, as he said at the commencement of his remarks, he should be most happy to support what had been done by the Council in that matter. (Hear, hear.)

Mr. Hargrave said he could not support Sir Dominie Corrigan's motion, considering that he was either utterly inattentive to the working of the Medical Act, or ignored its results. Two or three times during this meeting Sir Dominic had alluded to the character of the Naval Surgeons in a most marked manner. He had spoken of their ignorance of Latin, English, anatomy, Surgery, Materia Medica, and so on, and said that it was the dross of the Medical students who now sought for admission into that service; that no candidate well educated and of a good family and gentle blood, and "two or three and twenty years of age," would enter it to be snubbed, because he was "only the Doctor," or submit to the overbearing character of the captains, who were, as a rule, if not tyrannical, at least overbearing; and the Medical Service in the Navy was fast returning to the state of things which existed in the time of "Roderick Random." (Laughter, and "Oh!") He (Mr. Hargrave) was sure that the Government would grant no Royal Commission, as the Council failed in its duty in carrying out the provisions of the Medical Bill given to them, and he referred particularly to clauses 20 and 21, which granted to the Council full powers of appeal to the Privy Council. The Medical Council was deficient in action and independence in not having availed itself of this valuable privilege to control recognised parties. He recollected when he first had a seat on the Council, there was a motion brought forward bearing on the College of Surgeons of England, which had declined to accede to some of the recommendations, to appeal to the Privy Council against the proceedings of the College, which was lost by the casting vote of the then President, Sir Dominic voting with the President. As to the question of the education of Medical students, he maintained, from the great and numerous opportunities afforded him of observing, that there was a marked improvement in the bearing and conduct of the students, and that they were infinitely more attentive both to their lectures and Hospital attendance than they were formerly. (Hear, hear.) But the great obstructive to Medical improvement was Sir Dominic himself. When last year there issued the recommendation of visitation of examinations, he (Mr. Hargrave) opposed it in Council, as he considered it a most irksome duty to attend and report on the examinations of institutions which competed with his College, and he decidedly declined acceding to the recommendation. When the Irish Branch Council met in August, 1865, to consider this question, he joined Sir Dominic Corrigan, and still declined to follow the recommendation. The meeting was adjourned till the next day, that the subject might be further considered. He went home and slept upon it, changed his mind, and agreed to support the recommendation of the Council. Sir Dominic would not attend one of the examinations. He (Mr. Hargrave) visited the examination in Surgery in the University of Dublin last December, and he was much gratified to be able to judge for

himself, as he had heard so many conflicting and contradictory opinions as to the manner in which it was conducted, and he must say that he was very much pleased. He objected to their applying for a Royal Commission, as the Medical Bill gave the Council full powers, by appeal to the Privy Council, to remedy any abuse, and thus bring the provisions into harmony. (Hear, hear.)

Sir D. J. Corrigan rose to reply, but it was urged that the mover of an amendment had no right to reply.

The President ruled that if Sir Dominic had any personal explanations to make he could do so.

Dr. Acland said he wished to speak upon the amendment. When a member of the Council made such a proposition, and enforced it with a speech such as that they had heard from Sir Dominic Corrigan, he confessed that, considering the great time constantly given to discussions in that room, it would be most unseemly that they should hurry over the question. The last thing he should desire to put into the possession of Sir Dominic would be the power of going out of this Council and saying that when he seriously and deliberately brought forward a proposition of this kind they had shelved it, declining to entertain it. That was the last weapon he should like to put into Sir Dominic's hand. (Hear, hear.)

Dr. Parkes remarked that they were not hurrying over the question, as they had already been engaged three days upon it. He did not think it necessary to prolong the discussion.

The President intimated that Dr. Acland was quite in order.

Dr. Acland said it had just been mentioned, in comment apparently upon the few anticipatory observations he had made, that the Council had already been three days discussing this question. That was quite true. But there was one thing which he should very much like to put to the Council — and that was, whether a large portion of that discussion had not been caused, as was said by Mr. Hargrave, by Sir Dominic Corrigan himself? (Hear, hear.) And he would put it to the practical sense of the individual members of the Council, whether, if it had not been for the course adopted by Sir Dominic, in full right -he did not doubt the right, but the reason of it—the three days spent upon this Amendment Bill might not have been wholly spared if Sir Dominic Corrigan had had the straightforwardness to inform them beforehand of his intention, after three days' deliberation, to pull them up short, and to bring forward this proposition, which was to be reported all over the kingdom in the different journals. (Hear, hear.) He was extremely sorry to differ from those who thought it better to take no notice of what Sir Dominic had brought forward. He (Dr. Acland) had always had this opinion—and he was sure the Council would forgive him (if they thought there was any necessity for it) for frankly expressing an opinion that had been several times expressed before, that the constitution of that body was one which was extremely difficult to work, and, as an executive, nearly impossible. (Hear, hear.) But they did not make the constitution. The question was, whether each, according to his capacities, did the utmost he could to make it work? They all knew—and the mover of the amendment knew as well as any of them—whether they had, according to their abilities, from the time when they first were honoured with seats at that board—done the best they could to advance the real interests committed to the trust of the Council? (Hear, hear.) He had not the slightest doubt, from the sincere regard he entertained for the members of the Council individually, but that they could all answer that question on the whole honestly. With regard to the general statement bandied abroad as to the determination of each of them to defend his own particular interests, he simply denied it—(hear, hear)—that is to say, he denied it so far as his own knowledge went. He had lately said in private, and would repeat in public, that, with respect to the particular body which he had the honour of what was called "representing" (though he did not agree to the term so often used), if there was one thing more than another which would cause him to forfeit the confidence of his friends in Oxford it would be if they believed he could advocate any interests connected with that University that would interfere with the public good. (Hear, hear.) He knew that to be their feeling; and he had a right, within all reasonable limits, to attribute the same to other institutions; and he thought it insulting to that Council—and, what was more, insulting to their character as Englishmen—that they should have it reported all over the country that the particular ends of particular bodies was the moving principle of this Council; calling it, as Sir Dominic Corrigan often did, "a battle of shops." He would repeat, they did not make their constitution, and all that they could do was to work it as well as they were able. (Hear.) Now, he had no objection whatever to a Royal Commission. He should be very happy to see a Royal Commission appointed. He had not the slightest objection to answer any question to that or any other body concerning this Council, or anything they had had to do. But whether it was a proper and necessary thing for the Council to ask for a Royal Commission, *on the grounds alleged by Sir Dominic*, was another question altogether. He thought it was not proper now, nor was it necessary; but he repeated that he had not the slightest objection to it, and if it should help them out of their difficulties, and enable them to better discharge the duty imposed upon them, he for one should heartily welcome it. (Hear, hear.) The fact was this, that there was nothing more unreasonable or more unjust than to use *ex post facto* knowledge as though it had existed beforehand. It was a thing which no acute man, who was also a fair man, ever would do. (Hear, hear.) This body was originally constituted as it was by a kind of necessity under the then existing circumstances. Starting from the point from which they did start, all they could do was to work it for the best. It was originally necessary, in order to construct a Council at all, that the interests of the Corporations and Universities should be represented, and this involved many difficulties. But there were a great many difficult and troublesome things in England, arising from the relations and differences that existed between local institutions and what was called central administration. What they had to do was not to put difficulties in each other's way, but each to help the other to work and to do the best he could for the country. He would state two things which he thought were fatal to the easy working of this body. On finding himself on a former occasion in a minority upon them, there were only one or two circumstances which induced him to remain in the Council, and those were, first of all, personal regard for the colleagues with whom he had the honour and privilege of sitting, and the great pleasure he had in meeting them from year to year, deriving many advantages from that intercourse. Feeling thus, he could not do otherwise than help to work the thing which he nevertheless considered almost unworkable. That was one consideration. The other was that there was not any practical good in hastily withdrawing from a body which still had to go on equally hampered, inasmuch as some one else would be placed in his position. He should, then, have withdrawn from the Medical Council—first, when the majority introduced reporters after several years of opposition; and, secondly, when the same majority ruled that it was inconsistent with the working of the Council that they should appoint small standing committees for investigating and reporting on particular objects—an arrangement to which he had had occasion often to allude before. In his judgment, two things were absolutely necessary for the carrying on with success and credit the business of this body. One was, that they should deliberate amongst themselves, unfettered by the loss of entire freedom of debate. In a deliberative and executive body, such as they were, they had made it all but unworkable by making their table a public one. He would ask any person who had ever sat on a Commission or a Council of the Royal Society, or any other councils he could mention, charged with joint deliberative and executive functions, whether managing their business in public did not practically amount to being unable to manage it at all. The second point was with reference to the Committees. They had been charged with the duty of settling the most delicate and intricate details of education, of examining, and of visiting examinations. They endeavoured to settle those details around that Board in the course of four or five days, amidst the pressure of much minor business, when every man of judgment and experience must feel that it would be far easier, at all events, to do it by a Committee of three or four deliberating and corresponding during the long interval between the sessions and bringing up reports to the General Council. When, two years ago, they made it a settled principle that they would not have these standing committees to make elaborate reports upon certain points, he thought there was a second chance gone of their being able to carry on their work well. There was one other thing of which he would like to remind Sir Dominic Corrigan. That was with regard to the statement he had before been pleased to make, that the Council had "done nothing." On the other hand, he told them that they had no powers; and on the other, that they did not exercise them. The fact was, they had, considering the

circumstanees, done a great deal. He would use the strongest words that ordinary society allowed, and when Sir Dominic Corrigan said they had done nothing, he would say that everybody knew that was not the case. Why, what had the Council done since its appointment? The National Pharmacopœia had been constructed. The registration of the Profession had been effected, and now was become a pieee of office routine. Much had been done for education. Although all had not been done which might have been done, it was throwing dust in the eyes of the public, who had not full knowledge of the facts, to announce that nothing had been accomplished. (Hear, hear.) Look at it in a practical point of view—and let Sir Dominic attend to this—did he (Sir Dominic) mean to say that the habits of the Practitioners in the country, the habits of students, were to be altered in a moment, without regard to previous circumstances, involved in vested interests, in existing corporations, teachers, and examiners? It was impossible; it could not be. In the very nature of things it must be that, for a time, men would come up for examination ill prepared. He repeated that Sir Dominic had advanced what members of the Council knew not to be the ease. He might say, perhaps, it was cruel, he would say it was not just, to throw broadcast over the country such allegations. He defied Sir D. J. Corrigan, or any other person, fairly to charge members of the Council with being more indifferent to this matter than he was himself. (Hear, hear.) Was it true there was no improvement in education? Was it true that no attempts were being made to improve the qualifications of the Profession in the best sense of the word? Was it true there was a single corporation or University in Great Britain or Ireland that had not been endeavouring—to use Mr. Syme's words used two or three years ago—to meet the "moral suasion" of this Council? (Hear, hear.) He simply believed it was not the fact. He should like to be told which body had set itself determinately to protect abuses. If such a body were represented in this Council, let Sir Dominic Corrigan say which it was, and let its representative explain to them if it be so or not. (Hear.) It was unjust to state things which did not truly represent the case as it really was. He repeated, with regard to education, Professional and non-Professional, that it was his firm belief, —and he could be contradicted if proved to be wrong,—that there had been a sincere endeavour from the passing of the Medical Act on the part of the bodies to raise the education of the students, and to fit the students for the due discharge of their duty in life, according to what was practically possible in their respective stations. When he said that, he did not at all doubt there were still many imperfections. At Oxford, for instance, there had been difficulty, as all knew, in getting physical science incorporated in the studies of the place; but was anybody who should come there and find things not yet perfected there going to say that there was the power to make them so at once? Why, if any one could show him anything that was wrong, he would undertake to show him more than he could find out for himself. He should like very much that Sir D. J. Corrigan press this matter. He had not the slightest objection to it. If it turned out that it was proper and necessary to have a Commission, by all means let them have it. But he should vote against asking for it, as a member of this body and on the grounds alluded to, because he did not think it was necessary or proper that this body should seek it. If it came, it was perfectly welcome; and if it would help to remedy their difficulties, by all means let them thankfully accept it. (Hear, hear.) He thought if they did not have this Commission they were bound to appoint at once a Committee such as he had moved for last year, which should show in what way they could have the business of the Council thoroughly sifted and brought before them. The fact was, he thought the want of Standing Committees had been a great practical administrative blot in their proceedings. It had been at first almost a necessary part of their constitution, under the existing circumstances of the three kingdoms, that they should meet at first with something of jealousy; and there had been suspicions with regard to their motives and proceedings, arising from the number of conflicting interests represented. But would Sir Dominic say that it had not been an advantage to all of them—himself included—to come there and deliberate on all the questions that had come before them? He appealed, therefore, to any old member of the Council whether this body had not worked as harmoniously together for the public good as any body constituted in so heterogenous a manner could have done in the same time? (Hear, hear.) Of course, they would be much to blame if they did not take steps to make the wheels run more smoothly. If they would not give powers to a standing Exeeutive Committee to complete the business in the intervals between the sessions—business of the kind which could only be prepared in leisure—then he must say he thought they would be greatly to blame. He appealed even to those who had been most warmly opposed to himself on this subject—he appealed to their candour—whether if two years ago they had appointed a standing Committee to draw up a careful report within the sueceeding twelve months on the whole question of education, of the mode of conducting examinations, and visiting examinations in three separate documents, they would not have been much more forward than they were, and whether they would not have produced a valuable Report containing the views of the Council carefully set forth which would have been of the utmost service to them? (Hear, hear.) He admired greatly the ability and energy of Sir D. J. Corrigan, and he only wished he had a small portion of them, and then he should be able to grapple with him better, and would do it. (Laughter.) If Sir Dominic failed in getting a Royal Commission, what he sincerely hoped he would do would be to join them with his great abilities in seeing how they could exercise the powers they really possessed in a calm and judicial manner—not talking about the coercion of the various interests committed to them, but with a feeling of trust and confidence in his colleagues, and in the good intentions of the several bodies they were called upon to represent, seriously and truly, and, to use the Scotch expression, "loyally" endeavour under the great difficulties that existed among them to work the machinery they possessed. (Cheers.)

Dr. Stokes said he could not give a silent vote on this occasion. It was only right he should state to the Council what in his humble experience he believed to be true; and he could declare most positively that there was nothing more remarkable than the great advance which had taken place in the mental training of Medical students from the very first year in which the question of education was agitated in this Council. (Hear, hear.) He was verified in this statement by the experience of a large number of his friends in Dublin who were occupied in the teaching of Medicine. Whether they looked to the general attainments of students in Arts, or to the great question of Professional studies, it appeared to the persons engaged, as he had been, that they had descended into a new stratum of men altogether. How had all this been brought about? Not by coercive regulations. (Hear, hear.) It would not do for it to go forth to the public that they were to take the standard of the rejected candidates of the Navy Board as an example of the class of rejected Medical students. The improvement which had taken place was the result of moral suasion, which was going on more and more. His report upon the examination of the Royal College of Surgeons had not been presented to the Council, but he could safely aver that the class examined there could no more have answered as they did seven years ago than they could fly. Out of fifteen examined four were rejected; and there were several young men whose answering in Greek and Latin was really admirable. (Hear, hear.)

After a few words from Mr. Syme,

Sir D. J. Corrigan referred to some of the reeent examinations to prove that the education of the students had not improved of late, and said he would next allude to the words applied to him by Dr. Acland, whom he never saw in a passion before. (Cries of "Oh, oh!")

Dr. Alexander Wood: I do not think Sir Dominic is quite right in saying that Dr. Acland was in a passion. I only wish he was in a passion oftener if that is a passion. (Hear, hear.)

Sir D. J. Corrigan remarked that Dr. Acland said he was unjust, and had accused him of a want of straightforwardness. That was a personal attack, and he wished to rebut that attack. The want of straightforwardness arose from the fact, as Dr. Acland had put it, that he did not tell the Council weeks ago what he intended to do. He would appeal to the Council whether he had not a right to bring forward a proposition when he thought it was the right time to do it, and when he hoped it would be carried. He would conclude with a few lines of a German fable, which he thought would be appropriate on the present occasion:—

> "'I protest, since they will give me no praise,
> I'll trumpet myself to the end of my days;'
> So saying, away to the forest he flew,
> And ever since then has been crying 'Cuckoo!'"

(Laughter.)

Dr. Andrew Wood, in reply, remarked that if, as Sir

Dominic Corrigan had said, Dr. Acland was in a passion when he spoke on this occasion—if he was mad, there was "method in his madness." Dr. Acland had said that he regretted reporters were introdueed into the Council, but he (Dr. Wood) rejoiced that reporters were present that day to take down and give curreney to Dr. Acland's speech, which was as manly, as eloquent, and as true a speech as any he had ever heard at that board. It was a speech that did great honour to Dr. Acland, who gave emphatie utterance to what he (Dr. Wood) was certain was the feeling of the great mass of the gentlemen who sat around the table in repelling the charges which had been made so recklessly against the Council as individuals, and against the bodies they represented. (Sir D. Corrigan here made a remark across the table which did not reach our reporter's ear.) Sir Dominic Corrigan might not care much for what he (Dr. Wood) said, but he begged to remind him that there sat with him as colleagues around that table those who had feelings in their breasts which could not but be acutely touched by accusations such as had been made that day. He could not refrain from saying that; and more than that, he could not help telling Sir Dominic Corrigan that he was surprised that a man of his great eminence as a Physician should have taken the course he had done in this Council. Sir Dominic was a great Physician: there was no man who could diagnose a case of disease better than he could; but he would ask him, when he had made out the disease, when he had found by symptoms where the disease lay and what was its nature, would he sit down by the bedside and say to the patient, "No, I won't try to apply the remedy; go on and die?" Yet that was exactly what he said in this Council. (Hear, hear.) Again and again he was coming before them, and telling them, "There is your disease, there is your rottenness," and then he went on and told them in plain words, "I will not attempt to put you right; I will sit down here and mock at your helplessness, and come to abuse you, and hold you up to obloquy year after year." When in this Council some years ago a motion was made to represent the College of Surgeons of England to the Privy Council because they had refused to do what the recommendations of the Council set forth, on which side of the question was Sir Dominic Corrigan's name to be found on that occasion? It was on the side of not exercising the powers which this Council undoubtedly had. (Hear, hear.) And then again, as Mr. Hargrave had said, when last year it appeared by the returns laid upon the table of this Council that there were being sent forth into the country by various licensing bodies as qualified Practitioners men who were anything but a honour to those bodies who licensed them and to the Profession, not to say dangerous to the public, and when this Council set to work to endeavour, by all the power they had, and specially by a visitation of the examinations, to rectify that error, who was the man that said, "Do what you like, I will try to rectify nothing; I will refuse to act as a visitor?" It was Sir Dominic Corrigan. (Hear, hear.) He (Dr. Wood) could not understand on what principle Sir Dominic refused himself to do his duty as a member of this Council, and then came forward to upbraid unjustly his colleagues for failure in their duty. Every other man sitting round that board, he (Dr. Wood) felt assured, was impelled to perform his duty, a most important duty, by a conscientious conviction that it was right that he should do it, and do his utmost, to improve the Profession to which he belonged. (Hear, hear.) These were the feelings with which he had heard Sir Dominic Corrigan make this sudden and unwarrantable onslaught upon them. Those remarks of his would doubtless go forth to the public, and might, if uncontradicted, prove damaging to the character of the Council and to the working of the Medical Act; but he was thankful that Dr. Acland's able reply would also go forth at the same time. He felt perfectly convinced—let who might gainsay it—that they were going on, it might be slowly, but still steadily, and in an increasing ratio in the benefits they were conferring upon the Profession. He believed he had been as often in a minority in this Council as any other member of it; but had he on that account desisted from doing what he could to press the Council on to what he considered their duty? No; and he never would play such a pusilanimous part. (Cheers.) His duty, he felt—and that was a duty incumbent on all the members of the Council—was to come to its meetings and use what powers they possessed for the general good. Last year he did what he could to induce the Council to apply to Parliament for greater powers in regard to their educational clauses. He thought it right and proper to do this; and though he was out-voted more than once he did not take offence on that account; he did not sit down in helpless despair; he did not, though he thought their decision a wrong one, lavish abuse on the majority who held that it was inexpedient to apply for new powers; but he resolved, as far as he could—and he trusted the whole Council would do so too—to use the powers they had for the purpose of indueing bodies who might otherwise be inclined to lag behind to go forward in the improvement of their curriculum of study and examinations. He was satisfied, from what he knew of the tone of this Council at the present moment, that, so far from its members not being willing and anxious to do their duty and to exercise their powers when the occasion arose, there was a firm determination to do so; so that should any of the licensing bodies refuse to comply with essential parts of their recommendations, he had no doubt but that this Council would represent them to the Privy Council; and if this representation were carried in the Council by a sufficiently large majority, he had as little doubt the Privy Council would support them in doing their duty. He could have said a great deal more, had time allowed, in answer to the attack of Sir D. J. Corrigan, and it required a degree of virtue in him to resist the temptation to prolong his remarks; but having been challenged as they had been that day by Sir D. J. Corrigan, he felt it right to take up the gauntlet in defence of the Council and to say—

"Lay on, Macduff;
And damn'd be he that first cries 'Hold; enough!'"

(Cheers.)

The amendment was then put, and there were for it, 3; against it, 19. It was therefore declared lost.

Sir D. J. Corrigan required that the names and numbers of the majority and minority, and of those who declined to vote, be taken down.

This having been done by the Registrar, the original motion was put to the vote and carried.

It being now six o'clock, a resolution was agreed to that the standing order be suspended, and that the Council sit after this hour.

The President, having an engagement, was obliged to leave the chair, which was afterwards occupied by Dr. Acland.

It was moved by Dr. Andrew Wood, and seconded by Dr. Parkes, "That Mr. Ouvry be requested to read the statement of reasons for suggested alterations in the Home Office draft Bill, which is to be sent with the Council's amended draft Bill to the Home Office; as also the letter to be addressed by the President to Secretary Sir George Grey."

This resolution having been carried, Mr. Ouvry read the following:—

'Reasons of the General Medical Council for suggested Alterations in the Draft Bill to amend the Acts Relating to Practitioners in Medicine and Surgery.

"*Preamble.*—In the draft Bill prepared by the Home Office the preamble suggested by the Council has been omitted. The Council would submit, that it is desirable to state the grounds on which fresh legislation is thought necessary, and, therefore, that the preamble, either in the form suggested by the Council or in any more apt words, should be adopted.

"*Clause X.*—The Clause, as framed by the Home Office, is considered open to objection, inasmuch as it would give to the Registrar power to erase from the Register the names of gentlemen who have ceased to practise, although such gentlemen may wish to retain their names on the Register. This is not desired; the main object of the clause is to enable the Registrar to remove the names of persons who have really ceased to practise and whose addresses are not known. This will be affected by the proposed mode of sending letters, and the Council therefore have suggested a slight alteration in the clause in accordanee with this view.

"*Clauses XI. and XII.*—The Council have ventured to suggest a modification of these clauses. The main feature of the alteration is the doing away with the proposed Schedule (B) to the Act. The Council has done its utmost to meet the wishes of the Government in framing such schedule, but they have found the difficulty of the task to be so great, that they have ventured to propose that the list of bodies, whose diplsmas shall confer a qualification, shall be inserted in a list to be annually prepared by the General Medical Council and submitted to the Privy Council. By this means the General Medical Council will have the opportunity, from time to time, of making inquiries as to the status of the several foreign and colonial bodies, the nature and extent of their studies, and the quality of their examination, so as to judge whether they are worthy of recognition in the proposed list.

"It has appeared to the Council that the third provision of Clause XI., which authorises the Registrar to refuse to register any person who shall have been guilty of an offence which would prohibit him from practising in his own country, is open to objection on several grounds: 1st. It would cast a judicial responsibility on the Registrars, which, by the 29th Section of the 'Medical Act, 1858,' is given only to the General Council. 2nd. The terms of the clauses might be considered to cover offences which, although they might disqualify the Practitioner from practising in his own country, would not be considered as any objection to his practising in this country—offences, for instance, of a political nature or otherwise, not involving moral guilt. On these grounds the Council considers it safer to leave foreign Practitioners in the same position as the Practitioners of the United Kingdom, by making them amenable to the sections 29 and 30, of the 'Medical Act, 1858.'

"*Clauses XIII.*—The Council proposes to amend this section, so as to bring clauses 29 and 39 of the 'Medical Act, 1858,' within its operation.

"The Council is aware that the proposed addition to this clause does not fully meet a difficulty which the draft Bill prepared by the Home Office was intended to meet, inasmuch as there is no power to remove from the Register the name of any Colonial or Foreign Practitioner who may, in his own country, have been convicted of any crime or offence.

"The Council has failed to perceive any means in which this difficulty can be effectually met, owing partly to the difficulty of obtaining evidence of any such conviction, and the further difficulty of defining the class of offences which ought to exclude from the Register.

"The Council would be very glad if the advisers of the Government could suggest a clause adapted to the case.

"*Clause XIV.*—The Council consider it would be expedient not to limit this clause to the London University, but to extend it to any University in the United Kingdom, which now is, or hereafter shall be, legally entitled to confer the degree of Bachelor of Surgery.

"*Clause XVI.*—The Council proposes to amend this clause by striking out the reference to the proposed Schedule (B) to the Act, and by striking out the words 'of Medicine' after the word 'Doctor.' It is to be observed that the taking of the title of 'Doctor of Medicine' is prohibited by the earlier part of the clause, inasmuch as it is one of the designations enumerated in Schedule (A) to the 'Medical Act, 1858.' Its subsequent introduction therefore is wholly unnecessary, whereas the introduction of the title 'Doctor' simply is all important to the efficiency of the operation of the clause. The title 'Doctor' is the one most commonly assumed by unqualified persons practising Medicine; and if such practice be allowed to continue, it is obvious that any unqualified person, by assuming that designation, might evade the penalty of the clause. If it be said, by using the word 'Doctor' only in the clause, all Doctors, whether of philosophy, law, etc., are included, the answer is that the clause applies only to those who, not being registered, are practising Medicine under the title of Doctor. The Council beg to submit a print of the Bill amended in accordance with the above suggestions.

"Sir,—The Draft Bill framed by the Home Office for the Amendment of the Medical Acts has been very carefully considered by the General Medical Council, and, at the request of the Council, I have the honour to transmit herewith a print of the Bill framed by the Home Office, with such amendments therein as appear to the Council advisable.

"I have also the honour to transmit a statement of the reasons which have induced the Council to suggest the amendments; and I am to ask that you will, at your earliest convenience, be pleased to receive a deputation from the Council to consider the amendments in question.

"I have the honour to be, Sir,

"Your most obedient, humble Servant.

"The Right Hon. Sir George Grey, Bart.,
&c., &c., &c.
"Home Office."

Dr. Andrew Wood proposed, and Dr. Embleton seconded, "That the statement of reasons by Mr. Ouvry, and letter to be addressed by the President to the Home Secretary, be entered on the Minutes," which was agreed to.

Dr. Embleton brought up a Report of the Committee on the working of the system of registration of Medical students, adopted by the General Medical Council last year.

On the motion of Dr. Embleton, seconded by Dr. A. Smith, it was resolved, "That a Committee be appointed to report on the returns from the licensing bodies in compliance with recommendation No. 6, Sect. V., of the recommendations of the General Medical Council of 1865, and the register of students for the past year." The Committee consisted of Dr. Embleton (Chairman), Mr. Cooper, Dr. Thomson, Dr. Leet, Dr. Appjohn, and Dr. Stokes.

It was then moved by Dr. Embleton, seconded by Dr. Thomson, and agreed to, "That a Committee be appointed to revise the standing orders." The Committee consisted of Dr. Embleton (Chairman), Dr. Thomson, and Mr. Hargrave.

Dr. Embleton proposed and Dr. Thomson seconded, "That the recommendations of the General Medical Council on the subjects of preliminary examination, of registration of Medical students, and of Professional education and examination, be referred to a Committee for re-arrangement." Dr. Embleton (Chairman), Dr. A. Smith, and Dr. Thomson. This motion having been carried, the Council adjourned at half-past six o'clock.

Eighth Day.—Friday, May 25.

The Council met at two o'clock, and after confirming the minutes of yesterday's proceedings, resumed the adjourned consideration of the Report of the Committee on the subjects of general education.

Dr. Stokes moved, and Dr. Storrar seconded, "That natural philosophy, including mechanics, hydrostatics, and pneumatics, be adopted as one of the optional subjects."

Dr. Acland proposed the following amendment:—"That the optional subjects be divided into two classes, that one subject in each class be taken up by each candidate, and that where natural philosophy is not taken up in the Arts' examination it shall be required at a later period of study; that the following be the classes:—Greek and natural philosophy; German and French." He doubted whether the motion as it stood was worded so as to convey in the best manner to teachers and examiners the information which the Council wished to convey. He thought it required some further information, and it did appear to him to be of great consequence that in issuing regulations to teachers and examiners it should be an understood thing that if Physics were taken as one of the optional subjects the candidates should be required to be accurate in it up to a certain point. He suggested that the chairmen of committees should issue some more detailed instructions as to what the Council meant, and what it required from students.

Mr. Syme said it was very important that the Council should state accurately what they meant by their instructions. He strongly urged the necessity of requiring an examination in Physics during some period of a candidate's study.

Dr. Storrar said that no more details had been given because the Committee were anxious to leave the amount of the examination in natural philosophy to the examining bodies, and they exercised some care to draw up the list with as great an avoidance of specification and detail as possible. He did not differ from Mr. Syme in his opinion that provision should somewhere be made for securing that every Medical student should have a knowledge of natural philosophy, but the question at present before the Council was whether natural philosophy should form part of the preliminary examination, or whether it should form part of the Medical or the pre-Medical. At the present moment they were dealing with the education which could be got at school, and he apprehended the difficulty was that lads who came fresh from school at the age of 17 to pass a preliminary examination, would not have any amount of knowledge of natural history that was worth having. By putting Greek and natural philosophy in the relation to each other which Dr. Acland proposed, they would be inviting a certain number of men to take natural philosophy instead of Greek, which he thought would be, under the circumstances, very unadvisable. It appeared to him, as far as he could arrive at a conclusion, that the way out of it was for the several examining bodies who attached importance to these subjects—and he hoped they all did—to provide that natural philosophy should be compulsory either at one time or another, and that no man should pass a Medical examination if he had not passed a natural philosophy examination. He thought the matter might fairly stand as it was with regard to preliminary examinations, leaving it to the Medical bodies to require natural philosophy at some time or other.

Dr. Stokes trusted that the matter would rest where it now was. The object was to determine what students should learn at school.

Sir D. J. Corrigan said he was very much struck with Dr. Storrar's observation with reference to boys 16 and 17 years of age not being able to understand much of natural philosophy. He suggested that natural philosophy should be omitted altogether from the preliminary examination. Even in some of the best schools boys could not learn it. If they left it optional, a boy might come who was up in German, French, or Latin, but who knew nothing of natural philosophy. If he merely produced a certificate that he had passed an examination in natural philosophy, it would be at a time when his mind would be incapable of understanding it, even if he had the opportunity of learning it, and he would then probably pay no more attention to it. He suggested, therefore, to Dr. Stokes, that this subject should be withdrawn altogether, and that when the Committee was appointed to consider the Professional examination they should determine that natural philosophy should be a compulsory subject in the first Medical examination, the same examination in which chemistry was required.

Dr. Paget thought it would look very bad, seeing the importance which the Council attached to education, if the subject now under discussion appeared at all to be optional. He was very well aware that there was a generally expressed opinion that it should be required of Medical students at some time during their course of study. He quite agreed with Sir Dominic Corrigan that to examine boys just fresh from school in these subjects was really to agree to accept a very meagre knowledge of them indeed, and not sufficient for persons to have who were about to pursue the study of Medicine. He thought, therefore, that it would be better to leave these subjects out of the optional list altogether, and to require them at a subsequent period of study. Had he known that the discussion was coming on he should have been prepared with a motion to that effect.

Mr. Syme moved that natural philosophy should not appear as an optional subject.

Dr. Christison reminded the Council that the constant

cry throughout the Profession was that too many subjects were required already, and that they were now thinking of adding one of the most important subjects which they could require. He did not entirely agree with those gentlemen who would object to natural philosophy being studied. He thought it would be better to leave it optional, so that students might take it up if they liked, but he very seriously objected to their removing from their list of subjects for preliminary examination all notice whatever of natural philosophy—a subject which was so important in Professional examination. It was a most practical subject, and it was right that those who had an opportunity of studying it should do so. Of course, a knowledge of natural philosophy could not be obtained without an able lecturer and a complete apparatus, neither of which could be expected in all the small schools of the country. At the same time, he called the statement in question that the students who came forward were not able to acquire a knowledge of natural philosophy, for in the University of Edinburgh no difficulty of this sort was found to exist; he had known many students who had a most admirable knowledge of physics at the age of 16 or 17. He thought that Dr. Andrew Wood would confirm him in the statement that natural philosophy was required in the College of Surgeons of Edinburgh.

Dr. Andrew Wood said that, with regard to natural philosophy, they never required it till after the students were 21. At the same time, he was bound to say that the examinations had been very successful. Out of twenty-seven candidates twenty-three passed, and this was not because the examination-papers were easy, for he had seen them, and could testify to the contrary.

Dr. Christison said that although the time supposed to be taken by students was four years, in reality they generally took five years, and therefore they would have plenty of time to study the subject of Physics.

Dr. Andrew Wood would not like to see this subject disappear from the list of subjects, because sometimes students showed an aptitude for it, and studied it. If, however, they made too many subjects compulsory they would exclude a large number of students from the Profession who would be an honour to it. He would suggest that the matter should be left as it was, and that they should see how it would work.

Mr. Cæsar Hawkins agreed in the propriety of leaving natural philosophy as an optional subject. They might be told that they did not think it sufficiently important to make it compulsory, but the reply to that was that they wanted to show their leaning, and to give warning that though they might ask it now as an optional subject they might afterwards make it compulsory. He thought that it ought to be made compulsory at some time or the other if it had not been included in the preliminary examination.

Mr. Syme withdrew his amendment.

Dr. Acland pressed his amendment, and stated that he believed this subject was being taught in the schools throughout the country, and that in five or ten years' time it would be still more extensively taught.

Dr. Apjohn said that in the University he represented natural philosophy was looked upon as a most important subject.

Mr. Cooper expressed a hope that these subjects would neither of them be made compulsory.

Dr. Storrar said that Dr. Acland's proposition would make two of these subjects compulsory instead of one, as was originally intended. He thought, too, that it would have a tendency to exclude Greek, which, notwithstanding the importance he attached to natural philosophy, he held to be of considerable importance to a Medical student. He was as anxious as anybody that Physics should be studied, and hoped it would soon be made compulsory; but he believed that Dr. Acland's amendment would act injuriously, and therefore he hoped that he would not press it.

Dr. Acland's amendment was not seconded, and the original motion was carried.

Dr. Stokes proposed, and Dr. Storrar seconded, the following motion—"That the following paragraphs of the Report be adopted, viz.:—

"The Committee recommend that certificates of proficiency be received from all bodies legally authorised to examine in general education in Great Britain and Ireland, and from the several licensing bodies enumerated in Schedule (A) of the Medical Act in Great Britain and Ireland, which bear evidence that the candidates have been examined and approved in the above subjects.

"In the case of certificates received from similar educational and licensing bodies in other parts of the empire and foreign countries, satisfactory evidence must be given to the Medical Council (or Branch Councils) that such certificates are equivalent to those recognised in the United Kingdom."

Mr. Cæsar Hawkins said they were now doing away with the present list of the Medical Council and leaving the matter in the hands of the licensing bodies, and it would, therefore, be necessary for the Council to have some means of supervising the diplomas granted by those bodies. He also gave some explanation of a statement made by Sir D. J. Corrigan as to a diploma of the Belfast College being refused by the Royal College of Surgeons.

After a few words from Dr. Storrar, the following amendment was proposed by Dr. Embleton, and seconded by Mr. Cæsar Hawkins—"That the foregoing paragraph be adopted, with the following addition:—

"That it be delegated to the Executive Committee to prepare annually and lay before the Council for recognition a list of examining bodies whose examinations shall fulfil the conditions of the Medical Council as regards preliminary education."

The amendment was carried, and, having been put as a substantive motion, was agreed to.

On the motion of Dr. Embleton, seconded by Mr. Hargrave, the following resolution was carried—"That the regulations of the General Medical Council as to preliminary education adopted during the present Session do not come into operation till October, 1868, and that in the meantime the previous regulations remain in force."

Dr. Stokes proposed, and Dr. Storrar seconded—"That the concluding paragraph of the Report be adopted, viz.:—

"The Education Committee having considered the letter and resolution of the Irish Medical Association forwarded by Dr. Mackesy, and referred to them, recommend that the resolution be entered on the minutes. The Committee further recommend the forwarding this resolution of the Council to Dr. Mackesy."

Dr. Andrew Wood proposed, and Dr. Parkes seconded—"The previous question," as an amendment, which was rejected.

The following amendment was then moved by Dr. Embleton, seconded by Dr. Alexander Wood, and carried—"That the concluding paragraph of the Report be not adopted; but that the Registrar be requested to acknowledge the receipt of Dr. Mackesy's letter, and the resolution of the Irish Medical Association, and to inform him that the subject of them has received the full consideration of the Council."

The amendment was then carried as a substantive motion, and on the motion of Dr. Stokes, seconded by Dr. Storrar, the Report of the Committee, as amended, was agreed to.

The Registrar then read the following report of the Pharmacopœia Committee:—

"The Pharmacopœia Committee have to report that since the date of their last Report Messrs. Redwood and Warrington have continued to be engaged in the duty assigned to them; and they have so far completed their work, that the whole of the matter, with the exception of the Appendix, is now in type. The Committee have reason to hope that the volume will be ready for circulation, in proof, amongst the members of Council, in three months from the present time. Under these circumstances, the Committee beg leave to direct the attention of the Council to the resolution adopted at the meeting of last year (Minutes, vol. iii., p. 285), as follows:—

"'That it is desirable to have a proof copy of the new Pharmacopœia in the hands of the members of the General Medical Council at least one month before the meeting of the General Medical Council, at which the opinion of the Medical Council is to be given relative to its being published, in order to afford to each member of Council the opportunity of making such suggestions to the Committee as may appear desirable.'

"As the Committee anticipate that the work will be ready some considerable time before the next ordinary general meeting of the Council, the Committee would wish to receive such further directions as the Council may feel it necessary to give them on this subject. The Committee, before concluding their Report, desire, in reference to an impression which seems to prevail, that some unnecessary delay has taken place in the production of the Pharmacopœia, to assure the Council that no time has been spent in the work which was not necessary.

"The Committee beg to inform the Council that they have not hitherto had occasion to draw upon the fund placed at their disposal by order of the Council.—(Minutes, vol. iii., p. 285.)

"May 21st, 1866." "R. Christison, Chairman.

Dr. Christison moved, and Dr. Quain seconded—"That this Report be adopted."

Dr. A. Smith asked one or two questions as to the progress of the Pharmacopœia and the sums which had been expended on it, and was answered by Dr. Christison.

Dr. Apjohn said that the Report of the Pharmacopœia Committee being now before the Council, a sense of duty compelled him to bring an important subject connected with this report under the consideration of the members. The fact of his being a member of the Committee made the task he was about to enter upon rather unpleasant; but under the circumstances he felt that it was one from the discharge of which he could not shrink. On May 2, 1864, it was resolved, on the motion of Dr. Quain, seconded by Mr. Syme, that the

Pharmacopœia Committee should be appointed, and that it should consist of the following members :—Dr. Christison (chairman), Dr. Sharpey, Dr. Apjohn, and Dr. Quain. Some meetings of this Committee were held at Dr. Quain's residence in Harley-street, during the week of the meeting of the Council, and several preliminary topics were considered. The most important of these was the question of the manner in which the chemical composition of definite therapeutic compounds should be expressed in the Pharmacopœia—whether it should be given in parts per cent., or represented by a chemical formula; and, after much discussion, it was finally resolved that inquiries should be instituted as to whether, in the new edition of the Parisian Codex preparing for the press, chemical formulæ were to be used, and that the practice in relation to the British Pharmacopœia should be governed by the result—that was to say, if they should find that the Codex included formulæ, then they should be introduced into the British Pharmacopœia, and *vice versâ*, if not found in the Codex they should not be introduced into the British Pharmacopœia. The task, too, of making the necessary inquiry was assigned to Professor Redwood, and after communicating with Professor Guibourt, of Paris, he reported as follows :—"I have received a letter from Professor Guibourt, of Paris, from which I learn that in the new French Codex, now in course of preparation, the composition of bodies of definite chemical composition will be represented by symbols and proportional numbers, the old atomic numbers being used. This was the plan agreed upon at the last meeting, and it will at once reconcile that decision with our previous arrangement that we should follow the example of the Codex, while at the same time it will meet the views of Dr. Apjohn, and I hope those also of Dr. Christison." This extract was from a letter dated 11th January, 1866, addressed by Professor Redwood to Dr. Quain, and was forwarded to him two days afterwards with a note from Dr. Quain, in which he said, "I send you Professor Redwood's letter to me, which I hope you will consider satisfactory." This was no doubt very satisfactory to him (Dr. Apjohn), who attached great importance to symbolic notation and atomic weights, and he was simple enough to consider the question settled. Such, however, was not the case. At a meeting of the Pharmacopœia Committee, held at Dr. Quain's on the previous Monday (May 21), the resolution which had been agreed upon after much inquiry and deliberation, was rescinded, and it was decided to abandon symbols and equivalents altogether, and return to the old percentage method of expressing the composition of compounds. The Council would no doubt be anxious to become acquainted with the cause of so sudden a change of opinion on the part of the Committee. To enlighten the Council on this point it would be necessary for him to read the document he held in his hand, which purported to be a letter or memorial addressed to the President of the General Medical Council by the President and Council of the Chemical Society. It was as follows :—

"*To the President of the General Council of Medical Education and Registration.*

"Burlington House, 19th March, 1866.

"Sir,—The President and Council of the Chemical Society venture to call the attention of the Medical Council to the system of chemical notation adopted in the British Pharmacopœia; and as they are informed that a new edition of that Pharmacopœia is in course of preparation, they entertain a hope that it may not be an inopportune moment to urge upon the Medical Council the desirableness of considering whether, in the forthcoming edition of the work, the use of chemical symbols could not be advantageously dispensed with altogether. In the few cases which may seem specially to call for the use of such formulæ, a per-centage representation of the composition of the body would, it appears, supply all the necessary data.

"The grounds on which the President and Council of the Chemical Society have been induced to suggest this course are these:

"The system of notation at present adopted in the British Pharmacopœia is constructed in conformity with views which are rapidly disappearing from chemical teaching in this country.

"The Pharmacopœia is necessarily the text-book on which the examinations of Students of Medicine and Pharmacy in Pharmaceutical Chemistry are based. It appears, therefore, extremely desirable that no work shall be put forth on official authority, such as that of the Medical Council, which shall be at variance with the views propounded by many of the most active experimental leaders and principal teachers of chemical science; or which shall oblige the teacher to adopt a double numerical system in his exposition of the facts of chemical science to his pupils—a course which is always a source of embarrassment both to professor and learner.

"It is obvious that the adoption of a plan such as the one now suggested does not necessitate any expression of opinion on the part of the Medical Council upon a subject which is still under discussion. At the same time, it will relieve the Council from the inconvenience of appearing pledged to the maintenance of doctrines which are no longer believed to be correct by many of the most competent to form an opinion on the subject.

"The President and Council of the Chemical Society trust that the importance of the subject will sufficiently explain their anxiety to bring this matter under the consideration of the Medical Council.

"Wm. Allen Miller,
"President of the Chemical Society.

"To Dr. Burrows."

Having put the Council in possession of this document, which, for some reason he was quite unable to explain, had not before this been brought under their notice, he proceeded to make some remarks upon it. Notwithstanding the respect he entertained for the Chemical Society as a body, and especially for his distinguished and excellent friend Dr. Miller, the president of the Society, he could not but think that the memorial and letter included some statements which, as far as his information extended, were not in strict accordance with the facts. It was not true, as stated in that memorial, that "the system of notation at present adopted in the 'British Pharmacopœia' is constructed in conformity with the views which are rapidly disappearing from chemical teaching in this country." He was in a position to assert positively that, so far as respects Ireland, that was not the case. In Dublin they had numerous Professors and teachers of Chemistry, several of them being persons of eminence in this department of science, and the lectures delivered by all, without exception, were based upon the ordinary chemical notation and equivalent numbers; and to this statement he might add that the gentlemen who filled the chairs of chemistry in the Queen's Colleges, all of whom, particularly Professor Andrews, of Belfast, were chemists of established reputation, did not in their teaching adopt any symbols or atomic weights but those which, until a comparatively recent period, had been in general use. What he had said of Ireland might, he was informed, be repeated of Scotland. The Professors of Chemistry in the Scottish Universities and Medical Schools, men of undoubted ability and eminence, did not in their lectures burden the students with new theoretical views, but were satisfied to rest their teaching upon facts on which there could be no controversy. There were, however, in England persons who thought it was of comparatively little importance to consider what was done in Ireland or Scotland, that they should look exclusively to London, and be governed by the practice which prevailed in this metropolis. Now, without saying that he fully admitted the justice of this doctrine, he begged to add that he had taken the trouble to find out what was the prevalent course pursued in the London schools of chemistry, and he had ascertained as the result of his inquiries that the great majority of the London chemists adhered to the old notation and the old atomic numbers. He stated this to be his opinion at the meeting of the Pharmacopœia Committee held at Dr. Quain's on the previous Monday, but the statement was received with much incredulity, and after a good deal of discussion it was decided to call in Professor Redwood and inquire of him how the matter really was. He (Professor Redwood) was accordingly introduced, and the question having been put to him by Dr. Christison, he replied that there were in this metropolis a few chemists who based their teaching on unitary views, but that the great majority of the London teachers still employed the symbols and the atomic weights in ordinary use.

The time for adjournment having arrived, the President asked Dr. Apjohn whether he would like to conclude his statement that evening, or adjourn and resume it on the following day. Dr. Apjohn preferred the latter course, and the meeting accordingly adjourned.

Saturday, May 26, was entirely occupied by the Adjourned Consideration of the Report of the Pharmacopœia Committee.

Monday, May 28.—The Report of the Committee on a Communication from the Secretary of State for War was considered; also the Report of the Committee on Returns of Examinations and their Results from the Licensing Bodies, and on the Register of Medical Students for the last year; and the Re-arrangement of the Recommendations of the Council on Education and Examination was adopted.

Tuesday, May 29.—The Council met at 1 o'clock. The amended Report of the Committee on the Registration of Medical Students was adopted. A letter from the Metric Committee of the British Association for the Advancement of Science, and the Returns from the Medical Departments of the Army and Navy were considered. The Reports of the Finance Committee and of the Committee on Returns from the Licensing Bodies were adopted. Important motions by Dr. Fleming, enlarging the constitution and powers of the Executive Committee, were agreed to; some other important

and some routine business settled; and the Session was brought to an end.

The details of these days we are compelled to defer till next week.

ORIGINAL COMMUNICATIONS.

CASE OF EPILEPSY.

By Dr. FRASER,
Senior Physician to the London Hospital.

A. B., a private gentleman, died at 64 years of age; originally robust and healthy, and never had an illness, except a severe attack of small-pox in infancy: a man of great classical learning, with great talent for the abstruse sciences, helped by a powerful memory. For the last thirty years of his life had indulged freely in the use of ardent spirits, and, before restriction was employed, not unfrequently drank four quarts of whisky per day. The appetite was usually good, and in that also a restriction was found necessary.

In the year 1833, having previously had several what he called "bilious attacks,"—always removed by a dose of calomel—one morning while shaving he experienced a momentary and indescribable sensation in his head, compelling him to lay the razor down, and yet so obscure as to create no alarm, either to himself or family. Two months afterwards, whilst at breakfast, he experienced a similar sensation, but could give no description of his sensations. Shortly after the second attack he was seized with diarrhœa, which continued for some days, causing great weakness, and followed by a total loss of the use of the lower extremities. After a tedious recovery, his general strength was much diminished; the unpleasant sensations in the head were more frequently experienced, and gradually assumed a character such as to render their effects perceptible to spectators. Without warning, and it might be while talking or eating, he would suddenly stop and, bending the neck forwards, place his hands on the temples, and moan for ten or thirty seconds, and then rapidly recover consciousness. If standing, he attempted to reach a chair, and if walking staggered forwards, but never fell. In the year 1835 these fits became more frequent, sometimes five or six in twelve hours, and since that time they had continued with much the same character, sometimes with intervals of a week or weeks, or even months, and then suddenly recurred daily.

In February, 1839, a more severe form made its appearance, the smaller still continuing, and it would appear that a cessation of the smaller always preceded a severe attack. The latter began with violent struggling, and a grasping at near objects. The shoulders were drawn backwards, and the head and neck to one side, like to a combination of opisthotonos with pleurosthotonos; the eyes open, mouth twisted, and severe spasm of the respiratory muscles; the teeth clenched. The tongue had never been bitten, although no precautions were used, nor were the accessions of the fits announced by a scream. This stage continued for ten or twenty minutes, the convulsions gradually lessening, and a state of sopor supervened, with puffing of air through the lips, but no saliva appeared, nor was real stertorous breathing heard. The second or soporific stage continued nearly the same time, and then consciousness gradually returned, and he almost always immediately made water, and not unfrequently a copious alvine evacuation followed. He recognised those around, although vision was still indistinct, and in grasping an object he either passed his hand too far or not far enough.

Since February, 1839, he has had twelve of these severe attacks. At this time he was able to walk a short distance and take daily drives; was much emaciated, although the appetite was good, and he was still allowed nearly half a pint of spirits per day. The memory was nearly lost, although the integrity of the judgment was unimpaired when called into action. Various attempts were made to trace a connexion between the attacks, and the effects of diet, mode of life, or any other contingent circumstances; but no conclusion was arrived at. A periodicity was thought to exist, as the small attacks would recur always at the same hour, whether that happened to be morning, noon, or night, and the three last severe attacks each had an interval of exactly three months.

There is little or nothing to say on the treatment. Leeches were applied to the temples, cupping to the nape of the neck, but the general health was the chief aim. At one time purgatives were used, but the fits were clearly aggravated by their use. This case is a marked instance of the "Petit mal" of the French writers, and shows the slowly insidious course which the malady sometimes follows, before severe symptoms appear. The curious fact that a cessation of the slight attacks generally preceded a severe attack I cannot explain, except by the very mechanical idea that the peculiar state of the nervous system which induces the disease becomes pent up, and when it obtains egress, it is by a sudden and strong demonstration. Although there is no doubt but that it was a case of epilepsy, I may mention that it wanted what Hall considers essential to constitute an epileptic seizure—viz., an injury or wounding of the tongue, also the scream so characteristic of the accession of a fit. The complete loss of memory, the power of reason remaining entire, are corroborative of the doctrine which inculcates that the healthy action of a particular portion of the brain is necessary for the action of the faculty of memory. The following notes add to the interest of the case:—

On November 9, 1842, the Medical attendant wrote as follows:—"He has had a severe attack of sciatica, and it is surprising that he has scarcely had one of the epileptic attacks, and these few very slight, since the sciatica began."

On January 25, 1843—"He has had three bad fits since December 22, making up for the three previous months during which he had none. The same holds good as to slight fits.

"February 10, 1843.—A severe fit a few nights ago; the action of the heart is most inordinate, and great congestion in lungs; eyes fixed and iris insensible; copious urinary discharge on recovery, and complete unconsciousness of what has passed.

"Died on March 10. No post mortem allowed."

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 340.)

We continue here the record of the cases in which Mr. Wells has completed ovariotomy in the Samaritan Hospital, in the order in which the operations were performed. He operated on the 4th of April on a case in which it was known that the uterus and both the ovaries were diseased, and removed the greater part of a fibro-cystic tumour of doubtful origin. The tumour has been referred to a Committee of the Pathological Society, and we shall publish the case when the report of the Committee is complete.

Case 79.—*Adherent Cyst, Never Tapped—Ovariotomy under Local Anæsthesia—Sixty-nine Pounds Removed—Death in Fifty-two hours.*

Dr. Sadler, of Barnsley, wrote on February 21, 1866, to Mr. Spencer Wells asking for the admission of a patient to the Samaritan Hospital, whom he believed to be suffering from an enormous ovarian cyst, with some ascites and complete prolapse of the uterus. She came to town, and was admitted on March 10. She was single, 23 years of age, and had been in good health until about three years ago. Her first complaint was numbness in the upper part of the left thigh. Soon after, about December, 1862, the abdomen began to enlarge, and had gone on increasing ever since. Menstruation had ceased in July, 1863. Measurement on March 12 showed the girth at the umbilical level to be 54 inches; the distance from ensiform cartilage to pubes 32 inches, and from the spine of the right ilium to the left 40 inches. The whole abdomen was occupied by an enormous cyst, both loins being dull, and the right flank being the only part resonant on percussion. The ensiform cartilage and false ribs were pushed forwards and outwards, and the upper border of the cyst had pushed the liver and apex of the heart up to the level of the nipples. The superficial abdominal and thoracic veins were large and numerous. The uterus was completely prolapsed between the thighs of the patient, forming a tumour as large as a cocoa nut, covered by the everted vagina, with parts of the bladder and rectum. The mucous membrane had become skin-like, and

the lips of the os uteri were abraded. This prolapse had not been reduced for more than six months. Fluid, free in the peritoneal cavity, caused considerable projection of the umbilicus.

The question of tapping, as a preparation for ovariotomy, was seriously considered. Mr. Wells stated that the evident advantages would be relief to pressure on the thoracic and pelvic viscera, and lessening the shock of operation. But the dangers of first tappings in very large cysts are so serious; or, to speak more correctly, the dangerous effects of the rapid re-accumulation of fluid are so great, that it seemed advisable to avoid them by immediate ovariotomy.

The operation was performed on March 14. Professor Hughes, of Dublin, and Dr. Skoldberg, of Stockholm, were present. Owing to the extreme compression of the lungs and displacement of the heart, Mr. Wells determined to try the effect of local anæsthesia by Dr. Richardson's ether spray rather than give chloroform. It answered completely, as the first incision and the tapping were completed without the patient being in the least conscious of anything being done. But when it became necessary to separate adhesions, a little chloroform was administered. On making an incision, four inches long, midway between the umbilicus and symphisis pubis, the peritoneum bulged up between the lips of the wound. It was opened by a trochar, and several pints of ovarian fluid, which had been free in the peritoneal cavity, escaped. The peritoneum was then opened, and an adherent cyst was tapped, emptied, and gradually withdrawn, extensive adhesions to the abdominal wall, in some places very firm, being separated as the cyst was drawn out. A pedicle as thick as three fingers was secured about three inches from the right side of the uterus by a small clamp. Several pints of fluid were then pressed and sponged from the peritoneal cavity. One bleeding vessel in the abdominal wall was stopped by torsion. The left ovary was found to be healthy. The prolapsed uterus was replaced; and the wound was closed in the usual manner. The fluid removed weighed sixty-four pounds, and the cyst walls with small cysts removed entire, five pounds—total sixty-nine pounds.

The patient was very quiet and comfortable after the operation; was not sick, required no opium, and an abundance of urine was removed by the catheter, but no perspiration could be induced. The pulse ranged from 130 to 140, and the heart did not change its position in the least. In the morning of the day after operation, this condition persisting, Mr. Wells thought of venesection, but as the kidneys acted very freely he deferred it. Thirty-two hours after operation, the skin being still hot and dry, the pulse 160 with an occasional intermission, and the superficial veins very full, he opened a vein in the arm. The blood ran very slowly at first, but afterwards more freely. The pulse became fuller and fell to 140. The blood drawn separated into 5 ounces of clear serum, and $5\frac{1}{2}$ ounces of firm clot, with one-tenth by measurement of fibrine on its surface.

On the morning of the second day she was said to have passed a fair night. She had not been sick; no opium had been given, as there was no pain; plenty of clear urine had passed, but the skin was still dry and hot, and the pulse 160 and irregular. The abdomen was not distended, but the stomach was tympanitic and high up behind the ribs, the heart not moving from the position it occupied before the operation. Quinine was given by mouth and rectum, but the patient gradually sank, and died 52 hours after operation.

On examination of the body, the thorax was found resonant up to the space between the fourth and fifth ribs, and the ribs were widely pressed outwards. There was no distension of abdomen, and the wound was perfectly closed. About two pints of serous fluid were in the peritoneal cavity, but neither blood clot nor ovarian fluid. The process of repair on the surfaces where the adhesions had been separated had been commenced by a layer of lymph, but there were no other signs of peritonitis. The pedicle was perfectly secured, and exerted no traction on the uterus. The left ovary was healthy, as was the uterus, with the exception of the abrasion around the os. The upper border of the liver was on a level with the right fourth rib, the apex of the heart with the space between the fourth and fifth ribs on the left. The right lung and pleura were healthy. The left lung adhered all over its surface, and adhesions between its lower lobe and the diaphragm held up the diaphragm, and prevented it and the heart from descending. The heart was healthy, though rather soft. A firm fibrinous clot filled both its right cavities, adhered to their walls, and extended along the pulmonary artery beyond its bifurcation. There was no deficiency of blood in the vessels, and the muscular tissue throughout the body was very healthy in appearance.

Medical Times and Gazette.

SATURDAY, JUNE 2.

GENERAL MEDICAL COUNCIL.

The sittings of Tuesday, Wednesday, and Thursday, May 22, 23, and 24, were almost wholly absorbed by the "Medical Acts Amendment Bill." The debates were long, prolix, and, at times, desultory. It will be remembered that last year the Council themselves, after a lengthened discussion, drew up a "Medical Acts Amendment Bill," which was transmitted to the Home Office, and this year the Home Office returned to the Council a "revised draft" of the Bill. A Committee was appointed to consider the Home Office Draft Bill, and, having given in its report on Monday, May 21, the discussion on it in the Council was opened on the Tuesday, and continued through that and the following day; the Bill, "as amended in Committee of the whole Council" was then remitted to the former Committee. The consideration of their second Report, and further amendments of the Bill occupied the Thursday, but the Bill was then finally settled, and was ordered to be transmitted to the Home Office, together with "a statement of the reasons which have induced the Council to suggest the amendments" agreed to by them, and a request for an early reception of a deputation from the Council in reference to the Bill.

There are only three or four additions and alterations of any importance to be found in the Bill as now drafted, when it is compared with the Bill of last Session. A great deal of time was spent over the registration clauses, and the changes made are most of them good, but we confess that we do not sympathise with the anxiety of the Council to remove from the Register the names of persons "who have ceased to practise," but who have not requested the removal of their names. No definition is given of the phrase, "having ceased to practise." Suppose that A, a registered Practitioner, goes abroad for a year or two, say to Australia, what harm can possibly arise from his name remaining on the Register? but according to these new regulations it may be arbitrarily removed during his absence; the Registrar having evolved from his inner consciousness—no other source of information is mentioned—the idea that A has ceased to practise, addresses to him a registered letter, according to his "registered address," inquiring whether such is the case, but A being on the high seas, or wandering (in search of health perhaps) in Australia, does not receive the letter, though "registered," nor that which follows it three months and fourteen days later; or, at any rate, does not get either in such time that his answer can reach the Registrar within six months and fourteen days from the date of the first letter; the consequence is

that he "shall be deemed to have ceased to practise, and not desire to have his name retained on the Register." What mischief his name could in any way have caused, we do not see, nor why he should be thus exposed on his return to the annoyance of finding himself Registerially defunct, and the trouble of getting his Registerial life restored.

We are glad that the Council rejected a proposal to omit the last paragraph of clause 10—that, viz., which provides "that a person whose name has been erased from the Register with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this section, by reason of his being engaged gratuitously in the cure or treatment of any disease or injury." Under the circumstances, this provision can hardly open the door to any serious abuse, while without it a retired Practitioner might be now and then exposed to great annoyance and hardship.

The clauses giving the Council power to register, under certain conditions, approved colonial or foreign diplomas, will meet with general approval. When a student has, by going through the legal course of study and examination obtained a diploma, qualifying him to practise, from a foreign University of high standing, such as that of Paris, Vienna, or Copenhagen, it is surely a very illiberal and oppressive thing to deny him registration, and to require from him a fresh course of study and examination here before he can be qualified to practise. If it be objected that foreign countries do not to this degree admit the validity of English diplomas, we reply that "two wrongs do not make a right," and that it will not be the first time that England has set other countries an example of liberality and progress. We have not the least fear of our being "swamped by an influx of foreign degrees;" or "inundated by a horde of unwashed foreigners" of no social standing, and of disgraceful habits of life:—such gentry would find even starvation more expensive here than on the Continent; but we think the Council have acted very wisely in keeping in their own hands the duty of preparing an annual list of approved colonial and foreign Universities and Colleges, instead of adding a schedule of them to the Bill. Such a schedule might very possibly receive some strange additions during the passage of the Bill through Parliament.

Government required, as a matter of course, that the degree of Bachelor of Surgery of the University of London should be admitted to the registration which the Council had the hardihood to deny it last year, and the Council have, and very rightly, enlarged the admitting clause, so as to make it apply to "the degree of Bachelor of Surgery conferred by any University in the United Kingdom which now is, or hereafter shall be, legally entitled to confer the same."

The penalty clause, section 40 of the original Act, is amended so as to make penal the assumption of any Medical title "by any person practising Medicine or Surgery, or engaged in the cure or treatment of diseases or injuries, not being registered under the Medical Acts." The Bill of the Council prohibited the assumption of the title "Doctor," but in the Home Office Bill the words "of Medicine" were inserted after the word "Doctor." These added words the Council have struck out, and most rightly insist that "the introduction of the title 'Doctor' simply is all-important to the efficiency of the operation of the clause;" and they press upon the notice of the Home Office the fact that the title 'Doctor' is the one most commonly assumed by unqualified Practitioners, and that as the clause applies only to persons "who, not being registered, are practising Medicine under the title of Doctor," the objection that the word Doctor includes all Doctors, whether of philosophy, law, etc., cannot be held to have any force.

These several points include, we believe, all that is important in the proposed "Medical Acts Amendment Bill;" they do not amount to much, but they are, we think, worth gaining. We do not see, however, that there is the slightest chance of the Bill passing this year. Sir George Grey has distinctly declined "to undertake the charge of the Bill at present," and suggests that some member of the House of Lords or Commons might be found by the Council who would undertake it. We think such a mode of proceeding would be derogatory to the dignity of the Council; any measure coming from them ought to have in the fullest possible way the support of Government; to go to Parliament without it, even with so small a measure as that now proposed, would, we believe, be to court defeat; (a) and defeat would lower still further the influence and power of the Council. On the final motion "That the Report of the Medical Acts Amendment Committee be adopted as amended by the Council," Sir Dominic Corrigan moved, as an amendment, to ask for a Royal Commission to inquire into the workings of the Medical Acts, etc. We commend his speech to the notice of all who may like to read very forcibly expressed everything that can be said against the Council. The whole discussion, indeed, is somewhat instructive and very entertaining; speakers got so excited that they became eloquent and poetical, and even a Scottish member went so far as to quote naughty language from Shakespeare. Sir Dominie's speech might be entitled "contemptuous condemnation of the Council, by one of themselves;" there is indisputably a great deal of truth in it; and if Government would seriously and earnestly take up the subject of Medical education and Medical policy, a Royal Commission might be of great value; but we cannot think that Sir D. J. Corrigan showed wisdom, good policy, or good taste either as to the time when he brought forward his motion, or the tone and manner in which he supported it. Its adoption would have rendered useless the three days' labours of the Council, and have shelved the whole of the subjects now under consideration for, probably, two or three years to come. Now it may be only too true that the Council have done very little, and it is certainly true that the little they have done has been effected by a great expenditure of time and talk, and at no slight cost to the Profession. But they have done something; they have effected considerable improvement in the education of Medical students; or, at any rate, this has advanced not a little contemporaneously with the existence of the Council. And they have "recommended" more; they have, at a cost of £5000, laid the foundations of a National Pharmacopœia; and they have, for certain fees, registered all grades of the Profession higgledy piggledy together in a large annual volume, which any one who chooses may buy. Let us be just, and not forget these works. Dr. Acland's speech against the motion was eloquent, and full of good sense and manliness; but the irrepressible Baronet, in his reply, accused him of being in a passion, and concluded by quoting, as "appropriate on the present occasion," the lines—

> "I protest, since they will give me no praise,
> I'll trumpet myself to the end of my days;
> So saying, away to the forest he flew,
> And ever since then has been crying 'Cuckoo.'

But we do not exactly understand whether he meant them to be applied to himself or to his colleague.

On Friday the adjourned consideration of the Report of the Committee on the subjects of general education was resumed, and it was agreed "That natural philosophy, including mechanics, hydrostatics, and pneumaties, be adopted as one of the optional subjects." It is a real satisfaction to be able to report that the Council have at last determined to recommend "That the following subjects constitute a minimum to be required of candidates for preliminary examination, viz.:—

Compulsory Subjects—

1. English language, including grammar and composition.
2. Arithmetic, including vulgar and decimal fractions; algebra, including simple equations.

(a) We see that on Tuesday, the 29th, the Council delegated to the Executive Committee authority to act, as regards the passing of the Bill, very much in the spirit of these observations.

3. Geometry: first two books of Euclid.
4. Latin, including translation and grammar; and
5. One of the following

Optional Subjects—

1. Greek. After the year 1869, Greek shall be one of the compulsory subjects.
2. French.
3. German.
4. Natural philosophy, including mechanics, hydrostatics, and pneumatics."

Can any one seriously think that these subjects take too high and large a range for the examination of a youth of 17, who is designed for one of the "learned and liberal Professions?" It is very possible that the requiring such a degree of preliminary education may lessen the number of Medical students, but that will be partly because those who are utterly unfit for the Profession will be warned off, and so the Profession will rise in character and tone, and partly because so many avenues to competency and position are now open to well-educated youths, which used to be accessible only through interest, and because the greatly increased engineering and commercial enterprise of the day affords a much wider field than of old to the energies and intellects of the sons of the middle classes. But shall it be therefore said that we must pitch the general education to be asked of Medical men so low as to tempt the indolent and small-brained? The same causes have much reduced the number of yearly candidates for Holy Orders, but we have never heard it seriously proposed to lower the education of the clergy! Away, then, with such arguments! If our Profession is to continue to hold a high and honoured place among the callings of gentlemen, we must raise the standard of mental training to be required from all who enter it, and demand that it shall at least come up to the average liberal education of lads in this middle of the nineteenth century. And if the supply of Medical men should threaten to fall short of the demand, the continually and vastly-increasing wealth of the country must, and doubtless very soon would, apply a remedy. In the Church every effort is being made to increase the value of all small Livings and of Curacies; and so in our Profession, some of the increase of national wealth must be fructified in paying Medical services better, in increasing the pay of the Army, Navy, and Poor-law Medical Officers; and much less gratuitous service must be demanded from the Profession. Let gentlemen feel assured of meeting with honourable treatment and fair remuneration, and there will never be any lack of candidates for the Medical Profession. Something might have been urged in favour of allowing chemistry, natural history, natural philosophy, or the like subjects, instead of algebra, or geometry, or Greek; but very few, if any, schools are at all prepared to teach those subjects, and the Medical Council is the last body to venture on attempting to alter the educational system of the country, even were it desirable, which we do not say, that they should do so. Nearly all the arguments against making Greek compulsory would have applied equally well to Latin, and would, in fact, have tended to reduce the requirements to the famous three "R's," Reading, 'Riting, and 'Rithmetic. We rejoice, then, that the Council have at last adopted "a minimum" of subjects for the preliminary education; but our joy is largely tempered by the reflections that it has taken them eight years to achieve this labour, that they still venture only to *recommend* this minimum, and that their "recommendations" are not intended to come into operation till October 1, 1868.

A great deal of difficulty has been created about the insertion of Medical titles in the Army List. In May, 1864, the King and Queen's College of Physicians of Ireland complained to the Director-General of the Army Medical Department that if a Medical officer possessed a Medical degree he had M.D. appended to his name, while if he had a diploma from a College of Physicians he got no Medical affix. The matter was brought before the Council that year, and they passed a resolution that "it would not be advisable to insert the letters Phys.," but that the "several Medical qualifications which Army Surgeons possess, as in the Medical Register, might be entered after their names in the Army List." The matter came again before the Council in 1865, and they sent to the War Office a new resolution recommending "that initials, indicating the several Medical qualifications which Army Surgeons possess should be inserted after their names without distinction or preference to one degree or licence over another;" each Surgeon to be allowed, however, only one qualification. This year Lord De Grey politely asks for a list of "*initials*." How, for instance, he asks, is the licence of the King and Queen's College of Physicians in Ireland to be expressed by initials? and if a man possesses more than one qualification, who is to determine which shall be initialed in the Army List? We suspect his Lordship rather chuckled over his questions, and thought he had posed the Council, and we confess to having thought so too. The matter was referred to a committee, and they recommended that abbreviations be used to signify the Medical degree or licence possessed without in any way distinguishing what University, College, or company it proceeded from. Thus—

M.D. } signifying University graduates, without
M.B. } specifying any particulars.
Ph. signifying "Physician" in like manner, without specifying any particulars.
Ap. signifying "Apothecary" in like manner, without specifying any particulars.

It might have been objected that this would have been cutting the Gordian knot rather than untying it, and that these abbreviations do not "designate the several Medical qualifications possessed," but only the *kind* of qualification. One might also have been tempted to wonder what superiority the combination "Ph." possessed over the discarded "Phys." And one felt that the Army List would certainly need to give a glossary, or how would the multitude ever have arrived at the meaning of "Ph." or of "Ap.?" The former might have been translated into Pharmacologist or Pharisee, as well as Physician; and many would have been reminded by the latter of the old smokejack, which was for ever repeating, "Once I was 'ap—'ap—'appy, but now I am meescrable," and they would have suspected some reference to the repudiated Warrant of 1857, and the present state of the Army Medical Department. Perhaps, however, it would have been generally felt that the Committee deserved to be congratulated on having found so 'appy and so ap-posite a solution to what seemed a rather thorny question, and we were prepared to congratulate them accordingly.

The Council, however, lacked the boldness of their ingenious Committee, and resolved "That the Registrar acknowledge with thanks Sir E. Lugard's letter, and inform him that on further consideration the Medical Council has decided not to urge the matter referred to in Sir Edward's letter on the attention of the Secretary for War." A "most lame and impotent conclusion," truly; the Council completely backing out from all the advice they have offered the War Office on the subject. How such conduct must increase any influence the opinion of the Council may be politely supposed to have hitherto had with that department of Her Majesty's Government!

Notwithstanding the recommendation of their own Committee, the Council could not persuade themselves to allow the resolution of the Irish Medical Association to be placed on the Minutes, but they inform Dr. Mackesy that both the resolution and his letter "have received their full consideration." Acting on the *omne ignotum* principle, the public will imagine that the resolution must be charged with most terrible thunder.

A "Memorial of the County and City of Cork Medical

Protection Association" has been admitted on the Minutes, this honour being in place of "full consideration," we suspect. The Memorial is good, and well deserves all the "consideration" the Council could have given it.

The new edition of the Pharmacopœia is so far complete that "the whole of the matter, with the exception of the Appendix, is now in type." The Council directed that as soon as the proof is quite ready a copy should be sent to each member of the Council for his observations, to elaborate which he should be allowed one month; then the Pharmacopœia Committee should "duly consider" all such observations, and "hand over the proof, when finally approved, to the Executive Committee for publication." And they also, moved thereto by a letter from the President of the Chemical Society, agreed that "it be an instruction to the Pharmacopœia Committee to give for each therapeutic compound of definite constitution occurring in the forthcoming edition of the Pharmacopœia, two formulæ—the first being that in ordinary use at present, the second being one constructed in accordance with the more recent view of what is called the "unitary system." There is evidently a good deal of work still before that Committee. We venture to suppose that the expression "therapeutic compound" in the above instruction should be read "chemical compound."

There is also to be inserted a "complete comparative table of metric and imperial weights and measures, with instructions for their mutual conversion."

THE CHOLERA AT LIVERPOOL.

(From a Correspondent.)

There have not appeared any fresh cases of cholera among the emigrants at Bank Hall since Monday, the 14th; nor to this date (22nd) is there any suspicion of the disease having been localised in any place or among any residents of the borough.

This gratifying fact will not, we trust, cause any relaxation of precautionary and preventive measures on the part of the parochial and municipal authorities, for such present immunity does not imply security in the future. In 1854 the cholera, as now, reached Liverpool through the transit of emigrants, but did not immediately spread among the other inhabitants. Thus, though in the week ending April 8 of that year there had occurred numerous deaths among the passengers and crew of the American vessel *Winchester*, the disease did not fix itself in the town with anything like epidemic virulence until the third week of July, when a fresh importation of sick emigrants was attacked by cholera on board the ship *Derigo*. Then, unfortunately, there were co-existent all the elimaterial causes and exciters of the disease, and from that time until the latter end of October it raged with fatal intensity.

The rate of mortality from cholera has been as follows:—Of the 38 cases treated by Mr. Rayner on the Hospital ship *Jessie Munn*, 23 died and 15 recovered; of the 18 admitted into the Workhouse Hospital, 8 have died, 9 been cured, and one remains under treatment.

All on board the *Jessie Munn* are to be landed to-day (May 22) and conveyed to the convalescent wards of the Workhouse. The reports from the depôt at Birkenhead are equally satisfactory.

May 22.

From the 22nd the health of all the emigrants continued to improve so steadily and satisfactorily that Captain Prior, the Government emigration agent, having satisfied himself that a clean bill of health could be reasonably granted to the ship and passengers, authorised the *Helvetia* to prepare for sea, and to-day, May 29, at 12 o'clock (four weeks since the period of his first start), she again sailed from the Mersey. Mr. Rayner, late of the *Jessie Munn* Hospital ship, has consented to go out with the passengers as Surgeon.

The cholera has not appeared among the residents of the town; but the Select Vestry and health authorities are quietly making those arrangements which will be required by the exigencies of an epidemic, and by the provisions of the "Diseases Prevention Act."

May 29.

THE APPENDIX TO THE REPORT OF THE CATTLE PLAGUE COMMISSIONERS.

We have already given our readers a general account of the conclusions arrived at by the Commissioners as to the Medical history of Rinderpest, and intend now to offer an analysis of the data upon which these conclusions are based. And we may congratulate the Commissioners on the fruit of their labours. The results obtained by those gentlemen who severally undertook lines of special investigation possess a general value which it is impossible to overrate, a very wide range of applicability—far beyond the narrow limit of Rinderpest alone—to the pathology and progress, indeed, of all acute diseases. Rinderpest has furnished the occasion whereby a large addition has been made to our common stock of Medical knowledge, and has helped to bring out large generalisations, which must very considerably modify many of our present opinions as regards the causation and treatment of disease.

In reading through the details of the Report, a marked unanimity between the opinions and results of the different observers is evident; it is strikingly illustrated in regard to the pathology and symptomatology of the disease. Even the most novel points in one are in harmony with the observations recorded in other sections of the Report. This is proof not only that Rinderpest and its circumstances have been most severely interrogated, but the observations afforded us are eminently trustworthy. The *special* investigations carried on have brought to light not only much reliable information in regard to *diseased*, but also *healthy* conditions, of which we were before quite ignorant. When the investigators appointed by the Commissioners entered upon their researches, they at once discovered that as regards Rinderpest, science was so far deficient as to afford really very few data of comparison. The object proposed was, of course, to ascertain the degree and nature of the departure from health. This was very difficult, inasmuch as our knowledge of the healthy state in many particulars was uncertain. For instance, Dr. Marcet says, "I found it necessary to institute a series of investigations on the chemistry of bovine animals in the state of health in order to obtain a standard of comparison wherefrom to draw results as to the morbid changes due to the disease."—P. 55. In his report on disinfection, Dr. Angus Smith enters into the meaning and principles of disinfection in general. He observes "the results obtained by M. Pasteur regarding the existence of organised substances, as we may call them, or germs, is so definite, clear, and important that we must begin as on a new foundation, and date theories of many diseases, and also of disinfection and cure, from this era." This is a matter of congratulation, for it has presented us with an essay on disinfection which will be received as one of the most valuable contributions that have been made to science.

The ideas of the different observers have been running towards the same point of view in regard to another most important matter—viz., the nature of the poison at work. One cannot refuse to see that although there are many chemico-mechanical actions, yet the phenomena seems to indicate that the poison is of a *living* nature.

The Commissioners, who are entitled to immense praise, express their obligations to the gentlemen whom they selected to investigate the epidemic from special points of view, and

we cannot too cordially award the highest praise to each and every one, expressing at the same time a fear lest we fail in this short report to do them justice.

The first Report is that of Dr. Sanderson, who was requested "to study the disease in animals of different species, and, in particular, to investigate its characters when produced by inoculation as compared with those which are met with in animals to whom it has been communicated by natural infection," and also to ascertain its mode of propagation. The following are the more important conclusions :—

1. *General Characters and Progress.*—It appears that what we understand by the term fever existed several days before any *local* change could be detected; and in this, as in all other respects, such as duration and development, Rinderpest observes a very marked uniformity. Dr. Sanderson gives us a full account of the natural course of the disease, dividing it into three stages—the first, which is characterised by a rise in temperature only; the second, comprising the third, fourth, and fifth days, when the more ordinary symptoms are developed; and the third, in which there is a rapid fall of temperature and cessation of vital functions. These different features are fully described. Death occurs on the seventh day.

2. *Alterations in the Temperature.*—We have already given some of the more important conclusions upon this matter, more especially as showing that the onset of the disease may be recognised at a very early period. It now only remains to notice peculiarities observed during the further progress of the disease. The increase of temperature is greater in those animals which were inoculated and which recovered, than in others which died—indeed, a mere increase of temperature is not of much moment, in a prognostic sense. In fatal cases, however, the acme was reached a day earlier than usual, and where a favourable issue resulted, the rise and fall was more regular and gradual. Recovery is also preceded by a fall in temperature, but the decline is gradual, and does not set in till about the seventh or eighth day.

3. *Alterations in the Urinary Secretion.*—Dr. Sanderson tells us that the quantity of urea is found to be greatest on the fifth day, and in fatal cases the percentage is nearly doubled, "the increase being greatest at the same period of the disease at which the total daily excretion of urea was most rapid." We shall recur to this in speaking of Dr. Marcet's report.

4. *Alterations of the Pulse.*—The acceleration of the pulse is very inconsiderable in the early stages; later, there is a slight increase in frequency perhaps. The pulse is somewhat slower in those animals which recover, quicker in those which die, and especially accelerated in the stage of collapse; but the frequency of the pulse is of little importance, either for diagnosis or prognosis. The quality, however, is a good test.

5. *Alterations in the Respiratory Functions.*—Dr. Sanderson finds that in the early stages there is little alteration as regards the *rate* of breathing. Much more is learnt, we are told, by observing the *mode* of respiration. "During the first stage of the disease respiration is performed in a perfectly natural manner, but about the fifth day irregularities begin to be observable," the rythm of the chest movements is altered, and expiration is accompanied by moaning. On the sixth day "the chest dilates suddenly, but apparently with considerable effort, in consequence of the unnatural permanent expansion of the lungs due to obstructed expiration. This inspiratory movement is immediately followed by closure of the glottis . . . . the closure of the glottis is always attended by a sound . . . . so loud that it can be heard at a distance. This sound coincides with the resisted expulsive effort," etc. The glottis remains closed for a while, and then the confined air is expelled with the peculiar grunting noise, after which a fresh inspiration is made; thus, as Dr. Sanderson points out, the rest or pause does not occur at the end of expiration when the lungs are relaxed, as it were, but when the latter are inflated, that is, in the middle of the respiratory act, or rather in the middle of the expiration, as some of the air escapes after inspiration before the glottis closes. "At the moment that closure takes place the air confined in the chest is strongly compressed by the action of the expiratory muscles, and in this way gives rise to the interlobular emphysema which is so commonly observed in cattle plague."

Dr. Sanderson then proceeds to explain how the closure of the glottis is effected, drawing attention to the similarity of breathing between that of the Rinderpest animal and that observed after section of the pneumogastric nerve :—

"In all animals, as is well known, the vocal chords separate from each other in inspiration and approach in expiration, these movements being very inconsiderable in the tranquil condition, but increasing in activity whenever the breathing is excited or interfered with. Hence we may readily understand that in the hyperæmic and tumid larynx of cattle plague, the expiratory narrowing of the glottis becomes complete, while even during inspiration the opening is insufficient to allow the free ingress of air. Hence the permanent dilatation of the chest, the enfeebled action of the diaphragm arising from the permanent depression of its central tendon, the laborious, but relatively fruitless, action of the other inspiratory muscles in expanding the thoracic walls, the fixation of the chest during the prolonged closure of the glottis, and the noisy expulsion of the imprisoned air through the narrow chink the moment that the vocal chords separate from each other for inspiration."

6. *Alterations of the Visible Mucous Membrane.*—Dr. Sanderson lays great stress on these as in themselves the most constant and important characters of cattle plague, especially those seen about the mucous membrane of the mouth, but we defer an account of them till we take up the "Morbid Anatomy" of Rinderpest. It is only just, however, to observe that Dr. Sanderson calls particular attention to the "perfect agreement in the time at which the first local manifestations of disease could be detected." About two days intervenes between the first rise in temperature and the development of local change. He then discusses in detail the alterations of the alvine dejections; those of the skin, which we shall by-and-by refer to; the alterations of the functions of the brain and nervous system; the diagnosis; remarking that "cattle plague may be discriminated from all other diseases whatsoever by the alterations of the visible mucous membranes generally, and particularly by those of the lips and gums," especially in conjunction with the change in temperature.

Then the phenomena of cattle plague in sheep are descanted upon; the effect of inoculation, which would, on the whole, seem to be occasionally beneficial. The experiments of Professors Jensen, Unterberger, Rasdolsky, Raupach, and others are referred to. The difference of opinion upon the point whether the virus loses any of its virulence by transmission through several animals of the same species would seem to be very great. Dr. Sanderson's Report concludes with some tables, forming a complete record of his valuable observations.

Dr. Marcet's Report follows next in order. His researches concern the muscular tissue and solids of the body, in a chemical sense.

The Blood.—In the earliest stages the water is increased, in later stages diminished; coincidently with the diminution occurs an increase in the solids of the blood. The proportion of *albumen* seems to rise and fall with that of the water; in one case only was it absolutely increased. The *fibrin* is always in excess, and such excess is an early feature.

The proportion of *mineral constituents* does not seem to vary from that of health.

Muscular Tissue.—The flesh of diseased contains more soluble albumen than that of healthy beasts; and, moreover, the rate of diffusion of albumen would appear to be slower throughout the former than the latter. Dr. Marcet remarks that the "excess of soluble albumen may be considered either as due to a process of solution or albuminous degeneration of the muscular tissue; or to an increased supply of albumen

to the muscle from the blood," . . . the nutrition of the muscle is seriously altered from that of health.

Urine.—An increase in the amount of *urea* occurs just as the temperature begins to rise, and augments in direct proportion to the increase of the latter, thus confirming the conclusions of previous observers in other diseases. The total *amount* of urine secreted varies little from that of health. The *specific gravity* falls always as the disease advances, from decrease in the amount of mineral constituents. *Albumen* is generally found in the urine about the fourth day after the rise of temperature, and gradually increases. The reaction, at first alkaline, in the latest stages becomes acid.

The Milk.—The specific gravity and quantity diminish, and the fatty matters seem to be increased.

As in the case of Dr. Sanderson's, the Report of Dr. Marcet ends with a mass of tabular matter, which is the best evidence of carefully-conducted research.

Nor is less credit due to Dr. Murchison for his Report, which follows next in order. Basing his observations on the symptoms, anatomical lesions, and pathological relations of Rinderpest, Dr. Murchison argues out solidly the conclusion that Rinderpest is neither typhoid, typhus, scarlet fever, erysipelas, influenza, nor dysentery; that it has alliances to the exanthemata, chiefly to variola, from which, however, it differs in striking particulars.

(*We shall continue our observations on the Report next week.*)

REVIEWS.

Lectures on Clinical Medicine delivered at the Hôtel-Dieu, Paris. By A. Trousseau, Professor of Clinical Medicine in the Faculty of Medicine, Paris, etc. Translated and Edited with Notes and Appendices by P. Victor Bazire, M.D. Lond. and Paris, Assistant-Physician to the National Hospital for the Paralysed and Epileptic, etc. London: Hardwicke. 1866. Pp. 276. Part. I.

This book furnishes us with an example of the best kind of clinical teaching, and we are all much indebted to Dr. Victor Bazire for supplying the Profession in England with a translation of M. Trousseau's admirable lectures; for, whatever may be said to the contrary, it is only when such books come to us in the dress of our own vernacular that they obtain an extensive circulation in this country. French and German works are doubtless read largely, but it is mainly by a superior class of men that this occurs. There is a certain amount of trouble involved in studying the originals which a great many busy men cannot or feel disinclined to take, and to such some of the most valuable contributions made on the Continent to Medical literature are as if they did not exist. Now, this is a book which deserves to be popularised, and we scarcely know of any work better fitted for presentation to a young man when entering upon the practical work of his life. The delineation of the recorded cases is graphic, and their narration devoid of that prolixity which, desirable as it is for the purposes of the man who is about to subject them to an extended analysis, is highly undesirable when the object is to point a practical lesson. The translation, so far as the Anglicising goes, is perfect; it does not read, as some similar productions do, *like* a translation; and this is saying a great deal in its favour. The only objection we have to make on this score is, that the Anglicising has, we think, been carried a short step too far, and that it would have been as well in those instances where examples of efforts at speech on the part of some patients are described to have employed the French words which were pronounced instead of giving them in English. This, however, is a very trivial defect, which may well be condoned good-naturedly. Having said this much of the general character of the work, we may proceed to review it more at length.

The translator has exercised a sound discretion in subjecting the lectures to re-arrangement. The present volume contains lectures upon Venesection in Cerebral Hæmorrhage and Apoplexy, upon Apoplectiform Cerebral Congestion and its Relations to Epilepsy and Eclampsia, upon Epilepsy, upon Epileptiform Neuralgia, upon Glosso-laryngeal Paralysis, Progressive Locomotor Ataxy, and upon Aphasia. Now, of course, we cannot be expected to review all these lectures. Like most of those we address, we shall content ourselves with sitting humbly "at the feet of Gamaliel," and presenting a few samples of the teaching that issues from his lips.

The first two lectures treat of a most important subject—apoplexy, cerebral hæmorrhage, cerebral congestion, epilepsy, eclampsia, and the therapeutic application of blood-letting in relation to these diseases. The opponents to blood-letting in such cases will be glad to be strengthened by the authority of a man of M. Trousseau's extended and mature experience; while probably such as still adhere to the practice of their early instructors will be induced to reconsider the subject in the light thrown upon it by the facts and arguments of the author. The extreme rarity of apoplexy, using the term in its classical signification, is much insisted upon by M. Trousseau. He tells us that in his long experience he has *never once* seen a patient struck down suddenly by apoplexy, either in his Hospital, private, or consulting practice; *without exception*, wherever the attack had occurred in the presence of witnesses, it had come on gradually, had generally been slight at the outset, coma supervening in from ten minutes to several hours afterwards. "In no single instance, I repeat, have I seen a man with cerebral hæmorrhage struck down as by a blow, and dropping instantly into a state of unconsciousness." With regard to the softening of the brain substance found often associated with cerebral hæmorrhage after death, M. Trousseau holds the doctrine that it is an effect, not the cause of the hæmorrhage, neither does he believe that the changes that are often observed in the coats of the blood-vessels are an essential condition for its production. M. Trousseau has entirely abandoned the use of blood-letting, purgatives, and revulsives in apoplectic seizures, and for the best of all reasons, namely, that experience has taught him that patients do better without them. But in addition to this, the grand test of any therapeutical practice, he appeals to the analogy between cerebral and other hæmorrhages, as, for instance, where extravasation takes place under the skin, in which latter case no one would expect blood-letting to facilitate the absorption of the effused blood; and as to its use in arresting the "molimen hæmorrhagieum," he considers, and proves at length in another lecture, that the part played by congestion has been greatly exaggerated. He regards, and we think truly, the apoplectic phenomena as more allied to syncope than to congestion, and that bleeding is, therefore, contra-indicated, not demanded. "Instead of bleeding my patients, or putting them on low diet, and keeping them in bed, I do not draw blood from them, I recommend to them to get up if possible—at least, to remain in the sitting posture—and I feed them." When febrile action occurs, as it rarely fails to do in hæmorrhage of a certain amount, M. Trousseau still abstains from the lancet. Still he points out how difficult it is under such circumstances to do so when a young Practitioner is opposed by the prejudices of a patient's friends, or by the authority of any one older and more experienced than himself. His advice is—"Save your responsibility in such cases" (for in such the fever often ushers in fatal brain symptoms), "avoiding at the same time what your conscience forbids, open a vein, but in such a way as only to draw an insignificant quantity of blood, and explain to the friends that it would be dangerous to go further."

As respects the diagnosis between cerebral hæmorrhage and softening as the cause of hemiplegia, M. Trousseau affirms the proposition of Recamier that "when hemiplegia, complete and absolute, occurs *suddenly* (and I insist on this point—the suddenness of attack) without loss of consciousness, softening of the brain may be diagnosed. Whenever, on the contrary, the complete loss of motor power is attended by loss of consciousness—whenever, especially, the individual has become suddenly comatose, hæmorrhage may be diagnosed, and hæmorrhage to a considerable amount. But when the intellect is affected to some extent, but not entirely—when there is obtuseness, but not complete loss of sensibility—whilst there is absolute loss of motor power, as in the case of our patient in St. Agnes ward, we must always, according to Recamier, diagnose hæmorrhage in connexion with softening, or what has been termed capillary hæmorrhage."—P. 14. Another interesting point is referred to. It is well known that, as a rule, in hemiplegia, when amendment begins to take place, the earliest improvement is observed in the motor power of the lower extremity, and the weakness persists longest in the upper. M. Trousseau, however, adds that when the reverse obtains, and the arm regains power quicker and better than the leg, the patient is worse off. "Three years ago I was sent for to see a general officer, a near relative of mine.

He had been seized that morning a little before breakfast with paralysis of the right side. For three or four days after this his symptoms looked unfavourable, but fever soon ceased, and a fortnight after the attack he could write, shave himself, and walk pretty well. The extreme precision of the movements required for writing and shaving showed clearly enough that his arm was considerably better than his leg, for he walked very lame. After the lapse of a few months his leg became stiff and painful, and he walked with more difficulty. A stick was no longer enough for him, and he required the help of a friend's arm; later, even with this help, he was unable to walk. At that time the arm itself began to lose power, and the intellect failed in proportion. Subsequently the poor man could not leave his arm-chair, and suffered excruciating pain in the paralysed side, especially in the leg. At last he died in a state of perfect imbecility. . . . . Now, gentlemen, if you ask me why our prognosis should be unfavourable when the arm regains power more completely and rapidly than the leg, I must confess my ignorance, and content myself with noting a fact which has often enough occurred in my practice to have attracted my attention. I cannot say whether a morbid process goes on round the clot causing chronic softening or irregular cicatrices, but whatever the cause may be the fact remains, and seems to me to possess some value." —P. 16.

M. Trousseau does not believe in cerebral congestion as the cause of any variety of apoplexy. The cases of so-called "apoplectiform cerebral congestion" he regards as truly cases of epilepsy. Neither does he regard congestion as playing any important part in the phenomena of apoplexy. The stupor of apoplexy he regards as due in part at least to what he terms "*cerebral surprise;*" and he holds that "the same cerebro-spinal modification which causes the fit of epilepsy or eclampsia (which two conditions M. Trousseau regards as pathologically identical), the insultus, the ictus epilepticus, is sufficient to produce the apoplectic stupor which follows it." —P. 36.

We will now turn to the end of the volume—the lecture upon aphasia—which M. Trousseau commences with the brief narration of a series of most interesting cases, upon which, amongst other conclusions, he bases the following:—That aphasia is produced in nearly all cases by an injury to the frontal lobes of the cerebrum, and that this lesion is almost exclusively confined to the left hemisphere, repudiating altogether thus the explanation of those who would account for the habitual association of aphasia with hemiplegia of the right side of the body by placing the organ of the manifestations of thought by speech in the two anterior lobes of the brain. He says "there is no doubt that the intellect is deeply injured in aphasia, and when the affection gets well under our eyes, as it pretty frequently happens, we witness day after day the resurrection of the faculties, and we see them progress exactly as in the convalescence of a grave disease; we see physical aptitudes return day after day." He narrates cases in proof of this, and amongst others that of a man called Paquet, who sometimes read all day long and seemed to understand what he read. "The following experiment proved categorically that he understood much less than he seemed to do. I took up his book and read aloud a few lines at the bottom of a page, asking him to follow me with his eyes, and to turn the page when I came to the last line, but he never could do it correctly." This man read the same tales over and over again, and always with the same degree of attention—a task which no one who recollected what he read could tolerate—yet a remarkable thing about him was that he played draughts and dominoes pretty well, and was cunning enough to cheat at the game and enjoy the joke. M. Trousseau remarks also upon those remarkable cases of aphasia where the intellect is only partially impaired. He regards the condition as one not involving merely a defect of co-ordination of the movements necessary for phonation, but as dependent upon amnesia, and this of a kind which leaves certain kinds of memory untouched. This he holds is not strange when we consider that among healthy persons some possess a strong memory for certain things while others readily escape them. "One man has a good memory for localities, another for names, a third for dates or for figures, and each of these *varieties* of memory, if I may be allowed the expression, is independent of the rest. So that, if it were admitted that an aphasic patient suffers after all from loss of memory, it should be added that he has lost all recollection of the mode of expressing thoughts in writing, in speaking, and by gesture.—P. 270.

We content ourselves with this very partial review of the volume, because we believe we have said enough to induce the Profession in England, now that the book is so accessible, to study it carefully for themselves.

Traite Théorique et Pratique des Maladies de l'Oreille et des Organes de l'Audition. Par le Dr. J. P. Bonnafont.

A Treatise on Diseases of the Ear. By Dr. J. P. Bonnafont, etc., etc. Paris: Baillière et Fils.

This volume is a very valuable contribution to the little-studied branch of Surgery of which it treats. It is, at any rate, free from quackery, and contains a large number of well-observed and well-treated cases. Dr. Bonnafont's strong point appears to us to be manipulative Surgery, in respect to which the procedures he recommends are often very skilful and ingenious, though we have sometimes found simpler methods efficient. Dr. Bonnafont, for example, uses various curved knives and scissors for the removal of polypi, introducing them close to the root, a proceeding requiring some delicacy; we find, however, the ordinary snare armed with a moderately firm fish-line (which is much better than any metal wire) quite sufficient. Dr. Bonnafont also does not seem to be aware of the great efficacy of mildly astringent or absorbent powders, combined with other suitable treatment, in aiding the permanent removal of these growths, frequently so obstinately recurrent. Our author is a great advocate for artificial perforation of the membrana tympani, a proceeding which, he says, if judiciously performed, would benefit one-fifth of all cases of deafness. The only affections in which he recommends it are diseased conditions of the membrane; never in obstruction of the Eustachian tube, which, he says, invariably yields in his hands to the persevering use of elastic bougies, gradually increasing in diameter from about half a line to a line and a half. When the membrana tympani is thickened and the nervous power is unimpaired, perforation, by his statement, almost invariably succeeds—that is, it succeeds for a time; for unhappily (if it be unhappy) such artificial orifices are exceedingly hard to keep pervious. In fact, Dr. Bonnafont says he has never succeeded in doing so, though he has introduced bougies, cauterised, and in one case constructed a canula, expanding at the extremity by a spring, which the patient wore through the orifice for forty-five days, but it healed up afterwards, to the patient's and Doctor's great regret.

In this last respect our experience in the main agrees with Dr. Bonnafont's, though we have in some few cases seen artificial perforations continue permanently open; why, we cannot exactly tell. Nor do we know exactly (being unable here entirely to agree with our author) why it is that perforation of the membrane succeeds when it does succeed, or fails when it does not. Certainly it is by no means successful in all cases of thickening of the membrane with good nervous power; and we have found it beneficial for the time it lasted when the membrane was not thickened, but thin, relaxed, and soft. It is difficult to ascribe the benefit of the operation in such cases as these to its effect upon the membrana tympani itself, when we see continually with what disordered, degenerate, relaxed, softened, hardened, thickened, and thinned membranes a very tolerable hearing may coexist. To our mind the subject seems to need further light, and we look for it with great hope in a more exact knowledge of the relations between the membrane and the ossicula, and through these between the former and the tension of the labyrinthine fluids, and other conditions essential to perfect hearing. We agree with Dr. Bonnafont that some method of keeping open an incision in the membrana tympani is a desideratum in Surgery. So also, though in a less degree, is a method of inducing the healing of ulcerated ones, on which our author gives us less information. A great deal, however, may be effected in this direction. The chief condition of success appears to us to be to make and to keep the exposed tympanic cavity free from accumulations of secretion. This is often difficult, on account of the sac-like form of the tympanum, and still more on account of the viscid and tenacious character of the secretion itself, which is often quite irremoveable by any amount of syringing. We have found, however, that by filling the meatus with a warm solution of sulphate of zinc, and passing at the same time a current of air freely through the Eustachian tube—either by the patient blowing with closed nose, or by inflating the nasal cavity while the patient swallows—the secretion may be coagulated, and by patience the cavity may be entirely cleared. The rapidity with which

healing of a perforated membrane sometimes ensues upon a persevering employment of this plan is remarkable. It is by no means always the case that an improvement of hearing immediately ensues; sometimes there is a diminution, probably from contraction or the formation of adhesions, which, however, is not necessarily permanent.

The great idea of Dr. Bonnafont's book, on which he particularly prides himself, is one from which, regretfully (for his enthusiasm is almost catching), we are obliged to dissent. He holds that affections of the nervous apparatus, and of the conducting media, may be absolutely distinguished by the degree to which the power of hearing sounds conveyed through the bones of the head is retained or lost. For this purpose he uses various watches and tuning-forks, and he claims to be the first person who introduced the practice. We are afraid it must be said that experience does not support the notion, plausible though it is. The state of the tympanum appears very powerfully to influence the perception of sounds conveyed by the cranial bones; and, though we may probably say of a person who hears well a variety of sounds through this channel, that his auditory nerve can hardly be much amiss, the converse certainly does not always hold good. Deaf persons also are sometimes met with who hear a tuning-fork very badly when placed on the top of the head, but very fairly when placed on the teeth—that is, of course, as compared with other persons not deaf. There are some, also, in whom a pressure on the meatus greatly deadens a sound conveyed through the skull, and in whom, therefore, it can scarcely be doubted a pressure arising *within* the tympanum would have a similar effect.

We fear that all the large part of the volume before us which is devoted to the illustration of this theory must be held doubtful, and that we must be content to grope farther for a satisfactory method of diagnosing in all cases between tympanic and nervous deafness—the great want (among many great ones) of Aural Surgery. Not that the indications given by this means are valueless; they are only insufficient, and other symptoms (as, for example, some pertaining to the differing effects of pressure on the perception of bone-conducted sound) promise ere long to advance our knowledge on this knotty point at least one step farther. In the future, also, doubtless the results of ophthalmoscopy will be found more or less available for the interpretation of the affections of the kindred organ.

Some interesting physiological observations precede the practical part of Dr. Bonnafont's volume. He is of opinion—and our own examination supports his view—that the tensor tympani and stapedius muscles act in opposite ways upon the membrana tympani, the tensor moving the malleus somewhat forward and rendering the posterior fibres of the membrane tense, at the same time relaxing the anterior ones, and the stapedius relaxing the posterior and tensifying the anterior. He conceives accordingly that different parts of the membrane are subservient to the audition of different pitches and kinds of sounds; the longer anterior radiating fibres receiving grave sounds, the shorter posterior fibres responding to acute ones, and that the opposing muscles are called into play accordingly to fit each part of the membrane for its special function. Dr. Bonnafont even thinks that in cases of perforation he has been able to distinguish a special deficiency to certain classes of sounds, according to the portion of the membrane that was wanting—a point that surely deserves a minute testing. The tensor tympani muscle is more powerful than the stapedius, because acute sounds, for which it has to adapt the short posterior fibres, require a higher tension.

One unaccountable statement in the volume we cannot overlook. Dr. Bonnafont describes (page 18) the membrana tympani as "dry and deprived of blood-vessels and nerves." This must surely be an oversight. The author himself, in another page, records how he has seen the membrane become of a bright red colour from filling of its vessels under the influence of loud and acute musical notes, and in yet another tells us how he touches it with a blunt probe before incising it, in order to deaden its sensibility. Not many such slips as these, however, are to be met with in his book, for which all who look with interest on the progress of this department of Surgery must heartily thank him.

Bequests.—Mrs. Rosetta Waddell, of Halford House, Regent's-park, has bequeathed £200 to St. Bartholomew's Hospital, and £50 each to King's College and the Charing-cross Hospitals.

GENERAL CORRESPONDENCE.

THE AUGUST EXAMINATION FOR THE ARMY.

[To the Editor of the Medical Times and Gazette.]

Sir,—The Director-General of the Army Medical Department has begun to advertise for candidates for the competitive examination in August next. Now, I have no hesitation in saying that if he succeeds in obtaining young men for his Department, all hope of any change in the present state of things will be gone.

I am induced to place a few facts before your readers:—

1. There are upwards of 800 Assistant-Surgeons in Her Majesty's army, and the present rate of promotion is from thirty to forty per annum.

2. The mortality amongst the very junior ranks of the Army Medical Service is so great that it attracted the attention of an eminent statist some years ago.

3. The batch of Medical candidates before the last thought so little of their prospects that they memorialised to be transferred from the British to the Indian Army.

4. The last batch of candidates is said to have been attracted by the publication of the Report of the late Committee; if so, these gentlemen will have ample time to enjoy their little illusion. One thing is quite clear—viz., their coming forward has been a sufficient reason for the Government deferring all action in the matter. I am, &c.

May 29. Sauve qui Peut!

OBITUARY.

DEATH OF JAMES T. ALEXANDER, ESQ.

The Edinburgh papers record the death of this gentleman, who was well known, not only as a Surgeon but as the senior magistrate of the Scottish metropolis. Bailie Alexander was an able and active magistrate, and it appears that his death was hastened by his devotion to the public service. He had been for some time suffering from organic disease, which had been kept in abeyance by strict Medical regimen. "Unhappily," says the *Daily Review*, "his anxiety to be present at the recent Licensing Court led him to disregard the restraint imposed upon him, and the symptoms of his trouble returned in a more serious form, and advanced rapidly during the past fortnight towards an unfavourable termination. He had the regular and frequent visits of Dr. Smart, and the advice of Professor Syme, Dr. Begbie, senior, and Dr. Patrick H. Watson, for consultation; but the malady was of too obstinate a character to yield to the remedial measures employed."

In his public capacity he distinguished himself by his care of the charities of the City. The same paper states that "He was one of the two trustees appointed under the settlement of the late John T. Mackenzie, Esq., of Manor-place. Along with his colleague, the late Richard Gordon, Esq., of Halmyre, he had the disposal of several thousands of pounds from Mackenzie's Trust, for charitable purposes; and at various times he granted sums of money to benevolent institutions, with discriminating liberality. He took a great interest in the Magdalene Asylum, and in the Training House for Friendless Girls; and one of the last acts of his public life was to hand over the new asylum at Dalry to the trustees free of debt, he having given £2500 to the Building Fund of that Institution. It was a most congenial occupation for Mr. Alexander to be helpful to such institutions; for though of an ardent and hasty temperament, his kindly disposition and genuine delight in being serviceable to the unfortunate was well known to all his friends, and to none better than to the poor of St. Cuthbert's parish, where he was for many years a district Surgeon. It is a good many years since a magistrate of the city has died in office; and though not of a strong constitution, Mr. Alexander was one of the last who would have been thought near the termination of his career, so full was he of cheerful animation and heartiness in all his intercourse with his friends and the public.

The College Lectures.—Professor Hancock will commence his course of lectures on Monday next, at 4 o'clock, in the theatre of the College of Surgeons, and deliver six lectures on the Anatomy and Surgery of the Foot.

BOOKS RECEIVED.

The Indian Medical Gazette: a Monthly Record of Medicine, Surgery, Obstetrics, Jurisprudence, and the Collateral Sciences, and of Medical Intelligence, Indian and European. Pp. 24. Nos. 1 and 2. Wyman, Calcutta.

*** No. 1, January, 1866, opens with an introductory editorial, stating that, though well aware of previous failures and present impediments, the conductors of the *Indian Medical Gazette* look cheerfully to the future, and desire to make their paper "the medium of really practical knowledge," and the stimulant of good fellowship between the members of our Profession. Dr. Heckford, of Calcutta, has papers on Syphilitic Cirrhosis, Obscure Cases of Renal Disease, and Atalactasis Pulmonum. Dr. A. M. Mantell describes a male hermaphrodite, 50 years old, considered by his or her friends and himself a woman. Baboo Chatterjee gives some important statistics of tetanus for the last four years. Mr. C. P. Costello a Case of Popliteal Aneurism Cured by Combined Pressure and Flexion. An important and extraordinary case of recovery after wounds and protrusion of the intestines is recorded by Mr. J. F. Barter, who ought to report it more at length. Dr. Fleming relates the history of an abdominal aneurism. Mr. Reddie contributes interesting cases from practice. Professor Fayrer proposes that a man show should be held in Calcutta. There is a list of Indian Medical plants by Dr. Waring, whose researches into native resources are, both financially and commercially, likely to be of great benefit to the Government. The article finishes with a list of indigenous drugs by Baboo Loll Dey, extracts from European journals, and Correspondence. No. 2, February, 1866, contains several very valuable papers on Linear Extraction, by Dr. C. Macnamara; on Cholera, by Mr. Switzer; Practical Observations on European Life in India, by Mr. Macdonald; on the Physiological Effects of Quinine, by Dr. Farquhar. Cases of practice are contributed by Surgeon-Major Goldie, Mr. Dymock, and Drs. Palmer, Fayrer, and Partridge. The English correspondent's letter is interesting. The *Indian Medical Gazette* is well got up, and promises to be a success.

On Sewer Rivers. (Manchester Statistical Society.) By George Greaves, M.R.C.S., Cons. Med. Officer, to Charlton Union Hospital, Lecturer on Obstetric Medicine, formerly Lecturer on Forensic Medicine and Public Health, Manchester Royal School of Medicine. Pp. 24.

*** An attempt, and a successful one, too, to show that the present mode of dealing with the night soil in favour with the authorities at Manchester, is the best that could be imagined for the generation of fœcal emanations, and their retention in and about the house of the inhabitants. Manchester has a high death rate, and the author believes that it will not be materially lessened until the filth which is now retained within the majority of houses be washed away and carried, not into the rivers, but by special channels away from the city, where it may be harmless. This idea is well and solidly worked out.

A Visit to Vichy. By Prosser James, M.D. Pp. 50.

*** Comprises a sketch of its mineral springs, thermal establishment, and a summary account of the medicinal uses of the waters, salts, and lozenges, written in a pleasant style, and well adapted to give those who have no inclination to go deeply into matters, practical information.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following Members of the College, having undergone the necessary Examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 30th ult.:—

James Cotton Byles, L.S.A., Albert-terrace, Victoria-park-road, Diploma of Membership dated June 24, 1859; George Shannon, M.D. Queen's University, Ireland, Magherafett, Co. Derry, January 26, 1864; John Murray Gibbes, M.B. and M.C. Aberdeen, Sidmouth, Devon, November 15, 1865; Hugh Ferguson, Haverstock-hill, April 24, 1866; David Hawley Burn Anderson, April 24, 1866; John Mildred Creed, Melbourne, Australia, April 24, 1866; Frederick Stocks, Wakefield, April 25, 1866; William French Thurston, South Bank, Notting-hill, April 27, 1866; Joseph William Smith, Weaverham, Cheshire, April 27, 1866; Joseph Riley, Barnes, April 27, 1866; David Johnstone, Magherafett, Co. Derry, May 22, 1866; and Reuben Bolton, M.D. and M.C. Queen's University, Ireland, 1865, Bangor, Co. Down (not a Member).

It is stated that three out of the fifteen candidates failed to acquit themselves to the satisfaction of the Board.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 24, 1866:—

Rowland Hills, Conisboro', Doncaster; Charles Aveling, St. Thomas's Hospital; Edward England Phillips, Norfolk-crescent, Bath; John Williams, Fishguard, Pembrokeshire.

The following gentlemen also on the same day passed their First Examination:—

Frederick William Salzmann, Guy's Hospital; Frederick Smith, Westminster Hospital; Thos. Henry Hickman, St. Bartholomew's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ORTON, CHARLES, L.R.C.P.E., M.R.C.S. Eng., has been appointed one of the Medical Officers to the North Staffordshire Infirmary.

BIRTHS.

BOWER.—On May 26, at 2, Clarence-villas, Windsor, the wife of E. Bower, M.D., of a daughter.

GRENFELL.—On May 22, at 3, Clarence-street, Penzance, the wife of Henry Grenfell, M.R.C.S., of a son.

MIDDLETON.—On May 23, at Brussels, the wife of J. W. Middleton, M.D., of a daughter.

ORTON.—On May 28, at Newcastle-under-Lyme, the wife of C. Orton, L.R.C.P., of a daughter.

PHILLIPS.—On May 22, at Oxford-road, Manchester, the wife of C. D. F. Phillips, M.D., of a son.

SPENDER.—On May 21, at 37, Gay-street, Bath, the wife of J. K. Spender, M.R.C.S., of a daughter.

WEBB.—On May 19, at 9, St. George's road, Pimlico, the wife of E. L. Webb, M.R.C.P., of a son.

MARRIAGES.

EBBAGE—JEAFFRESON.—On May 24, at the parish church, Edmonton, T. Ebbage, F.R.C.S., of Leamington, to Amelia, elder daughter of the Rev. C. Jeaffreson, M.A.

HALL—FIRTH.—On May 24, at the parish church, Sheffield, W. Hall, M.R.C.S., to Sarah, elder daughter of W. Firth, Esq.

HARRIS—JEAFFRESON.—On May 24, at the parish church, Edmonton, W. John Harris, M.R.C.S., of Worthing, to Florentia Caroline, younger daughter of the Rev. C. Jeaffreson, M.A.

PROBERT—MORGAN.—On May 29, at the parish church, Bedwas, J. Probert, Surgeon Plymouth Iron Works, Merthyr Tydvil, to Anne, youngest daughter of the late T. Morgan, Esq.

DEATHS.

BRADSHAW, F., L.R.C.P.E., at Sierra Leone, on April 6, aged 28.

BROUGHAM, S., M.R.C.S., at Falmouth, on May 20, aged 72.

GILLELAND, W. L., M.D., at Castle-street, Hereford, on May 21.

RITCHIE, D., M.D., at Dalgairn, Cupar Fife, N.B. (late Deputy-Inspector-General of Her Majesty's Bombay Medical Service), on May 24.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Braintree Union.—The Finchingfield District is vacant; area 8387; population 2441; salary £50 per annum.

East Retford Union.—Mr. Johnstone has resigned the Scrooby District; area 2572; population 373; salary £2 per annum.

Faversham Union.—Mr. Adams has resigned the Fourth District; area 11,640; population 3572; salary £69 per annum.

Helston Union.—Mr. Joseph Williams has resigned the Third District; area 18,862; population 9308; salary £53 per annum.

APPOINTMENTS.

Dewsbury Union.—John Whitworth, M.R.C.S.E., L.S.A., to the Workhouse.

Hay Union.—Joseph E. Smith, M.R.C.S.E., L.S.A., to the Herefordshire District and the Workhouse. Adam L. Bogle, L.F.P.&S. Glas., M.R.C.S.E., to the Radnorshire District.

South Shields Union.—Jacob S. Denham, M.R.C.S.E., M.D.Glas., to the Workhouse.

PARLIAMENTARY.—In the House of Commons, on Wednesday, May 30, the Nuisances Removal Bill was read a third time and passed.

NEW DISTINCTION CONFERRED ON A PHYSICIAN.—The *Gazette* of Friday, May 25, contains the appointment of William Mackenzie, Esq., M.D., C.B., Deputy Inspector-General of Hospitals, Madras establishment, to be a Companion of the Most Exalted Order of the Star of India.

USEFULNESS OF MEDICAL MEMBERS IN PARLIAMENT.—Sir M. Farquhar was seized with an attack of illness on Monday evening, and fell down in one of the lobbies of the House of Commons. In the course of a few hours he was so far recovered as to be removed to his home under the care of Dr. Brady and Mr. Clement, M.P.'s.

RECOVERY FROM DROWNING. — At Newport, Isle of Wight, a child of three years fell into a millstream, and was not taken out until it had been more than ten minutes in the water. It was, however, restored to life in an hour and three-quarters by Mr. Porter, who acted upon the directions of the Lifeboat Society.

THE CHARTERHOUSE.—The Governors of the Charterhouse have appointed Dr. Frederic J. Farre, F.L.S., Physician of the Charterhouse. Dr. Farre was captain and gold medallist of Charterhouse School about the year 1822, and graduated 32nd wrangler of St. John's College, Cambridge, in 1827, proceeding M.D. in 1837. In 1838 he became F.R.C.P., in 1841, 1842, and in 1854 was a Censor of the College, and in 1846, 1847, 1848, a member of the Council. He was lecturer on Materia Medica at the College 1843-5, and is Physician and lecturer on Materia Materia to St. Bartholomew's Hospital, Consulting Physician to the London Ophthalmic Hospital and to the West City Dispensary.

College of Science for Ireland.—The Commission on the College of Science for Ireland, appointed by the Lords of the Committee of Council on Education, met on May 17, and has held several meetings during the past week. The following members attended:—The Earl of Rosse, Lord Talbot de Malahide, Dr. Carpenter, the Rev. B. M. Cowie, Professor Frankland, Mr. Gregory, M.P., Colonel Harness, R.E., Professor Huxley, Professor Jukes, Sir R. Kane, General Sabine, Professor Sullivan, Professor Tyndall, and Captain Donelly, R.E.

Sutton and another *v.* Imoff and Another.—The partner of the plaintiff in this action was Mr. John Potter Sargeant, whose name, it will be recollected, was recently erased from the list of members of the Royal College of Surgeons, and from the Medical Register. The action arose out of the transactions which led to the conviction of Sutton and Sargeant for forging the label of Messrs. Broadwood, the pianoforte manufacturers. After a protracted trial the jury separated, without being able to agree on a verdict.

Ladd *v.* Fennemore—Nisi Prius, Westminster, May 26.—This was an action brought to recover a sum of £21 for Surgical attendance upon the mother of the defendant, and services rendered in curing her of a fracture of the leg. The defendant denied his liability to pay more than seven guineas, which sum was brought into court. The plaintiff, however, claimed 20 guineas, being, as he alleged, the amount agreed upon between himself and the defendant. The defendant denied *in toto* that any such agreement as that set up had been entered into, and on this point the evidence of the plaintiff and the defendant was, as Mr. Justice Keating observed, "unhappily" contradictory. The jury found a verdict for the plaintiff for £13 13s., being the difference between the sum paid into court and the amount which the plaintiff said that the defendant had agreed to pay. Immediate execution was granted.

On May 28, at a meeting of the Royal Dublin Society, Dr. Mapother read a valuable paper on labourers' dwellings, which was followed by a discussion on the sanitary condition of the working classes, and the best means of promoting their health and comfort.

Charge of Criminal Abortion.—At the Birmingham Police Court, on May 25, Ellen Elizabeth Owen, 37, better known as Madame Owen, of Lease-lane and Summer-lane, Birmingham, herbalist; Wm. Vernon Smith, 54, Surgeon, residing in Harding-street, and Wm. Bromfield, were charged with conspiring together and inducing a young woman named Elizabeth Ellsmore, 22 years of age, to procure abortion. The girl is said to be suffering from the effects of an operation alleged to have been performed by Smith, and as her life seemed to be in danger, her deposition was taken by a magistrate. It was to the effect that she had applied to Owen at the instigation of her paramour Bromfield, and taken two quantities of pills given her by Owen, that these had produced no effect, and that then she had undergone an operation at the hands of Smith, and had been subsequently delivered of twins. The prisoners were remanded. *** The girl has since died. We do not find the name of W. Vernon Smith in the Medical Directory.

Workhouse Medical Officers.—The Poor-Law Board has recently addressed to the Medical officers of the London Workhouses a series of questions concerning the present accommodation, nursing, and treatment of the sick poor in workhouse infirmaries, and having asked for suggestions on the subject, the Medical officers met on Wednesday in conference at the Freemasons' Tavern, and agreed upon certain principles which should guide their answers. A resolution was passed unanimously that pauper nurses were insufficiently trained and untrustworthy, and should be substituted by paid nurses. On the subject of space it was resolved that not less than 1000 cubic feet of air and 80 feet of area per bed could be asked for to sick paupers, that being the allowance of sick convicts, and less than the allowance of sick soldiers. In military Hospitals 1200 feet is the minimum, and the London Hospitals give from 1500 to 2000 feet. The present average in infirmaries of workhouses is about 500 feet, often less, and 30 to 40 feet of area per bed. As to light, they asked for one window to two beds, which is the military allowance. One Medical officer said that he had only one to 4½ beds, and others had less light than that. Instances were quoted by Medical officers present to illustrate the importance of having resident Medical officers, and of relieving the Medical officer from the charge of providing the drugs which he prescribes. In order to carry out these requirements and to give day rooms to the infirm it was stated that every workhouse in London would require to be considerably enlarged, and that a majority would need to be reconstructed in a manner to fit them for receiving sick persons.

Royal College of Surgeons.—The Fellows of this Institution have just received the annual invitation to attend in the hall of the College on Thursday, the 5th day of July, to proceed to the election of two Fellows into the Council in the room of Messrs. James Luke and John Hilton, who go out by rotation, but who are eligible for re-election. Enclosed in the circular are extracts from the charter relating to these elections, from which it appears that unless any new candidates are brought forward within ten days from this date (June 1), the whole will be a *pro formâ* affair, and will end in the re-election of the above-named gentlemen. The names of certain Fellows have been mentioned as likely to be nominated; but at the hour of going to press no candidates had appeared. From an examination of the roll of the Fellows, the following names appear according to seniority—viz., Messrs. Travers, Erasmus Wilson, Holthouse, Gay, Ure, De Morgan, Dixon, Hewett, and Charles Hawkins. In the provinces, appear Carden, of Worcester; Jordan, of Manchester; Jackson, of Sheffield; Parker and Middlemore, of Birmingham; Hey and Teale, of Leeds; Smith, of Bristol; Long, of Liverpool; Embleton, of Newcastle; Hammond, of Cambridge, etc.

The College Fellowship.—The first Professional examinations under the new regulations, for the Fellowship of the Royal College of Surgeons of England, commenced on Tuesday last, when six senior and four junior candidates offered themselves, to all of whom the following questions were submitted on the first day in Anatomy and Physiology, viz.:—1. Describe the head and neck of the femur, and the trochanter major in the child. What are the blood-vessels and nerves which supply them? and enumerate the changes which take place in these parts until old age. 2. Describe the various means by which the urinary organs and their appendages are maintained in their position, and all the differences which exist between them in a male child and in an adult. 3. Describe accurately the course of the tendons at the inner and outer ankle and in the sole of the foot, their insertions and relations, and all the functions these tendons perform. 4. Give an account of the structure of the spinal cord. Enumerate the experiments which have been performed with the view of ascertaining its functions. 5. Describe the minute structure of the skin and its appendages, and the functions they perform. 6. By what means is the heat of the animal body produced, regulated, and maintained? On May 31, in Pathology and Surgery:—1. Describe the causes, the symptoms, and the progress of acute inflammation and necrosis of the femur, the several means adopted by nature to effect a cure, and the Surgical aid you would employ. 2. Describe the various fractures which may occur to the neck of the femur, the trochanter major, and the acetabulum, with the symptoms and the appropriate treatment in each case. 3. How are fractures of the base of the cranium caused? What symptoms usually accompany these injuries? What effects may they produce on the brain and cerebral nerves? What treatment would you adopt? 4. Under what circumstances would you consider it advisable to perform the operation of ovariotomy? Describe what would be the best manner of proceeding, the means by which you would secure the bleeding vessels, the difficulties and the dangers which attend this operation, the after treatment, and the proportion of cases which prove fatal. 5. Under what circumstances is it necessary to remove the astralagus? Describe the difficulties which attend this operation, and the probable results. 6. Describe the various diseases of the iris and the accidents to which it is subject, the effects they produce, and the constitutional and Surgical treatment you would employ for their cure or relief.

Jacksonian Prizes.—The Council of the Royal College of Surgeons has just announced the following as the subjects for the above prizes for the present and succeeding years, viz.:—*Jacksonian Prize of Twenty Guineas.*—There are two subjects for prizes for the present year, 1866—namely, "Ovariotomy; Pathology and Diagnosis of Cases suitable for the Operation, with the Best Method of Performing it, and the Results of recorded Cases;" and "Fractures into Joints; their Modes of Union, with the Treatment and Result. The Dissertation to be illustrated by Cases, Preparations, and

Drawings." There are also two subjects for prizes for the ensuing year, 1867—namely, "The Injuries and Diseases of the Jaw, including those of the Antrum, with the Treatment by Operation or otherwise; the Dissertation to be illustrated by Preparations and Drawings;" and "The various Deformities resulting from Severe Burns on the Surface of the Body, the Structural Changes occasioned by these Injuries, the best Modes of Preventing Deformities, and the Treatment, Operative or otherwise, adapted to Correct them; the Dissertation to be illustrated by Cases, Drawings, Photographs, and Casts.——*The Collegial Triennial Anatomical Prize of Fifty Guineas.*—The subject of this prize is "The Anatomical Structure of those parts of the Eyeball which are contained within the Sclerotic and Cornea; with illustrations drawn from each of the Five Great Divisions of the Vertebrata." The dissertations for these prizes are to be sent in on or before Christmas Day, 1866 and 1867 respectively.

PRESENTATION TO A MEMBER OF THE MEDICAL PROFESSION.—The members of the Liverpool Medical Institution have recently presented a valedictory address to James Dawson, Esq., F.R.C.S., of Wray Castle, Windermere, who was one of the chief promoters in founding the Institution some thirty years ago, and who has ever since maintained a warm interest in its progress—having on several occasions given liberal donations towards different objects for the improvement of the building. The address, engrossed on vellum and illuminated in the highest style of art by Messrs. W. and J. Audsley, of Liverpool, and handsomely bound in morocco, was as follows:—"To James Dawson, Esq., F.R.C.S. We, the undersigned, members of the Liverpool Medical Institution, cannot allow the occasion of your ceasing to hold the office of President to pass away without recording our high appreciation of the valuable services you have rendered in the long period of twenty-six years during which you have occupied that important official position. We desire gratefully to acknowledge the cordial co-operation and the substantial aid you have from time to time afforded us in carrying out various efforts to increase the efficiency of the Institution with the rise and progress of which your name has been so honourably and so usefully identified; and we gladly avail ourselves of this opportunity of recognising the due regard for the duties as well as for the privileges of Professional reputation and success evinced by you, in thus maintaining in your retirement from the active duties of your Profession, and in the removal from the scene of your early labours, an unceasing interest in the prosperity of a Society which has proved so valuable and so useful to the Medical Profession of your native town. With every sincere wish that you may yet be spared to enjoy much happiness in your peaceful retirement. We remain, dear Sir, your faithfully." (Here follow eighty-seven signatures.

This Return shows that 1932 attacks were reported to have occurred during the week ended May 19, being an increase of 20 on the previous week.

A considerable, but varying, number of "back cases" are reported every week. These cases, however, do not necessarily relate to the previous week only; they generally comprehend arrears of from six to eight weeks, and, in some instances, a longer period.

Note.—4 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Cambridge, 2; Cumberland 1; and Salop, 1. These inspectors returned 51 cases last week.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

We are compelled to postpone Dr. Beale's reply to Dr. Moxon's observations till next week.

A Candidate.—The list of those gentlemen who underwent the examinations on Tuesday, Wednesday, and Thursday for the Fellowship of the College of Surgeons cannot be published until after the names have been submitted to the Council by the Court of Examiners.

A Reader.—Whilst there are in Dublin such eminent Surgeons as Mr. Hargrave, Mr. Butcher, Mr. Tufnel, Mr. Smyly, and others, it would be extreme presumption on our parts to prescribe for you without seeing the case.

A Provincial Fellow.—You will not be entitled to vote at the ensuing election, in consequence of not having signed the bye-laws. We are informed that a great number of Fellows have neglected this duty. Write at once to the Secretary, who will let you know at what meeting you can attend for this purpose before July 5.

Curiosus.—See a very amusing book called "Life in Normandy." You will find there an account of the *poulp pieuvre, alias* gigantic cuttlefish, *alias* kraken. That such a creature could drown and eat a man, or sink a ship, is quite certain, if it were large enough. It is merely a question of dimensions.

Mr. Thelwall, Farndon.—Nothing can be done. The woman's death seems accounted for, and there is no charge against any one. There is consequently no *locus standi.* The conduct of the legal authority does not seem to have been courteous towards the Medical attendants nor such as to secure the fullest account of the facts; but the one point is a matter of taste; for the other he is responsible to the Court of Queen's Bench, if it were worth while to apply to that Court, which it seems not to be.

THE ARMSTRONG TESTIMONIAL—RUDMAN *v.* ARMSTRONG.

The following subscription has been received—A Sympathiser, Bermondsey, 10s.

CHOLERA LITERATURE.

Book Notices.—The lengthened reports which we have felt it expedient to give of the debates in the Medical Council have sadly interfered with our duties, so far as they relate to notices of new books and pamphlets. Cholera literature begins to accumulate, whether relating to theory, prevention, or treatment. Dr. *Duncan*, of Kirkealdy, sends us a sensible pamphlet on Sulphurous Acid Gas as Prophylactic and Curative.—Dr. *Hearne*, of Southampton, strenuously argues for the Non-Contagiousness of Cholera, and the Absurdity of Quarantine. We would refer Dr. Hearne to some most able Memoranda on Asiatic Cholera by Dr. *Wm. Budd*, a Physician whose sagacity is now beginning to be appreciated. Dr. Budd originated the doctrine that cholera (and typhoid) spread by the diffusion of the excretions of the patients. Dr. Hearne will, we think, find all his exceptional and non-contagious cases accounted for by Dr. Budd. "A Memorandum of a Plan of United Action in the Case of an Epidemic of Cholera to be Communicated to Vestries and District Boards by the Metropolitan Medical Officers of Health" blows a loud blast in harmony with Dr. Budd. It bears the *imprimatur* of about forty Medical Officers of Health, and seems to have been drawn up with great care.—Dr. *Burrall* sends a very practical and sensible little volume on Asiatic Cholera (W. Wood and Co., New York)—quite a *resumé* for the practical man who wants to know what to believe and do. He does full justice to English writers.—Mr. *Harry Leach* gives us some Brief Notes of the last Epidemic of Cholera in Turkey. Non-intercourse and treatment of diarrhœa are well insisted on as preventives. Dr. R. J. *Spitta*, M.D. Lond., has issued some Brief Remarks on Cholera, with Practical Rules. He believes that the cholera poison enters the alimentary canal; that there it excites local symptoms, intense irritation, sickness, purging, rice-water stools, etc.; but that, if absorbed into the blood, it there produces the real blue Asiatic cholera, with its symptoms of collapse. Hence the treatment of the premonitory stage is one thing, that of the true cholera blood disease another. Dr. Spitta's pamphlet is so clear, logical, and sensible, that it is well worth a shilling, more particularly as it is short and can be read and digested in ten minutes. Dr. *Austin Flint's* Lecture on the Theory of Elimination as applied to epidemic cholera in the *Medical Record* of New York, May 1, 1866, is a well-planned, heavy, and well-delivered blow at Dr. G. Johnson's theories. He believes "that the practice which the theory of elimination requires is likely to lead to an incalculable loss of life." The current numbers of the same journal contain a series of lectures on cholera by *Dr. A. Clark*, in which Dr. Johnson's views of collapse are treated with great respect, as deserving full criticism, but not absolute acquiescence. Dr. Clark evidently is not satisfied as to the state of the lungs—the very corner-stone of Dr. Johnson's theory, and says, "In a somewhat critical examination of the reports of the post-mortem examinations of many Physicians intrusted with Cholera Hospitals the possibility of 'extreme anæmia' of the lungs in the algide stage had not occurred to my mind till I saw the papers of Dr. Johnson."—*L'Union Médicale* contains an interesting abstract of recent cholera literature in France.

On the Preservation of Vaccine Lymph.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—It is satisfactory to find from your editorial abstract that Dr. Müller, of the Berlin Vaccine Institution, has made practical observations upon the best way of attaining to so important a result as the preservation and storing of vaccine lymph, which observations agree exactly with my own, published exactly sixteen years ago in your journal. I enclose copies of several such communications upon the subject for your perusal, leaving you to decide whether their republication at this time would be attended by any public advantage. It seems to me that no more valuable use could be made of your pages than by opening them in any way you prefer, for the investigation of the best methods of providing for the supply of vaccine lymph, which question is quite the initial problem for the framers of Vaccination Acts to settle.

As soon as I had carefully proved that mixing the vaccine virus with pure glycerine did not (if properly done) impair its efficacy, I called the attention of the Presidents of the London Colleges of Physicians and Surgeons (the late Dr. Paris and Mr. Cæsar Hawkins) to the case of a child I vaccinated with lymph mixed with glycerine six months previously. This was, in every respect, a genuine, well-developed case of the vaccine disease. Since that period I have had no communication upon this subject with any persons officially connected with the Vaccine Board; but now that Dr. Müller is working in the same field, this very important matter is likely to be thoroughly canvassed, and it will, probably, be determined by those whose duty it is to look into it, whether we propose a practicable and safe solution of this question of supply. I have, in common with many of my Medical friends, who could bear testimony to the fact, over and over again proved the comfort and advantage of possessing a reliable stock of lymph during the prevalence of epidemic small-pox. To be spared also, even in ordinary times, the constantly recurring annoyance of seeking for wet lymph in a hurry, and very often unsuccessfully, will be deemed no small boon by the harassed Practitioner, Poor-law or private. Moreover, to be enabled from the same stock of preserved lymph to supply a friend in his emergency is a peculiar satisfaction. I have little to add to the account you published of my mode of procedure, though, of course, long practice gives more accuracy in carrying it out. I prefer (though I do not attach much importance to this) the use of undiluted glycerine for admixture with the lymph. Put into a bottle and immersed in hot water for a few moments, it loses its syrupy consistence and becomes quite limpid and fit for mixing. The tendency of the mixed lymph, however, being to thicken again by keeping, it may readily be rendered moister, when any portion of the stock is wanted for use, by holding such portion over the steam of hot water, or by breathing upon it; then a stir with the point of a silver probe perfects it.

I am, &c.,

27, Nottingham-place, W., May 24. R. R. Cheyne, F.R.C.S.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·886 in. The reading rose to 30·23 in. on Monday, and fell to 29·46 in. on Saturday.

The direction of the wind was chiefly north-east.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 48·1°.

APPOINTMENTS FOR THE WEEK.

June 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

4. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

Epidemiological Society, 8 p.m. Election of Officers. Dr. Dickson, R.N., "On Scurvy in the Merchant Navy."

Odontological Society, 8 p.m. Meeting.

Royal Institution, 2 p.m. General Monthly Meeting.

5. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Royal Institution, 3 p.m. Professor Ansted, "On the Application of Physical Geography and Geology to the Fine Arts."

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m. Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

8. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Professor Frankland, "On the Source of Muscular Power."

GENERAL MEDICAL COUNCIL.

NINTH DAY.—SATURDAY, MAY 26.

The Council resumed its sitting to-day at one o'clock.

The minutes of the previous meeting were read and confirmed.

The PRESIDENT mentioned that a letter had been received from Mr. Ouvry, their solicitor, addressed to the Registrar, in which he said he had delivered the President's letter to Sir George Grey's private secretary, and impressed upon him the importance of an early appointment being made.

The first business on the programme was the adjourned consideration of the Report of the Pharmacopœia Committee.

The PRESIDENT reminded the Council that they dispersed on the previous evening when Dr. Apjohn was in the middle of his speech on this Report, and that accordingly he (Dr. Apjohn) should have resumed his statement this morning, but as he had not yet arrived the better course would be to go on with the consideration of certain portions of the Report, and when Dr. Apjohn arrived he could continue his observations. He (the President) had found the original copy of the memorial from the Chemical Society, which had been mislaid, and as considerable importance was attached to this document, and as it would tend to illumine the discussion on this subject, he would call upon the Registrar to read it for the benefit of all of them.

The REGISTRAR then read the letter in question. [A copy of this document appears in Dr. Apjohn's statement of the previous day, and therefore it is not necessary to reproduce it here.]

On the motion of Dr. QUAIN, seconded by Dr. STORRAR, it was resolved that this memorial be entered on the minutes.

Sir DOMINIC CORRIGAN asked for an explanation of the last paragraph of the Committee's Report, in which they stated "that they had not hitherto had occasion to draw upon any portion of the funds placed at their disposal by order of the Council." The import of that seemed to be that, although they had not withdrawn any portion of the funds, yet some liabilities had been incurred; and if it were so that should be stated.

Dr. QUAIN said the Committee had not incurred any liability whatever.

Dr. A. SMITH thought any person reading the Report would draw the same conclusion from the last paragraph as Sir Dominic Corrigan had done. His anxiety was that there should be no misconception out of doors.

The PRESIDENT intimated that they had better consider, in the first place, how far it would be practicable to alter the resolution passed last year, to the effect that it was desirable to have a proof copy of the Pharmacopœia in the hands of the members of the Council at least a month before their meeting, so as to meet the altered circumstances of the case.

Dr. STORRAR said a resolution had been placed in his hands which expressed the views of some of the members of the Committee. It was as follows:—"That as soon as the proof of the new edition of the Pharmacopœia is ready a copy of it be sent to each member of the Council, with instructions that he will, within one month, return it to the Secretary of the Pharmacopœia Committee, with such observations as he shall see fit to make thereon, to be submitted to the Pharmacopœia Committee; and that the Pharmacopœia Committee shall, after due consideration of such observations, hand over the proof, when finally approved, to the Executive Committee for publication." He then moved the adoption of this resolution.

Dr. ALDERSON seconded the motion, which was at once agreed to.

Dr. APJOHN entered the room at this stage of the proceedings, and after some little recrimination between the members of the Committee on a point of no public moment, and which seemed to arise out of a misunderstanding, he resumed his statement. After referring cursorily to what he stated on Friday, he considered the class-books in general use, wherein, he said, they had the fact confirmed that the teaching of chemistry on the unitary system had made but little progress. An excellent treatise on chemistry was published some years since by Abel and Bloxam, and much used by students in this city and elsewhere, and in it formulæ were used in accordance with the old table of equivalents. But the most comprehensive work (and in many respects it was an admirable one) was the treatise of Dr. Miller himself, which was found in the hands of almost every student. They would, no doubt, be anxious to know what was his system of notation. Until a very recent period he (Dr. Miller) did not teach chemistry on unitary principles, and of the three volumes of which his work consisted, one alone—the second—appeared at present in the unitary dress. These facts, he thought, did not sustain the statement in the letter of the President of the Chemical Society that "the system of notation at present adopted in the British Pharmacopœia is constructed in conformity with views which are rapidly disappearing from chemical teaching in this country." He should now turn to other evidence in support of the view of the subject which he had taken, and which he was desirous should be sanctioned by the authority of the Council. He held in his hand one of the most important and valuable works on theoretical and practical chemistry which had ever appeared in this country—namely, the "Dictionary of Chemistry and the Allied Branches of other Sciences," by Mr. Henry Watts. Many of those present were no doubt acquainted with the comprehensive nature of this Dictionary, and of the ability with which, generally speaking, the different articles had been written, and it was obviously not out of place to inquire how Mr. Watts had dealt with the question of notation. He would explain to the Council in his (Mr. Watts's) own words the course which, after due deliberation, he had thought it necessary to adopt, and the various reasons by which he had been actuated in taking this course. Mr. Watts said:—"In order that the work may, as far as possible, truly represent the present state of scientific chemistry, it has been found absolutely necessary to make the modern or 'unitary' scale of atomic weights the basis of the system of notation and mode of exposition adopted. Especial care has, however, been taken that the treatment of all articles which are likely to be consulted, for the sake of practical information, by manufacturers or others not exclusively employed in chemical pursuits, shall be such as to make them readily intelligible to all who possess a general knowledge of Chemistry, though they may not have followed closely the recent developments of the theoretical parts of the science. Hence, in all such articles as acetic acid, antimony, copper, etc., the formulæ were given according to the old notation, as well as according to that which is adopted in the rest of the work." The authority here quoted was one of considerable weight. It bore very expressly upon the course which he intended to propose, and he trusted it would receive more attention from the Council than had been accorded to it by the Pharmacopœia Committee, upon whom it did not seem to make any impression. It was not necessary to embark upon a discussion of the merits of the unitary system. The President and members of the Chemical Society did not require them to adopt a system which (to use their own words) "is still under discussion." What they did ask of them was to forego the use of symbols and equivalents altogether until the discussion was closed, lest the adoption of the ordinary system should retard the progress of certain views which those gentlemen entertained, and to which they attached immense importance. He had no antipathy whatever to these unitary views, and would say nothing against them, except that they involved more of hypothesis than those they were intended to displace, that they were with much more difficulty acquired by the student, and that forty-nine-fiftieths of existing chemists were unacquainted with them. That he had no insurmountable objection to unitary chemistry might, he thought, be inferred from the fact that in a letter he had written to Professor Miller, in reply to one which he received from him in relation to his letter to the President of the Medical Council, he had declared his readiness to support a proposition for giving in the Pharmacopœia the new formulæ as well as the old, of placing them side by side, and of thus allowing teachers and students to elect which of the two they would use. He had even gone further than this, and stated to Professor Miller that he would prefer the adoption of the unitary views in their integrity to the very retrograde proposition of banishing entirely from the Pharmacopœia the use of equivalents and symbolic notation. If this latter proposition should be carried out, their national formulary would be a sort of list of secret medicines, which might with propriety emanate from a college of quacks, but would be quite unworthy of the British Medical Council. He might, no doubt, be told that the constitution of therapeutic compounds might be expressed by the old percentage or numerical method; but would any person competent to express an opinion on the subject venture to assert that that method was comparable with that in which a for-

mula was used? Every candid person would acknowledge the vast superiority of the latter by reason of its brevity, its clearness, the facility with which it was retained in the memory, and the facility which it gave to their explanation of the reactions of chemical substances on each other in the processes by which several pharmaceutic compounds were prepared. But there was another phase of the question to which he would solicit attention. The President and Council of the Chemical Society might correctly state that "the Pharmacopœia was necessarily the test-book on which the examinations of students of Medicine and pharmaceutical pharmacy were based." Such was unquestionably the case; and from it he adduced the conclusion that they could not banish from the Pharmacopœia such practical results of the fundamental doctrines of chemical science as atomic weights and symbolic formulæ without bringing the standard of chemical knowledge for Medical students to a very low level indeed. These views he had attempted to enforce upon the other members of the Pharmacopœia Committee, but without success. He thought he had made some impression upon Dr. Sharpey; but even he voted against him. With respect to Dr. Christison, whose abilities and attainments he respected, he did not expect any support from him; for some years since, before the appointment of Professor Playfair to the chair of Chemistry in the University of Edinburgh, he had heard him state that he did not consider it necessary that Medical students should be acquainted with symbols, and that such knowledge was not required of them at the degree examination. As respected Dr. Quain, the remaining member of the Committee, he certainly did not anticipate any assistance from him in relation to the question under consideration; nor could he do more than conjecture how he would have voted, for when matters were ripe for a division he (Dr. Quain) had a Professional call, and the winding-up of matters was left to the other members of the Committee. The result he had already stated to them; and, dissenting from it on grounds which he considered warrantable, he had brought his appeal before this Council. In pursuance of the course he had taken, he now begged to propose the following resolution —"That it be an instruction to the Pharmacopœia Committee to give for each therapeutic compound, of definite constitution, occurring in the forthcoming edition of the Pharmacopœia, two formulæ—the first being that in ordinary use at present, the second being one constructed in accordance with the more recent views of what is called the 'unitary system.'"

Dr. A. Smith seconded the resolution.

Dr. Andrew Wood said he had made up his mind that if the old notation was to be adhered to he could not vote for it, because if the new notation was to take its place, as he had reason to believe it eventually would, and they adopted the old notation, they would be actually putting a drag on the knowledge of students and keeping them back; whereas, if they put in both systems of notation, the student would have them before him, whichever prevailed. He thought the Pharmacopœia would suffer in a scientific point of view if either was left out altogether.

Dr. Christison said that from what he had seen of the Pharmacopœia, all the proofs of which, with the exception of the Appendix, had passed through his hands, he felt convinced that if it was not satisfactory to the Medical Profession, it ought to be. In the former Pharmacopœia there were a few very decided errors; but from very careful inquiry amongst his friends in Scotland and Ireland he found that the new edition was deemed satisfactory generally by Practitioners. Throughout England there was a growing inclination to esteem their Pharmacopœia much higher than at first. He thought a great deal of the opposition manifested at the outset arose from the inevitable fact that Practitioners were obliged to depart from the old practice and to take up with the new. The Medical Profession would be reconciled to these changes by lapse of time; and so far as he could see the second edition of the Pharmacopœia would be welcomed generally by the Profession. When the Pharmacopœia under which Practitioners and druggists were at present prescribing was first methodised, the question of the introduction of chemical notation was agitated. Dr. Apjohn had alleged that the students of the Edinburgh University were not examined in, and not acquainted with chemical notation. That was a very strong statement, and was not true. The students of the Edinburgh University were not only examined in chemical notation, but were exceedingly well acquainted with it. In taking up the Report of Dr. Andrew Wood and Dr. Alexander Wood who formed the deputation of the Scottish Branch Council on examinations for degrees in Medicine in the University of Edinburgh, he found that one of the questions propounded by the Professor of Chemistry was, "solve the following equations, putting the proper values in the place of m and n:—

1. $nHCl + SbS_3 =$
2. $Fe_2O_3 3SO_3 + mNH_3 + nHO =$
3. $Ag + nHOSO_3 =$

Dr. Apjohn said his observations referred to a period anterior to the appointment of the present Professor.

Dr. Christison would come to what was of more consequence—namely, the merits of the question. He thought their Pharmacopœia should be a scientifically practical book, but not overloaded with what was merely scientific, and not of direct practical use for the Practitioner in Medicine and Pharmacy. Dr. Apjohn had stated that the Pharmaceutical Chemists, of Dublin, used the chemical notation, but he (Dr. Christison) doubted whether that was really the case. It was stated that various chemical teachers finding this in the Pharmacopœia were obliged to use the old symbols when they did not believe in them, but that certainly appeared to him to be very hard indeed upon the teacher. When the question of symbols came before them under the jurisdiction of the present Committee, there was a great deal of good-humoured discussion upon the subject, and luckily it occurred to some one that as the French Pharmaceutists were occupied with the Parisian Codex the Committee should agree to do just what the French were doing. That was the compromise they came to. A short time afterwards there came this remarkable letter from the President of the Chemical Society, not asking them to decide which notation should be introduced, or whether they should introduce two or more notations, but impressing upon them the desirableness of dispensing with the use of chemical symbols altogether. He begged the Council to observe who were the authorities who had given this opinion. They were all the principal authorities in chemistry in Great Britain; there were very few chemists, indeed, of any note who were not members of that Society. If that letter had been received at the time the Committee came to compromise, he should not have fallen in with that compromise, but should have resolved to leave to far better judges than they (the Committee) were, to decide what symbols should be adopted in chemical symbolical representation. After much discussion, the Committee came to the opinion that his view was right, and that chemical notation should be avoided in the present edition of the Pharmacopœia. Dr. Apjohn still differing from this view, he (Dr. Christison) proposed that Professor Redwood should be called in. There were very few men in the country who united so accurate a knowledge of chemistry, not only its science but its practical details, with an accurate knowledge of Pharmacy, or who was better acquainted with the condition of the chemical schools of the country than Professor Redwood. Having the whole case put before him, he did not state that he thought one thing or another, but he gave them a positive opinion that under present circumstances he would strongly recommend them not to introduce any symbolic notation in the Pharmacopœia. In the face of these expressions of opinion, how could the Pharmacopœia Committee come to any other conclusion than that to which they arrived—namely, that they had better wash their hands of this symbolic notation? This notation would give a colourable scientific appearance to the work, but why give scientific formulæ which were not of practical utility? It was said that it was a good exercise for students, but the Pharmacopœia was not designed to teach chemistry; it was produced to teach Pharmaceutical chemists how they were to prepare Physicians' and Surgeons' prescriptions, and the strength of the various articles they were in the habit of dispensing. Under these circumstances, he said he did not see any reason to alter the opinion he had formed upon this subject.

Dr. Apjohn was rather surprised, he said, at the course Dr. Christison had taken. It was very obvious that he (Dr. Christison) had changed his opinion, and the only way in which that change could be understood was in virtue of the force of the memorial from the Chemical Society.

After some further observations, the resolution was put to the Council, and carried, there being 11 votes for and 8 against.

Dr. Acland desired to submit an instruction to the Pharmacopœia Committee with a view of getting rid of a difficulty which, he was told, might occupy some time if brought on in any other way. His motion was, "That it be an instruction

to the Pharmacopœia Committee to take steps to ascertain whether any or what limits have been imposed by the Medical Acts on the reports and investigations which the General Medical Council might see fit to obtain, or direct, into the properties of the medicines and compounds of which the Council is required to furnish a list, and especially whether the Council is limited by the Act to inquiries as to the composition of articles in Materia Medica, and the means of preparing and compounding them." He said he wished to avoid taking legal opinion, and should be satisfied with the decision arrived at by the Pharmacopœia Committee. The Act desired them to make "a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weight and measures by which they were to be prepared and mixed; and containing such other matters and things relating thereto as the General Council shall think fit." So that he could not conceive the Committee would require legal opinion. It rested with them entirely to do as they "think fit." He hoped the Council would not think he was "stealing a march" upon them by bringing this forward at the present time.

Dr. Paget seconded the proposition.

Sir D. J. Corrigan suggested that Dr. Acland should withdraw this motion, as the Pharmacopœia Committee had quite enough on their hands without getting legal opinions.

Dr. Christison stated that there was an important branch of the inquiries referred to in the motion of Dr. Acland, to which he thought no doubt could exist the Council possessed the power of applying their funds. This was—inquiries by physiological experiment, for the purpose of determining the conditions of vegetation, modes of preparation, and means of preservation, by which vegetable remedies might always possess due strength, and, above all, uniformity of strength. Such inquiries might be conducted by experiments with Medicinal doses upon the functions of the human body, but more generally with poisonous doses of the more potent vegetable remedies on animals, the results in the latter way being more free from fallacy. Inquiries of this kind were much needed in the present day, because most of the rules for collecting, preparing, and preserving vegetable remedies were loose, unsatisfactory, and not a few erroneous. He had turned his attention many years ago to the subject, when he had more leisure than now for such researches, and had since returned to it from time to time. The results he obtained certainly astonished him, and convinced him that the whole matter required new and more exact investigation. He would venture to detain the Council with a single illustration. In the first edition of his work on Toxicology, published in 1814, Orfila mentioned that he had found many old extracts of powerful vegetables inert, or nearly so, as met with in the shops of the pharmaceutic chemists of Paris. The experiments of Orfila to this effect created a great distrust of the form of extract in the case of active medicinal plants, whose active parts had thus been proved to be very fugacious; and, although improved methods of preparing extracts had since improved undoubtedly both their strength at the first, and likewise their endurance, all well-informed Physicians still entertained, not without reason, great distrust of extracts, and of other preparations derived from extracts. Recently, however, he had himself found that, under certain conditions of preparation, even the extracts which Orfila had ascertained to be fugacious retained their virtues apparently for a very long time unimpaired. Many years ago he found that a carefully-prepared alcoholic extract of hemlock,—a plant whose properties assuredly were very apt to be lost in various circumstances,—was not in the slightest degree impaired in energy, as a poison to the lower animals, in the course of nine years. Last winter he made trial of two extracts of hyoscyamus prepared twenty years ago—the one from the annual, the other from the biennial variety of *Hyoscyamus Niger*, by the late Mr. Jacob Bell in the now usual way by evaporation of the expressed juice, with constant stirring, by steam-heat without boiling; and he found by trial on several persons that both of these extracts, though they had not been kept with any particular care, equally and quickly caused dilatation of the pupil, when introduced in a state of solution into the eye. He also tried at the same time an extract of belladonna of great age—one of the vacuum-extracts of the late Mr. Barry, who first introduced this particular form into pharmacy. The specimen belonged to the collection left by his (Dr. Christison's) predecessor in the University of Edinburgh (the late Dr. Duncan), and bore Mr. Barry's own label, with the date 1819. Nevertheless, repeated trial on several persons proved that, when introduced in small quantity into the eye forty-seven years after it was made, this extract occasioned as prompt, extreme, and during dilatation of the pupil as any recent, well-prepared extract. He could mention numerous other illustrations of the importance of studying with more attention than had ever yet been done by Physicians, pharmaceutic chemists, or even Professors of Materia Medica, the influence of time, mode of preserving, methods of preparing, and, above all, the influence of numerous circumstances connected with vegetation, on the activity of vegetable remedies. But he must not detain the Council with more details. All investigations on this subject were clearly within the province of the Council and its Pharmacopœia Committee, and the expense of them was as clearly chargeable against the funds of the Council; and few persons would doubt their important bearings on Medical practice, or that it might become expedient for the Council to carry on or encourage such investigations. As to the other branch of physiological inquiry included in Dr. Acland's motion—namely, into the therapeutic action of medicinal doses of remedies—an inquiry which could be carried on only, or chiefly, by trials on patients, especially in Hospitals—the competency of the Council to undertake that branch at the charge of the Council funds was a different question, into which he did not feel it desirable that he should enter at the present time.

Dr. Andrew Wood said he gave Dr. Acland more credit for his perseverance than for his discretion in desiring that they should become a body to make physiological experiments in regard to the action of medicines on the human body. If they were the British Association, the Medico-Chirurgical Society, or a scientific body in any respect, it would be quite right they should do so. But they were a body appointed to discharge quite another function, and if Dr. Acland did not think they had quite enough to do without making experiments, he must be the only member of the Council, he should think, who entertained that opinion. The experience of the past eight days showed them they had little enough time to go through their own proper duties. He did not see the use of getting the opinion of counsel, because they had a perfect right to devote any sum of money they chose to the preparation of the Pharmacopœia in its legitimate and *bonâ-fide* sense, and they were quite entitled to carry out such investigations as those suggested by Dr. Christison with regard to the growth of plants, from which drugs were derived. That would be germane to the Pharmacopœia. But when they were asked to select a number of people, and make experiments upon them, the Medical Council were asked to enter upon the wide field of inquiring into and giving utterance to their opinions regarding the practice of the Medical Profession; and that was not their function. Although the phraseology of the present motion was different from that of the motion brought forward on the first day of this session, yet the purport of it was identical, under a change of name, *Ecce iterum Crispinus*. He felt sure Dr. Christison was not aware of the *mare magnum* into which they were going to sail; and once on such an ocean, how they were to get out of it again he did not know. Let them stick to their functions. Let them perfect the registration and education of Medical Practitioners; let them apply their power to visiting the licensing bodies, in order that they might see how those bodies performed their duties. If when they had done what they ought to do, and their session occupied only four or five days, and they were thus enabled to save a great deal of money, he should then hope to go to the Profession and say, we shall now be glad to reduce the fee to £3 or £2, as the case may be," and that would give them greater satisfaction than it would to spend money for purposes other than those for which the Council was instituted. At present they had little money enough to carry out their proper function. Let the British Association carry out their own experiments.

Dr. Stokes said that he should like to know what their powers really were. All that Dr. Acland asked was that inquiry should be made by the Pharmacopœia Committee to ascertain whether or not the Council had the power of voting money for the purpose of making such experiments as those mentioned by Dr. Christison.

Dr. Alexander Wood remarked that Dr. Andrew Wood had now completely changed his tone and admitted the legality of Dr. Acland's proposition, but denied its expediency. (Dr. Andrew Wood: "No, no.") One of the most important duties laid down by the Act of Parliament was the preparation of a National Pharmacopœia; and it might perhaps turn out, when

the discussion of the exciting subjects connected with education and registration had passed away, that, after all, the preparation of a National Pharmacopœia, of a scientific nature, and worthy of the character of the Council, might not be the least important function they had to discharge. Now, he did not confess to be competent to decide whether such experiments were essential for the making of a Pharmacopœia or not; but if such an authority in this matter as Dr. Christison, Dr. Apjohn, or any member of the Committee, were to come to the Council and say he considered it essential that certain physiological experiments should be made either by themselves or some committee of the British Association, he should be inclined to listen to such a suggestion. He should like to know whether they were debarred by law from making a grant for that purpose. As the motion stood, he should vote for it; but supposing it were to be immediately followed by another, to the effect that they should vote money for the purpose, he should be opposed to it. He felt sure that, if by any experiments, undertaken by a competent body, they could improve the practice of Medicine, it would be a legitimate object for this Council, and would be welcomed over the kingdom far more than those interminable discussions about registration and the other matters with which their Minutes were filled, and which, after all, were not nearly so important to practical men who composed the great body of the Profession.

Dr. A. Smith thought it quite unnecessary at the present time to discuss whether the Pharmacopœia Committee had the power of applying the money of the Council to the investigation of any matter belonging to the preparation of the Pharmacopœia. That question had long been practically settled. When the Pharmacopœia was first being prepared, it would be found upon the Minutes of the Irish Branch Council that twenty-five guineas were paid to Mr. Scott, an able chemist in Dublin, for analysing a packet of James's Fever Powder, which had been made for sixty years, so that the Branch Committee of London had paid money for the investigation of certain questions in pharmacy. Therefore the power did exist, and they had established that fact by sanctioning this grant, which had been followed by others. With regard to the other part of the subject, he thought it impossible they could bring therapeutical investigations of the physiological action of drugs within the meaning of the clause in the Act, which said they were to construct "a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matters and things relating thereto as the General Council shall see fit." The words "relating thereto" must apply to the antecedent portion of that paragraph, and to nothing else. He did not think it necessary to waste more time upon the subject.

Dr. Acland then replied. In respect to the duty they owed to students, some of the things which had been advanced by Dr. Christison were amongst the most important points which engaged the attention of students, and, as Dr. Alexander Wood had said, some of those that required to be most taken up. Whatever the decision of the Council might be, he would have gone a long way to have heard what Dr. Christison had stated. He felt strongly on the subject before, but after what he (Dr. Christison) had said he did not see how they could have a doubt of its importance. It was quite true this matter emanated from one of the sections of the British Association last year, over which he was president. He simply desired that, being charged with the construction of a National Pharmacopœia, they should make it as perfect as possible. The Council had decided that what he proposed on a former occasion was not within their power, and all he asked them to do now was to put it in their power, in order that they might exercise it if they saw fit. He could not agree with Dr. Andrew Wood that the Pharmacopœia was altogether a secondary matter in the affairs of this Council. What Dr. Alexander Wood had said about it was the truth. If there was only great work which, if this body continued, it would have to do, it would be to perfect as far as possible the list of medicines and compounds and the manner of preparing them. He was not asking for £250 for this year or the next, but was simply desirous to know whether they had the power to make these experiments, and if they had not to take steps to introduce them into the Amendment Bill.

Dr. Quain said the Pharmacopœia Committee was not authorised to consult lawyers. That was a duty which belonged to the Executive Committee. He suggested whether Dr. Acland had not better substitute the words Executive Committee for Pharmacopœia Committee. He should vote against this duty being assigned to the latter Committee, inasmuch as they would be unable to perform it for want of time.

Dr. Acland would have no objection, he said, to alter his motion as suggested.

Sir D. J. Corrigan objected. The question before them had nothing to do with the Executive Committee, but the Pharmacopœia Committee.

The motion was then put, when there were 9 votes for and 9 against.

The President remarked that, as he had not voted, he could not, he believed, according to the Act, exercise the privilege of giving the casting vote. If he had voted when the resolution was put, he might exercise the privilege of recording a second vote when the numbers were equal. The motion, therefore, was not carried.

Dr, Acland asked for the names to be taken down.

This having been done by the Registrar,

Dr. Apjohn moved that that portion of the Committee's Report which said that no unnecessary delay had taken place be omitted. He was understood to intimate that there had been unnecessary delay.

Dr. Christison mentioned that there had been a delay in the production of the Pharmacopœia, but that delay, so far as he was aware, could not have been avoided, inasmuch as Mr. Warrington had been so unwell for a considerable time that he could not discharge his duties.

Dr. Quain said it was very hard indeed to accuse the Committee of unnecessary delay.

Some discussion took place on this part of the Report, the members of the Committee at first being inclined to eriminate each other, but after a few explanations it appeared that each had done the best he could to forward the work, and that the delay had arisen purely from the immense amount of labour necessary, and the difficulty of the undertaking.

Dr. Christison observed that, although he was nominally chairman of the Committee, he regarded Dr.. Quain as the moving party who had charge of the Pharmacopœia. He (Dr. Quain) had taken a great deal of trouble, and must have consumed a large portion of his time upon it.

The President said that, in the absence from London of Dr. Christison, chairman of the Committee, he had, in his right as President, attended the meetings of the Pharmacopœia Committee in London, and he had endeavoured to give them what assistance he could. He thought it was the bounden duty of the members in London to express their great obligations to Dr. Quain, who had been indefatigable in his endeavour to expedite the progress of the work. There was not the least doubt there had been delay, and the question was whether it had been unnecessary or not. When they considered the large amount of correspondence they had had with Drs. Christison and Apjohn, without whose assistance and advice those in London could not have done anything, they would see that in a work of this kind, which had to be conducted partly in London, partly in Dublin, and partly in Edinburgh, delay was inevitable. As far as the London members of the Committee were concerned, there had been no unnecessary delay. At times they had had to wait for communications from Dr. Christison and Dr. Apjohn, but when they had received those communications they had always been amply repaid by the value of the information afforded.

Dr. Apjohn withdrew the motion for the omission of the sentence in question.

Dr. Alexander Wood then proposed, and Dr. Acland seconded, "That while the Council regretted the delay which has taken place in the production of the Pharmacopœia, and are satisfied that it has not arisen from causes over which the Committee had any control, beg to acknowledge its thanks to the Committee for their exertions."

After some discussion this motion was withdrawn.

On the motion of Dr. Christison, seconded by Dr. Quain, the Report of the Pharmacopœia Committee was adopted.

The Council adjourned at four o'clock.

Tenth Day.—Monday, May 28.

The Council re-assembled at the usual hour, the President in the chair. The minutes of Saturday's meeting were read and confirmed.

The first business on the programme was to consider the report of the Committee appointed on Friday, May 18, 1866, to take into consideration a letter from the Secretary of State

for War. The Committee suggested that the following communication be forwarded in reply :—

Sir,—I am directed by the General Medical Council to acknowledge the receipt of your letter of the 26th, in which you inform me that Lord de Grey requests the Medical Council will favour him with their opinion as to the particular initials which should be used to designate the several Medical qualifications described in the table appended to the Medical Act, and for which abbreviations are therein laid down. For example, Licentiates of the King and Queen's College of Physicians in Ireland, in the Table of Abbreviations appended to the above-named Act, are thus described, "Lic. K. Q. Coll. Phys., Ireland." What initials should be used in this and similar cases?

With regard to the first question, the General Medical Council submits that it is only necessary to follow the precedent already existing in regard to the title "Surgeon" in the Army List. The title or qualification "Surgeon" (for it is both) does not mark the particular College or University which has conferred the required qualification, but leaves that to be ascertained by the Medical Register, published under Act of Parliament.

In like manner, in regard to Medical qualifications, the initials "M.D." or "M.B." are inserted after Surgeons' names, indicating that they possess such qualifications, without distinguishing the particular Universities from which these titles are obtained.

It appears to the General Medical Council that, following those precedents, it is only necessary in like manner to insert after the names of Surgeons having Medical qualifications from any one of the Royal Colleges of Physicians of England, Ireland, or Scotland, or from any University giving a licence in Medicine, the letters, "Ph.," signifying Physician, indicating that the qualification is that of Physician, in like manner as in the initial letters, "M.D." and "M.B.," not distinguishing the particular College or University from which the title "Physician" is obtained.

These observations apply equally to the only other initial letters proposed in the case of licentiates of Apothecaries' Companies of England and Ireland, viz.: That the initial letters "Ap." should be inserted in like manner, indicating the qualification without distinguishing the particular Company from which the qualification has proceeded.

With regard to the second question, viz. :—

"In the case also of a Surgeon who possesses more than one Medical qualification the Council is requested to specify which should be selected for insertion in the Army List. Suppose, for illustration, a Licentiate of the King and Queen's College, Dublin, is also a Doctor of Medicine of the University of Edinburgh, or a Member of the London College of Physicians, or a Licentiate of the Society of Apothecaries; which of these Medical qualifications is to have precedence, and by whom is this to be decided?"

The General Medical Council does not apprehend any difficulty.

The case put of a Surgeon having more than one Medical qualification is, and will be, of frequent occurrence in the Army. It is not uncommon for an Army Surgeon to have two Medical qualifications, one of "M.B." or "M.D." of a University, and another "Ph." from a College of Physicians.

It is only necessary to signify that one Medical qualification alone will be inserted, leaving it to the discretion of the Surgeon himself as to which he would select, or whether he would select any. A Surgeon who has two Medical qualifications—for instance, one from a Royal College of Physicians, and another from a University, may desire to have "M.D.," the University qualification, after his name; while another similarly circumstanced, may desire to have "Ph." after his name, designating that he is a Physician.

It is also of ordinary occurrence, and is a practice very much to be encouraged, that Army Surgeons take advantage of opportunities from leave of absence, or from being stationed where there are celebrated Medical schools, to acquire a Medical qualification higher than they had on entering the Army, and such Surgeons the General Medical Council apprehends would, of course, have the liberty of substituting from time the higher qualification for the original qualification inserted.

In conclusion, I am to observe that the additional initials proposed to be inserted in the Army List would be only two, viz. :—

Ph. . . . . Physician.
Ap. . . . . Apothecary.

The total initials required as indicating Medical qualifications would then be only four in number :—

Already Admitted.

M.D. . . . . } Signifying University graduates, without specifying particulars.
M.B. . . . . }

Proposed to be Added.

Ph. . . . . Signifying Physician in like manner, without specifying particulars.
Ap. . . . . Signifying Apothecary in like manner, without specifying particulars.

The General Medical Council hopes this simple proposal will meet with the approbation of the Secretary of State for War, as doing impartial justice to all parties, and removing the repeated complaints that have reached it on the subject, as explained in the former correspondence.

D. J. Corrigan, Chairman of Committee.

Lt.-General Sir E. Lugard, K.C.B., Under Secretary of State for War.

Sir D. J. Corrigan moved the adoption of the Report.

Dr. Smith seconded the resolution.

Dr. Parkes thought it would be exceedingly impolitie to accede to the proposal of that Committee. He did not think there was a single Army Apothecary who would desire to put "Apothecary" after his name, and for this reason, that the term "Surgeon," as used in the Army, always included a Medical degree or Medical licence. Under the Committee's proposal the name of an Army Surgeon was to appear, "Surgeon and Apotheeary," and another name might appear, "Surgeon and Physician," which would at once lead the members of the Army to suppose that those gentlemen had different qualifications, the one being superior to the other. He thought there would be a very strong objection indeed on the part of all Medical men in the Army to use the term "Apothecary," and he objected on principle to its introduetion in the Army List. The initials proposed for Apothecary were "Ap.," so that after the name of the Medical officer would stand the letters, "Surgeon and Ap.," and thus the Medieal officers in the Army would be considered to have some relation to certain animals from which they were not desirous to elaim descent. Then with regard to the initials "Phn.," no one would suppose they meant "Physician," and therefore he did not think Sir D. J. Corrigan had done wisely in dropping the initials "Phs." In avoiding Seylla he had drifted into Charybdis. In the Minutes of vol. iii., page 314, they would find this resolution of the General Medical Council, "That it is the opinion of the General Medical Council that it would not be advisable to insert the letters "Phys.," etc.; and if they sent the letter proposed to the Under-Secretary of State for War they would be receiving a reply asking them to reeoncile the letter of July, 1864, and that of May, 1866. On the receipt of such a letter this question of initials would pass into the limbo of those great subjects which had so long agitated this Counell. No great question, such as registration or education, could be settled under a period of eight years, and in that time every member of the Council who was not of Carlyle's opinion, that "silence is the first virtue of man," would have an opportunity of expressing his views upon this great question of "Phs." and "Phn."—phiz and fun. (Laughter.) The members of the Committee might be aequainted with a novel called the "Initials," and he could not help thinking they were anxious to furnish a second edition of that book. Possibly Sir D. J. Corrigan might have a still higher literary ambition, and wished to write a comedy, or, as was more probable, a farce, bringing in as *dramatis personæ* the members of the Council and the Under-Secretary of State for War. (Laughter.) He hoped Sir D. J. Corrigan would not press this matter to the inevitable discomfit of the authorities; and with a view to test the opinion of the Council, he would propose as an amendment, "That the Registrar acknowledge with thanks the receipt of Sir E. Lugard's letter, and inform him that on further consideration the Medical Council has decided not to urge the matter referred to in Sir Edward's letter on the attention of the Secretary of State for War."

Mr. Syme seconded the amendment.

Dr. Smith thought no more confusion could arisc by the adoption of the letters "Ap." than from such initials as "K.G." or "C.B." He should support the motion.

Dr. Andrew Wood said that if the letters "Ph." and "Ap." were really affixed to the names of gentlemen in the Army List, instead of their looking upon it as a boon, they would be asking why the Council had exposed them to such a thing? The best plan would be to adopt the amendment.

Mr. Cooper also supported the amendment.

Mr. Hargrave thought the statement made by Dr. Parkes was entitled to great weight, as he was so thoroughly conversant with the feeling of the Medical officers in the Army.

Dr. Storrar supported the amendment. They must eonsider there was not only a difference between a graduate of a University and a member of the College of Physicians, but there were also differences of a very important character in those respective Colleges. In the College of Physicians there were Fellows, Members, and Licentiates; and if these were all mixed up together under the initials "Phn.," possibly it would ereate a jealousy, inasmueh as a Fellow of the College of Physicians would not like to find himself designated exactly the same as a common Licentiate; that applied to other eolleges also; therefore he thought the wisest course was to adopt the amendment of Dr. Parkes.

Sir D. J. Corrigan, in reply, said that as the generie term "Surgeon" included all denominations, whether Fellows, Members, or Licentiates, so "Ph.," would include, as a generic term, all other qualifications. He reminded the Council that in drawing up the Report the Committee were only answering an inquiry from the Secretary of State for War. With regard to the observations of Dr. Parkes, he (Sir Dominic) felt really hurt. That gentleman had said he supposed he was not going to write a novel, but bring out a farce, in which the Secretary of State for War and the Director-General were to be amongst the characters.

Dr. Parkes: No, the members of the Council.

Sir D. J. Corrigan said that was all the worse, for before it was an insult to one, and now it was an insult to twenty-one. (Laughter.) He had never written a farce in his life, and if he did do so, it would certainly never be to hold up to ridicule a man holding such a high position as the Secretary of State for War, though he might probably think it worth while to

introduce his friend Dr. Parkes. (Laughter.) There was another part of Dr. Parkes' speech which was the bitterest censure he ever heard upon the Medical department of the Army. He had said that the letters "Ap." would be distasteful to them, and that any letters signifying "Apothecary" should be omitted. Was this Council to be a party to enabling the Army Medical Department to receive qualifications which they would be ashamed to avow? If the Medical authorities of the Army wished to conceal the appendage signifying "Apothecary" let them do so; they would not be obliged to use it. Dr. Parkes had altogether overlooked the sentence in the Report, which said, "It is only necessary to signify that one Medical qualification alone will be inserted, leaving it to the discretion of the Surgeon himself as to which he would select, or whether he would select any." On page 2 of the Army List there were no less than sixteen abbreviations, some of them consisting of four initial letters, and there was appended to each an explanation of what it meant. It was absurd to say that "Ap." would look like "ape," or that "Phs." was "phiz." On the same principle they might say that "M.D." was "madman," or that "C.B." was "cabman." (Laughter.) The simple question before them was, in what manner were Medical qualifications to be inserted? To that question the Committee had endeavoured to reply as fairly as they could, on the principle that all parties were to be treated with equal justice.

The amendment was then put, and there were 12 for and 4 against.

Sir D. J. Corrigan required that the names and numbers of those who voted, and of those who declined to vote, be taken down.

The President was about to put the amendment as an original motion, when

Dr. Quain said he would propose an amendment upon that, to the effect,—"That it be recommended to the Secretary of State that, under the difficulties of adapting initials capable of indicating the qualifications possessed by all Army Surgeons, to omit all initials as indicating Professional qualification."

Mr. Hargrave seconded this amendment.

Dr. Andrew Wood said they were asked to pass a disfranchising clause; but were they prepared to brave the tremendous clamour and declamation that would be made to the Council if they advised any such thing? He implored gentlemen not to vote for the amendment.

Dr. Alexander Wood did not see what this Council had to do with the way in which the Army List was published. The Council had no right to dictate to the Secretary of State for War, nor had they any right to assume an attitude of hostility to the Universities by striking out the University qualifications.

The amendment was then put and lost, there being 16 votes against and 4 for. The motion of Dr. Parkes was then carried by 14 votes against 4.

Dr. Parkes asked that the names of those who voted should be taken down.

The next business was the consideration of Reports on Visitations of Examinations.

[*** These Reports are very voluminous, and occupy no less than 116 pages.]

Dr. Alexander Wood congratulated the Council on the result of the first attempt. No man could look at these reports without being satisfied that they had done considerable good, and that they were susceptible of doing a great deal more good. He thought the result of the visitations of examinations by the Council had been highly satisfactory; and if they went on in the way in which they had begun, it was quite possible they would convince those who were most doubtful of the success of them that, after all, they were much more useful than they could have supposed. If he entertained the opinions so strongly stated at that table by Sir D. J. Corrigan as to the utter uselessness of this Council, the kind of Medical legislation he should go in for would not be a Royal Commission to examine this Council or any other body as to what was the best Bill, but an Act of Parliament which, without superseding the Examining Bodies who grant the degrees, should appoint visitors of these examinations with powers very similar to those given to the examiners of the primary schools throughout the country. The reports of the Branch Councils of England were highly satisfactory. One effect of these full reports would be that the examining bodies, who were really in earnest in wishing to raise their standards of examination, would look into them and see in what way they could improve their examinations. When he looked into these reports, he found there were special points to which attention was called by the visitors. What were they to do with these special points? Were they to let them remain in the Reports to be seen or not, as the case might be, by the bodies to whom they referred? Or, would it not be a better plan if, in the kindest and most friendly spirit, they appointed a Committee to extract from these reports those parts of the method of conducting the examinations, or the examinations themselves, which might appear to the visitors to be defective, and send them down to the various bodies, not as an injunction or a command, but as giving them power to see what to a looker-on, with all the advantage of being deputed by this Council, what appeared to be the weak point in their examination? In the second place, the Branch Councils should be requested to continue the system for another year, and if possible to amplify their reports a little. And thirdly, a Committee should be appointed to-day to report on the following day (it would not be an arduous duty) upon the various suggestions made by the visitors of examinations, and that those suggestions should be embodied in a separate report in the shape of recommendations to be sent to the various bodies. It would then be one of the duties of the visitors of examinations next session to say whether the bodies had concurred with the Council in their opinion as to the defective points in the examinations, and whether they had altered their examinations to correspond thereto. In the event of their refusing to alter, he would not say what step they should take. There were certain defects which ought to be dealt with seriously, but not this year. They should give an opportunity to the various bodies to amend their defects next year, and if the defects should be again reported upon as existing, it would then be for the Council to consider whether these bodies should not be dealt with in some special manner. They might exercise that famous power—the power of moral suasion,—which he must say had proved its efficacy in many a well-fought battle at that table. He then moved, "That the Reports of the Visitations of Examinations be received and entered on the Minutes."

Mr. Syme seconded the resolution, and was much gratified to hear what Dr. Alexander Wood had said with regard to them.

Mr. Hargrave said that several candidates who had been rejected at the examinations in Ireland had gone to the Royal Colleges of Surgeons of Edinburgh, and received their diploma. He thought the examinations there were too lenient.

Dr. Andrew Wood said he was surprised last year when Sir D. J. Corrigan moved a resolution, the effect of which was, if possible, to cripple the efficiency of their visitations; but he was thankful that, notwithstanding that resolution, the members of that Council, with one or two exceptions, had discharged their duty, under the circumstances, to the best of their ability. He, therefore, did think it was a hard thing that Sir Dominic should bring forward a motion refusing payment to those that did their duties in that Council at the very time that he refused to perform those duties himself.

Sir D. J. Corrigan rose to a point of order. The resolution to which Dr. Andrew Wood referred was not under discussion. He did not refuse to do the duty at that time, but he refused afterwards for certain reasons.

Dr. Andrew Wood did not think Sir Dominic should be so thin-skinned, as he was not so nice in regard to other people. All he could say was—

"Let the galled jade winee, our withers are unwrung."

Now, the great thing on the present occasion was, what was expected from the visitors. In Scotland they felt great difficulty indeed in knowing exactly what was expected of them. (Hear, hear.) They did not know whether they were expected to report a mere bald statement of the facts, or whether they were expected to observe all the details of the examinations. He had no doubt whatever that they would be very severely criticised; that, whereas some would be characterised as reports which had gone into the whole matter, others would be characterised as bald and useless. He trusted the public and the Profession would not judge from this year of what the visitations would be in future years; and he hoped they would be enabled, by instructions from this Council, as to the duties that were expected of the visitors, to bring before the Council and the Profession next year such reports as might redound to their credit. If he were called upon to specify what branch of these visitations was calculated best to secure the ends they had in view, he should say it was the reports which had been brought up by the English deputation. On the other hand, some of the reports were extremely partial; less

information had been given, because the visitors had not taken much trouble in regard to some of the bodies; and a cursory examination of these reports might lead to the idea that the bodies so reported upon were not so fully up to the duty which they had to discharge, or not so fully carrying out the measures which were necessary for testing the candidates for these diplomas. The body which he represented at this Council had been only partially reported upon. But so far as they were concerned their desire was to court the utmost publicity—not that they were anxious to magnify their own examinations or to say they were perfect, for he did not believe they were more perfect than were the examinations of the other bodies represented round that table. In page 6 of the English Returns he found an important and useful fact. It was the Report of Dr. Storrar and Mr. Cæsar Hawkins on the Royal College of Physicians of London, in which it was stated, "The College has altogether ceased to hold any preliminary examination of candidates for the licence, requiring proof of its having been undergone elsewhere." He thought that was an omen for good. Following that up, he might state what was happening in his own body. Before the passing of the Medical Act, and before the resolutions of this Council came into effect, they were called upon every year to examine 350 men in preliminary education. But he was happy to state that year by year since that period they were continually finding fewer men coming up to their preliminary examinations, and more men were going into the preliminary examinations of the University. He thought that was an omen for good. Dr. Andrew Wood then alluded to one or two facts in regard to the Scottish reports. At page 61, the report on the examination for degrees in Medicine of the University of Glasgow, by himself, Dr. Christison, Dr. Alexander Wood, and Professor Syme, they stated by whom the examination was carried on, and then said, "We observed, however, that during a considerable part of each examination there was no one present excepting the examining Professor and the candidate. We think it would be an improvement, were it so arranged that no examination should be conducted unless in the presence of not less than two Professors, or one Professor and one non-Professional examiner, one of whom should take jottings of the subjects of examination. This would be more satisfactory, both to the Professor and the candidate. Several of the Professors expressed to us their anxious wish that such an arrangement should be made imperative." That was what they reported on July 25, 1865, and if they turned to the next visitation at Glasgow on the 18th April, 1866, they would find it stated that the following rule had been introduced:—"It is expedient that at least two examiners be present during the examination of each candidate; it being at the same time competent to examine in presence of a greater number, or of the entire Board, in special cases." He quoted this to show that, by a sort of moral suasion, and without any enforcement by this Council, if they went in a liberal, proper, and generous way to the different bodies and made their suggestions, depend upon it, they would find them carried out. He read the resolutions he intended to propose to the Council, and would bring forward after the reports had been received and entered on the minutes. They were as follows:—"That the visitation of the examiners, preliminary as well as Professional, of the qualifying bodies, by the Branch Councils, or such of their members as they may depute, be continued during the ensuing year; that the reports of the visitors shall apply to every part of the examinations of each body, and shall include a statement of the facts observed, and of the opinions of the visitors as to the efficiency of the examinations, as also such remarks and suggestions on defects in them as circumstances may indicate; that the reports of the visitors be submitted in the first instance to the Branch Councils; and that thereafter the Branch Councils shall direct them to be printed and circulated confidentially amongst the Members of the General Council, so that they may be in a condition at the meeting of the General Council in 1867 to consider them maturely."

The President suggested that Dr. Andrew Wood might find the resolution to be sufficient for his purpose.

Mr. Cæsar Hawkins said they could not as yet form any comparison between the Reports, because those Reports were all drawn up on different systems. Dr. Storrar and himself had taken the same view of their duties as Dr. Acland and Dr. Paget had done—namely, that they were entitled to see that no one obtained a diploma who had not been subjected to examination, but they did not think it to be their duty to point out a single suggestion to the College of Physicians. If they entered into details in connexion with every body, as Dr. Andrew Wood had done with regard to one body, their discussion would be interminable, and they would have no chance of getting through it. He thought they might leave the Reports to circulate among the various bodies, and not enter on any other point. The visitations, if continued, ought all to be conducted on one system, so that a comparison might be instituted between them. There were a great number of bodies, some of which were teaching and others only examining establishments, and in the former of these there was a chance that the students would be examined by their own teachers, and all these circumstances ought to be borne in mind. Then, again, some men were better able to judge of one particular examination than they were of another, and he doubted whether the examinations carried on by the Branch Councils would ever be very useful.

Dr. Alderson believed that the visitations tended to elevate the examinations.

Dr. Thomson expressed his firm conviction that very great good must ultimately, and indeed very soon, result from the faithful and efficient carrying out of the system. With regard to the University of Glasgow, which had been referred to, it gave him very great satisfaction when his colleagues agreed to a rule that more than one examiner should be present. He thought this ought to be, not for the purpose entirely of avoiding any appearance of partiality on the part of the examiner, but for the advantage of the examiner himself. Whenever he had been engaged in performing the duty he had always felt very much embarrassed if he had to do it alone, and he was certain that he could do it more efficiently, both as regarded himself, the candidate, and the public, if others were present. He did not court publicity in examinations, but thought it was of great importance that there should be more than one examiner present. The question of exemption from examination on account of previous distinction in classes was one which might fairly be brought up. The first arose, he believed, in the University of Edinburgh, where the majority of the Senate were opposed to the system. Such was not the case in the University of Glasgow, where the majority of the Professors were in favour of it, but into this question he would not enter. The greatest oppression under which both the Profession and the students now laboured was the frequent repetition of examinations, and, whatever course might be decided upon for the future, he hoped that some credit would be given to the students for their conduct during their period of study. The system at present pursued at Glasgow was only a tentative one, and he felt that all the Professors would duly consider the remarks which had been made by the persons who had visited the examinations.

Mr. Cooper believed that in the Society of which he was the representative the examinations were eminently practical.

Dr. Fleming thought it would be well if some more definite plan were adopted for conducting examinations. He would not give an opinion as to the advisability of substituting class examination for other examinations. He knew how well Professor Syme conducted his examinations, and how he was acquainted with all the students, and knew precisely what each one was fitted for.

Dr. Paget, while admitting that it would be a good plan to continue the inspections for another year, wished it to be understood that the plan was a very imperfect one. The Act of Parliament under which they acted was passed for the purpose of equalising privileges, and they ought, therefore, to equalise the qualifications. It would be right for the visitations to be made in such a way as to enable them, in some measure, to compare the different degrees and qualifications in the respective countries, and not the English with the English, the Scotch with the Scotch, and the Irish with the Irish. He could not help noticing that the University of Glasgow was the only licensing body in Scotland, with the exception of the Professor of Surgery in Edinburgh, which had clinical examinations. If more was required from Medical students in clinical examinations, they would be more attentive to their clinical studies.

The motion for the reception of the report was then carried unanimously.

The President being obliged to leave the meeting, Dr. Alderson took the chair.

Dr. Andrew Wood proposed, and Dr. Thomson seconded, the resolution which he had already read.

Sir D. J. Corrigan moved the following amendment:—"That visitation of examinations carried out by members of the General or Branch Medical Councils being a reciprocal

visitation by the representatives of the several licensing bodies of one another's examinations is faulty in principle, and therefore can never command confidence. That any visitation of examinations would be worthless which did not include every examination, inasmuch as partial visitation could only testify as to the actual examinations visited—necessarily a very small proportion—and be no evidence whatever of the character of the examinations not visited, the larger proportion; that visitation of every examination would be impracticable, inasmuch as, in addition to preliminary examinations, there are annually about three thousand five hundred Professional examinations in the United Kingdom for degrees or licenses." His first objection to the visitation which had been carried on, and which was now proposed to be continued, was on principle. Their degrees and licences had been impugned. Men utterly ignorant of Anatomy, Surgery, Materia Medica, and English had up to the present moment been let loose upon the public. The Army and Navy Boards had very properly acted in this matter, by saying that such was the state of the men who were passed by the licensing bodies, every one of which bodies was represented at that table, that they dared not trust the lives of her Majesty's soldiers and sailors to their care; that, though there might be some whom they could trust, there were many they could not, and, under these circumstances, they felt obliged to institute an examination for themselves, in order to eliminate the unqualified students who were passed by the licensing bodies; and yet, if they looked to the reports of the visitations, which he voted for putting upon the Minutes, because they were the most valuable documents they had ever had, they would find that in every case the visitors expressed themselves satisfied that no persons were improperly passed in the subjects in which they had been examined. This was very satisfactory, but it was very strange in the face of the act of the Army and Navy Boards. Under these circumstances, what did they propose to do? They proposed to adopt a course which, as far as he knew, was without parallel in any body, from the House of Commons down to the smallest corporation in the kingdom. Their degrees being impugned by one of the highest authorities in England, they now proposed to inspect themselves, and the principle upon which they were going was that of the old Scottish proverbs—"Caw me; caw thee." "Hawks don't pick out hawks' een." When, some years ago, certain of the rotten boroughs in the country were impugned, did the parties impugned sit round a table and say they would inspect one another, and that they would send out a report which would show that they were the very model of purity? Yet this was exactly what they were proposing to do. Supposing some years ago, when the managers of the lunatic asylums were impugned, those managers had inspected and reported upon themselves, would the public have been satisfied? Why should they have an inspection of themselves by one another? He wanted them to look beyond the little circle of Medicine and of the licensing bodies, and to mix more with the world, and try to assimilate their proceedings to those of the world outside. He was sorry to say that many members of the Profession seemed to live in a world of their own, and it was a great misfortune that they did not mix more with men who were concerned with other important businesses in life. Supposing when the various boards of guardians were impugned they inspected themselves, would such a course inspire public confidence? Some years ago the conduct of the paid magistrates in Ireland was called in question; and if they had inspected themselves what would have been said? If, when the captains of emigrant ships were charged with neglect, would it inspire public confidence if they inspected and reported upon themselves? When the charges were lately brought against railway directors, would those directors have inspired public confidence if they had reported upon themselves? This was his objection to this system of visitation, that the parties who were on their trial were the persons who were going to try themselves. His second objection was, that it was impossible to carry the visitations out, inasmuch as there were 3500 examinations in the course of a year. Supposing they took 500 of those, were they willing to accept those as samples of the rest? If they had a basket given them with 500 eggs in it, would they, because fifty of them turned out good, take it for granted that the 450 were also good? When he looked to the reports, he found that only five days had been spent in visitation.

Dr. Andrew Wood said that he was in Edinburgh ten days himself.

Sir D. J. Corrigan stated if that were the fact it ought to have been stated. He knew of a case where the examination occupied only half an hour, and only two persons were present—namely, the President and the Secretary of the College. This was in a College that was represented at that Council; and he held a letter in his hand from the candidate, but he would not then mention his name, because it might seriously interfere with the young man. This reminded him of an occasion when he had to inspect a lunatic asylum. He found a number of women, all very nicely dressed, having clean wristlets, and very comfortable; but on saying to one of them that he was glad to see them so, she replied—"You are a Royal Commissioner, I think?" He answered that he was, and asked her how she knew; and she then said—"Don't you go to be a fool; we're not rigged out in this way every day!" Examinations could be "rigged out," too. His third objection to the system was, that it was one which was opposed to and at variance with the common-sense rule that was applied by the world outside. If a man wanted to test the purity of gold he would not examine how it was made, nor who was the maker, but would test the article itself. They ought to test the result, and not the process. When the Army and Navy Boards wanted to test the efficiency of the candidates, they did not inspect the bodies who had licensed them, but they examined the candidates themselves. If they carried the motion adopting this system, they ought properly to follow it up by sending a communication to the Army and Navy Board telling them that they were wrong in testing the article produced, and that they ought to test the process by which it was produced. When the Government wanted guns they never asked the makers to report upon themselves; but they tried the various guns, and then decided, and the same with armour plates. The London University—a body of whose proceedings he would ever speak with approbation—did not examine the schools and accept reports on, but they examined the pupils from those schools, and so tested, not the process, but the result; and this was what they all ought to do. If his amendment were accepted, he should follow it up by a proposition for carrying it into effect by appointing a body of examiners altogether independent of the Council to examine the candidates who had been passed by the several licensing bodies. It might be said that they had no power to make students come before them; but under the Act of Parliament he thought a very wide discretion was left to the Council as to the means by which they were to ascertain whether the qualifications possessed by any body were sufficient to ensure competency. There were three classes of men to be dealt with—one class who would be able to pass the body he proposed; another class who would fail, and then try again; and then a third class who would be afraid of it altogether. Since the last Session he had thought long and seriously on this matter, and he had come to the conclusions which he had now laid before them.

Dr. Aquilla Smith seconded the amendment.

Dr. Alexander Wood thought of great importance that the statements made by Sir Dominic Corrigan should not go forth without a complete answer being given to them, inasmuch as it would be a most damaging thing if such a speech were to go out without the contradiction which it naturally called forth. Sir Dominic Corrigan seemed to have forgotten altogether the Act of Parliament under which they acted. The duty which the Act imposed upon them they were striving to the best of their ability to perform. He himself differed to a certain extent from the conclusions which had been arrived at by the Council with reference to the best means of carrying out their duty, and he had proposed another plan, but he could not admit the justice of any one of the analogies which Sir Dominic Corrigan had used. His first statement was that the Council wished to justify itself before the country with regard to the men who passed. He knew of no such motive, their only object being to improve the examinations, and to ensure that candidates should be properly examined, and he cared not whether the means they took to do this approved themselves to the country or not. The amendment, like others which Sir Dominic Corrigan had for years past put forward, endeavoured to show that they were an incapable body, but he did not suggest any remedy for their incapacity. Sir Dominic said the other day that all the bodies were antagonistic to one another, but now, when it suited his purpose, he wanted to make out that they were willing to praise one another. He appealed to the reports to show the anxiety of the men who were engaged in making the visitations to do their duty. It was perfectly true that there were a vast number of examinations every year, and that it was impossible to overtake them; but would the body

which Sir Dominic Corrigan proposed be able to do it? Besides this, what power had they to bring students before them for examination? None at all! Another thing was that Sir Dominic Corrigan had referred to the Army and Navy Boards, as if they were the best judges of their examinations; but with all due respect to those gentlemen, he felt bound to say that it was not the best students who went before them, for as long as a man had a chance of decent and respectable employment in this country, he would not go to the Army and Navy Board to ask for it. In an address delivered not long ago at a University he heard a Professor tell the students that in the army they would be least regarded and worst paid, and he advised them not to go into it. He cordially supported the motion of Dr. Andrew Wood.

On the motion of Dr. Parkes, seconded by Dr. Storrar, the standing orders were suspended till a quarter past six.

The amendment was then put and lost, only two hands being held up for, and fifteen against it. The motion was carried.

It was proposed by Dr. Storrar, seconded by Dr. Andrew Wood, and agreed to, that the Council meet to-morrow at one o'clock.

Eleventh Day.—Tuesday, May 29.

The Council met to-day at one o'clock, in accordance with the resolution passed yesterday.

In the temporary absence of the President the chair was taken by Professor Syme.

The minutes of yesterday's meeting having been confirmed,

Dr. Embleton brought up the following amended Report of the Committee on the Registration of Medical Students, and moved its adoption, which was seconded by Mr. Hargrave:—

Report.

1. The Committee, having taken into consideration the working of the system of registration of students of last session, find that in each division of the kingdom there have been a certain number of students unregistered, in consequence of the difficulty of making the new regulations sufficiently understood by the students and their friends, and by the authorities of the several Universities, Schools, and Hospitals; but they believe that this difficulty is likely to be materially lessened in future years, and they recommend that the Council should leave the several Branch Councils to make such exceptions in reference to the year 1865 as may seem to them advisable, enforcing the regulations strictly for the future.

2. The Committee have also considered "the cases of students admitted to registration who have not passed the Examination in Arts or only a portion of such examination," and they find that in certain schools several students have been allowed to commence their recognised Medical education before having passed a Preliminary Examination in Arts; but they do not find that any student has actually been registered before having passed the Preliminary Examination.

The Committee strongly disapprove of the above irregularity on the part of Schools, and recommend that in future the whole of the Preliminary Examination should be required to be passed at one time, and that before either registration be allowed or Medical Education be commenced; and this recommendation, from the assurances they have received, they believe will now be literally complied with.

With respect to the students concerned, the Committee see no other course open to them than that of advising the Council that, under the circumstances named, they should be left to the favourable consideration of the Branch Councils, for they consider that it would be hard that, in the first year of a new system of registration, students should suffer through the irregularities above referred to.

3. The Committee have also paid attention to the "letter from Dr. Steele, Registrar of the Branch Council for Ireland, with an application from a student to be registered," and recommend that, as the registration of Medical students has been placed under the charge of the Branch Registrars, the decision in this case be left to the Branch Council for Ireland.

4. The Committee have carefully gone over the whole of the regulations respecting the registration of students, as laid down by the Council during the last session, have remodelled them in accordance with existing circumstances, and beg leave to submit them in the following form for the approval of the Council, believing as they do that, having been made more simple and clear, the new regulations will be found well-adapted to secure for the future a correct register of Medical students.

Registration of Medical Students, 1866.

The following regulations have been adopted by the General Medical Council, in reference to the registration of Medical students:—

1. Every Medical student shall be registered in the manner prescribed by the General Medical Council.

2. No Medical student shall be registered until he has passed a Preliminary Examination as required by the General Medical Council.

3. The commencement of the course of Professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration.

4. The registration of Medical students shall be placed under the charge of the Branch Registrars.

5. Each of the Branch Registrars shall keep a Register of Medical students according to the subjoined form.

Form for the Registration of Medical Students.

Date of Registration.	Name.	Preliminary Examination and Date.	Place of Medical Study.

6. Every person desirous of being registered as a Medical student shall apply to the Branch Registrar of the division of the United Kingdom in which he is residing, according to the annexed form, which may be had on application to the several qualifying bodies, Medical Schools, and Hospitals; and shall produce or forward to the Branch Registrar a certificate of his having passed a Preliminary Examination, as required by the General Medical Council, and a statement of his place of Medical study.

Form of Application for Registration as a Medical Student.

I hereby apply to be registered as a student in Medicine, in conformity with the regulations of the General Council of Medical Education and Registration of the United Kingdom, for which purpose I submit the following particulars:—

Name of Applicant. (To be written in words at length.) Surname.	Christian Name.	Preliminary Examination.	Date of Preliminary Examination.	Place of Medical Study.

Applicant's Signature .....
Address .....
Date of Application .....

To the Registrar of the Branch Council for.....

N.B.—The above form of application, duly and legibly filled up, must be forwarded to the Registrar, post free, and be accompanied by a certificate of the Applicant's having passed a Preliminary Examination, as required by the General Medical Council; and a statement of his place of Medical study.

Students who have commenced their Professional studies more than fifteen days before the 2nd October, 1865, are not required to be registered by any Branch Registrar.

7. The Branch Registrar shall enter the applicant's name, and other particulars, in the Students' Register, and shall give him a certificate of such registration.

8. Each of the Branch Registrars shall supply to the several qualifying bodies, Medical Schools, and Hospitals, in that part of the United Kingdom of which he is Registrar, a sufficient number of blank forms of application for the registration of Medical students.

9. The several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory.

10. A copy of the register of Medical students, prepared by each of the Branch Registrars, shall be transmitted, on or before the 31st December in each year, to the Registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered during the year, and supply copies of such authorised list to each of the bodies enumerated in Schedule (A) to the Medical Acts, and through the Branch Registrars to the several Medical Schools and Hospitals.

11. The several qualifying bodies are recommended not to admit, after October, 1870, to the final examination for a qualification under the Medical Acts, any candidate (not exempted from registration) whose name had not been entered in the Medical Students' Register at least four years previously.

In the case of candidates from other than schools of the United Kingdom, the Branch Councils shall have power to admit exceptions to this recommendation.

*** The Branch Councils are desired to take every means to make these regulations known to the Medical students at the various Medical schools.

Dr. Aquilla Smith said that before this Report was adopted he had a motion to make upon it, the object of which would be to get a better definition of the column in the Register, which was headed "Place of Medical Study." Looking over the list in the Students' Register of "Places of Medical Study," which might be said to be so far recognised, he found that their number was 39—namely, 26 in England, 7 in Ireland, and 6 in Scotland, but there were certain places mentioned in the list as being recognised which he had no recollection of having ever been recognised by the Council. Some of the places mentioned were under the head of Colleges—Newcastle-upon-Tyne, Queen's College, Birmingham, Sydenham School, Birmingham, Bristol School, Leeds School, Liverpool School; and under the head of Provincial Hospitals there were the Sussex County Hospital at Brighton, the General Infirmary at Hull, etc. The Council would know that many of these places had never been recognised by the Council as "places of Medical study," and he thought it was the duty of the Council to define what a "place of Medical study" was. The matter was very important with regard to all the future steps of study to know that students had spent a certain period of time in Medical study, and if they could not get complete registration they had better stop the whole thing. He would, therefore, propose as an amendment that before the adoption of the Report it was expedient for the Council to define what a "place of Medical study" was.

Dr. Alexander Wood thought the subject was of too much importance for them to enter upon it then, and that it would be best to adopt the Report, and for Dr. A. Smith to bring up the matter again next year. He suggested, therefore, to Dr. Aquilla Smith to withdraw his amendment.

Dr. A. Smith said he wished his amendment to appear

upon the Minutes, but, acting on a suggestion which had been made to him, he would withdraw the amendment, and afterwards propose it, with a slight alteration, as a substantive motion.

The motion for the adoption of the Report was then carried.

Dr. A. Smith proposed, and Dr. Alexander Wood seconded, the following motion:—"That it be delegated to the Branch Councils to report to the next meeting of the Medical Council as to whether the column headed 'Place of Medical Study' in the form of Register of Medical students now adopted should in future define more clearly the manner in which it is to be filled up, and if it is their opinion that it should, to suggest what appears to them to be the best means of doing so."

This resolution was agreed to.

The President here resumed his duties as chairman.

The Registrar next read the following letter from the Metric Committee of the British Association for the advancement of Science:—

To the General Council of Medical Education and Registration.

10, Farrar's Building, Temple, May, 1866.

Gentlemen,—We are desired by the Metric Committee of the British Association for the Advancement of Science to seek your aid in promoting the practical adoption of the Metric Weights and Measures Act, passed in 1864, being the 27 and 28 Vict. c. 117, "An Act to render permissive the use of Metric Weights and Measures in the United Kingdom." Although this law is of a permissive character only, yet it allows full scope for the extensive application of the new system, and we trust that every opportunity will be seized for resorting to it, with a view of putting an end to the manifold defects and inconveniences of the present practice.

We understand, with pleasure, that such an opportunity now occurs for introducing the metric decimal system into Medicine and Pharmacy, since the British Pharmacopœia, published in January, 1864, is about to appear in a second edition. The objection formerly urged to the introduction of the metric system side by side with the imperial, in all the formulæ for the preparation of drugs and chemicals, that the metric weights and measures were not yet sanctioned by the Legislature, is now removed by the passing of the Act; and we hope, therefore, that your Council will give its sanction to the proposed useful addition.

In submitting to you the desire of the Metric Committee of the British Association, that the knowledge of the Metric System may be promoted in Medicine and Pharmacy, we would only add that, for international purposes, and especially for the use of foreign Practitioners, and of British chemists in foreign countries, the ready comparison of the imperial with the metric weights and measures will be of great practical value; and, moreover, will tend to give effect to a reform expected to be highly useful to this country, and of extensive influence in social and international intercourse.

We have the honour to be, gentlemen,
Your obedient servants,
John Baring, F.R.S., LL.D.,
Chairman of the Committee.
James Yates, M.A., F.R.S.,
Member of the Committee.

Dr. Alexander Wood said he should move that the letter be referred to the Pharmacopœia Committee for their consideration, and that they be requested to report upon it at the next meeting of the Council.

Dr. Apjohn objected to the motion, because it would delay the publication of the Pharmacopœia till the Committee had had time to prepare and present their Report.

Dr. Sharpey said he would propose a resolution which he thought would be better than that of Dr. Alexander Wood. It was as follows:—"That the General Medical Council are not prepared to adopt, in its full extent, the suggestion of the Metric Committee of the British Association, but the Council will direct that a complete comparative table of metric and imperial weights and measures, with instructions for their mutual conversion, shall be inserted in the forthcoming edition of the 'British Pharmacopœia.'"

Dr. Parkes said he had himself written to the Chairman of the Pharmacopœia Committee on the subject, and had received a reply that, although the Committee would not bring the system into the work, they would probably introduce a full table of the comparative French weights and measures. No doubt this would be of great use to gentlemen in the army, who were in the habit of using the metric system. He was very anxious to see it done, but it could not be brought into this Pharmacopœia except in the short way he had mentioned.

Dr. A. Smith supported Dr. Sharpey's motion.

The original motion was withdrawn, and Dr. Sharpey's resolution was seconded by Dr. Apjohn, and carried unanimously.

The returns of examinations from the Medical Department of the Navy were next considered.

Dr. Andrew Wood said the Council, the Profession, and the licensing bodies ought to be extremely obliged to the Navy Department for granting these returns, which unquestionably tended to bring out the fact that men had been passed by the licensing bodies who failed when they came to the Navy examinations. But it must be remembered that all those who had thus failed had probably passed their examination by the bodies at least four years ago. He did not despair, in the face of these returns, but believed that all that was being done by the Council was being brought to bear upon the examining bodies, and if three or four years hence similar returns should be laid before them then they would have reason for very great regret and for believing that they had not done their duty, but not till then. It was of very great importance that they should get all the details. He would therefore propose the following resolution:—"That the Director-General of the Medical Department of the Navy be respectfully requested to furnish in future the Council with copies of the questions proposed to candidates for Navy Medical commissions, in the same way as is done by the Army Medical Department authorities."

Dr. Fleming seconded the motion.

Dr. Alexander Wood had no objection to the motion, but wished to say a few words, because he had noticed that year after year they had been sliding into a very dangerous position with regard to this matter. They had received these returns and entered them on their Minutes as though they were to be applied to test the efficiency of the various licensing bodies. He did not at all admit that they were so, and if they were to be put on the Minutes for that purpose he objected. What was the position which those bodies occupied? A gentleman presented himself at the College who had previously undergone a preliminary examination by one of the bodies recognised by the Council. They did not then examine into preliminary education at all, but only Professional, and he had known cases where the spelling was bad, but the examiners felt that they could not reject the man because of that, because he had been accepted by the first body. But he had a still stronger objection. Every one who had been connected with examinations knew that a great deal depended on the way in which questions were put and of the state of mind of the candidate. Some examiners, too, were much more stringent than others, and it often happened that as a man grew old the less stringent he became. He mentioned this because he did not wish it to go forth that the Navy examinations were a crucial test of the examinations of the licensing bodies. At the same time, he thought there was a great improvement in the examinations of all the bodies, and he was glad to see that this was the case in the body to which he belonged.

Mr. Syme said he knew of one case where a young man had passed a good examination by a University of Scotland, and yet was refused by the Navy Board, thus showing that men were but fallible.

Dr. Parkes believed that a great deal of good had been done by these returns being furnished. At the same time, he felt bound to say that neither the Army nor the Navy Board would hardly be justified in furnishing the returns in future if the Council was to be made the means of attacking gentlemen who entered into the service.

Sir D. J. Corrigan had listened with pain to the discussion. As long back as May, 1864, it was unanimously agreed to ask for these returns, which were of the greatest value; but he was sorry to see now that unfortunately, from some cause or another, attempts were being made to throw cold water upon them, and to disparage them. If the conversation which had just taken place in the Council reached the ears of the authorities, he should not be surprised to find that the returns in future were stopped. He was exceedingly sorry that a charge should have been brought against them that they had refused to pass a competent man. He had never regarded the returns as a crucial test of the licensing bodies; but they certainly did give the information that those bodies did allow men to enter the Profession who were so ignorant of Latin, English, Anatomy, Surgery, and Materia Medica, that they were not fit to be trusted. Dr. Wood's excuse was, that the bodies who examined in Professional education were not responsible because they did not examine in preliminary education; but they could not get away from this, that these men had been passed in their preliminay education by bodies which were recognised by the Council.

Mr. Cæsar Hawkins reminded the Council that the students who had this year applied for Professional examination had probably never been examined before by any body, and therefore it was no fault of the Council. Allowance must also be made for the memories of the candidates, and it was not at all unreasonable to suppose that men forgot something which they had learned several years before. The returns were of very little value unless they had the examination papers.

Mr. Syme explained that he had made no charge against a public department, but he only wished to show that the best men might be mistaken, and that therefore the returns must not be taken as a crucial test.

Dr. Paget thought it would be a great mistake if the furnishing of the returns should be interrupted. Although it was not a crucial test, yet it was a test of the thing produced, and it was much better to judge of the quality of that than it was of the process by which it was produced.

Dr. Andrew Wood withdrew not one sentence as to these returns being the touchstone of their examinations; and he held, moreover, that if they endeavoured to put aside this touchstone, and shut their eyes to the deficiencies which had been brought to light, they would not be doing that which was compatible with their duty. Let them boldly face the whole matter.

The motion was carried unanimously.

The Returns of the Examinations from the Army Medical Department were next considered, and the following motion was proposed by Dr. Andrew Wood, and seconded by Dr. Fleming—"That the best thanks of the Council be given to the Director-General of the Army Medical Department for the returns which he has been good enough to transmit to the Council, and that he be requested to furnish the Council in future with a statement of the subjects in which the rejected candidates have failed."

Dr. Parkes supported the motion, and said the Director-General was anxious to give the Council all the information they required.

The resolution was carried.

The following Report of the Finance Committee was then presented, and, on the motion of Dr. Sharpey, seconded by Dr. Storrar, was adopted:—

The Finance Committee beg leave to present a statement of the estimated and actual income and expenditure of the year 1865; also an estimate of the income from ordinary sources, and of the expenditure, as far as the Committee are able to judge, for the year 1866.

From the figures in the table it will appear that the actual income of the past year fell somewhat short of the estimate, but as, on the other hand, the actual expenditure is less than what was estimated, there is a small balance in favour of the Council.

In reference to these estimates, the Committee have to observe that it is scarcely possible to judge of the prospective expenditure with any near approach to accuracy, inasmuch as the amount is greatly dependent on the duration of the Sessions of Council, which cannot, with certainty, be determined beforehand.

A statement of the receipts and disbursements on account of the British Pharmacopœia, since the date of the account presented last year, and of the balance in the bank at the credit of the General Council, is given up to January, 1866.

W. Sharpey, Chairman.

The Report of the Committee on Returns from the Licensing Bodies was also considered and adopted.

Dr. Alexander Wood proposed a resolution, of which he had given notice:—"That the following addition be made to the Standing Orders of the Council:—

"*Chapter* [ ] *in Regard to Reports of Committees.*

"That no report from any Committee of the Council shall appear in the Minutes until it has first been printed in the 'Programme of Business.'"

Dr. Paget suggested that all the purposes of this resolution would be answered by a subsequent motion, of which Dr. Fleming had given notice.

*

Dr. Alexander Wood, at the suggestion of the Council, moved the adoption of the first paragraph of his resolution.

Dr. A. Smith seconded this proposition, which was carried.

The Registrar read a memorial from the County and City of Cork Medical Protection Association, pointing out that the Act of 1858 had fallen short of what was expected from it in its two principal objects—the protection of the public and a really improved system of Medical education. They suggested the expediency of the Council seeking for such modification of clause xli. of the Medical Act as would secure the prosecution of offenders against its provisions; but especially of seeking for the power to establish a uniform curriculum of studies, preliminary and Professional, which should be binding on all the educational bodies of the country.

On the motion of Dr. Storrar, seconded by Mr. Hargrave, it was resolved, "That this memorial be entered on the Minutes."

Dr. Fleming moved, in pursuance of notice,—"That the Executive Committee consist of six members exclusive of the President, instead of four, as at present; that of the six members to be elected, four be chosen from the English, one from the Scottish, and one from the Irish Branch Council." The alteration proposed was merely to add two members to the Executive Committee. The English constitution would remain exactly as it was, having four members and the President an *ex officio* member; and after what fell from the President in his admirable opening address, he had no doubt he would think it an advantage if the Irish and Scottish Branches were represented also.

Dr. Paget thought it would be an advantage to them if the Executive Committee had a little more power than it had had hitherto. The proposal seemed both moderate and reasonable. Instead of adding to the expenses of the Council, it would probably reduce them.

Dr. Alexander Wood moved the previous question, that the resolution be not agreed to. The great danger to be apprehended in this Council was that a small section of it should be delegated with a great part of the important business that came before the Council. As there was a great difference of opinion on almost every question which came before them, he thought their only safety was in keeping the Executive Committee in such a position that it could not take upon itself the functions of the Council in any way in the interval of the sessions. He did not think the addition of two single members—one from Scotland and the other from Ireland—would much improve the matter. The Branch Councils in Scotland and Ireland were small bodies, and were as much divided in opinion on different questions as the Council was. He had heard it stated by an eminent member of the Irish Branch Council that he considered the Amendment Bill wrong altogether; and if they were to refuse to send that member to represent them they would lose a most powerful, a most able, and eminent member of their body. [Sir D. J. Corrigan: "Exactly."] (Laughter.) The less power they delegated to the Executive Committee the safer it would be for the Council.

Mr. Syme opposed the motion.

Dr. A. Smith quite concurred in the principle of Dr. Fleming's motion. With regard to the expenses, he was satisfied it would be a considerable saving to the Council.

Dr. Sharpey said the Act gave the General Council power to appoint an Executive Committee; but he apprehended the Branch Councils could scarcely do that; and they would be called upon to do it in part, if they elected one member from the Scottish and one from the Irish Branches.

Dr. Fleming said the General Council must elect the two members of the Branch Councils. He asked the President to favour them with his view of this question.

The President said he did not think it worth while to occupy the time of the Council with his opinions on this subject, because, at the opening of the session, he did commit himself to an expression of opinion upon it, and that opinion he still entertained. So long as the Executive Committee was composed of members of the English Branch Council exclusively, the General Council ought to be jealous of delegating greater powers to it than it at present possessed; but if any means could be adopted by which they could get a fair representation on that Committee of the other Branch Councils, he thought further powers might be entrusted to it according to the Act of Parliament, and that such an Executive Committee might be able most materially to lighten the labours and shorten the sittings of the Council. If they asked his opinion as the President, he must say he thought one of the great defects in their organisation was that they had no means of carrying on business except through the large body sitting round that table. A great deal of the preparation of business which came before that Council might be transacted by the committee proposed, and, therefore, he thought it would certainly be a step in the right direction, if such a committee were appointed.

Dr. Fleming having briefly replied,

The amendment was withdrawn, and the resolution was put and carried, there being for, 12 votes, and against, 4.

A ballot of the whole Council was then taken for the Executive Committee, and the following members were elected:—Mr. Cæsar Hawkins 17, Dr. Acland 8, Dr. Paget 13, Dr. Andrew Wood 12, Dr. A. Smith 8, and Dr. Sharpey 17.

Dr. Fleming then moved, pursuant to notice, "That it be remitted to the Executive Committee to consider the whole form of procedure, which has hitherto been followed in conducting the business of the Council, and to report, on the first day of next session, any alterations which, in their opinion, would tend to expedite the transaction of business."

Dr. Alexander Wood seconded the resolution, which was agreed to without discussion.

Dr. Andrew Wood said they were all aware that this Council had resolved to propose a Bill for the amendment of the Medical Acts. They were in hopes that by this time they would have had some communication from the Government. Mr. Ouvry saw Sir George Grey's Private Secretary, and impressed upon him the importance of receiving a deputation from this Council, and receiving it during this session; but no communication had up to this time been received from Sir George Grey. It was quite clear that this Council, having prepared the Bill, ought not to separate without taking the proper steps for seeing that it was pressed upon the Government, and, therefore, he begged to propose the following resolution:—"That it be delegated to the Executive Committee to confer with the Government in regard to the proposed Bill for the amendment of the Medical Acts, to press on the Government the expediency of its being adopted as a Government measure, and to take all necessary steps for aiding the passing of the Bill through Parliament." They were aware that in a communication from Sir George Grey, which had been before the Council, a suggestion was thrown out that it might be the duty of the Council to get some private member of the House of Commons or the House of Lords to introduce the Bill. Now, he had taken as deep an interest in the proposed Bill as any man at that table, and he had no hesitation in saying that he believed it to be the duty of Government to take up a measure of that kind, and the more especially as this Bill had been sent to the Council from the Home Office for their observations upon it, and had been sent to them as a constituted body in the country whom they could advantageously consult. He had no hopes of passing a measure of this kind through Parliament, unless it were taken up as a Government measure. It would be beneath the dignity of this Council to put in this resolution anything implying they were willing the Bill should be brought forward by a private member. Some members of the Council, who were opposed to legislation altogether, might not feel inclined to give the Executive Committee power in this matter, but now that Committee had been put on a different foundation, they ought to place a considerable amount of confidence in it. Dr. Andrew Wood then formally proposed the resolution he had read.

Dr. Alexander Wood seconded the motion.

Sir D. J. Corrigan thought they were all agreed that unless it be taken up as a Government measure it would not be passed. He thought that it should be a distinct instruction to the Committee to abandon it in case the Government declined to take it up.

Dr. Alexander Wood would agree with the suggestion that the Committee should not go forward with the Bill unless it were taken up by the Government, but he objected to tie the hands of the Committee.

The resolution was then amended as follows, and agreed to:—"That it be delegated to the Executive Committee to confer with the Government regarding the proposed Bill for the amendment of the Medical Acts, to press on the Government the expediency of its being adopted as a Government measure, and at the same time to state that the Medical Council are of opinion that, unless the Bill be introduced by the Government, it would be unadvisable to proceed with it."

It was then proposed by Dr. A. Smith, seconded by Dr. Storrar, and resolved:—"That the powers and duties delegated to the Executive Committee, in accordance with sect. 9

of the Medical Act (see Standing Orders, sect. 6) shall be vested in the Committee until the next meeting of the General Medical Council."

Dr. Embleton then moved, pursuant to notice, "That the following be substituted for paragraph 7, Section V. of the Recommendations of the General Medical Council on Education and Examination. 'That each of the bodies named in Schedule (A) to the Medical Acts communicate confidentially to the Registrar of the General Medical Council, immediately after each Professional Examination, the names of candidates who have been rejected; that the Registrar shall then communicate these names also confidentially to each of those bodies; and that no candidate who has been rejected shall be admitted to re-examination by any of the bodies till after the expiration of three months.'"

Mr. Hargrave seconded the resolution.

As an amendment, Sir D. J. Corrigan moved,—"That paragraph 7, Section V., of the Recommendations of the General Council be struck out."

Dr. Storrar supported the amendment, and argued that a student's misfortune in not passing an examination ought not to prejudice him at a subsequent examination.

Sir Dominic Corrigan said that as regarded the body he represented, he was sure if the Council passed the resolution they would not comply with it.

Dr. Thomson said the resolution would have the effect of prejudicing the examiners against the students.

Mr. Hawkins strongly objected to the motion.

Dr. Embleton, in reply, said that certain students were in the habit of going from one part of Scotland to some other, and having been rejected at one place, they passed at another after a very slight examination. His motion was to prevent that.

The amendment was then carried by 10 against 4 votes.

It was about to be put as a substantive motion, when

Dr. Fleming proposed as an amendment that all the words after "bodies" should be left out, but, after some discussion, he withdrew, and the motion of Sir D. J. Corrigan was agreed to.

On the motion of Dr. Embleton, seconded by Mr. Hargrave, it was resolved,—"That the Report of the Committee appointed to rearrange the Recommendations of the General Medical Council on Education and Examination be adopted, and entered as amended, on the Minutes, and afterwards printed in a separate form and circulated as before."

It being six o'clock, it was resolved that the standing orders be suspended.

It was then moved by Dr. Smith, seconded by Dr. Sharpey, and agreed to,—"That a fourth volume of the Minutes of the General Medical Council, the Executive Committee, and the Branch Councils, with a complete Index up to the year 1866, be published without any unnecessary delay."

Dr. Sharpey was reappointed Treasurer.

It was then resolved:—"That the thanks of the Council are due, and are hereby tendered to the Treasurers, Dr. Sharpey and Dr. Quain, for their important services."

On the motion of Dr. Andrew Wood, seconded by Dr. Storrar, it was agreed,—"That the thanks of this Council are eminently due, and are hereby offered, to the Royal College of Physicians, London, for their obliging and courteous accommodation during the present session of the Medical Council."

A gratuity of twenty guineas was voted to the resident officials of the College of Physicians, for services rendered to the Council.

It was moved by Dr. A. Smith, seconded by Dr. Storrar, and agreed to,—"That a gratuity of twenty guineas be given to Mr. Bell, and the same to Mr. Roope, the clerks, in consideration of their extra services during the present session, and extra work consequent on the registration of Medical students, a duty which was not contemplated at the time that Mr. Bell and Mr. Roope were appointed."

It was further resolved, upon the motion of Dr. Paget, seconded by Dr. Embleton,—"That the cordial thanks of this Council are due, and are hereby tendered to Dr. Andrew Wood for his unwearied exertions and invaluable services as Chairman of the Business Committee during the past and present sessions of the Council."

The last motion was proposed by Dr. Andrew Wood, and seconded by Mr. Hargrave,—"That the thanks of the Council are cordially tendered to the President for his kind, courteous, and efficient services during the present session of the General Medical Council."

This resolution, which concluded the business of the session, was carried with great cordiality.

A formal meeting was then held to confirm the Minutes of this day's proceedings, and, these having been confirmed and signed by Mr. Syme, for the President, the Council broke up.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 591.)

Case 80.—*Non-adherent Cyst—Once Tapped—Ovariotomy—Recovery.*

An unmarried household servant, 24 years of age, applied to Mr. Wells in January, 1866, with an ovarian cyst, which filled the whole abdomen. She said she had been quite well till the end of 1864; then she began to feel weak, but continued to work. In June, 1865, her body began to increase, but she kept her place in Ipswich till October. Then she came to London, and went into the Homœopathic Hospital, where she was tapped six weeks after admission, twelve pints of clear fluid being removed, and a tumour on the right side remaining. An abscess formed at the place of puncture, and then she was dangerously ill, keeping her bed for a month after the tapping, on account, as she was told, of inflammation of both lungs. After she left the Hospital she again increased in size; looked ill and was very pale; menstruation was still regular and, as it always had been, rather excessive. Iron and quinine were ordered. On February 6 she looked better and felt stronger, but she had increased an inch and a-half in girth in seven days, and she suffered from increasing pain in the right hip. She was admitted to Hospital on February 26. The catamenia having ceased on the 19th, ovariotomy was fixed for March 7; but the catamenia appeared again on the 6th. It was discovered on closer inquiry that ever since the tapping there had been almost daily more or less uterine discharge. Dr. Jenner having carefully examined the chest and given his opinion that there was nothing in the heart or lungs to interfere with the operation, ovariotomy was performed on March 21. A non-adherent cyst was exposed by an incision extending five inches downwards from the umbilicus; a large cyst was tapped and emptied of nine pints of fluid. The incision was then extended two inches above the umbilicus, and the remainder of the tumour, consisting of a group of small cysts, was turned out entire. A pedicle as broad as two fingers extended from the right side of the uterus, and was so closely connected with the cæcum that the clamp would have produced dangerous traction. Mr. Wells, therefore, transfixed the pedicle, and tied it in two portions with strong silk, cutting off the ends of the ligature short, and returning the tied pedicle into the abdomen. The left ovary was healthy. The wound was closed as usual. The entire tumour weighed sixteen pounds. The patient complained of such severe pain on recovering from the chloroform, that a little more was given, and half a drachm of laudanum was injected into the rectum. The injection was repeated half an hour afterwards, and the patient then became easy. She had no bad symptoms afterwards. All the stitches were removed on the third day after operation, when the wound was well united. Some uterine discharge came on the same day, and continued for several days, and then a yellowish leucorrhœal discharge followed. Some pus was discharged from two stitch points near the umbilicus on the eleventh and twelfth days, all the rest of the wound being soundly healed. The bowels acted for the first time on the twelfth day. The patient left the Hospital in very good health twenty-six days after operation.

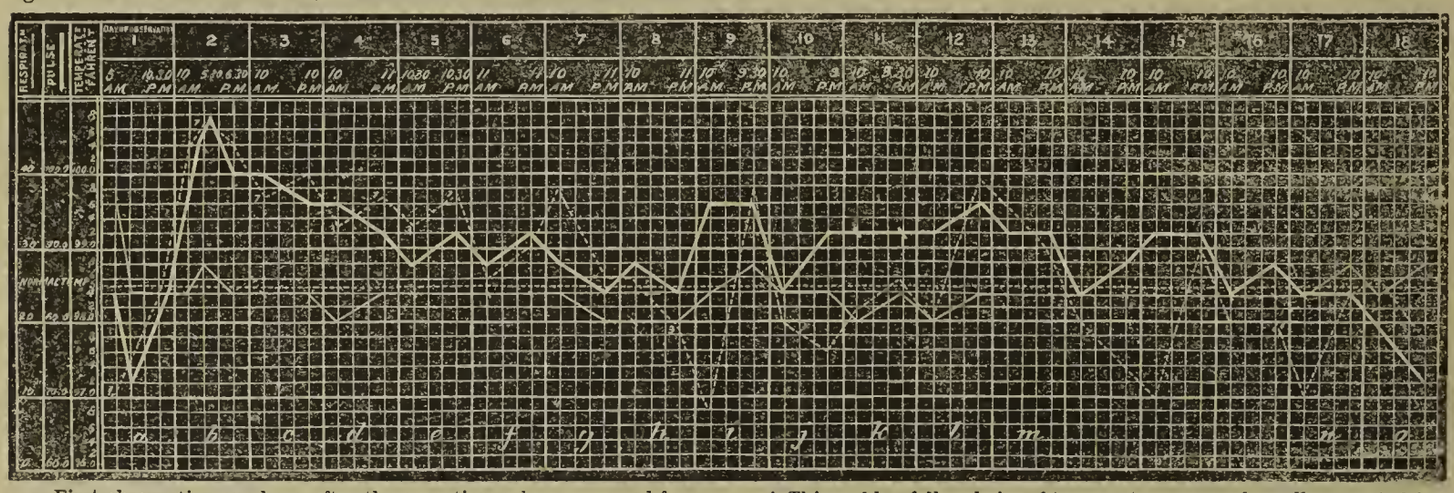
Case 81.—*Multilocular Cyst, never Tapped—Ovariotomy—Extensive Omental and Intestinal Adhesions—Recovery.*

A married woman, 46 years of age, mother of eleven children, was sent to Mr. Wells by Dr. Allan, of Guiseley, near Leeds, and was admitted March 24, 1866. The abdomen was filled by an elastic, moveable tumour, in which fluctuation was felt, though indistinctly. The uterus was normal, and none of the tumour could be felt in the pelvis. The general

health was good. Her last child was born in March, 1864. A few days afterwards she noticed a swelling in the right iliac region, and three months afterwards she began to feel pain occasionally in the same spot, and this pain became violent at each catamenial period for three or four months. Then the pain ceased, but the swelling went on increasing, slowly at first, but rapidly of late. As there was no cyst large enough to tap with any prospect of relief, it was agreed to perform ovariotomy on April 4, but the catamenia appeared the day before, and continued till the 13th. After a careful examination on the 15th, Mr. Wells diagnosed a compound ovarian cyst apparently free from adhesions to the abdominal wall, and with no close attachment to the uterus or within the pelvis. But a soft crepitus, felt all over the surface of the tumour, showed the presence either of recent lymph or of omentum. The absence of pain and fever almost excluded the possibility of lymph being present over so extensive a surface, and omentum was, therefore, looked for, and found at the operation, which was performed on April 18. Dr. Labbé, of Paris, Surgeon to the Salpetrière, and Dr. Lockwood, of New York, were among the visitors.

The tumour was exposed by an incision which extended from one inch above to eight inches below the umbilicus. Two bands of vascular adhesion, each about three inches long and two inches broad, connected the cyst on each side to the abdominal wall near the linea alba, but in such a way as to permit free movement of the cyst. These bands were tied and divided; the cyst was tapped; some pints of fluid were removed; and the partially emptied cyst drawn out and opened. Many large lumps of fatty fibrine then escaped. All the upper and back part of the cyst was then found to be closely enveloped by omentum and mesentery, with coils of small intestine. These were all carefully separated, and the pedicle was secured between two and three inches from the left side of the uterus by a small clamp, which was fixed outside with some little traction. There was very little bleeding; but four vessels in the omentum, which bled after some shreds had been cut away, were tied with fine silk. The ends of the ligatures were cut off short, and the omentum was returned. One of the bands of adhesion between the cyst and abdominal wall had been treated in the same way. The right ovary was healthy. Eleven pints of fluid were removed. The lumps of fibrine weighed one pound fourteen ounces, and the cyst wall one pound three ounces. The progress after operation was very satisfactory. The only opium given was three-tenths of a grain of acetate of morphia injected under the skin one hour after operation, and fifteen minims of laudanum into the rectum on the first day. All the sutures except the lowest were removed on the fourth, and the lowest on the fifth day. The urine being scanty, high coloured, and depositing mixed urates largely, citrate of potash was given freely, and with good effect. On the sixth day there was some superficial suppuration around the clamp. The clamp was removed on the eleventh day. The bowels acted on the twelfth, and on the sixteenth the catamenia came on with some customary pain. They went through the usual course, and the wound was soundly healed and the patient rapidly gaining strength when she left the Hospital on the twenty-sixth day after operation.

The following chart, on a plan which has been lately used by Mr. Wells, shows the daily range of pulse, respiration, and temperature in this case. The thin white line marks the rise and fall of the respirations, the thick white line of the pulse, and dotted line of the temperature. In the bedside charts used by Mr. Wells these lines are marked with coloured pencils—black, red, and yellow,—and the blank forms have a range of temperature from 94° Fahrenheit to 110°; of pulse from 50 to 160; and of respiration from 0 to 70. The range was so small in this case that it has been unnecessary to print the upper and lower part of the scale. It may be seen that the pulse never rose above 108, the temperature 100·7-10ths, and the respirations 36. The fall simultaneously in pulse, respiration, and temperature after the operation (shock), their rise for twenty-four hours afterwards, and then their gradual fall till the eighth day of observation are very interesting. The rise on the ninth day coincided with the maturation of a superficial abscess near the upper part of the closed wound.



a. First observation one hour after the operation, when recovered from the chloroform, at 4 p.m.; 3-10 gr. morph. subcutaneous.
b. No pain; sickness; skin moist; tongue moist, slightly furred; an enema with ℥15 laud., at 8 p.m.; urine loaded with lithates; citrate of potash.
c. Urine clear.
d. Urine slightly loaded with lithates.
e. More lithates in the urine. The stitches removed; wound united.
f. Urine clearer.
g. Suppuration in the wound round the clamp.
h. Very little discharge from the wound.
i. This sudden fall and rise of temperature cannot be well accounted for except by meteorologic causes. It was observed the same day in three other cases.
j. Had meat for the first time.
k. Enema in the morning.
l. The clamp removed. A small abscess forming at the left edge of the wound about one inch below umbilicus. Bowels not moved since operation.
m. Bowels moved.
n. Catamenia coming on, which are always very painful.
o. Catamenia.

As the rise and fall of temperature is of greater interest than the rate of the pulse, it may be well for the future to show in printing the range of temperature by the brightest line; but for the case-book the coloured pencils are far more convenient and effective. The registered thermometers of Mr. Casella, of Hatton-garden, as recommended by Dr. Aitken, are said by Mr. Wells to be the most convenient and reliable instruments for the bedside which he has yet obtained. But any glass instrument is easily broken, and our manufacturers would do well to turn their attention to the manufacture of some metallic instrument. In Mr. Gauntlett's chronometrical thermometer, by which the temperature of the air of Mr. Wells's ward for operation cases may be hourly recorded, a long hollow cylinder of zinc replaces the column of mercury in glass; and just as in the aneroid barometer a metallic chamber and spring show variations of atmospheric pressure by an index, it must be easy to indicate variations of temperature in a similar manner. Indeed, Mr. Wells informs us that a pocket registering thermometer has lately been made in Vienna not larger than a watch, which, if it prove to be equally delicate and accurate, will replace all fragile glass instruments, for use at the bedside.

An amateur morning concert will be given at Willis's Rooms on Tuesday, June 12, for the benefit of the London Infirmary for Epilepsy and Paralysis, Charles-street, Portman-square, under the immediate patronage of the Duchess of Grafton, the Duchess of St. Albans, the Countess of Derby, the Countess of Egmont, and other ladies. The programme is very attractive, and many of the most distinguished London amateurs will be amongst the performers.

Medical Times and Gazette.

SATURDAY, JUNE 9.

GENERAL MEDICAL COUNCIL.

The detailed reports of the last three days of the session will be found in another part of the journal; here we need only allude briefly to the most important of the matters discussed or decided on. As we mentioned last week, Saturday, May 26, was occupied wholly by the Report of the Pharmacopœia Committee. The question of chemical notation (we gave last week the resolution which was passed) took up a considerable time, and the rest of the sitting was given up to the consideration of Dr. Acland's proposition—that the Pharmacopœia Committee should ascertain whether the Council has any and what power to obtain or direct reports and investigations into the properties of medicines, etc. The proposal was not acceded to, the votes for and against it being equal. Years hence, when the Council has much less to do and has an overflowing exchequer, it may be very fitting and useful that it should undertake such investigations as Dr. Acland and Dr. Christison recommend; but at present the Council has more than enough on its hands, and so soon as it may find its income exceeding its expenses the propriety and advisability of lowering the registration fee will have to be considered. Before quitting the subject of the Pharmacopœia we must remark that every one will agree with the President in thanking Dr. Quain for his "indefatigable endeavours to expedite the progress of the work." Dr. Quain rarely occupies the time of the Council by any speech-making, but he is one of the most valuable of its working members.

On Monday, May 28, the first business before the Council was the Report of the Committee on the letter from the Secretary of State for War. We mentioned this Report and the result of the discussion on it last week.

Dr. Parkes's speech in support of his amendment, throwing over the whole matter—Committee Report and Council resolutions alike—was very sensible and very amusing, though not exactly complimentary to the wisdom of the Committee; and its chairman, Sir D. J. Corrigan, showed himself rather touchy and thin-skinned about it; Sir Dominic clearly does not like to be tarred with his own brush.

The "Reports of the Visitations of Examinations" were received and entered on the Minutes. The visitations are to be continued, and the next reports, which are to be fuller and more minute as to details, are to be in the hands of the members of Council before its next session. The Reports are much too important and numerous to be commented on at present; but we shall probably take an early opportunity of directing attention to them. The general opinion of the Council is evidently strongly in favour of these visitations, as likely to exercise great and highly useful influence upon the conduct and efficiency of examinations, and to furnish valuable information to guide the Council in making further "recommendations."

But Sir D. J. Corrigan could not resist the opportunity offered for one of his denunciations of the Council and all its works. He moved an amendment to the effect that the visitations are only reciprocal acts of politeness between similarly interested and inculpated bodies, and, therefore, a mere farce, and that examinations cannot be judged from samples, but before you can say whether they are good or bad you must attend every one of the 3500 that are held annually in the United Kingdom. He observed that when rotten boroughs were impugned the parties impugned had not the boldness "to sit round a table and say they would inspect one another, and would send out a report which would show that they were the very model of purity;" that the managers of Lunatic Asylums would not be trusted to inspect and report upon themselves; that examinations might be rigged; and so on, saying, as he always does, many very true things, and applying them very shrewdly, but by no means prettily or politely, and not proposing any better thing in the place of that he denounces. Sir Dominic really has been so combative in spirit this session, and shown apparently so much desire to overturn all that is, without being, as far as we can see, prepared with anything to replace it, that did our little Parliament contain a Whalley we should feel obliged to commend the Baronet to his close surveillance as a suspected Fenian.

On Tuesday the Report of the Committee on the Registration of Medical Students was adopted. The mode and form of registration have been slightly simplified. It is to be hoped that all the licensing bodies will soon be moved to consider that this Council-registration is all-sufficing. At present the unhappy student is grievously tormented and bewildered by the many registrations demanded of him.

The very sensible and respectful memorial of the County and City of Cork Medical Protection Association was simply ordered to be entered on the Minutes. There was no time, we suppose, for the consideration it merited.

The most important business of the day was the adoption of Dr. Fleming's motion to enlarge the Executive Committee by the addition of one Scottish and one Irish member. As now formed, the Committee consists of the President, Mr. Cæsar Hawkins, and Drs. Acland, Paget, Andrew Wood, A. Smith, and Sharpey. They are, among other things, "to consider the whole form of procedure which has hitherto been followed in conducting the business of the Council, and to report, on the first day of next session, any alterations which, in their opinion, would tend to expedite transaction of business."

The rest of the business was almost simply routine, and at the conclusion votes of thanks, in which every one will warmly and heartily concur, were passed to Dr. Andrew Wood "for his unwearied exertions and invaluable services as Chairman of the Business Committee during the past and present Session of the Council;" and to the President for his kind, courteous, and efficient services.

So ended the present Session of the General Medical Council; a Session of unusual activity and importance. A valuable educational recommendation has been carried; and an "Amended Medical Acts Bill" has been again thoroughly discussed, and finally settled. We venture to say "finally," because, though we have no hope of seeing the Bill passed by Parliament this year, we trust that it will not for any reason be thought necessary to discuss any of its details in the Council again next Session. It is a very meagre "Amendment Act," but such as it is, it has so long stopped the way, and has consumed such an immense amount of time, that we are thankful to believe it is got rid of at last. It will not in any degree increase the powers of the Council for the improvement of education; but though it has been frequently said that they now can only make "recommendations" for that purpose, and that they ought to ask Parliament for power to enforce their "recommendations," we believe that any such demand on their part would be perfectly futile and vain. Consider what the conduct of the

Council up to this time has been, and what they have done. They were called into existence in 1858, as "The General Council of Medical Education and Registration of the United Kingdom." They were obliged by the Act to adopt at once a system of registration, they could not delay that; but what have they done for education during these nine years? This is the question which Government would certainly ask, and it would further inquire—"How have you used the powers the Act of 1858 gave you, and in what way have they failed you?" The reply must be—"We have only now, after nine years, agreed on a minimum of subjects to be required as tests of general education in the preliminary examination. We have not yet determined on any scheme of Professional education, or of Professional examination; we have only got so far as to recommend that Professional education shall not commence till after the preliminary examination has been passed, and that it shall continue over not less than forty-eight months. Last year, the eighth year of our existence, we for the first time instituted visitations of examinations. We have had to regret that our 'recommendations' have in various ways and degrees been disregarded by some of the licensing bodies, and that year after year the returns from the Army and Navy Medical Departments have shown that men are continually gaining entrance into the Profession whom it would be dangerous to admit into those Services, but we have never used the power the Act gives us to report any licensing board to the Privy Council, nor in any way have sought the help of that body to enforce our 'recommendations:' we have relied solely on moral suasion."

We need not suggest what the answer of Government would be. It may be that only one talent was given to the Council, but if that talent has been kept so carefully buried, how shall they be intrusted with a greater number of talents?

We have been anxious to represent the labours of the Council each year in the most favourable light possible. We have been honestly desirous of upholding their authority and power in every way, of pointing out any good they effect, and of disregarding or silencing, if possible, any murmurs against them. By instinct and temperament, from associations and education, we have a profound reverence for "constituted authorities," and we have laboured to revere the General Medical Council; but year by year, the work has become harder, the difficulty of believing that they are an authority greater, the task of making excuses for them more and more burdensome. Year after year the same apology has to be offered for them as for a costly establishment belonging to a sister Profession, and with the defenders of the Irish Church the apologist for the Medical Council exclaims, "You do not sufficiently consider the difficulties they have to contend with." But it may be doubted whether, when it has to be annually repeated, such a defence does not become the most complete of condemnations?

The Council has been in existence nine years, and has cost the Profession £58,000—this, we believe, is a fair estimate of the sums paid for registration, for, up to the end of 1859, the Council had received in fees £34,500, and the average amount received in fees each year since, to the end of 1865, has certainly been as much as £3900—and when charged by one of themselves with having "done nothing," all that could be said in the eloquent defence made by another member, was, "They had, considering the circumstances, done a good deal. . . . The National Pharmacopœia had been constructed. The Registration of the Profession had been effected, and now was become a piece of office routine. Much had been done for education. Although all had not been done that might have been done, it was throwing dust in the eyes of the public, who had not a full knowledge of the facts, to announce that nothing had been accomplished." And another Member "could declare most positively that there was nothing more remarkable than the great advance which had taken place in the mental training of Medical students from the very first year in which the question of education was agitated in the Council.

Now grant all this to the full; say nothing about what the "National Pharmacopœia" is, or of how it has been almost repudiated by the Profession—nothing of the defects of uniform registration—nothing about the general advance of education throughout the country—pass by all these objections, and admit fully the defence offered, can it be pretended for a moment that it justifies an existence of nine years, and a cost of £58,000? that it answers in any degree the very lowest and most moderate expectations of the Profession? It is no real reply to urge, as Dr. Acland did, that "the habits of the Practitioners in the country, the habits of students, are not to be altered in a moment, without regard to previous circumstances, involved in vested interests, in existing corporations, teachers, and examiners." The fact that so many of the Council are "involved in vested interests" is, indeed, the strongest of all possible reasons why they should most carefully avoid any suspicion of dilatoriness; but no one has expected or desired any sudden or violent changes in the existing systems of Medical education and examination. It was to be expected, however, that the Council would, long ere this, have determined what changes were desirable, and have fixed a time for their coming into operation. Even had they granted to existing systems long years of grace, the Profession would then have been patient under the heavy tax they pay, for the good coming would have been visible. But as the years rolled on, and session after session the meetings of the Council were almost *vox et preterea nihil*—"neither gods nor men could stand it," and the Profession has become impatient and restive. All educational questions have been committed, re-committed, and re-re-committed, debated and re-debated, with most damnable iteration, though nearly every member of the Council is, or has been, teacher, examiner, or both, and might therefore be credited with a practical knowledge of the whole subject, and with being thoroughly alive to the importance of early legislation on it. And a like lavish expenditure of time has been bestowed on other subjects.

No one will believe for a moment that any one of the eminent men composing the Council has ever deliberately acted purely as the representative of the particular body which sent him there, but it can hardly be denied that now and then the conduct of a discussion has been of a character to afford some colour to such a reproach. Many of the members are calm, persevering, invaluable hard-workers, actuated by the single desire to elevate and improve the Profession, and respecting highly Carlyle's dictum that "Silence is the eternal duty of man;" but some others have yielded more or less largely to the temptations arising out of special endowments of speech and debating power, so that we have not greatly wondered at an observation 'that the business of the Council has been evidently managed on the division of labour principle, England undertaking mainly the thinking and acting, while the sister kingdoms relieved her of the chief part of the labour of talking!'

We thankfully acknowledge, however, that real and important progress has been made this Session, and as the two subjects that have hitherto consumed the largest amount of time may be considered as done with, we may hope that other matters of great and pressing importance will now be dealt with with commensurate earnestness and diligence. In such case the Profession will quickly forget what they may consider the shortcomings of past years.

We admit most willingly then that the Council has been of some real benefit, and has done some real work, but we do most earnestly deprecate, in the interests of the public, the Profession, and the Council itself, the great cost of time and money at which this has been effected. And we venture to entreat the members of the Council to be more uniformly and

continuously equal to the position in which they are placed, and the trust committed to them; and to remember that of all the difficulties they have had to contend with, the chief have arisen from within. If they will but, to adapt the words of Dr. Acland, exercise the powers they possess in a calm and judicial manner, and, showing trust and confidence in each other and in the good intentions of the several bodies they represent, seriously and loyally endeavour to work the machinery entrusted to them, they may still win the confidence and esteem of the Profession, and through and by the Profession earn a title to the national gratitude and respect.

THEORY AND PRACTICE IN DIARRHŒA AND CHOLERA.

We are compelled this week again to give the place of honour to the Medical Council and its proceedings, and to defer the full consideration we had intended of theories of cholera and methods of treatment. Still, we may make room for a few observations, just to clear the way, and serve as food for reflection.

Curationes morbum ostendunt, says Hippocrates. Tell us what does good in a disease, and we possibly learn something of the nature of it; for the effects of remedies are as much a part of the natural history of a disease as the pulse, tongue, and temperature. If a theory be propounded which is at variance with known facts as to the action of remedies, or which can be reconciled with the effects of some few remedies of one class only, and which requires the effects of other remedies of other classes, either to be denied or to be explained away, the question comes, which shall we give up—our facts or our theory? Every man must decide for himself, according to his taste and mental habits. For our part, we prefer the facts.

We must not forget, moreover, that no theory of any disease can be absolutely perfect. It can only be provisional; we must accept it, if we accept it at all, with the reservation—"So far as our present state of knowledge enables us to judge." See how triumphant the cell theory was a few short years ago! And what is it now? Our ideas of the composition of the blood, of the action of poisons, of the reaction of poisoned blood on the nervous system, and of this on the several organs, may all be looked upon as very imperfect, and sure to be modified ere long, and therefore as affording no solid basis for practice.

Again, supposing our theory of a disease to be perfect, does it of necessity lead to the correct treatment? It may, or may not; but this can only be decided by experiment. Theory may leave the propriety of any given measure quite a matter of doubt. Take bleeding in the cold stage of ague. It can be defended on theory, and can be shown to be indefensible on theory. It is to experiment that we must resort at last, and we may as well confess this at once.

The very term "elimination," which has been brought so much into use, also requires to be carefully sifted before it can be received as an absolute statement of fact or guide to practice. It is assumed, quite gratuitously, that the serous discharges of cholera are salutary efforts of Nature to get rid of a poison out of the blood; but we may ask—on practical grounds—is this the only way of elimination possible or necessary? We know as fact, from more than one Medical man who has imbibed cholera poison, whose whole body and blood have been impregnated with the nauseous smell, and who has had sickness, depression, and relaxed bowels, that these symptoms have been got rid of, not by elimination—so far as this word means purgation—but by *anti-elimination*: by actually resisting the tendency of the bowels to act; by taking laudanum and brandy-and-water, and, above all, by lying in bed, than which few remedies are more anti-purgative. That elimination by copious serous bowel discharges is necessary for the safety of persons who have imbibed cholera poison, is a proposition which admits of a plain "yes" or "no" answer; and we believe that the voice of the Profession would answer "No."

Again let us say, that if the idea of "Elimination" is set up as one Goddess, to be propitiated with appropriate offerings of sweet savour, "Nature" is another kind of fetish, which inspires tremendous reverence with the ignorant, but which the nineteenth century may surely smash without fear. What is meant by "Nature?" Is there an intelligent principle within us endowed with consciousness, intelligence, and will, which, on certain emergencies, makes such "efforts" as she may consider "salutary?" Are members of the Medical Profession bound to respect her efforts? We hope not, for to us she would seem a lunatic and a spendthrift, or worse. Because a poison has got into the blood, is "Nature" to kill the poor wretch she inhabits by vomiting or purging out all the serum of the blood, and stripping off the epithelium from the small intestines, under pretence that it is a "salutary effort" at elimination? If a rat gets into the kitchen, shall we set the house on fire? It would be about as sane a trick as these fictitious "salutary efforts" of hypothetical "Nature." Demoniacal possession would be no worse. Really it is too bad to have to caution men now against figures of speech and figments of the imagination, as if they were things that exist in the outer world.

Let us look at a parallel case. A woman has in her womb after delivery a piece of placenta or a clot of blood. "Nature" ought to expel them, but does not. Instead of this, then, she "sets up" a spasm of the womb, which prevents expulsion, and a bleeding that threatens the woman's life. Here there is clearly something in the womb to be "eliminated;" we know what it is, and can do it. But let us suppose otherwise: should we stand by, and promote hæmorrhage and spasm as a "salutary effort of Nature;" and beguile ourselves with stories of some women who had died after "natural salutary" hæmorrhage had been suppressed?

We need not, however, go to parallel cases. The experience of the world has shown that when cholera is present, as an epidemic, bowel disorders of every lesser grade are prevalent too. All experience shows the propriety of suppressing these lesser grades. For this purpose there is a great variety of remedies, including

Acids,
Alkalies,
Astringents,
Stimulants and carminatives,
Opiates,
Calomel,
Purgatives,
Enemata,
Meat diet;

and combinations or sequences of more than one of these; and experience shows that when the bowel disorder is suppressed, the patient is comparatively safe. We shall hope next week to resume the subject, and sift the relative value of these remedies, and the cases in which each may be used with benefit. Meanwhile we will only express our regret that Dr. G. Johnson's theories of cholera, elaborated with so much ingenuity, and propagated with so much enthusiasm, seem to us to be not easily reconcilable—so far as the effects of remedies are concerned—with the general experience of the Profession.

MORTALITY OF NEGROES IN AMERICA.

Our diplomatic officials are labouring with considerable industry and much ability to prove that they can really render valuable service in exchange for such honour and emolument as appertain to their profession. The Foreign Office has made the discovery that well-educated English gentlemen are good for something beyond wearing her Majesty's uniform and being civil to the British paterfamilias on his travels abroad. So the

members of the Consular body have been encouraged to observe and report upon such particulars relating to the places where they are accredited as may be useful and interesting to us at home, and the results of these observations are from time to time made public in the usual form.

A collection of such Consular reports will supply future historians with more trustworthy data than have ever before been available, and the Foreign Office is justly entitled to the credit of authorising so excellent a plan.

We have recently seen one of the latest of these reports, giving a comparative statement of the mortality in the City of Charleston, Carolina, in the years 1855 and 1865. Making every allowance for the disorganised state of things in the latter year, consequent on the unhappy strife only then just brought to a close, there is matter for grave speculation in the remarkable difference between the mortality of the City in the two periods. In 1855 Charleston was a thriving and opulent seaport; in 1865 it was but a shadow of its former self. Civil war in its most repulsive and relentless fashion had done its worst, and the City, with its commerce utterly destroyed, was broken down and in ashes. Mr. Consul Walker tells us that its population last year was scarcely more than half the number living there ten years ago. Yet the deaths increased from 1088 to 2068: they were doubled, whilst the numbers living out of which they occurred were diminished one-half in the interval. And this statement refers only to those deaths which occurred in civil life from the ordinary diseases to which the inhabitants are subject. The mortality, which in 1855 was computed at a rate of 1 death to every 50 inhabitants, rose in 1865 to 1 death to every 10 persons living. Dividing the population into two classes, we see that the increased mortality belongs almost entirely to the negroes; for, whilst in 1855 the total deaths comprised 402 whites and 686 negroes, in 1865 the deaths of white persons numbered 500, and of negroes 1508. It is probable—nay, certain—that very many more of these poor wretches died last year than were taken account of, by reason of the confusion then existing; and that consequently the actual mortality was even greater than the very shocking rate above given. Mr. Walker attributes the excessive death rate amongst the negroes in great measure to their habitual improvidence; but that of itself hardly suffices as an explanation. There was, likely enough, great scarcity of food in the city, and the despised race—who only become "our coloured brethren" for platform purposes—would, perhaps, get little benefit at the hands of Yankee soldiers from the "first-come, first-served" principle. Mr. Walker further states that of the 1508 deaths of negroes in 1865, no less than 603 died under five years of age.

And if such a state of things prevails in the green tree, what about the dry? As Mr. Walker points out, if in a town where a certain amount of Medical attendance and Hospital care are within reach, such a high rate of mortality has been possible, what may we reasonably believe has happened in remote districts out of the reach of scientific aid altogether? The death-rate amongst negroes in many such districts, and along the seaboard of North and South Carolina is believed to have been as high as *twenty-five per cent. of their numbers living!*

At this rate the *vexata quæstio* of the ultimate destiny of the negro in America will soon find a solution which will remove all difficulty in the matter: they will be "improved off the face of the earth." And that this solution finds even official acceptance is clear from the general tenor of the remarks on the decline of the coloured race which are to be found in the introduction to the American Census of 1860. There we are told in the plainest manner that the gradual extinction of that people is indicated with unerring certainty and with increasing rapidity, as whether free or slave they become diffused among the dominant race. The "uncongenial climate" causes a high rate of mortality from consumption and diseases of the respiratory system. In Philadelphia during the last six months of 1860 there were 148 births registered to 306 deaths amongst the free coloured; and although general observation discloses more favourable results, yet as a rule the deaths exceed the births of the race. Here is a prophetic view of the future of the negro in America, as developed by the Census returns:—"The extinction of slavery in widening the field for white labour and enterprise will tend to reduce the rate of increase of the coloured race, while its diffusion will lead to a more rapid admixture, the tendency of which, judging from the past, will be to impair it physically without improving it morally." But such a solution as the extinction of the race implies would entail a lasting disgrace upon the American people, who have used these unfortunate blacks for their own purposes hitherto, and who would thus be chargeable with the shame of abandoning them when no further end was attainable by their help.

The statesmen—if there be any—of the United States would find a far nobler sphere of operations in ameliorating the miserable condition of the slaves, to whom they have given freedom, than in political cabals and wrong-headed, unreasoning abuse of Old World institutions. The loss of thousands of human lives over and above the holocausts of the war, will be upon their heads until they cease to turn a deaf ear to the counsels of humanity and the cries of the wretched victims of their overweening vanity and selfishness.

THE WEEK.

THE CORONER FOR CENTRAL MIDDLESEX.

The dispute on the subject of the payment of fees to Medical witnesses, which has lately enlivened the columns of the daily papers, has, we think, been founded on a misunderstanding between Dr. Sansom and Dr. Lankester, and we can only regret that the public should have been made umpires in the matter. It is, no doubt, an anomaly that a Medical witness should be asked to sign a receipt for a sum of money which he has never received, and it is equally an anomaly that a Coroner should be called on to pay fees out of his own pocket which he himself will not receive until six weeks after. It is not, perhaps, to be wondered at that the latter circumstance should in process of time have given rise to the former. The controversy, however, has given occasion to Dr. Lankester to recommend, in the columns of the *Times* newspaper, that the Coroner should be "allowed to employ a competent expert at a fixed salary to make all post-mortem examinations, and to call in Medical attendants only where their evidence is necessary." We are afraid that some of Dr. Lankester's opponents may say that the Coroner for Central Middlesex, himself a Medical man, owing his present position to the support of his Medical brethren, proposes that a large revenue should be diverted from the Profession, and that the General Practitioner should be set aside as though unable to make a post-mortem examination. Surely the better way would be to pay the witnesses once in six weeks after their fees have been allowed and handed over by the county magistrates.

SOUTHWARK MEDICAL ASSOCIATION.

The members of this Society have recently been engaged in investigating certain charges of alleged un-Professional conduct preferred by Mr. Button against Dr. Bonney. Mr. Button, it appears, has been placed in a very awkward position in consequence of the spread of rumours to the effect that he was not a qualified Medical man, and had improperly treated a certain member of a club of which he was the Medical officer. Hence he had been suspended from the duties of his office. Mr. Button placed the matter in the hands of the Southwark Medical Association, which constituted itself a "court Medical." Having at several meetings gone fully into the whole matter, the Association ascertained

that Mr. Button had fair ground for complaint, inasmuch as an impression prevailed with the members of the club in question that Mr. Button was not a qualified Medical man; that that impression was founded on false statements; and that Mr. Button was completely exonerated from all shadow of unskilful treatment or neglect of any kind. Mr. Button's name is in the Medical Register, and we have pleasure in adding that he has long won the respect of his fellow Practitioners, and is deserving of the entire confidence of his patients.

THE COMMUNICABILITY OF RINDERPEST TO MAN.

The following notes have been communicated to us as bearing upon this question. A man named Daniel Woodcock died on the 21st of last September, at Oulton, after seven days' illness with symptoms supposed to be due to the action of Rinderpest poison. He was a strong man, whose duty it was to look after Rinderpest beasts, and bury them when dead. This work he disliked, and the peculiar smell of the diseased animals was a constant cause of complaint with him. A few days before his illness he complained more than usual of this disagreeable odour. On the morning after a harvest home held at this time, which he attended, he was attacked with sore throat and high fever, the tonsils and palate were covered with a thick yellow lymph, sloughing and black discolouration set in, and death speedily took place from rapid exhaustion. The Medical men who saw the case believed it to be diphtheria. The patient himself persisted that it was caught from the diseased cattle. Diphtheria was not prevalent in the neighbourhood, though isolated cases were constantly occurring in the district around, two deaths having taken place in an adjoining parish during the previous month. The present case seems to be one of severe diphtheria. Rinderpest communicates apparently a form of disease which is essentially "herpetic" in character.

THE HOSPITAL SHIP "BELLEISLE."

The Hospital ship *Belleisle* was towed up from the Medway to Greenwich at the end of last week, and is now moored close to the *Dreadnought*. As one of our old seventy-fours, she has ample accommodation for a large number of patients, and it is satisfactory to know that, by the exertions of the Seamen's Hospital Society, means are now actually provided for the isolation and immediate treatment of any cases of cholera that may arrive in the Thames. It is, indeed, difficult to say how much of good this prospective plan may not eventually accomplish. Some Medical, and many laymen, assert that the mere presence of a hulk brought up the river for such a purpose is calculated to cause a very unhealthy panic; but it must be equally patent to the minds of the most, that, in this question, at all events, it is better to be forearmed; and that if happily the *Belleisle* remain tenanted only by her shipkeeper, we shall not respect the less the principle that has succeeded in bringing her to these moorings, ready for action, to watch and to wait.

SUCCESSFUL APPLICATION OF DR. RICHARDSON'S METHOD OF LOCAL ANÆSTHESIA IN VETERINARY SURGERY.

The Messrs. Mavor, the eminent veterinary Surgeons, of Park-street, Grosvenor-square, have recently been using Dr. Richardson's method of local anæsthesia in operations on the horse, with the greatest possible success. The first operation was that of firing a mare in one fore-leg; the leg was first shaved, then the ether spray was applied from the knee to the foot until insensibility was produced, after which the actual cautery was carried at least sixteen times over the whole length of the narcotised part. The animal seemed to suffer no pain, remaining quiet the whole time. The second operation was one of firing on the hock joint—a very painful procedure; it, too, was performed with complete success. The iron was passed nearly forty times over a surface averaging three inches in length. A third operation was that of division of the metacarpal nerve on each side, immediately above the fetlock; in this case, the skin having first been made insensible, the nerve was laid bare, and a curved needle with a blunt point was passed under it; then the nerve was directly subjected to the ether spray, without the slightest evidence of pain, and when the nerve structure was entirely frozen and hard the division was made painlessly. In a fourth case after "docking" the ether spray was directed over the cut bleeding surface before applying the actual cautery to stop the hæmorrhage. The effect was most marked, the animal giving no sign of pain under the iron; the bleeding was also as effectually stopped as though the anæsthesia had not been supplied. Mr. Frederick Mavor informs us that some peculiarities are observed in the effects of the ether spray on horses as compared with those on men: thus the skin, instead of blanching, assumes rather a blue appearance, and the nerve tissue undergoes extreme contraction. The anæsthesia is produced within the minute, and more ether is not required than for the human subject. All the wounds have healed well, and not the slightest sign of slough has been observed. As we are promised by the Messrs. Mavor a detailed account of their experiences, we have only on this occasion to congratulate them heartily for having been the first veterinarians to apply the most recent advancement of Medical science to the relief of the inferior creation.

APPEAL ON BEHALF OF A WIDOW AND SIX ORPHANS BY DR. LETHEBY AND MR. SPENCER WATSON.

We beg to call special attention to this appeal, which will be found amongst the "Notices to Correspondents" in our present number. The facts stated, and guaranteed by names so respected, well deserve to move the compassion of our readers.

FROM ABROAD. — STATISTICS OF LUNACY IN FRANCE — M. DELPECH'S REPORT ON TRICHINIASIS—LIVING ENCAPSULED TRICHINÆ DATING TWENTY-FOUR YEARS.

A Report on the French Lunatic Asylums has recently been presented to the Emperor, embracing, however, only the septennial period 1856—60. At the end of this latter year there were 56 public Asylums—37 belonging to the departments, 1 to the State, and 19 to the hospices. There were also 42 private Asylums. On January 1, 1835, the period at which statistical accounts were first taken, there were 10,530 patients in these various Asylums, and on Jan. 1, 1861, there were 30,239 patients. These 30,239 were subdivided as follows:—Lunatics 26,450, idiots 3746, and cretins 43. From the year 1854 to 1860 the insane population of the Asylums consisted of 51·90 per cent. females and 48·10 per cent. males. From the year 1856 the patients have been classed according to the probabilities of their recovery, and from the data thus acquired it results that more than four-fifths offered no chance whatever of cure. According to one of the tables given, there were in 1851 24,433 lunatics treated *à domicile*, 34,004 in 1856, and 53,160 in 1861; while the numbers treated in the public Asylums for the respective years were 20,537, 26,286, and 31,054 — so that in the 10 years, 1851—61, the total number of lunatics in France had risen from 44,970 to 84,214. Comparing the lunatics with the population, we find that there is 1 male lunatic for every 915 males, 1 female lunatic for every 839 females, 1 idiot for every 796 males, and 1 idiot for every 1034 females. The annual movement of patients in both private and public Asylums during the years 1854—60, has consisted in 68,992 admissions, and 63,277 discharges or deaths. With reference to the respective influence of physical causes (excluding hereditary influence), 15,357 cases are returned during 1856—60 as due to physical, and 10,357 to moral causes. Hereditary influence has been observed in one-seventh of the cases, the same sex—as father to son, or mother to daughter—

usually transmitting it. During the years 1854—60 the recoveries amounted to only 8·69 per cent. among the males and 7·81 among the females. During the septennial period 1856—60 the deaths amounted to 26,560. As a general rule, the number of deaths is relatively considerable during the first two months after admission.

M. Delpech, who recently presented a report to the French Government upon the subject of trichiniasis founded upon his investigations during a visit to Germany, has just made one to the Academy of Medicine upon the same subject after a due consideration of the various documents and works relating to it which have been laid before that learned body. After an elaborate description of all the phenomena connected with trichiniasis, he concludes:—1. The apprehensions which have been entertained on the occasions of the epidemics which have been reported in Germany, are not justified until the present time by a single case occurring in France. 2. The cooking of pork, habitually much more complete in France, explains and assures such immunity, and there is now more reason than ever to insist upon a persistence in this salutary custom. 3. In the absence of an epidemic, or even of isolated cases of trichiniasis, there is no ground for organising any special hygienic measures, and especially for instituting a general and obligatory microscopic examination of the flesh of the pig. Nevertheless, it will not be without utility in reference to studying and examining into the subject, to establish inspectorates in some towns provided with *abattoirs*, in order to exhibit by a formal examination statistical conclusions in relation to the existence, absence, or proportion of trichiniasis in the porcine race. 4. As certain conditions under which the animal is brought up, and special precautions may exert a great influence in regard to trichiniasis, it is desirable that a knowledge of the precautions which should be taken in order to ensure security should be spread by means of circulars amongst the rural population.

In relation to this subject, we may refer to a very curious case related by Dr. Klopsch, of Breslau, in the April number of Virchow's *Archiv*. A lady, aged 38, consulted him in 1857 concerning a tumour of the right breast, and on interrogating her concerning her previous health, he found that this had always been very good except at one period—viz., in 1842—when, while residing at Dresden, she became the subject of severe pains in the joints and limbs, followed by paralysis. After a while anasarca appeared, and continued many weeks. At the end of three months from this her health began to improve, and after four months' confinement to bed she recovered. Later, she married and bore a child, and, in fact, continued in good health, with the exception of occasional muscular pains. The tumour in her breast had appeared since early in 1857, and exhibited the signs of carcinoma, and the glands of the axilla having become slowly affected, while the cancer cachexia was not developed, Professor Middledorpf amputated her breast in May, 1863. Two years later, cancerous infiltration of the axilla having appeared, and the patient's general health being good, it was resolved to excise such parts. While separating these from the subjacent intercostals, Professor Middeldorpf observed that they were beset with white granules, which he suspected to be trichina capsules. Examined microscopically, every portion of the muscle the size of a pin's head was found to contain four or five completely calcified trichina-capsules, trichinæ, on a section being made, being found free and living. This is the first instance on record in which twenty-four years after an invasion of trichiniasis, living trichinæ have been still discoverable. That they really were deposited in 1842 is shown, not only by the symptoms then present and the subsequent good health of the subject, but also by the fact of two of her servants having then died suffering from similar symptoms. It is an interesting speculation how far there is any etiological connexion between the trichiniasis and the cancerous degeneration.

PARLIAMENTARY. — CAPITAL PUNISHMENT AMENDMENT BILL—LUNACY ACTS (SCOTLAND) AMENDMENT BILL—PAYMENT OF POOR-LAW MEDICAL OFFICERS IN IRELAND.

On Thursday, May 31, in the House of Lords,

In Committee upon the Law of Capital Punishment Amendment Bill, a discussion arose upon clause 4, which classed murders under two heads—of the first and of the second degree.

Lord Grey objected to this division of the crime of murder, and proposed the omission of the clause.

The Lord Chancellor justified the distinction between wilful murders and others of a less heinous character, by citing the authority of a majority of the judges and of the Commissioners who had reported upon the subject.

After a brief debate, in the course of which Lord Russell and the Duke of Richmond spoke in favour of the clause, and Lords Romilly and Longford against it, the Committee divided, and the numbers being equal, the clause was, according to the practice of the House, declared to be negatived.

Upon the motion of the Lord Chancellor, further progress in Committee was postponed, in order that the Bill as altered might be reconsidered.

In the House of Commons,

The Lords' amendments to the Lunacy Acts (Scotland) Amendment Bill were considered and agreed to.

On Tuesday, June 5,

Mr. M'Evoy moved a resolution to the effect that the time had now arrived for the Government to adopt the recommendations of the Select Committee of 1858, that "Her Majesty's Government should take into consideration the claims of Ireland to a grant of the half-cost of Medical officers of Unions, with the view of providing for the same in future, as is now the practice in England and Scotland," fortified, as such recommendation is, by the Report of the Select Committee on Taxation of Ireland in June, 1865.

The Chancellor of the Exchequer intimated his readiness to grant the concession required, and would make the necessary provision in next year's Estimates. After a short discussion the motion was withdrawn.

THE MEDICAL COUNCIL AND THE PUBLIC SERVICES.

(From a Correspondent.)

The revelations which have taken place at several meetings of the General Medical Council may be taken as a proof of the unpopularity of our public services. It is simply a libel upon our Profession to represent the "failures" at the Army and Navy Medical examinations as fair specimens of the ordinary run of young Medical men. A certain number of men—thoroughly ill-educated in every sense of the word—have managed to "cram" the necessary amount of information, and, with singular good luck for themselves, but with lamentably bad luck for the public and the credit of our examining Boards, these men have succeeded in obtaining a civil qualification before their mental stuffing has been dissipated. The possession of a diploma is not everything, however. Such men possess none of the elements necessary for success in civil practice. They form a kind of floating Medical population, passing from village to village, never succeeding in acquiring a "footing" anywhere, but eventually, perhaps, becoming assistants to some hard-worked Practitioner. To such men as these the necessities of the Government afford the chance of an opening. They endeavour to cram up a little fresh information, and most miserably go to pieces at the Admiralty or Chelsea.

At the meeting of the Medical Council on the 24th of May last, Mr. Hargrave, in answer to Sir D. J. Corrigan, "maintained that the Report of the Navy Board was not a fair criterion of the attainments of Medical students. It was well known that no young man of gentle birth and good education would go into the Navy and submit to be snubbed by the officers, who, if not tyrannical, were certainly overbearing. . . . . The Navy was rapidly reverting to the state of things existing in the time of 'Roderick Random.'"

Dr. Stokes also made some corroborative remarks, and added "that there had been for some years, from whatever causes, an indisposition among the better class of students to enter the public service. That was certainly the case with reference to the Army, and still more so with regard to the Navy. The result was, that the sweepings of the class of Medical students presented themselves for examination before those Boards, and no doubt amongst them there were many candidates who knew nothing of Latin and very little of English."

We very much fear that this state of things must continue until a change comes over the conduct of the authorities, and our past experience compels us to advise young men not to go up for the Army examination in August, in the "hope that things will mend." If the Horse Guards can get men enough the recommendations of the Committee will be waste paper, and things will remain as they are.

THE APPENDIX TO THE THIRD REPORT OF THE CATTLE PLAGUE COMMISSIONERS.

(Continued from page 596.)

Dr. Bristowe's report is a very full one, and bears the imprint of very cautious observation. "My notes," says Dr. Bristowe, "were mostly taken down from my dictation while the autopsies to which they relate were in progress, and may be regarded therefore as fairly accurate reproductions of my impressions at the time of examination," but the report also "expresses my more mature opinions on many points on which my opinions were unformed at the time the post-mortem accounts were written," especially in regard to the cutaneous eruption.

The condition of the skin first claims attention. Dr. Sanderson and Dr. Bristowe agree closely as to their conclusions upon this point. The eruption resembles somewhat eczema impetiginodes in the more hairy parts; in the less hairy parts, impetigo or a modified small-pox. "I have never yet, however," says Dr. Bristowe, "discovered either a true vesicle or a true pustule, nor have I satisfied myself that true pus is ever secreted (except accidentally) in this disease by any part of the skin or of the glandular tissue connected therewith. The eruption appears to me to consist in congestion (inflammatory, doubtless) of the capillary plexus of the true skin, and of those involutions of that plexus which are distributed upon the sebaceous glands, with consequent desquamation and increased growth of epidermis and superabundant formation and discharge of sebaceous matter and the development of variable proportions of nuclear, pus-like corpuscles." It is a sebaceous accumulation, which, when removed, exposes the true skin, which is congested, this congestion leading sometimes to extravasation. Sometimes the crust is tied, as it were, to the true skin by the sheaths of the hairs, which become hypertrophied. It does not cover over any collection of pus. The follicles are enlarged usually. Microscopically, there is congestion of the capillaries of the true skin without "any development in its substance of abnormal morphological elements;"—shedding of the epidermis and proliferation of the sebaceous cells in the glands and outside the glands forming the crusts, mixed up with nuclear bodies resembling pus corpuscles, but without a distinct cell wall, or apparently a nucleus, changed into what seems to be an aggregation of molecules by acetic acid, and believed to be modified sebaceous cells.

Dr. Bristowe then proceeds to give an elaborate summary of the alterations found in the internal organs. Commencing at the mouth and fauces, he shows that the changes have no relation to aphtha or diphtheria, being due to congestion, separation of epithelium, and hyperactivity of the mucous glands; then discusses the morbid anatomy of the tongue, palate, and other parts, observing that the microscopic examination of "the whitish granular exudation on the lips and gums, tip of the tongue, base of the tongue and fauces, shows that it consists partly of healthy epithelial scales which have become granular, and partly of the masses of nuclear bodies like those observed in connexion with the cutaneous crusts."

The changes met with by different observers in the stomach have been very fully placed before the Profession already. Dr. Bristowe remarks especially, however, upon the sloughs observed in the stomachs and the atrophous state of the follicles—changes "due in the first instance to extravasation of blood and in the second place to the changes which that extravasated blood itself undergoes and to the changes which its presence induces in the tissues amongst and into which it is extravasated; that, in fact, the congestion, the submucous hæmorrhage, the sloughing, and the cicatrisation, are in successive dependence on one another." All observers agree that the lesions of Peyer's patches, characteristic of typhoid fever, are absent. The bronchi and lungs are affected after the same manner as other organs. The frequent occurrence of interlobular emphysema is noticed and accounted for by the peculiarity of the structure of the bovine lung—viz., the abundance of interlobular cellular tissue, and in harmony with Dr. Sanderson's view. Emphysema is very common, too, in the general tract of cellular tissue; sometimes also about the loins around the kidneys. It has been regarded as due to the disengagement of gas from quasi-putrefactive change. This Dr. Bristowe believes to be entirely erroneous, for these reasons:—(1) Its strangeness, if due to decomposition of living tissues; (2) the absence of ill smell, in the gas or tissues amongst which gas is contained; (3) its presence in those tissues least liable to decompose (the cellular and muscular); (4) its non-increase by post-mortem decomposition; (5) the origin at the posterior mediastinum and root of the lungs, as an invariable antecedent to that elsewhere. Indeed, says Dr. Bristowe, "I do not for a moment hesitate to assert, as the result of my observations, that in all cases the emphysema begins in the cellular tissue of the interlobular spaces of the lungs, that it spreads thence to the roots of the lungs and posterior mediastinum, diffusing itself around the base of the pericardium, upwards along the œsophagus and trachea into the neck, and downward along the œsophagus and other parts towards the abdomen," etc. The Report concludes with some general remarks—(1) On the tendency to decomposition observed in animals dead of cattle plague, which varies very considerably, the muscular and cellular structure remaining unchanged after decomposition has commenced in the viscera; (2) the relative frequency with which organs and tissues are affected; (3) the remarkable similarity in the nature of the morbid processes seen in different parts of the body, as typified by the changes in the skin, though there may be a greater proclivity in one part than another to disease; (4) the rapidity of the reparative process; (5) the nature of Rinderpest, its essentially distinct character; (6) the morbid anatomy of the disease in sheep, goats, deer, etc. Lastly, there is an enormous mass of most valuable post-mortem detail and tabulated matter.

We have derived especial pleasure and profit from careful and repeated perusal of Dr. Lionel Beale's Report, which, avowedly devoted to "Microscopical Researches on the Cattle Plague," embraces topics of the greatest interest in the field of pathology generally. The whole of the reports have our most unqualified eulogium, but we are bound to say that Dr. Beale's observations bear particularly upon the facts of diseased conditions in general, opening out as they do in a very special manner what may be called tissue actions as contradistinguished from blood alterations. Dr. Beale's researches, if true in their inferential aspect, must very materially modify present pathological notions as to the cause, especially of inflammatory conditions. Of course, we offer no opinion here. Dr. Beale takes as his starting point the con-

gested state of the capillary vessels so constantly seen in Rinderpest, and proceeds to show that as this is "by no means uniform in all different textures, or of equal degree in every part of the same tissue, while the capillaries of some organs (those between the uriniferous tubules of the kidney, those of the lobules of the liver, those of the mammary, and probably some other glands) are not as much congested as they are often found in healthy animals killed suddenly, it cannot be referred" *to any general impediment in the circulation;* but, on the other hand, congestion would seem to have a local origin, for there are patches of various sizes, "but distinctly separated from one another by uncongested, or only slightly congested, portions of tissue . . . of an intensely dark red colour, of circular form, as though the congestion had commenced and radiated away from a central spot. The result of the congestion is an increased pouring out of nutrient matter and a growth of the germinal matter (usually termed nuclei). *Dr. Beale thinks that whatever causes the local congestion is the cause of Rinderpest.*

1. *Changes in the Vessels and in the Blood.*—The small vessels, arteries, and veins, of congested spots are distended with blood corpuscles; the arteries are at first relaxed, but become subsequently more or less contracted, so that their outline is more or less uneven, the diameter varying very much in the smallest distance, the coats are granular; oftentimes, indeed, there is considerable atrophy. These changes are seen in the annexed illustration (Fig. 1), showing the capillaries of the mucous surface of the fourth stomach, encircling the mucous glands.

Fig. 1.—Surface of mucous membrane of fourth stomach, corresponding to a thin depressed circular spot like an ulcer: superficial capillary vessels varying very much in calibre, filled with granular matter and minute particles of germinal matter. The orifices of several gastric glands are seen, and the deeper vessels also obstructed on a lower plane. × 350.

In addition to these changes, there is another alteration of most striking character present in every case—viz., *a large increase in the size of the masses of germinal matter in the walls of the vessels.* This is well seen in Fig. 2, which represents a capillary from the connective tissue of the alimentary mucous membrane.

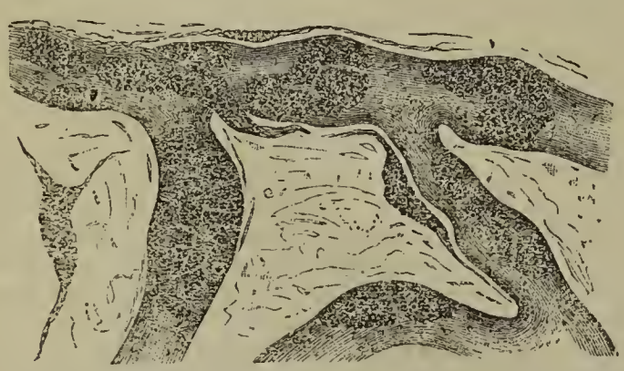

Fig. 2.—The masses of germinal matter of the capillary are very much enlarged, and are dividing and subdividing to form new masses. × 700.

The vessels are sometimes distended with red corpuscles (more or less altered), sometimes filled with a colourless or slightly yellowish fluid; the white corpuscles are always increased in the small veins and capillaries; in addition myelin masses are seen, with germinal matter in large amount.

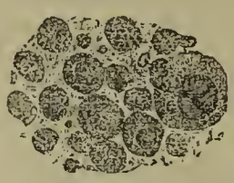

Fig. 3. — Very small masses of germinal matter, interior of small vein. × $\frac{1}{50}$

Fig. 3 represents some of the contents found in a vein in one of the congested spots — organised or germinal material. The germinal matter also of the *epithelia lining* is augmented so much as oftentimes to form projections and interfere with the circulation through the vessels. This germinal matter may actually plug up a capillary, as is represented at B in Fig. 4.

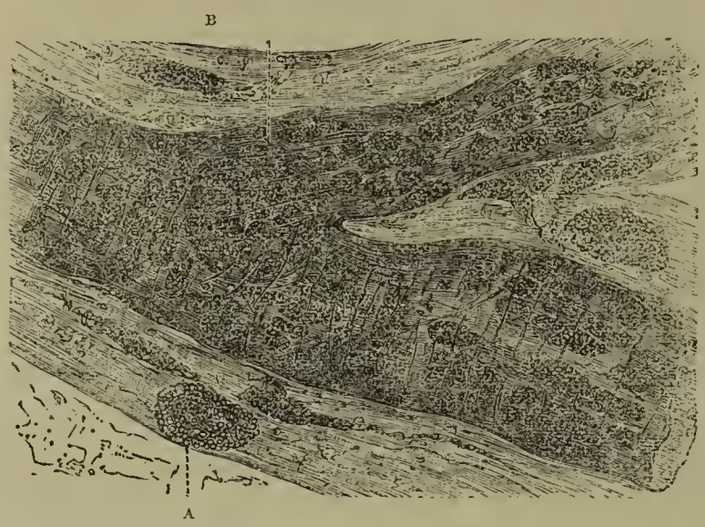

Fig. 4.—Small artery from connective tissue beneath depression of mucous membrane of fourth stomach. Cattle plague. A, Small cells with numerous oil globules; B, A large mass of germinal matter obstructing capillary. × 700.

Dr. Beale discusses the origin of these germinal masses, and thinks they may be enlarged white corpuscles; the adhesion together and subsequent growth of other particles; the growth of germs derived from without; or, lastly, an outgrowth from the lining membrane. The cause, however, of the congestion is at present doubtful; it may be due to the impediment offered by the increase of material just noticed. Dr. Beale notices that inflammatory lymph is not frequently met with, and thinks this is due to the fact that the capillaries become completely obstructed before time has elapsed for the outpouring of liquor sanguinis. In inflammation, however, the stage of dilatation is more prolonged, and the arrest less sudden; as a consequence of this, the thin walls allow the passage of fluid more readily. It would appear, then, that the local congestions produced by the increase of germinal matter lead in turn to an alteration in the composition of the blood and the tissues around. A like increase of nuclear elements is observed in the tissues generally, and also upon the free mucous surfaces, as a consequence of the congestions. The swelling and elevation above the level of the skin are due to circumscribed growths of the elements of the derma and the cuticular cells; the nuclear structures being abnormally in excess, these increase amongst the bundles of the fibrous tissue, making their way, in part, to the surface, in fact, separating the bundles of the areolar structure, and even causing atrophy, by feeding, as it were, on the latter; hence the fibres are replaced by "an amorphous mass of minute masses of germinal matter, varying much in form and products resulting from the decay of some of these particles."

The connective tissue corpuscles increase in size. These changes are well seen in Fig. 6, contrasted with the healthy state shown in Fig. 7.

The germinal masses here appear to be derived from the connective tissue corpuscles, and also from particles introduced from without.

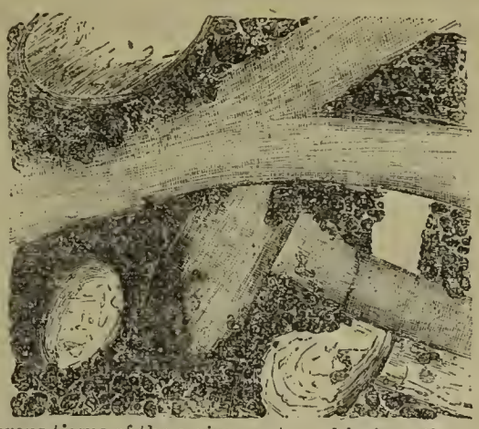

Fig. 5.—Fibrous tissue of the corium or true skin from the softened part of the papule. The intervals between the fibres are occupied with germinal matter, "contagium," growing and multiplying rapidly. × 215.

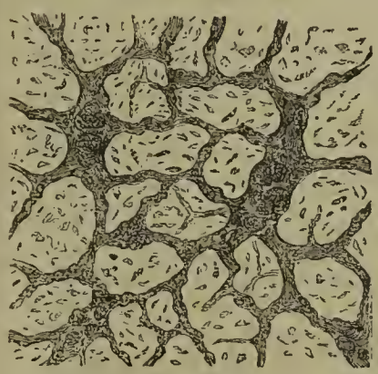

Fig. 6.—Enlarged connective tissue corpuscles. Surface of mucous membrane over epiglottis—Cattle plague just beneath the epithelium. × 700.

Fig. 7.—Connective tissue corpuscles. Surface of healthy mucous membrane over epiglottis just beneath the epithelium. × 700.

The same increase is found in the cuticle, especially about the middle layers, the true epithelial cells being replaced by the nuclear structures, which invade from the exterior, as seen in Fig. 8.

Fig. 8.—Cuticular cells under scab. Eruption on mamma, showing how the cells are invaded by the growth and multiplication of the minute particles of germinal matter (contagium?). × 700.

Dr. Beale gives full details of the special changes of a similar kind in the various secretions and in the alimentary tract, but we have not space to give details. After some remarks upon the general increase of germinal matter formed throughout the tissues of the body, Dr. Beale notices the bearing of this matter upon the question of rise of temperature. "It will have been remarked that the changes which I have demonstrated in connexion with the germinal matter of the tissues generally in *fevers* precisely resemble those observed locally in *inflammations*. In fact, the local phenomena of inflammation precisely correspond up to a certain stage with the general phenomena of fever. The former reach a degree to which the latter cannot attain, because, as it is scarcely necessary to observe, the death of the man or animal must occur long before *general* suppuration could be brought about.

"It is remarkable that while this increase in the germinal matter is taking place, the temperature rises some degrees above the normal standard, and I think that the elevation of temperature in this disease, as well as in fevers and inflammations generally, can scarcely be due to increased oxidation, for both respiration and circulation are often seriously impeded, but attribute it rather to the phenomena occurring during the increase of the germinal matter and connected with this increase. If this is so, it is probable that an increase of germinal matter is *invariably* associated with the development of heat."

After discussing many other interesting points, Dr. Beale sums up thus:—"Without, therefore, pretending to be able to identify the actual *materies morbi* of the cattle plague, or to distinguish it positively from other forms of germinal matter, present in the fluids on the different free surfaces and in the tissues in such vast numbers, I think the facts and arguments adduced tend to prove—first, that it is germinal matter; secondly, that the particles are not directly descended from any form of germinal matter of the organism of the infected animal, but that they have resulted from the multiplication of particles introduced from without; thirdly, that it is capable of growing and multiplying in the blood; fourthly, that the particles are so minute that they readily pass through the walls of the capillaries and multiply freely in the interstices between the tissue elements or epithelial cells; and lastly, that these particles are capable of living under many different conditions—that they live and grow at the expense of the various tissue elements and retain their vitality, although the germinal matter of the normal textures, after growing and multiplying to a great extent, has ceased to exist." But more than this, if we would still wish for some more definite answer, it is clear that we should be most likely to find the contagious material in the secretions of the vagina, the eyes, the nose, or intestines, which are admitted by all to hold the poison of cattle plague. Dr. Beale believes that such particles as we represent in Figs. 9 and 10, the one from the fibrous tissue of the skin, the other from the vaginal mucus. Also those observed amongst the bundles of fibrous tissue already shown in Fig. 5 and in Fig. 8, from the skin.

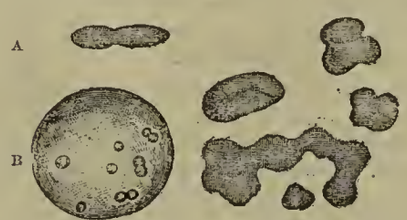

Fig. 9.—Particles from the vaginal mucus of a cow. Cattle plague. A, Bacterium amongst these. B, A mass of germinal matter containing minute particles like fungi. These are seen in the white blood and pus corpuscle, etc. × 2800.

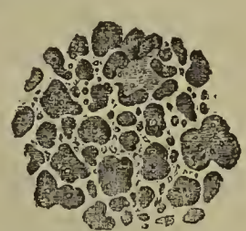

Fig. 10.—Minute particles of germinal matter (contagium?) from the fibrous tissue of the skin, beneath the eruption (Fig. 8). × 1800.

Fig. 11.—A small portion of one of the smallest vessels represented in Fig. 1, showing particles of germinal matter coloured deep red by carmine. × 2800.

We take it that these particles are the nuclear corpuscles noticed by Dr. Bristowe and Dr. Sanderson, especially in the skin eruption. Similar particles are found in the breath and surrounding air of diseased beasts. Hence, though the normal nuclear elements are increased in quantity, there is a large addition of foreign material produced by the growth of substance derived from without the organism. We suppose Dr. Beale would see an analogy between the agency of the various other cells and the poison of Rinderpest. Dr. Beale, therefore, considers that the "poison," "virus," "contagium," "materies morbi," consists of the germinal or living matter constituting the cell-like or nuclear bodies found in such number not only in all contagious fevers, but in specific inflammation and other affections, syphilis, gonorrhœa, etc. "It consists of very minute particles of matter in a living state, each capable of growing and multiplying rapidly when placed under favourable circumstances. The rate of growth and multiplication far exceeds that at which the normal germinal matter of the blood and tissues multiplies, and that they appropriate the pabulum of the tissues, and even grow at their expense," leading to all the many general symptoms of Rinderpest.

Dr. Beale's Report contains many more most interesting

questions, but we have attempted to draw attention to the bare outline of the more important points which have an immediate interest to the Practitioner in reference to the causation of epidemic diseases.

Dr. Beale's hypothesis puts into very definite shape the ideas which have long been loosely held as to the influence of organic life in the production of disease. No doubt a large number of chemical actions are at work, and play most important parts in disease, but it is not unlikely that these in their turn are dependent upon the action of living material; it has lately been shown that fermentative changes are dependant upon the *nutritive act* of the torula cells, and in a similar sense it is admissible to entertain the idea that epidemic disease may be in some way connected with the development and increase of germinal growing living matter.

REVIEWS.

On the Influence of Physical and Chemical Agents upon Blood, with Special Reference to the Mutual Action of the Blood and the Respiratory Gases. By George Harley, M.D., F.R.C.P., etc. (*Phil. Trans.*, 1865, vol. ii.)

The following are the points investigated by Dr. Harley:—1. The effect of simple diffusion in producing a change in the mixture of gases confined with blood. 2. The influence of motion on the changes reciprocally exerted upon each other by blood and atmospheric air. 3. The influence of time on the interchange of the respiratory gases. 4. The influence of temperature on the same from 0° C. to 38° C. 5. The influence of the age of the blood, including the effect of the putrefaction. The second part of the paper is devoted to the consideration of the influence of chemical agents, especially such as are usually denominated powerful poisons.

Annual Report of the Committee of the Manchester and Salford Sanitary Association for 1865.

This report contains some interesting and important charts, showing upon each for Manchester and Marylebone the distribution of a large number of cases of measles, scarlatina, whooping cough, diarrhœa, bronchitis, and small-pox over the several months of the years 1861-1865. The curves bear out the following statement in the report, "that notwithstanding the differing influence of position, climate, manufactures, occupations, etc., bearing upon the inhabitants of these two places, there is a remarkable correspondence between the undulations of several of the diseases. . . . The close relations existing between even the lesser undulations of the waves of disease at two places so distant from one another and differing so much in other respects, points to the influence of some still mysterious but wide-spread agencies, and makes it evident that neither imperfect sanitary conditions nor simple contagion will account for all the phenomena of their production and propagation."

Army Medical Department: Statistical, Sanitary, and Medical Reports. Vol. V., for the year 1863. Presented to both Houses of Parliament by command of Her Majesty. 1865.

The interest of these reports is by no means limited to the several branches of the service, and it is a pity they are not generally read. Amongst other papers, for example, is one by Dr. Parkes on Liebig's Extractum Carnis, embracing the results of a chemical examination of the substance, and those of practical trials in health and disease. He says, "I believe the Extractum Carnis to be a very valuable food for giving nitrogen, salts, and lactic acid; and if its composition is studied, and its combination with other food properly made, it will, I believe, be extremely valuable in disease. For the Military Surgeon it is likely to be very useful in active service, not only for the wounded and sick, but for healthy men. Its small bulk, ease of cooking, savoury taste, and great restorative action would make it most useful in rapid expeditions. As a breakfast before action, as few minutes would prepare it, it would be invaluable, or it might even be eaten cold and as a restorative during exhaustive fighting. If cooked flour and butter be mixed with it, it might be used for many days." —P. 459.

GENERAL CORRESPONDENCE.

CASE OF INJURY TO THE BRAIN.

Letter from Dr. Alfred E. Wilmot.

[To the Editor of the Medical Times and Gazette.]

Sir,—Reading in the *Medical Times and Gazette* of April 21 an interesting case of "injury to the brain, with death from extravasation ten days after the injury," in corroboration of the excellent remarks then made by Mr. Campbell de Morgan, I beg to forward for publication the following case of injury to the brain, with death from extravasation on the seventh day:—

D.T., aged 52, a cab-driver, living at Bridlington-quay. On the evening of the 14th of April he returned home intoxicated, and was with difficulty taken upstairs and put to bed (the staircase was very narrow and precipitous, about 10 feet high). On being left alone he got out of bed, and trying to go down stairs, he fell backwards on to his head, descending with great force on the stone floor below. He was rendered immediately unconscious. I was called in about three hours after the accident, and found him in bed completely insensible. His respiration was easy and regular, and skin warm, excepting that of the feet. There was no paralysis of face or limb. Pupils natural, but conjunctivæ quite insensible to the touch; pulse 80, and compressible; deglutition very slightly, if at all, affected. There were two lacerated scalp wounds. He had bled much from the nose and mouth, but it had all ceased when I arrived. At the end of three hours he began to show signs of returning consciousness; he vomited some dark coagulated blood; his conjunctivæ became sensible, his pulse stronger, and he slowly moved his hand to his head.

15th.—Consciousness increased. By persevering in asking questions, an effort at an answer could occasionally be obtained, and he was induced to take some slight nourishment, but immediately afterwards relapsed into his former condition.

16th.—On questioning him he complained of his head aching, and of pain in his left shoulder, which had been injured in the fall. Tongue, foul; pulse, stronger; bowels slightly relieved.

17th.—Is now so far conscious that he speaks voluntarily; makes his wants known in a muttering way; complains of thirst.

18th.—Improving.

19th.—Expressed himself much better, and desirous of getting up. Headache continues; appetite pretty good; skin of natural temperature.

20th.—Had been progressing favourably up to about 8 or 9 this morning, when, from some cause or other (whether he had been moved or had tried to get out of bed, I know not), the breathing gradually became laborious; the right pupil was very much contracted. Most profound coma supervened, and he expired at 4 a.m.

Sectio Cadaveris Twenty Hours after Death.—On removing the dura mater, a hæmorrhagic extravasation was found to have occurred below the arachnoid. It covered nearly the whole of the surface of the hemispheres, but was thickest in the left temporal region. When the brain was raised, the extravasation was seen, in the subarachnoid space at its base, to be still more abundant, especially in the right half of the middle fossa of the skull. It extended from the space anterior to the optic commissure, to the spinal cord; and, on dividing the latter organ in the extraction of the brain, a considerable quantity of blood flowed out, or (to borrow a more expressive term) welled up from its subarachnoid cavity. At about the centre of the base of the middle lobe, the brain had suffered a severe laceration, about the size of a crown piece. The cerebral substance at the injured spot had lost its consistence, and presented that peculiar yellowish or fawn-coloured appearance characteristic of softening under those circumstances. The substance of the hemispheres was healthy, and there was no observable abnormality in the ventricles. There was no fracture of the skull. I am, &c.,

Alfred Wilmot, M.R.C.S.E. and L.R.C.P. Lond.

Bridlington, Yorkshire, May 1.

University Honours to Scientific Men.—At a Congregation at Cambridge on May 31, the honorary degree of LL.D. was conferred upon Professor Sedgwick, M. Alphonse De Candolle, and Dr. J. D. Hooker.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 31, 1866:—

Frederick Smith, Westminster; James Shirwen Greene, St. George's, near Wellington; Charles James Cullingworth, Bawtry, Yorkshire; Vincent Edmund Noel, Westbury-terrace, Plymouth; Joseph William Smith, Weaverham, Cheshire; Richard Walter Owen, Withers, Shrewsbury; Thomas Bond, 6, Carey-street, London; Ridgway Robert S. C. C. Lloyd, Doncaster; Herbert Chrippes Upton, Petworth-park, Sussex.

As an Assistant:—

William F. G. Wilson Sympson, Fenny Stratford, Bucks.

The following gentleman also on the same day passed his First Examination:—

Charles James Worts, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CLARKE, F. W., M.R.C.S., L.S.A., has been appointed Medical Officer to the Oxford Lying-in Charity District No. 2.

CLEMENTS, GEORGE, M.R.C.S.E., L.M., L.S.A., has been appointed Resident Medical Officer to the Salford Union.

MURRAY, JOHN, M.B., M.R.C.S., has been elected one of the Resident Clinical Assistants at the Middlesex Hospital.

SPENCER, H. B., M.D., has been appointed Medical Officer to the Oxford Lying-in Charity District No. 1.

BIRTHS.

ALLINGHAM.—On June 5, at 36, Finsbury-square, the wife of W. Allingham, F.R.C.S., of a son.

ARNISON.—On June 1, at Allandale Town, Northumberland, the wife of G. Arnison, M.R.C.S., of a daughter.

BOWER.—On May 26, at 2, Clarence-villas, Windsor, the wife of E. Bower, M.D., of a daughter.

BOWMAN.—On May 25, at Sunderland, the wife of H. O. Bowman, M.D., of a son.

FORESTER.—On May 25, at Claremont-square, the wife of H. Forester, M.D., of a son.

KINGSFORD.—On June 1, at Upper Clapton, the wife of C. D. Kingsford, M.D., of a daughter.

LYSTER.—On June 3, at 8, Devonshire-road, Princes-park, Liverpool, the wife of C. E. Lyster, M.D, of a daughter.

POTTER.—On May 24, at Collumpton, Devon, the wife of S. R. Potter, M.D., of a son.

POWER.—On June 1, at 43, Upper Seymour-street, Portman-square, the wife of H. Power, M.B., of a daughter.

TANNER.—On May 31, at 9, Henrietta-street, Cavendish-square, the wife of T. H. Tanner, M.D., of a daughter.

MARRIAGES.

DON—ELLIOTT.—On June 5, at St. Andrew's Church, Plymouth, W. G. Don, M.D., 28th Regiment, to Louisa Jane, second daughter of Captain E. G. Elliott, R.N.

ELLIOTT—HALLEN.—On May 22, at St. Woollas Church, Newport, Monmouthshire, Richard Elliott, Assistant-Surgeon 95th Regiment, to Helena Augusta, youngest daughter of S. T. Hallen, Esq.

FORSHALL—SCRIMGEOUR.—On May 31, at St. Michael's, Highgate, F. H. Forshall, L.R.C.P., to Frances Maria, eldest daughter of W. W. Scrimgeour, Esq.

WATSON—EATON.—On May 24, at Ancaster Church, Lincolnshire, A. M. Watson, M.D., to Fanny Elizabeth, younger daughter of F. Eaton, Esq.

DEATHS.

HAYNES, R. L., F.R.C.S.E., at 1, Haringey-park, Crouch End, Hornsey, on May 31, aged 57.

NESBITT, F. A., F.R.C.S., at Norwood, on May 24, aged 34.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Carnarvon Union.—Mr. John L. Jones has resigned the Llandwrog District; area 28,457; population 8518; salary £60 per annum.

Chesterfield Union.—Mr. Simpson has resigned the Bolsover District; area 10,366; population 2402; salary £20 per annum.

East London Union.—Dr. William Lobb has resigned the Aldersgate District; population 6188; salary £65 per annum.

Ely Union.—Mr. William B. Buller has resigned the Sutton District; area 16,170; population 3466; salary £50 per annum.

Plymouth Incorporation.—Mr. William Dale has resigned the Fourth District; salary £95 per annum.

Tisbury Union.—Mr. R. C. Shettle has resigned the Donhead District; area 19,842; population 4151; salary £74 10s. per annum.

APPOINTMENTS.

Dudley Union.—John Smith, M.R.C.S.E., L.S.A., to the Second Sedgley District. Henry Gilbert, M.R.C.S.E., L.S.A., to the Third Sedgley District.

Hastings Union.—Daniel M. Forbes, L.R.C.P. Edin., M.R.C.S. Edin., to the Third District.

Leominster Union.—James Beavan, M.R.C.S.E., L.S.A. Lond., L.S.A. Dub., to the First District and the Workhouse.

Stow Union.—Arthur Pearse, M.D. Edin., M.R.C.S.E., to the Hinderclay District.

Warwick Union.—Thomas W. Bullock, M.R.C.S.E., L.S.A., to the Workhouse.

ROYAL INSTITUTION OF GREAT BRITAIN.—General monthly meeting, Monday, June 4, 1866; W. Pole, Esq., F.R.S., in the chair. Edward Beanes, Esq., C.E., F.C.S., and Robert C. L. Bevan, Esq., were elected members of the Royal Institution. The special thanks of the members were returned to Sir Henry Holland, Bart., for his eighth annual donation of £40 to "The Donation Fund for the Promotion of Experimental Researches." The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the College, held on Monday, the 4th inst., the undermentioned gentlemen were elected to the following offices for the ensuing year, viz.:—*President*—Richard G. H. Butcher. *Vice-President*—Awly P. Banon. *Secretary*—William Colles. *Council*—Arthur Jacob, William Hargrave, Robert Adams, James Barker, William Colles, Hans Irvine, Robert Pentland, Samuel G. Wilmot, Thomas L. Mackesy, Rawdon Macnamara, Hamilton Labatt, Benjamin M'Dowell, Edward Ledwich, William Jameson, Alexander Carte, James H. Wharton, George W. Hatchell, Albert J. Walsh, and Edward D. Mapother, Esqrs.

THE body of the lamented Preston King, late Collector of Customs for New York city, was found floating in the Atlantic basin on the 14th ultimo, and identified beyond doubt. It had been six months and a day under the waters of the bay, until the cord by which the bag of shot was fastened had rotted off, when it rose to the surface and floated.

THE Government and people of Nova Scotia are honouring the memory of Dr. Slater, the Physician who lost his life by cholera while devotedly serving on board the plague steamer *England*. The House of Assembly has unanimously voted the sum of two thousand dollars to the widow, and the people propose to raise a monument near the scene of his labours.

IRISH MEDICAL ASSOCIATION.—The annual meeting of this Association was held on Monday, June 4, in the Royal College of Surgeons, Stephen's Green, Dublin. The chair was taken by Dr. Thomas L. Mackesy, President, who in his address called attention to the necessity of adopting prompt measures to ensure the proper preliminary education of those entering upon the study of Medicine and Surgery. He also dwelt upon the immense importance of the Parliamentary representation of the Medical Profession in its collective capacity, and pointed this out as the only means by which there could be proper legislation for the sanitary improvement of towns, as well as on such subjects as infant mortality, the sanitary regulation of factories, the pollution of public streams, the sale of poisons, etc. He showed that the Medical constituency of England, Scotland, and Ireland would be about 19,000, who would send to Parliament gentlemen whose practical experience, knowledge, and social and intellectual standing would be of the greatest advantage to the public at large. The annual report, which was read by Dr. Quinan, Secretary, announced a great increase of the strength and influence of the Association, and reviewed the proceedings of the past year. Several important matters were then discussed, and the following resolutions were passed:—"1. That, convinced as we are by increasing experience of the paramount importance of securing to the country competent Practitioners in Medicine and Surgery, we desire to record our anxious wish to see the powers of the Medical Council so enlarged that we may look with confidence to its enforcing a high and uniform standard of education, both preliminary and Professional, on the licensing bodies throughout the kingdom." 2. "That the sanitary laws are so complicated, and their execution so divided between corporate bodies, boards of guardians, and dispensary committees, as to render them almost inoperative. We therefore feel called upon to urge on the Government the expediency of making them into one Act, and placing its administration under an efficient executive body." Dr. Mapother, in moving the second resolution, said that there were about twenty-two Acts concerning sanitary matters and the improvement of the dwellings of the poor, which were of a most complicated

character. In England there was a comprehensive Bill in force, called the Public Health Act, which included all the sanitary legislation required, and which was about to be extended to Ireland, with such modifications as would be though desirable. 3. "That, having a due regard to the interests of the sick poor and the ratepayers, as well as to the interests of the Medical men holding office under the Poor Law and Medical Charities Act, it is the duty of the Irish Medical Association to press with all its might to obtain a legal provision securing to those officers a retiring allowance when from age or infirmity, or length of service, they are no longer equal to the discharge of their onerous duties." 4. "That we cordially agree in the recommendation adopted, and frequently pressed upon Government, by the boards of guardians throughout the country, to the effect that at least one-half of the salaries of the Medical officer should be paid out of the Consolidated Fund." 5. "That the present unsatisfactory state of the law with regard to the remuneration of Medical witnesses, when summoned by the Crown, renders it necessary that a scale of payments should be adopted; and further, we are of opinion that Medical witnesses are entitled to reasonable travelling and hotel expenses." 6. "That this meeting cannot separate without expressing the warm acknowledgment and thanks of the Medical Profession to the press of Ireland, whose able and continued advocacy furnishes us with unanswerable evidence of the justice and importance of our claims." 7. "That the honorary secretary be requested to convey to Sir Dominic Corrigan, Bart., the thanks of the Irish Medical Association, for his late frank and disinterested statement before the Medical Council of those defects which at present tend to impair the character and efficiency of the examinations for Medical and Surgical degrees or diplomas."

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending May 12.	Week ending May 19.	Week ending May 26.	Back cases reported in the week ending May 26, 1866.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

This Return shows that 1207 attacks were reported to have occurred during the week ended May 26, being a decrease of 725 on the previous week.

A considerable, but varying, number of "back cases" are reported every week. These cases, however, do not necessarily relate to the previous week only; they generally comprehend arrears of from six to eight weeks, and, in some instances, a longer period.

Note.—4 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Chester, 1; Lincoln, 2; and Flint, 1. These inspectors returned 34 cases last week.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The annual meeting of the above most excellent Society was held in the Hall of the King and Queen's College of Physicians, Kildare-street, Dublin, on Monday, June 4, Dr. Beatty, President of the College, in the chair. The Report was read by Dr. M'Clintock, one of the honorary Secretaries. The deaths of two members of the Central Committee, Dr. Edward Hulton, of Dublin, and Dr. Richard Corbett, of Cork, were referred to. It was stated that the legacies of the late Mr. Carmichael (£4500) and of Dr. Colvan (£500) had not yet been received. The Bombay auxiliary was announced to be in a most prosperous condition, and the zealous and successful services of Drs. Lord and Joynt in connexion with it, were acknowledged with thanks. The funds of the Society exhibited an increase of about £80, as compared with those of the preceding year. The total number of applications for relief were seventy, being about the same as that for each of the last few years. Seven of the present recipients are Medical men; fifty-four applicants claim relief as the widows, and eight as the children of Medical men. The treasurer had received £100 from Dr. Banks, and Dr. Mackesy had added £20 to his original donation. Dr. Bennett moved a vote of thanks to the editors of various newspapers in Ireland who had advocated the claims of the Society. The press, he said, had supported not only this association, but everything connected with the interests of the Medical Profession, and his own experience showed that there was a kindred spirit between the members of the press and the Medical Profession of Ireland. Dr. Dwyer seconded the resolution, which was carried unanimously. Dr. Churchill having been called to the second chair, the proceedings terminated with a vote of thanks to Dr. Beatty.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. H. W. Rumsey is thanked for his communication.

We are sorry that Dr. Lionel Beale's reply to Dr. Moxon is again postponed through press of matter.

A Fellow.—In order to be on the safe side, let the papers be sent in to the office this morning (Saturday).

M.P., Reform Club.—Dr. Robert Brady, who died in 1700, was chosen representative for the University of Cambridge in that Parliament which met at Oxford.

F.R.C.S., Cheltenham.—You should write to the Secretary, as, on inquiry, we find that notices have been sent to all the Fellows whose addresses are known at the College, and residing within the United Kingdom.

Helminthologist.—Specimens of the trichina found in the muscles of the patients who died in the London and Middlesex Hospitals may be obtained of Mr. Norman, 178, City-road.

C.B.—Our correspondent begs the question at issue. The customary right of Licentiates of the College of Physicians to the title of Doctor—if they choose to adopt it—is at least 200 years old.

The Cincinnati *Gazette* says that pure "essence of coffee" is now made in that city out of the "cheapest, dirtiest molasses," which is boiled until it ropes, cooled in pans, and when hard, broken up and pulverised. Ground rye is then mixed with it, after which it is boxed up, each box being sold at 80c., and labelled "pure essence of coffee."

List of Parishes in the Metropolitan District Governed under Local Acts.—St. James, Clerkenwell; St. George, Hanover-square; St. Giles in the Fields and St. George, Bloomsbury; St. Mary, Islington; St. James, Westminster; St. Luke, Middlesex; St. Margaret and St. John, Westminster; St. Marylebone, St. Pancras, St. Leonard, Shoreditch; St. Mary, Newington.

G. P. R., M.D.—You will find your inquiry answered in the following lines, which may still be seen on a tombstone to the memory of Dr. Thomas Crossfield in Hendon Churchyard:—

"Beneath this stone a queer one lies,
Who cares not now who laughs or cries.
He laughed when sober, but when mellow
Was a har'em scar'em fellow.
He introduced the use of savin,
In those diseases like to spavin.
He gave to none designed offence,
So *Honi soit qui mal y pense.*"

Mercury in Hydrophobia.—An instance has been reported by the *Wolverhampton Chronicle* of an attack of hydrophobia apparently cured by the administration of mercury and the production of salivation. An anonymous writer in the *Times* has also given the following account of the coincidence of recovery with mercurial fumigation:—

"When we were at Ahmednuggur in 1853-4 we were acquainted with Dr. David Wyllie, civil Surgeon there. He told us of a case the day it happened, coming to see us directly after the patient was relieved. That morning a boy was brought into the Hospital suffering from hydrophobia. Dr. Wyllie immediately had a pan of live charcoal brought and placed on the ground under a cane-bottomed chair. The boy was entirely undressed, placed on the chair, and enveloped in blankets. Then several grains of mercury (I forget now many) were thrown on the charcoal, and the fumes so impregnated the boy's body that in a quarter of an hour the saliva was pouring out of his mouth; the rigidity caused by the spasms ceased, and the poison came out of the boy. What happened after, whether the malady ever recurred, I know not; but the boy lived, and so did all other cases treated by Dr. Wyllie when taken in time."

The Profession well know that mercury is a very old remedy in canine madness, but that it has fallen into disuse through frequent failures. Derault, of Bordeaux, James, Losig, and others, believed that they had observed favourable effects from its employment, but it has completely failed since in numerous trials. The Indian case wears an apocryphal aspect. Salivation in a quarter of an hour is somewhat rapid, even when the method employed is fumigation, and the decided statement of the writer as to the exit of the poison stamps his tale as worthy of the same amount of credence as most of the Medical scientific discoveries published in the *Times* newspaper.

Book Notices, etc.—Mr. Nugent Charles *Walsh* has just published (Renshaw) "The Medical Officer's Vade-Mecum, or Poor-Law Surgeon's Guide; containing the Regulations at present in force relating to the Relief of the Poor in Sickness, and the Appointment, Qualifications, Duties, and Remuneration of Union Medical Officers in England and Wales; with a Note on Vaccination and Public Vaccinators; to which is added an Appendix containing the Medical Acts, Dr. Farr's Statistical Nosology for Classification of Disease and Causes of Death, with other useful matter, and a copious Index." This book, which is a very compact one, must be of great value to every Poor-law Medical officer who desires to know his own duties and responsibilities, as well as those of the Board of Guardians whom he serves. It will give an additional value to this book that its author is barrister-at-law, and holds office under the Poor-law Board. We may add that he is the son of the late Charles R. Walsh, whose memory is dear to all who value the progress of sanitary and social reform.—Mr. John *Storie* believes that flesh and sugar used as food cause increased mortality from diseases of the respiratory organs, and gives us a pamphlet in favour of vegetarianism.—Dr. Henry W. *Williams's* "Recent Advances in Ophthalmic Science," published by Tickner and Field, of Boston, U.S., promises to be a very useful and intelligible guide to the knowledge of astigmatism, iridectomy, the use of Calabar bean, and other topics of modern ophthalmology.—We are glad to receive the *Medical Reporter*, a fortnightly record of Medicine and Surgery, published by Pinckard, of St. Louis. Dr. Maughs's inquiry into "causes why higher organisms are less plastic than lower ones," is of great philosophical interest.—Dr. *Waring* sends us from the *Pharmaceutical Journal* an account of new euphorbiaceous and other purgative seeds. That *lime juice* is a remedy for over-purgation caused by such seeds is an interesting fact.—Dr. W. *Turner* sends a second part of his observations on malformations of the organs of generation, especially on "fœtation" in a rudimentary uterine cornu.—The *American Journal of Medical Sciences* for April, 1866, is as full as ever of valuable matter, new and collected.—Dr. *Edwards* and Mr. *Willett* have published Statistical Tables of Patients under Treatment in St. Bartholomew's Hospital during 1865.

Cholera Literature.

(Continued from page 601.)

In the *Australian Medical Journal* for March, 1866—which, by the bye, contains a case of tetanus successfully treated by the application of ice to the spine, *with* chloroform and atropine—is a paper on epidemic cholera by Dr. *Dougan Bird*. He thoroughly believes in the transmissibility of the disease by the excretions of the patients, giving in his full adhesion to the doctrines of Snow and Dr. Budd. He asserts summer diarrhœa to be a distinct disease *in toto* from cholera; yet afterwards makes admission to the effect that some diarrhœa is cholera in a mild form, and that the evacuations of some diarrhœa patients will give rise to cholera, especially, as he believes, during the stage of decomposition. He gives small comfort to the people of Melbourne, the soil of which city he describes emphatically as *night soil*. He speaks in high terms of Dr. French's investigation of cholera, and of his theories, which involve paralysis of the heart; and does equal justice to Dr. Chapman, though he repudiates the idea that cholera is caused by heat. As to treatment, he speaks in favour of bleeding; also of brandy and salt; objects to opium in collapse, but decidedly favours the suppression of diarrhœa by that remedy. In the discussion which followed, Dr. Tracy praised the practice he had seen followed by Dr. Buchanan, of Glasgow, viz., a large dose of laudanum by mouth and rectum, hot vapour bath; and white of egg, milk and water, and salt for drink. Mr. Gillbee believed in calomel and opium in large doses. He had treated the disease on board ship. Dr. Girdlestone, who had seen the disease at Merthyr Tydvil, gave an emetic, followed by cold saline drink, heat to the feet, and small doses of laudanum with soda and ipecacuanha. Dr. Black, believing that the disease consisted in paralysis of the sympathetic, would give a scruple of quinine and calomel, and then saline drinks. Dr. Macarthy would simply use ordinary astringents with opiates. Dr. Motherwell had seen many cases in 1832, and trusted to small doses of opium, with pure air. Be it observed, that cholera has never appeared at Melbourne, nor, judging from Dr. Bird's remarks, has Dr. G. Johnson's book reached that place.

(To be continued.)

Parochianus wishes us to insert the following return of cost of Medical attendance and nursing in Workhouses:—

	Medical officer.	Nurses for sick and imbeciles.	Number of beds in sick wards.	Cost per bed per annum for Medical attendance & nursing—about.
	£	£		£ s. d.
Bethnal-green	160	102	406	0 12 11
Chelsea	100	50	66	2 6 0
Holborn	125	30	487	0 6 4
London, City of	275	173	317	1 9 0
St. Martin's-in-Fields	150	42	48	4 0 0
Shoreditch	126	256	263	1 9 0
Strand	105	35	40*	3 1 6
Lambeth	300	165	426	1 1 10
Wandsworth & Clapham	100	40	158	0 17 9

This shows merely the cost for Medical attendance and paid nurses. The maintenance of the occupants of the beds is not included.

The number of beds is according to the most recent return on the subject.

* All fever cases are sent away.

The Nitro-Glycerine Explosion in San Francisco.—"Such a scene," writes the *New York Times'* correspondent, "I never before witnessed. The yard was completely filled with bricks and rubbish. Men, crushed down by beams and timbers, were groaning and imploring release; others were clambering among the ruins, endeavouring to afford assistance. Shreds of flesh and fragments of limbs lay mingled with broken boxes and splinters of wood. . . . . News of the disaster spread rapidly through the city, and all who had relatives employed in the vicinity came gathering around in a horror of suspense and fear. One lady stood at the gate crying, 'My husband, my husband; let me see my husband.' Poor creature! He was literally blown into fragments. Not even the trunk was left entire. It seemed as though the whole body had been rolled through a piece of machinery studded with knives, which, after mincing the flesh, scattered it far and wide, as a farmer in spring sows wheat. Another body was shattered beyond identification, though not to the same horrible extent. At the undertaker's yesterday I saw a basket full of human flesh that never can be identified, as the shreds were picked up in various parts of the yard, and probably belonged to two or three different bodies. Little wonder that the Sepoys had such a horror of being blown from a cannon's mouth; for it indeed looks in such a case as though there would be considerable confusion at the last day in each man's claiming his own. Mr. H. Cox, steward of the Union Club, was among the wounded, probably fatally; his flesh was filled with splinters of wood and pieces of bone like a quiver with arrows, and so intense were his sufferings that on being rescued from the ruins he begged some one, for humanity's sake, to shoot him through the head, or lend him a pistol that he himself might end his misery. Some idea of the force of the explosion can be formed when it is known that in Leisdorff-street, a block east of the scene of the accident, a piece of skull, with the scalp adhering, was picked up, while a fragment of shoulder was seen pattied against the wall, like one of the paper pellets which boys throw about at school. In a store opposite the Express building half a human head, containing the brain intact, was found; in California-street lay a fragment of a skull, nearly 300 feet distant; a tailor working at his bench some 150 feet away was startled to his feet by the explosion, and frightened nearly into convulsions by a human arm which was dashed through the window and deposited amid the snips of cloth that lay before him. In the billiard-room of the Union Club an abdomen hung impaled upon a broken rafter against which it had been hurled. Around on the adjoining roofs lay shreds of human flesh and vital organs. Of course great excitement was caused when it became known that a large amount of the oil is stored within the city limits. At the meeting of the board of supervisors in the evening a resolution was agreed to that the chief of police be directed to destroy it all, wherever in the city it may be. A member represented that there is no law for this, but the *vigilante* element still remains in the breasts of the San Franciscans, and when a thing should be done they seldom stop to consult law. I would not advise your merchants to ship any more nitro-glycerine out here, unless they wish to receive an infernal machine by return mail."

The Correction of Inverted Images on the Retina.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall be much obliged to you if you kindly insert the following in the earliest number of the *Medical Times and Gazette*:—

Why do we see objects *erect* or *upright* from *inverted* images on the retina?

Before I offer my explanation on this much-disputed subject, I shall speak generally of the structure of the retina. This consists, principally, of two distinct portions: first, the expansion of the optic nerve in front; and second, a peculiar apparatus behind, consisting of what are called "cones and rods," and "granules and vesicles," the latter bodies being situated in front of the former. The relative position of the nerve expansion and the hind apparatus has for a long time been misunderstood, but it has at last been finally decided in the way I have described.

It has also been lately known to physiologists that the two portions of the retina are as distinct from each other in function as in structure. The anterior portion, the expansion of the optic nerve, is not at all concerned in receiving primarily the stimulus of light, but this function is exercised only by the posterior portion. This is evident from the facts, that the optic disc (where the structure of the retina consists only of the expansion of the nerve and none of that hind apparatus) is most deficient in the power of receiving visual impressions; while the "yellow spot," where no other structure is present, except the 'cones," is the most sensible portion of the entire retina—(Dr. Carpenter, "Physiology," par. 605). From this it follows unequivocally that the stimulus cannot act primarily on the nerve expansion, but only on the posterior apparatus behind, and, therefore, the image of the object that is seen is not formed upon it (the nerve), but upon that apparatus behind it. Consequently, the inverted image formed by the rays of light from the object is situated behind the expansion of the optic nerve, and not in front nor upon it. Now, it can be very easily understood how this inverted image behind the expansion of the optic nerve gives rise to an impression of upright image on it, and is communicated in that condition to the percipient principle.

It is not necessary to enter into discussion on the other explanations which have been given of this phenomenon to make place for this. The explanation of Volkmann and Muller appears to me unnatural, because it is complicated and inconsistent with the simple and straightforward dealing of nature, and that of Dr. Carpenter, although he maintains that an upright image is really what is presented to the mind in vision, is alike complicated, and, therefore, unlike the work of nature. But the above which I have attempted appears much simpler and consistent with that pervading character of all nature's plans of work, which is absolute truthfulness, even in all their bearings, and simplicity. And this is the only recommendation with which it has come to me, and the only ground on which I have accepted it in preference to others.

I am, &c. Mati. Lal Mitra.

4, Cumin-place, Grange, Edinburgh, March 22.

Poor Law Medical Reform.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Permit me, through the medium of your journal, to inform the public vaccinators of England and Wales that I have received a note from a Member of the Select Committee on Vaccination, written in haste, in which it is stated "We have got through the Bill in Committee, have raised the fees—that is, we raised the minimum, the guardians cannot pay less, may pay more." I need scarcely say this is so far satisfactory. As soon as the Bill has been reprinted, I am to have a copy, and shall then be able to lay before your readers further particulars of the changes recommended by the Select Committee to Parliament for adoption.

I am, &c.,

12, Royal-terrace, Weymouth, June 2. Richard Griffin.

*** Since the above was in type, we have received a telegram from Mr. Griffin to the effect that the Amended Bill does not fully carry out the above statements.

Appeal on Behalf of a Widow and Six Orphans.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you allow us to make use of your valuable space for the purpose of advocating the cause of the family of a deceased member of our Profession and of entreating your readers to come to their aid? The relation of the following circumstances will, we are sure, be sufficient to show the distressing nature of the case and how deserving of sympathy the subjects of the appeal are.

In September last a Surgeon, whose name we are not at liberty to publish, arrived at Venezuela, in Central America, having been appointed by the Quebrada Railway and Mining Company to Medical supervision of their officials and workmen, and leaving behind him in England his wife and six children, the youngest an infant of less than a year old and the eldest of 12 years of age. Almost immediately after his arrival he was attacked by fever, and died within a fortnight. His wife and family are entirely unprovided for; no pension is allowed them by the company in whose service this gentleman lost his life. They are now living on the scanty charity of relations, who are unable to spare more than a mere pittance for their support, which it is doubtful whether they will be able to continue. The widow has spared no exertions in endeavouring to obtain admission for her children into various orphan asylums, and is sanguine of succeeding in her second application to the British Orphan Asylum; but at present not one of the six children has any provision whatever. The object she has in view is to obtain by subscription a sum sufficient to enable her to open a boarding-house, as she considers that her chances of succeeding in that direction are better than in any other.

Further particulars and the name of the deceased gentleman may be obtained by application to Dr. Letheby, 17, Sussex-place, Regent's-park; the Rev. Robert Jones, incumbent of All Saints, Rotherhithe; the Rev. R. S. Drew, incumbent of St. Barnabas, South Kensington; or to the undersigned.

The Editor of this journal has kindly consented to receive subscriptions, which may also be sent to the undersigned, for the "Widow of a Deceased Surgeon."

We are, &c.

Hy. Letheby.
W. Spencer Watson.

27, Montague-street, Russell-square, W.C., June 6.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·633 in. The atmospheric pressure rose to 29·81 in. on Wednesday, and fell to 29·51 in. on Friday.

The general direction of the wind was S.W., E, S.E.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 52·0°

APPOINTMENTS FOR THE WEEK.

June 9. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p m.

Royal Institution, 3 p.m. Professor Huxley, "On Ethnology."

11. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

12. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Ethnological Society of London, 8 p.m. John Crawfurd, Esq., "On Cæsar's Account of Britain and its Inhabitants in Reference to Ethnology."

Royal Medical and Chirurgical Society, 8½ p.m. Mr. Balmanno Squire, "On the Influence of Pregnancy, Lactation, etc., on Chronic Disease of the Skin." Dr. T. C. Allbutt, "On Premature Menstruation, and on Myeloid Transformation of the Lung."

13. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m. Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

Microscopical Society, 8 p.m. Mr. R. Beck, "On the Function of some Peculiar Vibrating Hairs on Spiders and Insects."

14. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

15. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Professor Tyndall, F.R.S., "Experiments on the Vibrations of Strings."

ORIGINAL COMMUNICATIONS.

ON THE NATURE OF VITAL FORCE

(PARTLY IN REPLY TO DR. MOXON).

By LIONEL S. BEALE, M.B., F.R.S.

I THANK Dr. Moxon for drawing attention to the consideration of the nature of *vital force*, which, as he says most truly, is of paramount importance.

The question must be of interest, not only to physiologists, but to Physicians; for, notwithstanding all that has been recently so very confidently affirmed with reference to the mechanics and chemistry of health and disease, no one is yet able to explain the simplest changes occurring in the healthy body or in the course of disease, unless he admit the influence of phenomena properly called *vital*, no changes like them being known to occur except in things that "live," which were derived from things that lived before them.

If, however, I understand Dr. Moxon's paper rightly, it is an attempt to show that the doctrine which attributes the formation of structures and compounds in living beings to the working of a *peculiar agency totally distinct from every form or mode of ordinary force*, is not irreconcileable with the doctrine which advocates that the forces at work in living things are only *physical and chemical forces*. My own opinion is, that the two views cannot be reconciled. When I use the terms *vital force*, *vital action*, etc., I refer to that which cannot be explained by physics or chemistry. If only the *movements* of living matter can be accounted for by what is now known of physics and chemistry, let the explanation be given. I hold that they cannot, and that it is a mere authoritative dictum, utterly unsupported by evidence, to assert that these movements are due to the operation of mechanical or chemical forces only. No *mechanism* or machinery has been, or can be, demonstrated in the moving matter. Moreover, there is nothing in nature besides living matter which came from pre-existing living matter that moves like it. If the chemico-mechanical school cannot account for these simple movements, is it very likely they can afford us much real information concerning the *formation* and *increase* of such living moving matter? It may be grand to talk about highly complex albuminoid matter in a state of rapid chemical change, and so on; but all this means nothing whatever.

Dr. Moxon thinks that I do not invalidate my opponent's position when I show that "the *mechanical arrangements* by which the *chemist* on the one hand and *living substance* on the other," etc. Now, I have asked over and over again to be shown the *mechanical arrangements* of the living substance; but hitherto no one has been able to see the supposed mechanism. As far as I can learn, living substance works absolutely without any mechanical arrangements whatever. It is incumbent, therefore, upon those who speak of mechanical arrangements to demonstrate them, and if they cannot do so they should candidly confess that the supposed mechanical arrangements in active living matter existed only in imagination, and that therefore the term has no meaning, and ought no longer to be employed in speaking of living matter.

The attempt to make any compromise between views so absolutely conflicting is hopeless, and only leads people away from the consideration of the real matter at issue. It is not a question whether vital force *may be* correlated heat, etc., but if it actually *is so*, as has been affirmed of late years over and over again. And upon this I have only to remark further, that while it has been very positively proved that heat, electricity, motion, etc., *are* correlated, nothing at present known justifies the conclusion that heat, motion, or any other mode of force, and *life*, are so correlated. "Life" seems to direct or condition force, and the idea of force directing force seems absurd; for if force could direct force, might not much of the work effected by machinery be done without it, or, at least, some force setting free arrangement be an efficient and cheap substitute for the human designing, directing, and superintending apparatus?

Again, Dr. Moxon grants (with me?) that the "*simplicity*" of the proceedings in living matter contrast very strikingly with the "*complexity*" of the chemist's proceedings, etc. Now, I think I have stated distinctly that I did not suppose the difference was a difference of simplicity or complexity, but a difference of kind,—an absolute, not a relative difference. I maintain that *chemical* and *vital* changes differ from one another in their essential nature. A mass of living matter will take up matter of different composition around it, and convert it into matter like itself without chemist or apparatus. Will any form of non-living matter do this? The chemist by no means ignores himself in his laboratory, and yet he will not admit anything corresponding to him in what he terms the living laboratory in which the changes go on even without apparatus and under conditions totally different from those present in the laboratory. If the chemist worked with more complicated apparatus than the cell, it would be correct to compare the complexity of the one with the simplicity of the other. But the "cell apparatus" is neither simple nor complex. It exists not.

It is surely premature to refer to "nervous agency" in connexion with this question of vitality. The nerve-cells are made, or make themselves, before they *act*. I shall be happy indeed to proceed in the inquiry to the utmost possible limits, but we ought, I think, to advance steadily step by step. What good can come of discussing about mental activity, until we are agreed as to how the apparatus concerned in the process is produced?

It seems to me that those who wish to teach us anything should begin with simple things and advance gradually to those more complex, and if we are to learn anything about living things in general, surely our instructors should commence with the consideration of the phenomena occurring in the simplest forms of life, or in the earliest and simplest stage of development of a complex creature. Every child can be taught that a little bit of soft transparent stuff takes up matter around it which is not like it, and *converts* this into matter like itself, and so increases in size, and that it divides and subdivides, and thus from one mass, many masses result. This is what goes on in the development of the simplest thing, and in man himself. Not only is the process common to every known form of living matter, but it is *peculiar* to living matter, and is not known to occur in any other state.

A common cold cannot come on without the increase of living matter, which is practically ignored by physicists, chemists, and the Chemico-mechanical School of Medicine. The increase of living matter occurs in all fevers and inflammations. There is not a disease in which such changes are not at work, and every remedial measure we employ does good or harm by bringing about conditions which are favourable or unfavourable to the growth and multiplication of such soft transparent semifluid living moving matter. If the facts can be explained by chemistry and mechanics, let us have the explanation, but if not, let us confess we cannot explain them, or refer them to the influence of vital power until a more satisfactory explanation is discovered.

Why is it that some philosophers exhibit little inclination to begin by inquiring about the simplest living things? One would have thought that this was just the point at which Mr. Mill or Mr. Herbert Spencer would have desired to commence. Here is a thing increasing in size, and then separating so as to produce many like things. How does it increase? Of course, by drawing matter to itself. But by virtue of what *property* does it do so? how does it divide? why does one portion separate from another portion? First, matter seems to draw matter towards it, and then this same matter separates itself, and one portion moves away from another. Simple phenomena easily stated, easily proved, due to antecedent phenomena, and these to anterior occurrences. Doubtless, if it were not that physiology is embarrassed by "natural difficulties" (Mill) (a), these things would have been explained long ago; but if we argue as if we understood them when we do not understand anything about them, we are not likely to gain much by the process, or to teach others anything really worth their learning.

The nature of life must, of course, be studied from every possible point of view, and it would be very unreasonable to offer objections to conclusions arrived at from the psychological side. But as what we call *consciousness* is not absolutely necessary to life, seeing that some things living never exhibit consciousness at any period of their existence, and that all of those in which it is manifested are devoid of it at the earlier periods of life, I think it quite fair to ask that in the first place the phenomena *absolutely essential to life* and of course their antecedent phenomena, should be alone discussed. I think that unless we restrict ourselves in the first instance to the consideration of the matter in its simplest state, we shall soon become involved in hopeless confusion.

To me the *dignity* of vital force is a matter of no importance whatever. I want simply to know why a minute particle

(a) Are not the difficulties *phenomenal* rather than *natural*?

of colourless transparent matter is able to make matter like itself out of matter differing from it in composition and properties, and how under certain circumstances it gives rise to matter differing in composition from both. I am told that it does so by virtue of its molecular machinery, and I am told that the matter in which the changes occur is a force-conditioning machine or a laboratory. Then, I remark, if it be a laboratory the various chemicals come together of their own accord, take up their own proper positions, decompose one another, arrange and rearrange their own elements, and so give rise to various compounds, and all this without any apparatus and without any chemist!

Of course if chemists and physicists should discover any compound capable of increase by making a compound like itself out of matter of a different composition placed in its immediate neighbourhood, and this of continuing the process, or if a machine could be formed which would make another machine like itself out of wood, iron, etc., placed near to it, they would have some reason for comparing living things with lifeless matter, but hitherto the comparisons made will not stand; nor has any object been gained by making them, unless it be an object to lead people to believe that to be an explanation of a fact which is no explanation at all. I cannot account for certain phenomena unless I resort to the hypothesis of the existence of vital power or vital force which differs entirely in its action from any known forms of ordinary force. Some have asserted that they can do so. I beg them to *explain*.

It is useless to say that vital force *may be* another form or mode of heat, unless arguments can be advanced in favour of the possibility. By all means let the idea of *vital power* be upset clearly, decidedly, for once and for all, if this can be done. I hold it because I cannot escape from it; teach me how to explain the facts without it, and I will be taught, but I will not submit to be forced into confusion by force while I retain power to resist. If vitality is to be upset by *force*, the friends of *force* must be fair, convincing by argument, and not attempt to smother thought by unthinking force.

It has always appeared to me strangely significant that those who attribute so much to *force* almost invariably avoid the all-important question of *form*. To say that *form* is due to the character of the machinery which conditions force is no explanation whatever, unless the formation of the *machinery* and the manner in which it acquired its *character* be explained. But *force alone* never formed any machinery whatever and never gave form, order, or character to anything living or lifeless. Will any one venture to say that the influence exerted by the spermatozoon upon the *form* of the new being is due to any peculiar manifestation of ordinary force? Some force-devotees may perhaps regard the most beautiful works of art as well as living creatures as mere force productions, and hold that *form* is the child of *force*. Force is very powerful, but unless a something directs it, will *form* appear? Is not that something the master, are not force and matter his tools, and does not the *form* result from the particular way in which the master works? Whatever name be given to this something, I cannot conceive how it can be a correlate of physico-chemical *force*. We might as well try to prove that the man who made a machine was a correlate of the heat that set it in motion after it was made. Does not "*life*" exist before brain and nerves, the instruments of mind, are formed? If therefore mental activity be a correlate of heat, how can "life," which manifests itself in man's organism before mind is evolved—which sometimes exists independently of mind, but without which mind could not exist, be also a correlate of heat? Life does not necessarily involve mental activity, although we cannot have mental activity without life. Life and mental activity cannot be correlative, but mental activity may be one of the results of the working of vital force or power.

THE PUBLIC HOSPITAL AT JAMAICA.—The following testimony to the good state of the Jamaica Hospital was recently given at a public meeting in that island by Mr. Harvey, a member of the Society of Friends, who, with Mr. Brewin, was delegated by the Society to make a tour of inspection in the disturbed districts:—"The public Hospital he knew was somewhat dangerous ground to tread upon, but he could not refrain from speaking of the order, cleanliness, and indications of careful supervision he had witnessed there. The site was no doubt bad, and many of the buildings unsuitable; nevertheless, it was a credit to the colony."

THE TREATMENT OF CHOLERA.

By GEORGE JOHNSON, M.D., Lond., F.R.C.P.,
Physician to King's College Hospital, Professor of Medicine in King's College.

DR. WHITTLE, in his interesting paper (*Medical Times and Gazette*, May 19, 1866) "On Bleeding in Cholera," after expressing a general concurrence with me in my theory of the disease, refers to certain points of theory and of practice with regard to which he differs from me. I am desirous to convince Dr. Whittle and others that the difference between us is much less than he appears to imagine.

Dr. Whittle doubts whether the vomiting in cholera is the result of an effort to expel the poison, and he intimates that this symptom may be occasioned by sympathy with some distant organ analogous to that which occurs in nephritis, in hydrocephalus, and in pregnancy. Now the objections to this explanation of the vomiting in cholera are, first, the negative fact that there is no evidence of irritation of any distant organ with which the stomach would be likely to sympathise in the manner supposed. Then there is the positive fact that during the progress of cholera a large amount of morbid secretions is poured into the stomach, and it seems reasonable to conclude that the act of vomiting is intended to expel these offensive materials. That these morbid secretions should have an emetic action appears so extremely probable that we have no need to explain the vomiting by an imaginary nervous sympathy.

But the most interesting part of Dr. Whittle's communication is his statement that all stimulants, astringents, and opiates are injurious by *increasing* vomiting and purging; while, on the contrary, calomel stops the vomiting immediately, and after a few doses the purging. Now in the main I agree with this statement, but my explanation of the facts would be different from Dr. Whittle's.

First, I should somewhat qualify the statement that opium *always* increases the purging; it sometimes abruptly stops the purging, but rarely without subsequent ill-effects, such as profound collapse or consecutive fever. In many cases, however, opiates and astringents tend to increase and to prolong the purging. What, then, is the explanation of this? I know of no more probable explanation than this: that they tend to retain within the body a rapidly self-multiplying morbid poison, whose action is that of a strong purgative. What, then, is the *modus operandi* of calomel in quickly arresting the vomiting and purging? Dr. Whittle appears to think that it has some specific sedative action. Now I venture to suggest that the following may be the true explanation. The calomel certainly does not act as a direct astringent; it does not prevent the escape of the morbid secretions from the digestive canal, but rather, by a stimulant action on the intestines, it quickens the expulsion of the offensive materials, and then the purging quickly ceases. This I believe to be the true explanation of the apparent anomaly that opium acts as a purgative, and calomel or castor oil as a sedative or an astringent. In both cases the action is indirect. The opium is indirectly purgative by retaining within the body a purgative morbid poison. The calomel or the castor oil is indirectly sedative or astringent by quickening the expulsion of irritating excreta.

The unexpected and apparently anomalous results of various remedies in cases of cholera admit of no satisfactory explanation if we ignore the existence of a morbid poison which, in all cases, tends to excite an eliminative secretion from the mucous membrane of the alimentary canal, and which in the more severe cases tends to obstruct the pulmonary circulation, and so to cause collapse. This arrest of blood in the lungs gives the explanation of the paradox, that during collapse venesection in suitable cases increases the volume and power of the pulse, while alcoholic stimulants have the opposite effect. Venesection lessens the distension of the right cavities of the heart, and so increases their contractile power. Brandy, on the contrary, appears to increase the distension, which results from the block in the lungs, and thus the contractile force of the right heart is diminished. Less blood, therefore, is transmitted to the left side of the heart, and the volume and force of the arterial pulse are lessened. Here, then, we have the apparent anomaly that during cholera collapse bleeding acts as a stimulant, and brandy as a sedative or depressant. Yet this apparent anomaly admits of a simple and intelligible physiological explanation. In the case of cholera, above all other forms of disease, a correct physio-

logical interpretation of the symptoms is essential for successful treatment and for a correct estimate of the true influence of remedies.

In conclusion, I wish to offer a few additional remarks on the eliminative treatment of epidemic diarrhœa and cholera. And in doing so I beg to say that I am as fully conscious of the weighty responsibility which rests upon any one writing on this subject as is the author of the very able, temperate, and fair review of my book which has recently appeared in this journal. I am aware that many Practitioners cannot think of giving a purgative to a sufferer from cholera without a feeling of dread. I am sure that this dread is mainly the result of an imperfect apprehension of what a purgative is intended to do and of what it actually does. The disease is usually attended with a profuse drain of fluid from the blood. To increase that drain would be mischievous, and might be fatal. A few doses of castor oil do not increase that peculiar excretion which constitutes the purging of cholera. I know that they do not, by actual observation, and if we look a little closely into the matter, we shall see that an ordinary purgative cannot have the effect which is so much dreaded. Let us consider for a moment the physiology of choleraic diarrhœa. A specific poison enters the blood. This is as nearly certain as any proposition in pathology can be. This poison acts as a ferment, and induces peculiar morbid changes in certain blood constituents. While these changes are going on there is often a general feeling of *malaise* and constitutional disturbance before there are any intestinal symptoms. At length after a period varying from a few hours to four or five days, the morbidly changed blood materials are excreted through the mucous membrane of the alimentary canal. The cholera secretions have a disagreeable fishy odour, quite unlike that of any other morbid product; and there can scarcely be a doubt that the blood changes which result in the cholera stools are as peculiar and specific a product of the cholera poison as the blood changes induced by the small-pox poison and the consequent eruption are peculiar to that disease. Moreover, I maintain—and here I speak deliberately, and I am sure with reason on my side—I maintain that castor oil, or any other purgative passing through the intestinal canal, can no more increase the peculiar choleraic discharges than castor oil applied to the skin can increase the eruption of small-pox. To do either the one or the other the drug must increase the specific blood changes, and nothing can effect this but the specific poison of each disease. Opium, as we have seen, may *indirectly* increase the choleraic discharges by retarding the escape of the cholera poison, and so allowing it a longer time to work its destructive changes in the blood. No drug that we know of can directly bring about any such result. But it is sometimes said that an attack of cholera has directly followed the action of a purgative. This must have happened frequently, but it affords no proof that the purgative caused the attack. In such cases we may safely assume that the specific poison of cholera had entered the system, and the zymotic changes induced by it in the blood probably caused the feeling of derangement for which the purgative dose was taken.

What, then, is the object to be attained by emetics and purgatives in cholera? The object is to stimulate the stomach and intestines to eject their morbid contents, which otherwise might be retained and re-absorbed. There is reason to believe that the intestines are more tolerant of the morbid secretions than the blood-vessels are of their morbid contents. Choleraic diarrhœa is often painless; the morbid secretions have but little irritant action on the bowel, which sometimes becomes over-distended and paralysed by its accumulated contents, and still more frequently the choleraic secretions are but slowly and imperfectly discharged without the aid of some artificial evacuant. On these grounds, then, I maintain that the exhibition of such a purgative as castor oil—mild and unirritating, yet quick in operation—is not only a safe, but often, probably, a life-preserving practice.

Hydrophobia.—Two cases have been reported in London during the past week,—one that of a boy, aged 15, who died at the Middlesex Hospital. He had been bitten by a dog many weeks previously. Subcutaneous injection of morphia and the administration of bromide of ammonium were tried, but with no good result. The other was a case of an old lady, aged 80, who died at Islington with all the symptoms of rabies, after a short illness. She had been bitten five months before by a pet lap dog.

NIGHT BLINDNESS.

By J. W. HULKE, F.R.C.S.E.,

Assistant-Surgeon of the Middlesex Hospital and Royal London Ophthalmic Hospital.

Professor Laycock's communication in the *Medical Times and Gazette* of April 21 leads me to send a few cases selected from my note-books for the purpose of illustrating the two conditions of which night blindness is the common symptom.

The first is exhausted sensitiveness of the retina caused by prolonged exposure to glaring light, which makes the bacillary layer of the retina incapable of being sufficiently stimulated by twilight for perception.

This affection is common among sailors in tropical seas. Men suffering from it cannot see to do their work on deck after the sun goes down, except perhaps at full moon when the sky is clear; while in a well-lighted cabin their visual acuity is not much diminished. I have examined many cases of this kind without finding any organic change appreciable with the ophthalmoscope. After a few days, or at most a week or two, ashore the night blindness disappears, but subsequent attacks are not unusual when those who have once suffered are exposed to the same cause.

Rest and tonics comprise the treatment. The very frequent occurrence of night blindness in men suffering from scurvy has led to the idea that here it may depend on purpura of the retina, but I have never yet seen this, though I have often looked for it in night-blind scurvy patients. Their liability proceeds from their feebleness, in which the retina shares.

Case 1.—A sailor, aged 20, with fair complexion and light blue eyes, applied at the Royal London Ophthalmic Hospital on January 30, 1864. Seven weeks previously, on his homeward voyage from Calcutta, he had become night-blind. He could do his work during the day, but at sunset his sight grew so dim that he could not see things about him on deck; yet in the cabin by candlelight he saw fairly, though not so well as by daylight. On his outward voyage he had had a similar attack. At St. Helena a Surgeon who had examined him reported him a malingerer. There were no objective signs of disease, except perhaps slight anæmia of the retina. Quinine was prescribed. In a few days the night blindness had quite gone.

Case 2.—A sailor, aged 22, came to the Royal London Ophthalmic Hospital on January 30, 1864. He was a strong, hearty-looking fellow, with black hair and dark hazel eyes. In July, 1863, on his outward voyage to Calcutta, three weeks before reaching port, his sight after sunset became so defective that on deck he could not see his hand a few inches before his eyes, but in the cabin with a candle he saw well enough; he also saw sufficiently well to get through his work at full moon when the sky was clear. He recovered after being on shore a few days. On the homeward voyage, a fortnight after leaving Calcutta, he again became night-blind, and had continued so. A Surgeon at St. Helena had reported him also a malingerer. He again quickly recovered.

Case 3.—A hearty-looking, weather-beaten sailor, aged 32, came under my care at the Royal London Ophthalmic Hospital, July 9, 1862. He said that eighteen days before, while off the Western Islands, he found that after a very fiery sunset he could not see the stars. The sky had been very bright for several preceding days. His shipmates thought he was shamming. He had had two previous attacks of the same kind: the first at Auckland, the second at Calcutta. With the exception of slight injection of the conjunctiva, externally his eyes had a healthy appearance, and with the ophthalmoscope I could not detect any signs of organic disease in the optic nerve or retina. He recovered after being on shore for a few days.

Case 4.—A sailor, aged 19, was brought to the Royal London Ophthalmic Hospital May 25, 1865, two days after reaching port. On his homeward voyage from China he had scurvy and became night-blind, unable to see on deck after sunset, but seeing fairly in the cabin by candlelight. His gums were very swollen and spongy, and bled easily. No morbid appearances were discoverable with the ophthalmoscope.

The second condition of which night blindness is a symptom is a contracted state of the visual field depending on structural alterations in the choroid and retina, characterised by very definite ophthalmoscopic signs. The bottom of the eye is overlaid with dots and clusters of black pigment scattered and massed, and often grouped along the course of the retinal

vessels. The pigment is a derivative of the choroidal epithelium, and lies on the surface of the choroid, and also among the withered retinal tissues. Between the clusters the epithelium is wasted, and the other tissues of the choroid are seen to be atrophied. These alterations progress from the front of the choroid and retina towards the optic nerve, and they are attended with a corresponding diminution of the area of the visual field, which becomes so small that the patient has not a general view of surrounding objects and stumbles over them at night, though so long as the centre of the retina remains unimplicated, the smallest type can be read in the contracted field. Ultimately, the optic nerve grows anæmic, the entire retina is involved in atrophy, and these final changes are marked by diminution of visual acuteness ending in blindness.

The disease has been named Retinitis Pigmentosa, and the name may be retained if we remember that the primary seat of the affection is the choroid. Usually it begins in early life, and it runs a very slow course, protracted through many years. Liebreich, who devoted much time to its investigation, found that about half the sufferers from it were the children of blood-relations. Hitherto my own inquiries on this point have always met with a negative answer. The disease is frequently traceable to inherited syphilis, and it often affects several members in a family.

Case 1.—In the present month, a woman, aged 44, brought two sons to the Middlesex Hospital; the elder, aged about 9 years, had night-blindness and a very contracted visual field, and the younger, 7 years old, had diminished central visual acuteness and a less contracted visual field. In both, the ophthalmoscopic signs of retinitis pigmentosa were well marked. Their mother's history contained evidence of constitutional syphilis. Healthy until her marriage, she had a scaly rash during her first pregnancy, and soon after the birth of the child iritis in the left eye, the sight of which continued to fail till quantitative perception of light only remained. Three weeks before coming to the Hospital, she was seized with tic in the supra and infra orbitar and malar branches of the fifth nerve on the left side, and soon after the left eye squinted inwards. When I saw her the pain had become less severe, but firm pressure upon the supra and infra orbitar foramina brought it on in great intensity. Tested with compasses, the sensitiveness of the surface supplied by these branches of the fifth was found to be much blunted. The upper border of the orbit was tender when firmly pressed. The left rectus externus was completely paralysed. The left pupil was occluded and excluded. The neuralgia and the paralysis were doubtless due to inflammation of the periorbita and fibrous investment of the fifth and sixth nerves; and there could be as little doubt that this, and the iritis, and the rash were consequences of syphilitic infection soon after marriage.

Case 2.—A tobacconist, aged 31, of fair complexion, spare build, and middle height, came to the Royal London Ophthalmic Hospital October 28, 1863, with the complaint that his sight, which had always been bad at night, had latterly become less acute than formerly during the day. There were no external signs of eye disease. The right eye read No. 18, the left No. 16 of Jæger's types, at about twelve inches distance, so that the visual acuteness was diminished, still he had not any difficulty in serving his customers in the day-time. In the twilight, however, he was afraid to leave his shop, for his sight was so imperfect that he stumbled against things in his way, and latterly had been obliged to be led. Both visual fields were extremely contracted. That of the right eye mapped upon a black-board at eight inches distance, was nearly circular and two and a-half inches in diameter, while that of the left eye was rather smaller and oblong. The fundus of each eye, from the anterior limit of the choroid and retina, nearly to the disc of the optic nerve, was thickly sprinkled with flocs of black pigment, scattered separately and clustered in groups of the most irregular figure. From its relation to the retinal vessels, this pigment was evidently on the surface of the choroid and in the outer layers of the retina. In each eye the yellow spot was slightly implicated in these morbid alterations, which accounted for the diminished visual acuity. The optic nerves were anæmic; their outline was slightly ragged, and the retinal vessels were small. These appearances unmistakably indicating structural disease progressing from the ora towards the optic nerve, and completely explained the centripetal contraction of the field of vision. The patient told me that his parents were not related; one brother's sight was affected in the same way that his own was, but other brothers and sisters had, so far as he knew, not any visual defect.

Case 3.—A labourer, aged 42, who was admitted into the Middlesex Hospital by Mr. Shaw for a node upon the malleolus externus, a tertiary syphilitic ulcer of the leg, and a sarcocele; was transferred to my care because he was night-blind. The visual defect began five years previously and had slowly progressed until he could not walk alone in the twilight. He could, however, read No. 1 of Jæger's types (brilliant). His visual field very much diminished, not uniformly, but very irregularly mutilated. Extensive atrophy and irregular pigmentation of the choroid and retina, corresponding to the mutilation of the visual field, were observed with the ophthalmoscope. He said that his sight had become defective five years before while suffering from a rash following a chancre.

Professor Laycock's cases, I have little doubt, fall in this category. An ophthalmoscopic examination by a competent observer would easily settle this question.

10, Old Burlington-street.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

TETANOID CONVULSIONS OVERCOME FOR A TIME BY APPLICATION OF ICE TO THE SPINE —DEATH—STRUMOUS MENINGITIS.

(Under the care of Dr. JOHN W. OGLE.)

The patient, Henry F., aged 2 years, was a stout, well-made child, of a family free from consumption or other special taint, and had cut fourteen teeth. He had been ailing, with want of appetite and dulness of manner, for eight or ten days, but had not complained of pain in any part. On February 15 he had a powder given to him of some kind or other, obtained at the druggist's. On the following night he slept well, but about 9 a.m. on the 16th he began to be attacked with convulsions, and about 11 o'clock he was brought to the Hospital in a state of general convulsions, but affected chiefly on the right side of the body. At this time he was placed in a hot bath. Dr. Ogle saw him at half-past twelve o'clock, when he was still convulsed; but then it was chiefly the left side that was affected—the left arm, hand, and leg, and the muscles of the face being violently convulsed, in a clonic manner. The eyelids were widely separated, and the eyeballs quite fixed and, to a slight degree, rolling from side to side. The pupils were larger than natural, but of equal size and unaffected by light. The tongue, which could not well be seen owing to fixing of the jaws, appeared to be clean. On touching the surfaces of the eyes or edges of their lids, but little reflex action could be produced. The surface of the body was much above the natural temperature, and the colour of the face was slightly, but manifestly, livid. The respiration was slow, and attended by a degree of moaning. Dr. Ogle ordered an enema with castor-oil and turpentine to be at once given, and the gums to be examined for the purpose of seeing if they required lancing. It was, however, found impossible to open the mouth. He then ordered an ice-bag to be applied and kept in close contact with the back the entire length of the spine. At two o'clock the convulsions were much the same, the right side being now mainly affected, the hands being clenched and the teeth firmly closed. The surface was warm; the head was frequently rolled from side to side on the pillow. The ice application was continued, and gradually the convulsions abated, and the child was considered by the apothecary well enough to be allowed to go home in the evening. The gums, etc., were found to be not swollen.

On the following day, as he was evidently not so well, the child was again brought to the Hospital, under Dr. Pitman's care, and grey powder was given at bedtime. Antimony and salines were also given. On the day after (the 18th) one convulsive seizure took place, affecting both sides of the body, and then the child appeared to be better, no feverish symptoms remaining. It was only noticed that the child had somewhat of a wild, rather staring expression of countenance, the pupils being rather dilated. Nothing further occurred until the morning of the 19th, when convulsions recurred, in which the child died.

On post-mortem examination, the brain was found much and universally congested, and the grey substance dark in colour. The pia mater was universally injected, and many miliary scrofulous deposits were found attached to its inner surface, especially in the great longitudinal fissure, and on the velum interpositum, and on the upper surface of the cerebellum. A small quantity of recent fibrine existed beneath the arachnoïd at the inner side of each Sylvian fissure, the neighbourhood of the optic commissure and pons Varolii being almost free. The lungs contained about five or six small miliary scrofulous deposits; the heart, liver, and kidneys were natural; the spleen also contained a few scrofulous deposits.

Remarks.—In commenting upon this case, Dr. Ogle drew attention to several points appearing to deserve notice. In the first place, the *spasm* which existed was such that, at the outset, it seemed to have quite the character of tetanus, or of the convulsion produced by strychnia; and suspicion of the latter was the more strong at first when it was made known that the child had had some kind of powder exhibited previous to the setting in of convulsions; but as it was found on investigation that the convulsions did not occur until several hours afterwards, this suspicion fell to the ground, especially when it proved that the spasm was, to a considerable extent, *unilateral*. This unilateral character of the spasm was also most interesting, considering that, as it ultimately proved, the spasm was connected with a general state of meningitis. At first, owing to the absence of fever, the suddenness of attack, etc., Dr. Ogle thought the case was one of mere congestion of the nervous centres; and, indeed, was even, after all, inclined to suppose that the early convulsions may have coincided with a simple state of congestion prior to the effusion or production of lymph, which, as it was subsequently ascertained, occurred within the cranium. If so, of course the formation of this lymph (considering how speedily death took place after the first symptoms set in) must have been very rapid; but Dr. Ogle pointed out that a very few hours may suffice for the formation of such lymph and so-termed exudation. The substantial relief from the ice application was not a little interesting, and speculation upon the probability of a greater and more permanent benefit from a longer application of the ice could not be resisted. A noticeable symptom was the *lividity* of the face—one evidently connected with some pulmonary congestion. This symptom might have been thought to be the result of interference with the movements of the chest-walls by reason of spasm of the thoracic muscles; but as it was associated with a *slowness*, and at the same time *regularity*, of respiration the juster inference was, that it was the result of some intra-cranial disturbance. The *dilated* state of the pupils Dr. Ogle was more inclined to connect with the general strumous condition of the body than with the cerebral effusion, etc.

ST. MARY'S HOSPITAL.

DELIRIUM IN A RHEUMATIC SUBJECT PRECEDED BY NEURALGIA—DEATH BY COLLAPSE ON THE THIRD DAY—IMPAIRED NUTRITION OF BRAIN AND HEART—CLINICAL REMARKS.

(Under the care of Dr. HANDFIELD JONES.)

G. B., aged 43, admitted January 18, 1866. A very broad made man, park-keeper; is quite temperate, according to his wife's statement. Has been in Hospital four times before with rheumatic fever and its sequelæ. Never suffered from rheumatism until he jumped into the Serpentine to save a drowning person; has not been well since. Ill this time three days. Was in Hospital eighteen months ago, and has been well ever since till now. Was taken with pain over the right eye, which continues; had vomiting at same time, or rather dry retching, "which strains him all to pieces." The pain and retching occur mostly at night. Is quite light-headed while the pain is on; "does not know what he is doing: goes quite mad." Hands tremble very much when the vomiting comes on. He says that the vomiting brings on the pain in the head, which is not limited to the brow, but extends some way across the forehead. He feels as weak as possible. Urine scanty, high coloured, just as it was when his joints were affected. Tongue rough, whity. Appetite very bad; has eaten nothing for a week. Bowels open. Sounds of heart normal; also its rhythm, dulness area not increased. Lungs acting normally. Liver rather depressed; extends some two fingers' breadth below ribs. Pupils rather large, conjunctiva not injected. Ordered simple diet, beef-tea, and pudding.

19th.—Became delirious about 10 p.m., so much so that restraint became necessary, and he has been removed to another ward. He is now struggling a great deal with his hands, which are confined, and perspiring profusely. Pulse frequent, soft, and weak. Bowels not open. Eyes not notably congested; pupils were much dilated, but became contracted after a dose of morph. mur. gr.j. last night. Urine scanty and red yesternight; bladder not distended. Liq. opii. sed. ♏xij. was injected subcutaneously, and he was ordered calomel, gr. v., statim; tr. digitalis, ♏xx.; tr. hyosey., ♏xxx.; aq., ℥j., 2dis horis.

20th.—Was not tranquillised at all by the liq. opii injection, but was very much so by pouring, for about half-an-hour, a stream of cold water on the head, after which he slept for about three hours, and has been tolerably tranquil all day. Does not require restraint. Head markedly hot; eyes rather muddy, not injected. Heart's sounds very weak. Pulse 108, weak and open. Tongue whity. Bowels not open. Takes four eggs daily, besides beef-tea and milk. Podophyllin, gr. ½; aloes, gr. iij.; ext. cannabis Indic., gr. ⅓, in pil., h. n.

21st.—Was sleeping quietly when he was visited about 9 p.m., but in the morning was found sinking, and died soon after.

Post-mortem on 22nd.—Heart extremely flabby; its muscular tissue of a dull, dirty, yellowish colour; the valves normal, the pericardium universally adherent; it weighed 16 oz., but seemed small in comparison to the size of body. The apex lay just opposite to the fifth rib, and would have beat in the fourth intercostal space. The whole heart was covered by a thin layer of lung, except a very small portion of the apex. The cavities of the auricles contained large black coagula; the right ventricle contained a coagulum, which extended into the pulmonary artery, and was black below, but consisted of decolourised fibrine above; the sinuses of Valsalva contained projections of pale fibrine. The muscular fibres of the left ventricle presented well-marked nuclei, and showed no trace of fatty degeneration; those of the right were thus altered, but not in an advanced degree, nor equally in all parts, some had almost entirely escaped. The lungs were collapsed, and did not appear at all emphysematous. They were extremely congested posteriorly, appearing black and solid in their posterior two-thirds. The kidneys were pale, their surface rather granular; they were rather small. On microscopic examination the tubes were found infarcted with epithelium, but not at all disintegrated; the Malpighian tufts appeared for the most part healthy. The brain weighed only 44 oz., was pale, but firm, the veins were congested, the small vessels empty; there was a large quantity of subarachnoid fluid at the posterior part of the hemispheres; the dura mater lay in folds, not having been well filled by the shrunken encephalon.

Clinical Remarks by Dr. Jones.—This man's previous history proves that his delirium was unconnected with alcoholic excess. It also shows, and the post-mortem evidence is confirmatory, that he had been subject to acute rheumatism. The urine on admission was described as scanty and red, as it had been during his attacks of articular inflammation. It was reasonable to regard his present illness as of the same nature as those he had had before, but the great weakness, the orbital neuralgia, the associated gastric disturbance, and especially the cerebral derangement (though I did not witness it on the first visit) should have roused my attention more than they did to the probability that we should not have to deal with an orderly, regular rheumatic fever, but with one of ataxic quality. That the delirium was not owing to uræmic poisoning is, I think, tolerably certain, although I had not the opportunity of examining the urine. The supervention of marked brain disorder in connexion with pain in the head is a point of much interest. As I read the phenomena, it seems to imply that the same pathological condition which had befallen the frontal nerves extended to the hemispheres, and involved their cells and fibres in a like functional derangement. We know that neuralgic suffering is in all such cases as the above a cry of distress, an indication of impaired vital action, and not in any wise of exalted or increased. It is, in fact, as I have argued in my Lumleian lectures, an approach to sensory paralysis. The state of the brain, as revealed by the post-mortem, was quite such as warrants our applying to its delirium Romberg's metaphorical description of neuralgia—the prayer of the nerve for healthy blood. The organ was shrunken, pale, and below the normal weight by at least four ounces. The large amount of subarachnoid fluid present was a clear evidence, and a sort of measure of the atrophy which had taken place.

That this had come to pass during the fatal illness there can be little question; there is nothing to show that the cerebral functions were previously at all impaired. "*Il saute aux yeux*," we may say, that such a condition of brain as we have just described could be benefited in no other way than by supporting stimulants and nourishing food. The latter was given in fair quantity, the former was withheld, I fear erroneously. I think it very possible that if brandy and milk in combination had been administered largely we might have escaped the fatal collapse. At the same time observe that no measures were employed of a directly lowering kind. Digitalis, you know, in common with many others, I regard as primarily a cardiac tonic, and therefore its exhibition was decidedly indicated by the feeble quality of the heart's action. The cold douche to the head appeared to be markedly beneficial, and by calming the delirium was probably conservative of strength rather than depressing. The collapse did not occur till more than twenty-four hours after it had been employed. The very flaccid state of the heart was, I believe, the result of exhaustion, and was owing partly to the prolonged struggling and partly to the depressing influence of the rheumatic miasm on the nutrition of the muscular and nervous organs. Some fatty degeneration of the right ventricle probably existed previous to the illness, but not enough to influence materially the issue of the disorder. The retching or vomiting which he complained of so much on admission was doubtless chiefly dependent on the orbital neuralgia, just as it is so commonly on the early stage of serious cerebral disease. I would by no means affirm that the majority of cases of what is popularly termed "sick headache" are produced in this way— viz., by a reflex disorder of the gastric nerves consecutive to a primary one of the brain or cranial nerves, but I am sure that instances of the latter kind are not rare. A lady, whom I attended a long time, told me that she used always to suffer with headache and sickness after a day of sight seeing. Here the exciting cause of the gastric derangement was evidently cerebral fatigue, and rest and restoratives were undoubtedly more called for than blue pill and purgatives. I have so often expressed my opinion to you as to the variable and differing quality of morbid action even in cases which appear in many respects alike, and are called by the same name, that you will be quite prepared for the remarks that all cases of rheumatic delirium which you may meet with will not be similar to the one we have just reviewed. In my work on "Functional Nervous Disorders," at pp. 164—166, you will find two cases related, in one of which large doses of antimony and in the other opium proved successful, while, as I have stated in the present instance, Dr. Todd's method of free stimulation would probably have been most serviceable. The impression which I would have the history to leave on your minds is, that you have witnessed a case of active, violent, rheumatic delirium, quite independent of alcoholic influence, which though occurring in a robust-looking male, who was not depressed by any long existing cause of debility, was from the first of highly asthenic quality, induced great wasting of the encephalon, and flaccidity (loss of contractile energy) of the heart, and terminated fatally by exhaustion in about fifty-eight hours after the delirium supervened. As corollaries to the case, I will add (*a*) the evident relation existing between neuralgia and delirium, the latter differing from the former only in its *locale* and in the greater intensity of the disorder; and (*b*) that it is generally better in doubtful cases to err on the side of too much than too little stimulus.

Glasgow Royal Infirmary.—At their meeting on the 7th inst., the directors of the Glasgow Royal Infirmary appointed Dr. Eben. Watson Surgeon to that Institution, in room of Dr. Lyon, who has resigned.

The Law on Capital Punishment.—Lord St. Leonards has proposed an amendment to the Government measure, which is, to omit part four of the Bill, in reference to executions within prisons. The provision as to murder of the first and second degree has already been expunged.

The Disused Burying Grounds of the Holborn District.—In the last Report of Dr. Gibbon, the Medical Officer of Health for this district, he calls attention to the useless and neglected condition of these grounds, and to the benefit that would accrue to the population were they converted into gardens for recreation. The disused burying grounds in this district are three in number, and their extent is about six acres.

SATURDAY, JUNE 16.

CHOLERA AND DIARRHŒA—NATURE AND ART IN THE TREATMENT OF POISONING.

It may be of use before we go further just to examine the prevalent notions of the "efforts of Nature," and of the necessity of "elimination" which form part at least of the basis of theories which demand a purgative treatment for diarrhœa and cholera.

As for "Nature," she is a mere sham. Civilised man repudiates the blind following of Nature. The instincts of Nature prompt to a thousand acts which are to be yielded to only if sanctioned by conscience. Nature prompts to deeds of lust, revenge, and theft, and we dare not, in the domain of morality, sanction any natural cravings whatever, unless reason, conscience, law, and public morality concur.

So as regards physical changes in living beings, what we call "Nature" signifies really things as they are—uninterfered with and let take their own course. And just as we check Nature by conscience in things moral, so we check her by reason and experience in things physical or Medical. If our experience shows us that any given sort of illness does well without medicine, or that any given spontaneous process leads to recovery, we let well alone, and call this leaving the case to "Nature." On the contrary, if our experience shows that the "efforts of Nature," or, in plain words, existing symptoms or actions, may be increased to the patient's benefit, we take measures accordingly, and call it "seconding the efforts of Nature." Or if general experience shows any given set of symptoms to be mischievous, we do not hesitate to suppress them; and if we are of imaginative minds we call this "restraining" or "checking the excessive efforts of Nature."

Anyhow, the word "Nature" is a mere cloak, a cobweb, a phantom. If it suits us, we respect her efforts; if not, we set her at nought; but, in either case, it is not "Nature," but our own reason and experience (if we have any) that we follow.

So much for Nature. But, inasmuch as a respect is professed for her "efforts," and it may be supposed that we are doing the correct thing in following her suggestions, let us see how "Nature" best deals with poison, and how experience teaches us to treat cases in which the "efforts of Nature" may be either inadequate or excessive.

Let us take the case first of a mineral or vegetable poison, say calomel, or arsenic, or elaterium. Either of these substances in certain quantity sets up vomiting and purging, by which, after a time, "Nature eliminates the poison," and the patient recovers. But let us suppose the dose very large, so that it gets, as we may believe, into the blood, that the vomiting and purging are intense and exhausting, does the Physician aim at elimination pure and simple? Not a bit of it. He seeks to put the patient into a state that shall render him less sensitive to the effects of the poison. He diminishes and

controls the efforts of Nature, so that a large dose of poison may act like a small one, and a weak system like a strong one. The stronger the system the less violently does Nature react against the poison, and that which will make a weak system act like a strong one is *opium*. Give repeated doses of calomel till they purge, producing perhaps intense tenesmus and bloody stools, and what is the treatment? Opium. Under the influence of this, the poison is no more heard of; pain and discharge cease; and we may suppose that the poison eliminates itself quietly, without damaging the alimentary canal.

Let us next take the case of poisons of a zymotic order —typhoid or cholera. If a moderate dose be administered to a patient in first-rate health and spirits, how does "Nature" act? Why, she may not condescend to notice it. It is on patients exhausted, ill-fed, or already prone to illness, that the poison acts as a specific poison. To produce its full effects, it must provoke certain reactions in the system of the recipient; it must feed on the patient and multiply itself; and it is the weak, ill-fed, nervous, irritable, and exhausted who fall into those reactions and permit that multiplication most readily. Suppose, then, such a population, breathing air, drinking water, swallowing dust, eating food with unwashed hands, all impregnated with cholera poison, and suffering from incipient bowel disorder; what is the indication? Is it to eliminate? Certainly not; but to recruit the forces, and to resist the action of the poison in the alimentary canal, and for fulfilling these indications the experience of half the world points to opium. Dr. MacCormac, writing in a late number of the *Medical Press and Circular*, relates the circumstances of a house-to-house visitation in an Irish town. "Do you purge?" was the question asked; and if the answer were "yes," an opium pill was put into the respondent's throat without ceremony. The result was successful. The system at large, and the alimentary canal in particular, were soothed, comforted, and rested; the poison was "locked up," but could do no harm—the patient was protected. And this, concurrently with the experience of hundreds of Practitioners in the last three cholera epidemics, shows that a soothing, astringent, and non-eliminative treatment of diarrhœa is a pretty good safeguard against the fully-developed phenomena of cholera.

We do not assert that opium is the only or always the best remedy for diarrhœa; on the contrary, we last week reckoned up half-a-dozen remedies or methods of treatment, each available in its proper case. But our present purpose is to show that they who follow "Nature", cannot object to a remedy which produces a state of things such as "Nature" presents when at her best.

We shall continue our remarks from week to week, in the hope that this and kindred questions may be well debated, fallacies cleared up, and something like truth arrived at in the end.

"LOCAL MUSEUM NOTES."(a)

If rapid and easy locomotion, with moderate freightage, had conferred on the homeward-bound traveller no other boon than depreciating the value of things brought from abroad called curiosities, he would still be deeply in its debt, to an extent, indeed, which the wayfarer now-a-days can hardly realise. Private collections of pickle bottles full of rum and lizards, monsters of the deep vaguely labelled Sea Devils, carved calabashes, and bags filled with crabs'-eye seeds are not now expected of him; whereas a few years ago the man required some courage, or a well-established reputation for filial piety, who could face his relations without being prepared, after the first transports of welcome, to produce a scorpion, a parrot in a big tin cage, a tattooed Sandwich Islander's head, or some other "dinna forget" element, which gives to the most humdrum travels a savour of romance.

Nothing could be less satisfactory, next to the materials of which they were composed, than the fate of such private collections. As they owed their interest entirely, or nearly so, to that taken in the donor, they were liable to be superseded on every fresh arrival. The history of a specimen was one of unrequited self-sacrifice from the moment when it was first induced to enter the pickle bottle, until, all its spirit flown, the cook turned it out on a dust-heap, and substituted onions.

Such souvenirs are seldom tendered now, and those who live at home at ease have ceased to expect them. Travellers send their spoil to depôts where they may be safe and within reach of the inquiring mind.

There is a great deal of the jackdaw in man—a vestige left of his mental condition when still a noble savage, a gorilla, or what you will. There is no difficulty in getting him to collect—indeed, it is hard to restrain him, he is always collecting, but in an imbecile, meaningless way. See him pluck a rose; watch him; he will put it in his mouth presently, and champ the petals, spitting them out in a little time, and wondering how came they there. Leave him by a recently-sifted dust-heap, and he will be soon poking it with his stick as earnestly as if it were the last cradleful out of Ballarat. Go into his lodgings at the sea-side and wonder—it is all you can—at how or why he has carried home the stones and water-worn oyster-shells on the mantelpiece, and which he will leave there on his departure. Depend upon it, he who went from Dan to Beersheba was collecting the whole way, but having no definite object, he found that all was barren, and reported accordingly.

Now, what Mr. Toynbee, the editor of "Museum Notes," proposes (and surely if a man ever had a claim on the public ear he has), is to guide this propensity for collecting, and turn it to good account. His scheme, which, if fully carried out, will be virtually a self-paid natural history survey of Great Britain, is "that the inhabitants of a parish, who feel disposed to form a local museum," should appoint a committee and a superintendent, that any one may become a collector, and for purposes of classification and identification be provided by the committee with museum papers and labels, and a map of the country for five miles round the parish church.

To these collectors any parishioners may send specimens; the collections may be begun at home, and if worth it, the expense of preparing objects will be defrayed. When they think it desirable the committee may provide cases made upon some definite plan, so that whenever a fitting room is provided for the museum these cases may form a regular continuous series.

The editor hopes that this plan will not only diffuse a liking for natural history, but brotherly love, and that men of all classes may be brought together in the great freemasonry of science.

The "Notes" (No. 1) contain a classified list, which gives us a general idea of what specimens may be preserved for consideration of the committee. They embrace natural history in almost its widest sense, beginning with the mineral kingdom, then the vegetable; and we are told that a collection should be made of the leaves of all species of plants in the district, in one sense no light undertaking, for

> "Various the trees and passing foliage here.
> Wild pear, and oak, and dusky juniper
> With briony between in trails of white—
> And ivy, and the suckle's streaky light
> And moss warm gleaming"—

all so easy to carry, too, except the names in one's head. In case 4 are to be kept all kinds of fruits; diseased specimens may also be preserved, and it is not unlikely that, as we see in daily life, the diseased specimens will outlive the healthy ones. The animal kingdom will include all, from Infusoria upwards;

(a) No. 1, Hardwicke, London. P. 16. Edited by the Treasurer of the Wimbledon Local Museum, to whom communications may be addressed, Beech Holme, Wimbledon-common.

insects and the softer orthoptera may have chloroform, but beetles must take the fatal plunge into boiling water. Of birds, the feathers, eggs, nests, bones, heads, and feet, are to be collected. Of the mammalia, which the editor rudely renders beasts, the smallest contributions will be received. Some good hints on this section are given, and ants recommended as bone-cleaners; we would here mention those victims of popular prejudice, the black beetles. A band box, with holes in the top, is not only a model prison for them, but a self-supporting institution. We once shut up many dozen beetles with a carious bone, and blush to add forgot all about them for several weeks; at the end of that time the bone was beautifully clean; there was a heap of wings and legs, and two gaunt survivors were walking solemnly round and round watching each other with conscious, hungry eyes.

Collectors need not confine themselves to actual specimens; observations on the weather, etc. will be received by the Committee, and accurate observations of every living thing may be recorded. Of

> "The ring-dove that repeats his pensive plea,
> Or startled gull, up screaming from the sea,
> Or a few cattle looking up askant,
> With sleepy eyes and meek mouths ruminant."

If not already suggested, we would venture to propose that photographs of the forefathers of the hamlet, or typical specimens of the inhabitants should be collected, also words and proverbs of the locality, and receipts for the quaint messes our forefathers swallowed, which puzzle the readers of old books, because no one records them.

> "O! che crudeltà! che non compose
> Un' operetta sopra la cucina
> Tra l'infinite sue miraculose."

We wish this scheme the success everywhere which it has already met with at Wimbledon. It will tend to open rustic eyes and hearts, there will be no talk of shutting up heaths and commons where gentle and simple wander over them with a common object; it will divert men's thoughts from impurities, and sanctify lovers' lanes; perchance, too, some village Owen may be saved by it for the service of Nature, and many others won to muse with love on her mysterious ways, while the shelves of local museums will, even of humble names, still keep the memory green.

THE PUBLIC SERVICES.

In a recent number of this journal we called the attention of the Profession to the very unsatisfactory nature of the reply vouchsafed by the Marquis of Hartington to Colonel North. We then expressed an opinion that things were looking very badly for the Army and Naval Medical officers. It now seems that our fears are to be realised. The late Commission at the Admiralty, and the publication of its Report, have had the desired effect. Candidates are forthcoming for the Army, and H.R.H. the Duke of Cambridge is said to have used the influence of his position against the adoption of that Report. He is said to have counselled delay. Another year over, a supply of Medical candidates just equal to the wants of the service, and we shall hear no more of concessions. The publication of the recommendations of the Committee will have effected the object the authorities had in view. A question may be asked perhaps of the Secretary for War, in the next Parliament, by some Member who is heartily sick of the matter. The reply will be—the Medical men are forthcoming! The well-meant endeavours of the late Committee will have been diverted from the good they intended into a source of positive injury.

In the *Army and Navy Gazette* we noticed a very commendable proposal from a Naval officer. Not only does he urge the employment of homœopathic practitioners, but he would go a step further, and have the authorities return to the days of Smollett, when the Medicine-man was a Surgeon's mate, with Professional knowledge equal to the application of a blister, or the administration of a clyster. If the combatant ranks of the Navy be such asses as seriously to advocate a measure like this, we would suggest that they recruited their Medical service from the members of the Veterinary College at once. They would be the most appropriate Surgeons for such patients, and would not lack the diploma which is such a stumbling-block in the way of the naval authorities.

It is very unfortunate, as it happened, that some of the English Medical Colleges have been so premature as to congratulate the Government on the satisfactory nature of the recommendations of the late Committee. Never were recommendations founded upon more economical and fair principles towards the Government, and we do most earnestly hope that the evils which any delay in giving them effect must surely produce may come home to Horse Guards and Admiralty alike. There are no Medical recruits for the Navy, and there was a time, not long distant, when Acting Assistant-Surgeons—of whose Professional and social qualifications we need say nothing—represented the young Medical element of the Army. The ball was at the foot of the Profession. A little longer starvation, and the just demands of that Profession would have been wrung from the authorities. Alas! 70 candidates appeared at Chelsea. A dissatisfied department found its rightful claims put off "to a more convenient season," while the Director-General and Horse Guards "went on their way rejoicing." Is it always to be so? Will the Profession never lay to heart the lesson which the Government has been reading it for the last four or five years.

CONTAGIOUS DISEASES BILL.

The new Act "for the better prevention of contagious diseases at certain naval and military stations" is an important measure in more senses than one. It serves to indicate the extent to which our soldiers and sailors are affected by such diseases, while it shows that the pressure of the great pecuniary loss thereby entailed upon the nation has overcome the prejudice and repugnance which Englishmen naturally feel against making them the subject of legislative enactment.

The old Bill was introduced as a tentative measure probably. It was found to be ineffective in its working, and inadequate to accomplish the purposes for which it was designed. "*The Contagious Diseases Act*, 1866," has been framed with the view of meeting these difficulties. The places embraced by it comprise our various garrison seaports and camps, and the expenses attending its execution are to be defrayed by the Admiralty and War Department. Provision is made for the appointment of Visiting Surgeons and Assistants, in addition to an Inspector of Hospitals, and for the appointment of certified Hospitals for the treatment of infected women.

Upon information being laid before a magistrate that a woman is a common prostitute, he may order the issue of a summons requiring her periodical Medical examination. In the event of her being found to be affected with a contagious disease, she is to be conveyed to some certified Hospital, and there detained for the necessary treatment and cure. Refusal to be examined, etc., renders the person liable to imprisonment. A woman may, if she likes, voluntarily submit to these periodical examinations. Supposing that any woman discontinues her course of life, she has only to satisfy a magistrate on that head, and enter into a recognisance, with or without sureties, as to the Justice seems fit, for her good behaviour for three months, to obtain relief from all such Medical examinations. The Act institutes certain penalties to be inflicted on the owners or occupiers of houses for harbouring women with contagious diseases.

Under the old Bill sufficient power was not given for detaining women in Hospital, nor for exercising a sufficient surveillance over them. There is not adequate Hospital accommodation in our garrison towns for the treatment of these cases at present. The Government, by the way, is never very

just in its dealings with our Profession. The stipend allowed to the resident Medical Officers is absurdly low, we believe, and we confess we do not see that the authorities have any right to obtain the gratuitous services of the Hospital staff.

We need not enter into the religious aspect of the question. The Bill was most urgently required. The Government ought certainly to make provision for guarding public servants against the evils arising from a life of celibacy, enforced on them for the good of the nation. It appears to us that it will prove a very merciful measure for the women themselves. Not only will these unfortunate creatures obtain relief from physical suffering and want, but their stay in Hospital will make a break in their course of life, during which an opportunity for quitting it will arise, such as they probably would never have had otherwise.

NITRO-GLYCERINE, *ALIAS* GLONOINE.

Our readers may probably be asked by their patients what is that *nitro-glycerine* which lately blew up a ship at Colon, and which seems likely to be such a dangerous article of merchandise? It is one of the *substitution bodies* found by peroxide of nitrogen, which are, perhaps, the most interesting products of modern chemistry.

Setting aside their peculiar scientific aspect, they already contribute so largely to the wants created by civilisation that their loss would be very materially felt could they no longer be brought into existence. Thus, there is gun-cotton, or *nitro-cellulose*, which offers such promise of taking the place of dirty, smoky gunpowder, and which, since the experiments in Austria, is largely occupying the attention of the chemist of our War Department on this account. How severely we should feel the loss of this substance to photography, which obtains from it its *collodion*, we need not say. Then there is *nitro-benzol*, to which substance is owing the commercially successful production of the brilliant and varied aniline and coal-tar dyes. Picric or trinitro-phenic acid is another nitro-substitution body which forms a valuable dyeing material. And now it seems likely that we are going to add to the uses of this class of substances that of *nitro-glycerine* for blasting purposes.

Nitro-substitution compounds possess some interest for members of our Profession. Gun-cotton, of course, is of interest as the basis of collodion, so useful for Surgical purposes. But they all are so, from their dangerous explosive properties, and from the very poisonous effects of some at least of them. Nitro-benzol, which, in addition to its extensive use in the manufacture of dye-stuffs, is largely used as a substitute for bitter-almond oil, under the name of *essence of mirbane*, as a flavouring material, is already familiar to the Profession as a poison. And if nitro-glycerine comes into use we shall then have to be prepared for deaths by this substance, which is no doubt an active poison. When a minute quantity of it is placed on the tongue, painful and persistent aching of the back of the head is produced, and sometimes vomiting.

Nitro-glycerine being probably a stranger to very many of our readers, they will perhaps be glad to learn a word or two about it. It is, then, an oily-looking, heavy liquid, insoluble in water, alcohol, and ether, and is said to have a sweetish, pungent, aromatic taste. It is formed, like other nitro-substitution products, by the action of strong nitric acid upon glycerine. Glycerine is dropped into a mixture of equal parts of strong nitric and sulphuric acids, kept cool. Nitro-glycerine collects at the bottom of the vessel, and when washed thoroughly with water is ready, and can be preserved for any time unchanged. Its chemical composition is described as being that of glycerine in which one-fourth of the hydrogen has been replaced by a chemically equivalent quantity of peroxide of nitrogen.

It explodes with great violence and suddenness on percussion or when heated to 356° Fah.; but, remarkably enough, it is unaffected when a lighted match is applied to it. It explodes under water as well as in the air. The force developed by its explosion is said to be *thirteen* times as great as that of its own bulk of gunpowder. The explosion gives rise to vapours very irritating to the air passages, probably from the formation of some acrolein and formic acid.

THE WEEK.

THE STRAND UNION.

The shocking state of things brought to light during the official inquiry into the state of the Strand Workhouse Infirmary has produced a general feeling of indignation, which is thoroughly well founded, and we hope will lead to a sweeping reform. Whilst we decline to speculate on the result of the colossal, and we fear Utopian scheme, for housing the sick poor proposed by the Association which is now endeavouring to ameliorate the condition of the inmates of the Metropolitan Workhouse Infirmaries, we fully accord to that Association the praise due to them for bringing such a state of things to light. It is right that Boards of Guardians who sanction and support such a system of neglect and cruelty should be held up to public reprobation. But we must not forget that it is quite possible to confound the innocent with the guilty, and that it would be in the highest degree unjust to attribute the faults of the Strand Board of Guardians to some other Boards, who we believe are doing all in their power to provide proper nursing and care for the sick of their charge. Mr. Rogers, the Medical officer of the Strand Union, has proved himself an excellent and benevolent Medical officer. We only wonder that he could continue to hold office so long under such masters.

THE NEW VACCINATION BILL.

In another column will be found a letter from the dauntless and indefatigable champion of the Poor-law Medical officers, detailing the improved rates of remuneration to which Public Vaccinators will be entitled under the Amended Vaccination Bill, should that measure become law. Too much praise cannot be given to Mr. Griffin for the vigilance and exertions which have succeeded in obtaining these terms from the Select Committee engaged in amending the Bill. For every primary successful vaccination performed at an appointed station within one mile of the Public Vaccinator's residence, the old fee of one shilling and sixpence is retained; but if the distance be more than a mile and less than two miles, two shillings; and if it be more than two miles and less than three, three shillings will be allowed. In addition, there is to be an extra gratuity of one shilling per case paid by the Treasury as a reward for careful and successful vaccination. This extra fee, it seems, is to depend on the Report of the Inspectors and the recommendation of the Medical Officer of the Privy Council. The fee for re-vaccination is to be two-thirds of that payable for successful primary vaccination. It will be seen that these provisions, in the event of their becoming law, will substantially increase the stipends of many of our Profession, and will thereby add another to the heavy obligations which the Medical attendants of the poor owe to Mr. Griffin. The following are some of the other provisions of the Bill:—Guardians are to divide unions and parishes into vaccination districts, such division being subject to the approval of the Poor-law Board; the qualification of the Vaccinator is to be prescribed by the Privy Council; the Guardians are to enter into contract with the Vaccinator to carry out the provisions of the Act, but no contract is to be valid unless approved by the Poor-law Board; the Guardians are to provide stations for public vaccination, and no public Vaccinator is to be paid for vaccination out of his district. The remainder of the Bill chiefly relates to certificates and registration of vaccination.

The penalty imposed on parents neglecting to have a child vaccinated is not to exceed twenty shillings.

THE ARMSTRONG FUND.

The Honorary Secretary of the Armstrong Fund, Mr. Hunt, has sent out a final circular stating that as sufficient money has been raised to meet Dr. Armstrong's legal expenses, no more subscriptions are required. This prompt method of meeting the expenses of prosecutions, such as the Messrs. Armstrong have been subjected to, is the most effective, not less than the most decisive, process for putting a stop altogether to trials of this vexatious and wicked character. The scoundrels who promote false actions for malapraxis are actuated by the belief that they shall either extort money without going to trial, or succeed by an accident of law if they push on to trial. In either case they feel they must win, while the Doctor must lose, certainly in pocket and probably in reputation. In many instances, we doubt not the opinion they form is the correct one; and it behoves us, therefore, the more carefully to let them see at every opportunity that the Profession has the heart, as it certainly has the means, to break their calculations, and to demonstrate the utter futility of their outrageous immorality. In a case like that of Dr. Armstrong, it is not the man we defend by these measures, it is the Profession; it is ourselves, as represented by him. We do more than defend, we *fore*-fend, as the old language, now well-nigh forgotten, wisely expresses. A member of our body, quite as guiltless as our friend Dr. Armstrong, might not have the means to meet a trial for malapraxis, and might sink before it, because he dare not make the venture to stand it out unless the Profession gave assurances, such as it now gives, that it will stand firmly and readily by to sustain every brother in a just cause. We have only to add that on Tuesday next the whole of the business for which the Armstrong Fund was formed will be completed, that the money so freely and quickly supplied will be paid over to Dr. Armstrong's legal advisers in full liquidation of their very moderate fees, and that afterwards the members and subscribers will give the Messrs. Armstrong a complimentary dinner, over which Dr. Richardson will preside, at the Rosherville Hotel, Gravesend.

OVARIOTOMY IN NEW ZEALAND.

We have great pleasure in making known that ovariotomy has been performed for the first time in New Zealand, and that the operation has proved successful. It was performed, on the 12th of last March, by Dr. Mackinnon, an Army Surgeon on duty there with his regiment. The patient was an unmarried lady, only 19 years of age. We believe we may congratulate Dr. Mackinnon not only on being the first to perform ovariotomy in New Zealand, but on being as yet the only one of our Army Surgeons who has followed the example of their civilian brethren. We trust that many more of the Medical officers in our public services will, in their colonial and foreign service, carry far and wide the good deeds and the fame of British Surgery.

FROM ABROAD.—SANITARY CONDITION OF THE FRENCH ARMY—THE PARIS INTERNATIONAL MEDICAL CONGRESS.

The Report on the sanitary condition of the French Army during 1864, which has just been issued, we have not yet had the opportunity of perusing; but we may present a few of the figures it contains, derived from an analysis made by M. Lefort. The first striking point about it, he observes, is the large number of men admitted into Hospital during the year. This amounted to 113,742 in an effective of 305,414 men—*i.e.*, 372 per 1000, which is a very large number when it is considered that it is composed of young and robust men, exempt from infirmities, the picked portion of the population, in fact. The proportion, as would naturally be anticipated, varied much according to locality. Thus for the soldiers in France it was 299 per 1000, in Algeria 620, and in Italy 477. The classification according to corps exhibits also great differences. Thus the special corps of Paris furnished 142 sick per 1000, the *Garde Impériale* 162, the engineers 240, the light infantry 249, the artillery 283, the infantry of the line 326, the cavalry 326, the *Ouvriers* 380, the *Train des Equipages* 400, the veterans 402, the corps in Italy 477, the *Infirmiers* 556, the *Corps d'Algérie* 592, the *Corps de France en Algérie* 651, the *Pénitenciers et Ateliers* 1090. Thus the infantry of the line sends double the number to Hospital as the guards, and while the high number of 556 attained by the *Infirmiers* is explained by the nature of their occupation, the enormous one of 1090 testifies to some important causes of insalubrity prevailing in the prisons and workshops of the Army. It seems that out of 711,116 patients who were admitted into the Hospitals and Infirmaries 37,752 were admitted for venereal affections—*i.e.*, 53 per 1000 patients, but as some of these may have been enumerated twice, it is preferable only to take into account those admitted into Hospital, and these amounted to 16,873, which in an effective of 305,414 gives 1 venereal patient in 18 soldiers for the year. In France the numbers were 1 in 29, in Algeria 1 in 14, and in Italy 1 in 22. As might be expected, the youngest soldiers are those most liable to sickness, and it was found that those of the first year contributed a proportion double that of the general mean. But in respect to the *mortality* during 1864 it was in France 2461 in a mean effective of 273,275 men, or 9·01 per 1000; in Algeria 1302 of 61,267 men, or 21·25 per 1000; and in Italy 127 deaths in 13,189 men, or 13·05 per 1000; total, 3935 deaths in an effective of 347,731 men—*i.e.*, 11·31 per 1000, or 1·31 more than in 1863. This increase has entirely arisen during the recent Algerian war, as the mortality in France itself decreased by 0·21, and in Italy by 4·87.

Steps are being taken in furtherance of the project of holding an International Medical Congress at Paris, in connexion with the Exhibition of 1867. A central Committee was formed last November, consisting of the following well-known gentlemen:—MM. Barthez, Béclard, Béhier, Bouchardat, Bouillaud, Broca, Dechambre, Denonvilliers, Follin, Gavarret, Gosselin, Jaccoud, Lasègue, Longet, Robin, Tardieu, Verneuil, Vidal, and Würtz. M. Bouillaud has been chosen President of the Committee, and the various Ministers having been applied to, have extended their warmest encouragement to the project. The Committee, in its address, expresses itself sanguine of success in this the first attempt to bring the members of the Profession of different countries together, "constituting not a mere meeting of Medical Practitioners, but an affirmation of the scientific movement of the epoch, and the first visible act of that intellectual alliance which unites the labourers of all countries." The plan of procedure will be hereafter announced, the Committee, in the meantime, calling for the support of the Medical press of all countries. Communications may be addressed to M. le docteur Jaccoud, Secretaire du Comité, 4, Rue Drouot.

PARLIAMENTARY.—CAPITAL PUNISHMENT AMENDMENT BILL—NUISANCES REMOVAL BILL—SURGEONS FOR THE NAVY—CERTIFYING SURGEON AT BATLEY—THE CHOLERA CONFERENCE—LUNACY ACTS (SCOTLAND) AMENDMENT BILL—GAS WORKS IN THE NEIGHBOURHOOD OF VICTORIA PARK—COAL SUPPLY—PUBLIC HEALTH BILL.

In the House of Lords on Thursday, June 7, the Lord Chancellor moved that the Law of Capital Punishment Amendment Bill should pass *pro formâ* through Committee, in order that it might be reprinted in its amended form.

Lord Brougham was strongly impressed with the importance of this Bill. He hoped some steps would be taken, with regard to the plea of insanity in cases of murder, in order to permit a verdict of manslaughter to be returned in cases where such a plea was made out.

The Nuisances Removal Bill was read a second time.

On Friday the same Bill went through Committee.

In the House of Commons on Monday, June 10, Sir J. Hay

asked the Secretary to the Admiralty whether there was still any difficulty in obtaining the services of good Medical Officers for Her Majesty's Navy; how many Assistant-Surgeons had entered the service since the 1st day of January; and what steps, if any, had been taken to carry out the recommendations of the Committee presided over by Admiral Sir A. Milne.

Mr. T. G. Baring said there was still very great difficulty in obtaining Assistant-Surgeons for the Navy, only three having entered the service since January 1 last. He hoped soon to be able to state the nature of the measures which would be taken, and which were based upon the recommendations of the Committee over which Sir Alexander Milne presided. The Admiralty were in communication with the Treasury upon the subject.

Mr. F. Beaumont asked the Secretary of State for the Home Department why the appointment of certifying Surgeon under the Factory Acts for the Batley district, vacant by death on April 16 last, was delayed by the inspector for a period of three weeks, and then filled by the nomination of a non-resident stranger, without the usual regard to the wishes of the millowners and manufacturers of the district, who supported the claims of resident candidates.

Sir G. Grey said the appointment of certifying Surgeon under the Factory Acts was placed by law in the hands of the Inspector, and not of the Secretary of State. Upon inquiry he had ascertained that the delay was occasioned by a doubt entertained in the first instance whether any fresh appointment was necessary, or whether there might not be a redistribution of offices. The gentleman selected from among nine or ten candidates had been a certified Surgeon in another district, and might therefore be considered experienced in the discharge of his duty. If any dissatisfaction were felt with his decisions, power existed to call in another opinion; but in no case had this been done.

Sir J. C. Jervoise asked the Under Secretary of State for Foreign Affairs what progress towards a settlement of the question had been made since the objection was taken by the English, Russian, Turkish, and Persian representatives at the Cholera Conference, Constantinople, to the proposal of the French representative for the stoppage of all sea communication between Arabia and Egypt, and for the presence of several vessels of war in the Red Sea in case of another epidemic.

Mr. Layard: The resolutions of the Cholera Conference, which have not yet been finally agreed to by the delegates, will probably be reduced to a convention, and when they are submitted in that form to Her Majesty's Government due consideration will be given to the measures proposed for adoption, as well as to the steps to be taken for enforcing them. Her Majesty's Government adhere to their opinion that great evils are likely to arise from the absolute prohibition of all departures by sea from Jeddah so long as cholera may be known to prevail among the pilgrims in Arabia. Her Majesty's Government have raised no objection to any measures of quarantine which the Turkish Government may consider it expedient to adopt, but they strongly deprecate the application to Indian pilgrims of measures of special and exceptional severity.

On Tuesday, June 10,

In the House of Lords, the Lunacy Acts (Scotland) Amendment Bill passed through Committee.

In the House of Commons, a long discussion took place on the Gaslight and Coke Company Bill, which, proposing to erect large gasworks in the neighbourhood of Victoria-park, was met with strong and deserved opposition. The Bill having passed through Committee, stood for "consideration of amendments," and ultimately it passed this stage by 169 to 138.

A long debate on the Coal Supply followed, during which Sir G. Grey, on the part of Government, intimated that an inquiry should be instituted by Royal Commission, on which it was hoped Sir R. Murchison would serve.

The Public Health Act was read a second time.

We regret to announce the death of Miss Lucy Nevill, head nurse of the Lincoln County Hospital. Miss Nevill has fallen a victim to diphtheria at the early age of 27. She was the daughter of the Rev. C. Nevill, of Thorney, and descended from an old county family. She was trained as a nurse at King's College Hospital, and devoted her whole life to the work of tending the sick.

THE APPENDIX TO THE THIRD REPORT OF THE CATTLE PLAGUE COMMISSIONERS.

(*Concluded.*)

Last week we gave an outline of Dr. Lionel Beale's observations in reference to the pathology of Rinderpest. Dr. Beale believes that the poison is composed of certain organic living particles, which, given off from infected beasts, are carried about in the air and effect lodgment, especially upon the moist mucous surfaces of the body, where they rapidly multiply amongst the soft epithelial structures, until at length reaching the capillary vessels beneath, they enter through the walls of the latter to the blood current, and are then disseminated, rapidly multiplying, throughout the body, giving rise, in the first instance, to the various local congestions we have already noticed as the early lesions of Rinderpest.

The Reports of Dr. Angus Smith and Mr. Crookes follow next in order. The former relates to disinfection and disinfectants in general; the latter to the use of disinfectants in arresting the spread of Rinderpest. Mr. Crookes, in fact, has put to test the conclusions which have been arrived at by Dr. Smith after a very extended experimental examination of the whole subject of disinfection.

Both Dr. Smith and Mr. Crookes enter into a criticism of the different hypotheses that have been put forward in regard to the nature of zymotic poisons. Both gentlemen have given their adhesion to what may be termed the "organic theory" of infectious diseases, believing that the poisons of the latter consist of organised living germs, and they thus confirm the theory taken by Dr. Beale.

There are many observers who are inclined to believe that the poisons of septic diseases partake of the nature of gases and are produced from the decomposition of various organic substances. There are others again—but these are few—who view such poisons as belonging rather to the class alkaloids. Dr. Richardson, as our readers know, takes this view in reference to pyæmia.

With regard to gases, Dr. Smith remarks that "whilst the decomposition of organised beings after death produces gases and vapours that are opposed to health, these gases or vapours are incapable of originating, although they may be capable of feeding, some of those diseases, such as cholera and plague, which have been observed at all times to come from a warmer climate. There must, however, be some first origin of these diseases . . . it seems probable that it requires a warmer sun and a richer vegetation than is to be found in the North. This, however, is sufficiently made out, that when these diseases come among us they take root with most effect in those places where decomposing matter is found." Chemists, "when they have examined products of the latter action (putrefaction), have found sulphuretted hydrogen, carburetted hydrogen, hydrogen, carbonic acid, nitrogen, ammonia, acetic, lactic, and butyric acids, and numerous uncertain bodies having no activity, and utterly incapable of producing those prodigious results that are found when that force begins to work which produces plague, small-pox, or black death." Dr. Smith further points out that the kind of action produced by these agents is altogether different from infection. If the poison were a gas it would become diffused when once it reached the air, and be destroyed; so that we are driven to entertain the "organic theory," and to ask is the cause of infectious disease "an organic substance in the process of decomposition conveying that decomposition to another body, or is it an organised germ?" First of all, in regard to the former of these two explanations. A body in a state of change, we have been taught, may induce or set up a like change. if brought in contact with a second body. This we have been accustomed to call "catalysis." We know that some fermentative (or catalytic) changes are to be explained differently—upon Pasteur's theory, but it is not unlikely that little bodies or masses

arise from putrid matter and float about in the air, ready to be deposited elsewhere; for, says Dr. Smith, "if we examine the action of sulphuric acid, water, and zinc, we find the particles of acid and water which are lifted into the air by the effervescence float about the apartment, and are carried to a considerable distance. They are globular bodies, visible to the naked eye, purely chemical, and not organised substances. Something of the kind may go on in putrifying organic matter and convey disease from part to part or place to place."

But the organic theory seems to be gaining favour day by day; and it is supposed that epidemic diseases are propagated by the diffusion and rapid multiplication of organic germs. "This view does, in fact, seem to explain many of the apparent vagaries, if we may so speak, of cholera and plague." "The germs of mischief may be conveyed as the wind or other agents may choose to move; and houses, where persons are in all respects cleanly in their habits, may be occasionally subjects of their attacks. But this does not contradict the great rule which seems everywhere observed, that they settle down in places where is found such natural food as animal, and especially decomposing animal and vegetable matter, and close dwellings always provide, unless when the germs grow better in living animals."

Now, disinfection in its widest sense is the destruction of all disagreeable gases and odours, as well as the arrest of the decomposition of bodies which give rise thereto, including therefore the term deodorisation; but the term antiseptic is applied to those bodies which prevent putrefaction, and disinfectant to those which remove the putrefactive state when once it is set a-going. The observations of Dr. Angus Smith apply chiefly "to organic bodies and the substances which they use for their multiplication, or the retention of their activity."

In reference to the present practice of disinfection, we are told justly enough that "as the matter stands we have a large collection of facts, very many proposals, and a very irregular practice."

In speaking of the general action of disinfectants, in reference to animal matter in a state of decomposition, Dr. Smith remarks that there is really a very "surprising variety in the modes of action." Some—*i.e.*, the metallic salts and mineral acids—combine with the elements of flesh, and the result is a compound which resists the action of the air; some, *ex.* charcoal, condense oxygen, and assist the destruction of the animal matter; some, *ex.* permanganate of potash, give out oxygen, and thus help the formation of carbonic acid; some, *ex.* sulphurous acid, absorb oxygen from the substance to be disinfected. There are, however, two classes—one containing substanees that act upon the air and are volatile, and the other those that act upon solids and liquids. Dr. Smith recommends McDougall's powder (mixed carbonates and sulphites), amongst the former class.

We are only able to skim over the very elaborate series of experiments recorded. Some were undertaken to determine the influence of certain substances on the putrefaction of organic bodies, and it would appear that fusel oil, methylated spirits, carbolic and phenylic alcohol, cresylic alcohol, oil of mustard, and oil of bitter almonds, with pyroligneous acid, preserve the meat in a good smelling, fresh condition, whilst animals are able "to live in an atmosphere so filled with these vapours that meat will not decompose." The strong acids are most perfect preventives of putrefaction, but destroy the healthy look of the flesh, the least objectionable being sulphurous acid. A third set of experiments was devoted to disinfection in water, and in this case, arsenious acid, corrosive sublimate, sulphate of copper, and chloride of zinc are the most active agents. The removal of smell is best effected by McDougall's powder, it is affirmed. The influence of air, of water, of ozone, are severally discussed in detail in the Report. Dr. Smith holds that "all disinfectants, like medicines, are poisonous in great quantities. It is believed that there is an amount which will destroy the germs of disease, and not destroy life. If the life is very weak it may yield before the disease. If the disease has made great advances it will require more to destroy it than even a strong life can bear;" and in the matter of practical application it appears that "the abundant use of tar acids is successful as a preventive, and it is likely that with healthy beasts chlorine and two or three more of the powerful gases might act as a cure when used as fumigators only—that being the readiest way."

Dr. Smith has detected in the air of "infected" regions certain small "round bodies, presenting no structure, or at least only feeble traces of it, and perhaps to be called cells," and heobserves that "the air of cowhouses and stables is to be recognised as containing more particles than the air of other places."

Mr. Crookes' Report is mainly devoted, as we have said, to the application of disinfectants in arresting the spread of the cattle plague, and enters fully into the organic theory. Mr. Crookes adduces many arguments in support of the latter, which we cannot here notice. The chief place is given to the value of antiseptics (sulphurous and tar acids) as against oxidising disinfectants—chlorine and ozone. "I started with a strong bias in favour of chlorine and ozone, but the irresistible force of the arguments derived from my experiments has caused me to alter my opinion." The effects of the two classes of agents are then detailed and illustrated by the narration of many experiments; after which follows an account of "Disinfecting experiments made on the farm," containing abundant testimony apparently to the success (as perfect prophylactics) of the antiseptics named.

Mr. Crookes generalises in conclusion thus,—"In dealing with the cattle plague it is possible to try testing experiments of a nature wholly inadmissible where human beings are concerned, and thus it is feasible to suppose that from the lessons derived from this pestilence we might obtain insight into meant of preventing or even curing zymotic diseases. Thus the theoretical views, the experiments, and results recorded in the preceding pages possess an interest beyond the immediate sphere of cattle plague. They point forcibly to the possible prevention and cure of all zymotic diseases which attack the human race, and thus possess a wider and more momentous significance than if they related only to cattle. Every argument brought forward, every experiment detailed, and every result obtained in the course of this investigation apply with overwhelming force to such visitations as typhus and typhoid fever, small-pox, diphtheria, and to that terrible scourge which has for some time past been threatening our shores.

"The free use of the disinfecting agents here pointed out might not only save the country from the ravages of this pestilence, but it would ameliorate the condition of the people. Although foul sewage and putrefying animal matter are probably insufficient to generate the first septic germ of zymotic disease, there can be no question that when such diseases do attack a population they spread with the greatest virulence wherever such putrescent materials abound. Highly important results might be expected to follow the general use of antiseptics, whether applied to farm buildings where large quantities of manure are produced or sewage, whatever its destination. . . . In tracts of land to which sewage, disinfected with carbolic acid, has been applied, the sheep are free from foot-rot, the potatoes from disease, obnoxious insects, such as turnip fly, gnats, and dung flies are absent, and grubs, larvæ, and the lower forms of animal life and infusoria disappear; whilst vegetation becomes remarkably healthy and luxuriant. It is highly probable that those imperceptible but injurious emanations from the soil known as malaria, would be destroyed; for Dr. Angus Smith has conclusively proved that the putrefactive decomposition in soils which produce malaria does not take place in presence of very minute quantities of carbolic acid." Mr. Crookes concludes:—"It may, therefore, be expected that by extend-

ing the sphere of operation of these preventive appliances we may not only diminish the loss of much valuable property and much sustenance of the people, but even diminish the risk and extend the term of the natural life of man."

The Report concludes with the investigations of Professors Varnall and Pritchard on treatment, an account of the labours of the Edinburgh Commission, and various miscellaneous papers and maps.

REVIEWS.

A System of Medicine. Edited by J. Russell Reynolds, M.D., F.R.C.P. Lond., etc. Vol. I. General Diseases. London: Macmillan and Co. 1866. Pp. 952.

"The object proposed to himself by the Editor of this 'System of Medicine' is to present within as small a compass as is consistent with its practical utility, such an account of all that constitutes both the natural history of disease and the science of pathology as shall be of service in either preventing the occurrence or detecting the presence and guiding the treatment of special forms of illness." This further explanation is needed, because if any one thinks that he will find in this work a digest of all that is known and all that has been written, or even of all the most important contributions which the labours of the last quarter of a century only have made to our acquaintance with morbid states of the human body, he will be greatly disappointed. In saying this, we are not disparaging in any way either the scheme of Dr. Reynolds or the execution of the volume before us. A "System of Medicine," except in the limited sense defined by the editor, this work is not: it is not intended so to be. But it is clear on looking through the articles that considerable latitude has been allowed to the various contributors in this respect. It has been left to each apparently to settle for himself what in his special subject is of practical utility and what is not. We do not see exactly how it could have been otherwise arranged. Dr. Reynolds must have had a very difficult task, on the one hand to avoid the undue extension of his project, and on the other its being dwarfed within too restricted a compass. We can thoroughly appreciate, and we would make every allowance for this difficulty—we think our readers and the Profession at large will do the same; but the result is that the articles are unequal in value, because unequal in comprehensiveness. Still, there are articles in this volume (and we may say with truth that the majority are of this character) that leave nothing to be desired in this respect. Having made these preliminary general observations, we proceed to point out how the present volume is made up.

The volume opens with an "Introduction" by the Editor, and this is followed by a series of articles or essays upon the several diseases entering into Dr. Reynolds' first great group of diseases—viz., "Those in which the whole organism appears primarily and prominently deranged." His second great group—"Those in which special organs or system of organs are in like manner affected," will be discussed hereafter.

We must of course pay our first compliment to the Editor, and we do so by making a pretty long extract from his introductory essay, and transcribing almost in full his philosophical defence of the term "functional diseases." He tells us very truly that it has of late years been much the fashion to object to any such phrase, but, on the other hand, the following three classes of facts have to be remembered:—

1st. That there are some structural alterations—such, for example, as atheroma in the vessels, which may, if an individual has been killed by an accident, be found extensively distributed throughout the body—the existence of which had neither been known nor suspected by the presentation of any functional change or symptom during life. On the other hand, a man may have suffered for many years from discomfort or marked derangement of the functions of the brain, heart, or lungs, and yet the most practical anatomist, with all means and appliances to help him, may fail to discover, post-mortem, any organic change which is sufficient to have accounted for them. 2nd. Another class of facts, constantly lost sight of by those who deny the existence of functional disease, is to be found in the relations between structure and function in health. At the end of a day's work, and after a night's repose, we might find the two extreme conditions of the organism as regards function. For twelve hours, every muscle, nerve, and organ has been doing its utmost, and, as we know, has been wearing out; during the hours of sleep, many organs have been doing little, and some nothing; whereas others have, as it seems, to work on without repose; but in all repair has been going on. By an examination of the body killed suddenly at the end of one or the other of these periods, it might be possible to infer which had been the condition immediately preceding death. But this inference would be based upon the relation exhibited between the *products* of functional activity, such as the nature, quantity, and quality of the secretions in their several receptacles, and the *raw materials* upon which the organs have to work, such as the nature, quantity, and quality of the chyle, lymph, and blood. It would not be formed upon regard directed only to the condition of organs which had been either in activity or repose. . . 3rd. A third class of facts to be remembered is, that in many diseases the only symptoms to be recognised are changes in the degree of activity with which certain organs perform their functions. No new element is introduced by some diseases into the category of vital actions; such affections as chorea, hysteria, epilepsy, might be shown to consist of mere modifications in the degree, time of occurrence, and combinations of functions, each of which taken *per se* is consistent with health. The sudden loss of consciousness in epilepsy, for example, is not more mysterious than is the sudden but every-day-recurring passage from wakefulness to sleep; the arrested respiration is similar in kind to that seen when the chest is fixed in the performance of any great muscular exertion involving the upper limbs; and still more similar to that which can scarcely be called morbid, the prolonged apnœa of a screaming child, whether the scream be the expression of terror, temper, or pain; the convulsive movements are neither more nor less than nerve and muscular functions, any of which might separately, and many of which might in combination be the expression of healthy vital activity. From these three classes of facts, therefore, we are compelled to admit that in the present state of science, the *onus probandi* lies with those who assert the constant presence of structural in association with functional changes; and we affirm that those who make the assertion have never proved their point. . . We do not believe that there is any altered function without a correlated change in the nutrition of the organ; but what we assert is that such change, as a matter of fact, is of such kind as to be undiscoverable by our senses, and as a matter of inference, from what we know of the relation between nutrition and function, is of such a nature that it may always be beyond the reach of observation."—P. 4.

We congratulate Dr. Reynolds on the selection of his coadjutors. Dr. Parkes writes the article upon Influenza, Dr. W. C. Maclean those on Malarial Fevers and Dysentery, Dr. Goodeve those on Diarrhœa and Epidemic Cholera, Dr. Bristowe, that upon Pyæmia, Dr. Sidney Ringer contributes the articles upon Parotitis, Measles, Sudamina, and Miliaria, Mr. William Squire the articles upon Croup and upon Diphtheria, Dr. Edward Smith that upon Hooping Cough, Mr. Jonathan Hutchinson the article upon Constitutional Syphilis, Dr. Gavin Milroy that upon Plague, Dr. Gee the articles upon Scarlet Fever and Chicken-pox, Dr. Aitken those upon Dengue and Rickets, Dr. Hermann Beigel the article upon Roseola, Mr. Marson that upon Small-pox, Dr. Seaton the essay upon Vaccination, Dr. Geo. Buchanan writes upon Typhus, and Dr. Harley upon Enteric Fever. The article Relapsing Fever is written by Dr. Begbie, that on Yellow Fever by Mr. J. D. Macdonald; Dr. Reynolds himself takes the article upon Erysipelas, while those upon Glanders and Hydrophobia are contributed by Mr. John Gamgee and Dr. Arthur Gamgee. The article on Scurvy is from the pen of Dr. Buzzard, that on Purpura is written by Dr. Hillier; those on Gout, Rheumatic Arthritis, and Rheumatism by Dr. Garrod, and that upon Gonorrhœal Rheumatism by Mr. Brodhurst.

Such a selection as the above relieves a reviewer of a great load of responsibility, at the same time that it very considerably lighten his task. Many of the names in the list are familiar to us all in connexion with the several subjects assigned to them in this volume. Several of them have appeared already before the Professional public in the same association. We take credit to ourselves that no reader of the *Medical Times and Gazette* can be at a loss to divine what Mr. Hutchinson, for example, is likely to have to say about constitutional syphilis, what Mr. Marson is likely to have to say about small-pox, Dr. Seaton about Vaccination, Dr. Milroy about Plague, Dr. Buchanan about Fever, or Dr. Garrod about Gout and Rheumatism; nor yet as to the mode

in which these gentlemen are likely to have performed their several parts. We could readily tell which are the most meagre articles, but these are so few, and are so overpowered by what is full and complete that we must leave the discovery to others. It would be invidious to name the best where all are good. Some of the contributors are known as careful and thoughtful writers, and we can say of these that in their several articles they fully maintain the character they had to preserve.

On the Safe Abolition of Pain in Labour and Surgical Operations by Anæsthesia with Mixed Vapours. By Robert Ellis, M.D., Surgeon-Accoucheur to the Chelsea, Brompton, and Belgrave Dispensary, etc. London: R. Hardwicke, 192, Piccadilly, W. Pp. 80.

The author truly observes that "the history of anæsthetics has unhappily a gloomy shadow to contrast with its long array of blessing and relief. That shadow is the occurrence of a sudden and unforeseen death to some of those who have applied to the discovery for immunity from a temporary pain." It is against the more common sources of danger that Dr. Ellis has tried to guard in his modification of the ordinary mode of anæsthetising—which, by the way, is founded on a suggestion of Dr. Harley's. The vapour of alcohol is mixed with that of chloroform, and thus the depression from pure chloroform is counteracted. There are four chapters in the little work. The first treats of defects in the existing anæsthetic process, the second is on the vaporisation of anæsthetic fluids, the third on the physiological influence of anæsthetics, and the fourth on the fluids and apparatus employed for the mixed vapours. The instrument invented and used by Dr. Ellis is commendable, if only in that it does not present a formidable appearance, and by a simple contrivance the relative proportions of the different vapours can be regulated to a nicety. Hence the process recommended in detail in the book would appear really to be "easy, agreeable, and safe." We verily believe that many Practitioners object to the use of chloroform on account of possible danger, and not, as would seem to imply, a belief in its unsuitableness. To all who are thus deterred, and to the Dental Profession especially, the plan proposed by Dr. Ellis will be doubly acceptable; and we have much pleasure in recommending it strongly to the notice of all Professional men. The book is well written, well illustrated, and well printed, and we only hope will be carefully read by all Practitioners.

A History of a Successful Case of Amputation at the Hip-Joint. By J. Sampson Gamgee, Surgeon to the Queen's Hospital, Birmingham. With four Photographs by Sarony and Pierre-Petit. London: Churchill and Sons. 1865.

We owe the author of this monograph an apology for not having noticed it before. We can assure him that the delay has not been owing to any want of appreciation on our part of the value and beauty of the costly volume before us. The case which it records was of sufficient interest, and its favourable termination sufficiently remarkable as a triumph of operative Surgery, to call for especial notice, even if it had been presented to us in the form of the shabbiest of pamphlets. But the accomplished Surgeon who has the merit of having brought the case to a successful issue has given its record to the world in a garb fully worthy of it. Paper, printing, binding, and illustrations are all of the most elaborate kind. The extreme beauty of the photographs places the book high amongst collections of the art, and confers on it a value quite independent of its Professional interest. The case was one of ossifying enchondroma of the thigh; the limb measured forty-eight inches in circumference, and was of ninety-nine pounds weight, or considerably more than half the entire weight of the patient, who some time before the operation only weighed 161 pounds. The operation was performed with the aid of Professor Lister's aortic tourniquet, and the same instrument was used to arrest a formidable arterial hæmorrhage which came on on the fourth day. The various steps and details of the operation, the account of the after treatment, and a valuable and suggestive chapter on Surgical dietetics, in which the liberal treatment of this patient in food and stimulants is contrasted with that pursued twenty years ago, when Mr. Sands Cox performed the same operation with success on a patient for whom "Little or no meat, wine, or beer was allowed," will be perused and studied with the greatest zest by practical Surgeons. The enormous mass removed by Mr. Gamgee is now deposited in the Musée Dupuytren, in Paris, and however we may regret that the valuable preparation should be lost to our collections, we cannot but feel pride that the Surgeons of France should have always before them so striking a testimony of the boldness, skill, and success of British art.

A Manual of Medical Jurisprudence. By Alfred Swaine Taylor, M.D., F.R.S. Eighth edition. London: Churchill and Sons. 1866.

Taylor's "Medical Jurisprudence" is undoubtedly, taking it as a whole, the most useful book on Forensic Medicine in the English language. This will be allowed even by those who have had occasion to differ from the author, and who would dissent on scientific grounds from certain opinions which Professor Taylor has in his practice and writings defended. The large amount of Medical facts which it contains, the clear scientific directions which it gives, and the knowledge which it displays of the working of law courts and the general machinery of legal inquiry, constitute it first amongst Medico-legal text-books, and readily account for the authority which it justly carries both with lawyers and Medical men. The present edition of the Manual differs in several respects from its predecessors. One great improvement in it is that it is more portable. Bulk has been lost certainly by the omission of the details of cases, but the facts—the salient points—are retained, and if fuller information on an individual case be required, it will be found in the larger work of the author on "The Principles and Practice of Medical Jurisprudence." Two new chapters on evidence and the duties and responsibilities of Medical witnesses are placed at the commencement of the volume. In the second the question whether a Medical man is bound to attend and give evidence when subpœnaed against his will is discussed, and Dr. Taylor acknowledges the value of the legal opinion which we obtained for our readers in reference to the case of Rich *v.* Pierpoint by quoting it as authoritative. The usefulness of the present edition is enhanced by forty-five well executed woodcuts of the miscroscopical appearances of poisons, and of chemical apparatus. We cordially recommend this edition of a standard work to students of both Professions.

Report by Dr. Buchanan on an Outbreak of Yellow Fever at Swansea.

Handbook for Yellow Fever, describing its Pathology and Treatment, as Observed in Unintermitted Practice during Half-a-century. To which is adjoined a Brief History of Pestilential Cholera and a Method of Cure, as Detailed in a Series of Official Reports Made during the Prevalence of the Epidemic in the Island of Trinidad in 1854. By Thomas Anderson, M.D., etc. London: Churchill. 1866. Pp. 80.

No two productions could possibly be more dissimilar than the above, and we most sincerely apologise to Dr. Buchanan for placing his admirable and exhaustive report in juxtaposition with Dr. Anderson's volume. But we have an excellent excuse. It would be false heraldry to place a metal upon a metal, so here we follow, we believe, strict rule by placing *or* upon *vert*. Contrast is everything in that ancient science—so, at least, we are told. That we have selected the proper colour for Dr. Anderson may be shown from the following extract:—"Sleeping among bags of onions, I have had occasion to observe, from the ammoniacal exhalations evolved is also a preventive [of cholera]. No people are before the Chinese in instinctive intelligence."—P. 75. Well, Dr. Anderson is an old man, and a moderate amount of twaddle is excusable, so we will be content to let him down easily. Still the above hint may just now be profitable to rural boards of guardians. "Cultivate the alliceæ sedulously, they will come in usefully for the paupers' broth in the winter, and save no end of money in house drainage and cleansing operations." Does not Dr. Anderson say so?—a man of half-a-century's experience.

The yellow fever was brought into Swansea by the *Heela*, which arrived at Swansea on September 9 last year, and Dr. Buchanan traces the subsequent outbreak case by case to communication with the ship. There is appended a meteorological table for the months of July, August, September, and October, in the years 1863 to 1865. "During the period of the outbreak an almost tropical heat prevailed at Swansea, and no rain fell. Probably the climatic conditions that foster yellow fever in the West Indies have never been better imitated in Great Britain."

The locality, too, where the cases occurred, a low-lying alluvial island at the mouth of a river, is such as is peculiarly favourable to the disease in its native latitudes." The following is Dr. Buchanan's final conclusion upon the question of contagion: "The conclusion, then, appears indisputable that if the fever was communicable at all by personal contagion, it was so only in an extremely feeble degree. If it had behaved like any of the more contagious fevers, such as small-pox, measles, typhus, or relapsing fever, it is quite certain that no such account as this could be given. The contrary belief that infection was received by each person severally direct from the *Hecla* is further rendered very strong by the fact that after the removal of the *Hecla* (and allowing for the incubation period in persons already infected), no fresh attack whatever occurred on the island or elsewhere, although the same climatic conditions persisted for some time after," p. 10.

We must also extract the following note *re* the working of the Common Lodging-house Act at Swansea, "The sanitary inspector finds difficulty in getting a conviction from the magistrates for taking lodgers into an unregistered house, inasmuch as the magistrates require evidence that the lodgers are different people, from one night to the other, before they consent to regard the house as a common lodging-house, and this evidence they insist on, even though it is admitted that members of several families occupy a single room." We are not aware that this difficulty has occurred in London, but it is well that health officers should be aware that it may arise in a defended case, and thus be prepared against such an objection to the summons.

The Physiology of Man; Designed to Represent the Existing State of Physiological Science, as applied to the Functions of the Human Body. By Austin Flint, jun., M.D., Professor of Physiology and Microscopy in the Belle Vue Hospital Medical College. Introduction; the Blood; Circulation; Respiration. With Index. P. 502. New York: Appleton and Co. 1866.

This work is to be issued in separate parts, each, however, forming a distinct treatise devoted to natural subdivisions of of the subject. The remaining volumes, three in number, will be issued yearly until the work is finished, and will likewise be severally complete in themselves. The introduction contains considerations of physiology generally, the vital properties of organised structures, proximate inorganic and organic non-nitrogenised and organic nitrogenised principles. Chapter 1 contains a full description of the blood, its composition, coagulation, and circulation; there is an exhaustive chapter with illustrations on the frequency and arrest of the heart's action, the movement of the blood in arteries, capillaries, and veins, and its peculiarities in different parts of the system, as within the skull and in erectile tissues. Respiration is also treated fully; with the movements of expiration, the changes respired air undergoes, the changes of blood in respiration, and the relations of the latter to nutrition. If published separately in flexible enduring wrappers and *interleaved*, Dr. Flint's word would be of great value to the student, as it is clearly written by a good practical physiologist. The bibliography of his subject might be easily added, with the opinions of any lecturer whom the student attends, upon the blank leaves we suggest to the binder of this excellent text-book.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

Edinburgh, May 25.

One of the most successful *conversaziones*, for which we are indebted to our Royal College of Surgeons, was given at the end of last month, when Professor Struthers, of Aberdeen, delivered an interesting and able lecture on the Edinburgh Anatomical School. The lecture appeared to have been fully appreciated by a large audience, and we are glad to learn that it will shortly be published. Dr. Struthers described the foundation and development of the Anatomical School—a history which in reality includes the origin of Medical teaching in Edinburgh—and gave extremely valuable biographical sketches of the well-known anatomical teachers who have been so illustriously connected with it. The period embraced in the lecture extended from 1505, a century before Harvey's great discovery, to about the year 1846. The interest of Dr. Struthers' lecture will be at once understood and its value appreciated when it is remembered that during this period the Anatomical chairs were held by men of such reputation as the three Munros, John and Charles Bell, Barclay, Fife, and Knox. We would gladly welcome a further contribution on this subject, carried down to the present day, and, apart from talent and taste in historical research, of which this lecture contains so distinct proof, there can be few men whose associations and enthusiastic devotion to anatomical science would better fit them for the task than the Professor of Anatomy at Aberdeen. There can be little doubt that Medical literature is sadly in want of historical research, and, probably, there is no department of history in which the student would find so unexhausted a field, waiting a systematic and, without fail, a rich and productive harvest.

A few days ago, an important paper was read by Dr. Spenee, before the Medico-Chirurgical Society, on the Mode of Action of Strychnia. Therapeutical Physiology is a subject which, in this country, receives so little attention that we gladly hail any original investigation which may be safely advanced as a creditable research by a British observer. The most important part of the paper consisted in an endeavour to prove by experiment that the reflex and motor functions of the spinal cord reside in distinctly different cells. The method followed in experimenting was to excise the heart of a frog so as to arrest the circulation, and then to cut through the cranium, in order to expose a section of the posterior part of the brain. Extract of nux vomica was then applied to the nerve substance, and allowed to soak down the cerebro-spinal axis. This caused spasm of the muscles from above downwards and an apparently excessive excitability of the integument, which also arose from above downwards. Dr. Spence supposes that he has detected a peculiar difference between the appearance and disappearance of the surface excitability and the muscular spasm. Shortly after the commencement of the experiment, when the whole animal was affected with spasm of the muscles, the over-excitability of the surface was limited to the upper part of the body, so that, at this stage, an irritation applied to the lower limbs caused only ordinary movements, but the slightest irritation of the throat or upper limbs produced general spasm. At the last stage of the experiment the upper part of the body had lost the excitability of its surface, but still its muscles were subject to spasms. No movement whatever could be excited by pinching the upper extremities, although the slightest touch applied to the posterior extremities produced spasm of all the limbs, anterior as well as posterior. From such facts Dr. Spence arrives at the conclusion that there is a distinct class of cells in the cord destitute of motor power, but possessing the property, on the one hand, of receiving impressions from the surface, and, on the other, of exciting the motor cells to action; and to this class of cells Dr. Spence refers the action of strychnia. Reference was then made to the manner in which strychnia affects these nerve cells, Dr. Harley's views on the mal-nutrition of the spinal cord being attacked. That the phenomena are not caused by a reception of non-oxygenated blood, Dr. Spence believes he has proved by an experiment in which a frog was kept in an atmosphere of pure oxygen for four hours, a poisonous dose of strychnia administered, and the animal returned to the oxygen atmosphere, and, still, unmodified symptoms of strychnia poisoning were developed. Allusion was then made to the resemblance which exists between strychnia poisoning and tetanus. From the fact that spasm occurs in the former independently of the blood and from other considerations, Dr. Spence thinks that in tetanus the nerve cells are primarily affected, the exudation observed by Lockhart Clarke being one of the products of the morbid action. The claims of woorari and nicotine as antidotes to strychnia were discussed, and it was stated by Dr. Spence that great error exists on this point, and has been caused by a misconception as to the quantity of strychnia required to produce death in cold-blooded animals. A frog received $\frac{1}{25}$th of a grain of acetate of strychnia, and recovered without the administration of any antidote. Dr. Spence concluded his paper by very interesting observations on the therapeutical applications of strychnia. These conclusions were the results of very ingenious and numerous experiments. The investigation is one for which the Medical Faculty of the University presented a gold medal to the author on his gradation.

His Royal Highness Prince Alfred received the degree of LL.D. from the University on Saturday, May 9. The Senatus took advantage of the presence of his Highness in Edinburgh, for the purpose of opening the Museum of Science and Art in

this city, to confer the degree; and as a former student of the University, the honour was an extremely appropriate one. The degree was conferred in the upper Library-hall by the Vice-Chancellor, Sir David Brewster, in the presence of the University officials, a large body of graduates, members of council and students, and a considerable number of the fair and curious public. From the University the Prince proceeded to the Museum by means of the covered connecting bridge, and here the usual formalities were gone through in the presence of a brilliant assemblage, numbering upwards of three thousand. The foundation-stone of this Museum, it will be remembered, was laid by the late Prince Consort, and was one of the last public actions of his very useful life. With this Museum is now incorporated the Natural History collection, which formerly occupied so large a portion of the University buildings. Although even now an extremely large and beautiful building, it is rather less than half finished, and will certainly be the largest, and probably the most splendid, public building in Scotland when completed according to the original design.

GENERAL CORRESPONDENCE.

WHERE ARE THE SHAM MEDICAL EXAMINATIONS CONDUCTED?

[To the Editor of the Medical Times and Gazette.]

Sir,—In one of the spirited speeches of Sir Dominic Corrigan (more power to him!) at the Medical Council Board he read a memorandum as to the mode in which an examination was conducted at one of the Medical Boards as follows:—

"Examination at —— on Friday, November 3, 1865, commencing at eleven o'clock and lasting half an hour; conducted entirely orally by the secretary in the presence of the president, no other person being present."

"The candidate," Sir Dominic remarked, "came back (to Ireland?) with the good news, and the next (a natural) result was that a batch of eleven candidates flew away from Ireland to get their diplomas on the same easy terms."

Now the name of the Board is to remain a mystery until the next meeting of the Council; but cannot we solve the question diagnostically by the method of exclusion? 1. We can exclude Ireland. The lucky drone "came back with the good news," and there was at once a flight of Paddies from Ireland. 2. Did they settle down at any of the Universities of Great Britain? Clearly not; for none have a president and secretary who act as examiners, and in none will one examination do. There are consequently the British Colleges left; but (3.) There is no public announcement that at the close of the last year eleven Irish passed the College of Physicians in London, and as to the Hall and College, the secretaries are not examiners; whereas, on November 5 one examining secretary was the sole performer. Consequently (4thly) we come to Scotland, and here we find we approach a solution. The Irish are strong on the pass-lists of the Colleges in Edinburgh and the Faculty of Physicians in Glasgow; the secretaries are most accomplished examiners, and the candidates give one a notion, although they do not affirm as much, that they are smartly handled. But then in a fog a donkey looks like a lion. Now which of these three sisters is it? A reference to the records under date November 5 might solve the interesting problem. Would the visitors of examinations kindly gratify the public curiosity?

An Admirer of Sir (not St.) Dominic.

King's College Students' Dinner and Testimonial to Sir Wm. Fergusson.—We understand that the annual dinner of old King's College students will be held on Thursday, June 21, at St. James's Hall, Piccadilly, and that the meeting will be greatly enhanced in interest by the presentation of a handsome service of plate to Sir William Fergusson, Bart., as a testimonial of the respect of his pupils and colleagues. Old King's men desirous of attending should write to Mr. Francis Mason, 10, Conduit-street, Hanover-square, before the 19th, as no tickets will be issued after that day.

The annual banquet of Licentiates in Dentistry of the Royal College of Surgeons of England was celebrated on Tuesday, June 5, at the Albion Tavern, Aldersgate-street, E.C., F. C. Skey, Esq., in the chair.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, May 8, 1866.

Dr. Alderson, F.R.S., President.

A paper by Mr. Joseph Toynbee was read on "Pathological and Surgical Observations on the Diseases of the Ear" (eighth series).

ON DISCONNEXION OF THE INCUS AND STAPES: ITS EFFECT UPON THE FUNCTION OF HEARING, AND ITS TREATMENT.

The author begins by some observations on the anatomy and physiology of the chain of bones. He gives an account of the tensor tympani ligament, whereby the membrana tympani and the chain of bones are kept in a naturally resilient state. And he then shows that the function of the chain of bones is twofold: (1) to transmit sonorous vibrations from the drum to the expansions of the auditory nerve; (2) to act as the analogue of the iris in the eye by adapting the labyrinth for the reception of sonorous vibrations having varying degrees of intensity. In proof of the first-named function, the experiments of MM. Sissajous and Dessains are cited, by which faint undulating lines were produced by a slender style attached to the base of the stapes during the vibration of the drum by sonorous undulations. In proof of the second function of the drum, the fact was cited that during the act of listening the stapedius muscle relaxes the membrana tympani and the membrane of the fenestra rotunda; on the contrary, when a loud sound is expected, the tensor tympani muscle draws tense the membrana tympani and the membrane of the fenestra rotunda. The pathological conditions alluded to in the paper are: (1) simple disconnexion of the incus and stapes; (2) disconnexion of the incus and stapes, the long process of the incus being absent. 1. The author shows that simple disconnexion of the stapes and incus, if attended with no other lesion, is not productive of any appreciable deafness, inasmuch as the tensor tympani ligament is able to keep the two bones in contact, and the action of the tympanic muscle is not interfered with. But if the membrana tympani or its ligaments is relaxed, in addition to the disconnexion of the stapes and incus, then the function of hearing is interfered with, and often only to this extent, that the patient can hear only when the voluntary act of listening is performed—that is to say, when by voluntary muscular effort the incus is held in contact with the stapes. In this class of cases, gentle pressure on the outer surface of the drum by any resilient body restores the natural power of hearing, and the distress produced by the necessity of constant listening is quite overcome. 2. But if the membrana tympani or its ligament is much relaxed, then no voluntary effort can bring the stapes and incus into contact, and great deafness is the result. This deafness is also remedied by the application of an artificial membrana tympani, which, gently pressing upon the outer part of the chain of bones, keeps the incus and stapes in contact. 3. This disconnexion of the incus and stapes also occurs in conjunction with partial or complete loss of the long process of the incus, the membrana tympani being entire. The treatment in this class of cases consists in pressing inwards the membrana tympani so as to place its inner surface in contact with the head of the stapes, and to retain the two structures in contact. The lesions above referred to also take place when the membrana tympani is perforate. When there is disconnexion of the incus and stapes, together with a thickening of the mucous membrane or the ligaments of the articulation, the treatment consists in keeping up gentle pressure upon the outer surface of the long process of the incus; when the long process of the incus is absent, the pressure must be upon the head of the stapes. In order to exercise gentle pressure upon the ossicles and still to allow the muscles to move the ossicles, the author has recently suggested a new kind of artificial drum, in the shape of a small globe, of india-rubber containing air.

Mr. Harvey said he considered the paper of much importance and interest, inasmuch as it would show the aural Surgeon the means of preventing much of the mischief this part of the organ was subjected to after long-continued and neglected catarrhal disease. He (Mr. Harvey) had paid some attention to the subject before the Society, and from the experience

thus derived he was not surprised to find the incus so often the seat of mischief and so often displaced, owing to the anatomical connection of this bone with the mastoid cells. His own examinations had been more especially directed to the ossicles and their capsular attachments, when attacked by rheumatism, gout, and certain forms of syphilis affecting the auditory functions as a consequence, which they often seriously imperil, and it not unfrequently happens that anchylosis supervenes. These lesions cannot be very accurately diagnosed at all times during life; yet he thought a sufficiently correct opinion might on many cases be made, from which a rational mode of treatment could be derived, and which would be a source of gratification to the Surgeon, and enable him to give much relief, and in some cases make a complete cure of the deafness. As regards the treatment of the cases brought forward by the author of the paper, where the incus was supposed to have been displaced, or, as suggested, dislocated from its attachments, he should like to be informed whether pressure alone had been adopted, or whether it had been combined with constitutional treatment. He thought two of the cases cited by the author pointed to such an amount of debility or relaxation of the structures as would have yielded to constitutional treatment—namely, that of giving an increased vitality to the system by tonics. The duration of time required for the cure was also a point of importance. There was another point of very grave consideration, and on which he would like to be more informed, whether the author had ever known epilepsy to have been brought into action by long-continued pressure on the ossicula; if so, he thought it would be preferable to pause rather than adopt such expedients as the author had suggested. He regretted that no history had been given of the preparations on the table by which more practical instruction would have been gained. Some useful suggestions thrown out and many difficulties inherent in the subject-matter might also have been cleared up.

Mr. Brooke said there was some advantage in the membrana tympani which had not been alluded to. Supposing the power of hearing to be feeble, it was possible, the membrana tympani being entire, to make the external auditory canal a reciprocating cavity by closing the external meatus. If the meatus be closed, and a tuning-fork be then applied to the head near the unclosed ear, it will be best heard by the closed one. Hence the importance of its collecting and comminuting vibrations, independently of the pressure it exerts on the tympanum.

Mr. Hinton said that some cases which had come under his observation tended to support what might appear to be the weakest part of Mr. Toynbee's paper—viz., the evidence of relaxation or disconnexion of the assicula when the membrana tympani was not perforated. In the cases referred to, of which he had seen several, the membrane was thin and relaxed, either all together or in its posterior portion, and consequently had fallen inwards to such a degree that the head of the stapes projected beneath it. In some of these cases he had found that a stream of air passed into the tympanum, filling the cavity and raising up the membrane, considerably increased the hearing power, but in others the opposite effect was produced; inflation of the tympanum diminished the hearing, which was restored either by sudden strong inspiration through the nose, or by pressing in a peculiar manner upon the meatus, both of which actions had the effect of placing the membrane visibly in contact with the stapes. In some instances in which an apparently similar collapse of the membrane existed on each side, the opposite effects were produced by inflation, showing that the condition of the parts contained without the tympanic cavity was different. When drawing or forcing the membrane inwards, in the mode above described, improved the hearing, the use of the artificial membrane had frequently been beneficial.

Mr. Savory said the author had brought forward so much in his paper that it seemed almost ungracious to ask for more. He (Mr. Savory), however, failed to find a cause for the conditions the author described. It had occurred to him that some of the cases might have had a traumatic origin, and he asked Mr. Toynbee if this view might not throw some light on the particular way in which the disconnexion was brought about.

Mr. Toynbee, in reply, said that it was quite possible for the incus to be separated from the stapes as the result of a blow—indeed, one of the specimens indicated such a cause of dislocation; but, as a rule, the incus and stapes were disconnected by one of the three following causes — (1) relaxation of the tensor tympani ligament or of the membrana tympani itself; (2) thickening of the tympanic mucous membrane with catarrh; (3) a loss of substance of the long process of the incus. Desirous of not encumbering the paper with pathological researches, he had deferred entering upon a consideration of the mode in which the pathological changes were effected, leaving the subject for a future paper. In reference to the difficulty of ascertaining the fact of the disconnection of the incus and stapes when the membrana tympani is entire, Mr. Toynbee said that the affirmative could only be decided when the history, appearances, and symptoms concurred to favour the conclusion. In no case had any brain symptoms been produced by the use of the artificial membrana tympani; indeed, it was highly improbable that the presence of the drum would produce such a result, as undue pressure on the chain of ossicles, and thence upon the vestibule, produces immediate increase of deafness. In many cases the artificial drum is dispensed with after a short time, as the chain of bones by its use appears to regain its normal resiliency; in other cases the artificial drum requires to be used at intervals. Considerable experience during many years has shown that the use of the artificial drum is attended with permanent advantage.

In reply to Mr. Brooke, Mr. Toynbee said that in the early study of the subject, he had reason to believe that the artificial drum acted beneficially by constituting the tympanum a closed cavity, and he was strengthened in this opinion by the beneficial effect following the use of a bubble of mucilage for the purpose of closing the aperture; recent researches in pathology, and in operative practice, had, however, induced him to adopt the conclusions cited in the paper, and he was disposed to believe that even the beneficial effect of the mucilage was due to the gentle pressure it exerted upon the chain of bones, thus conducing to render it continuous and resilient.

The President thought that much more would be gained by a close study of physiology as introductory to pathological investigation. He said that whilst we were fully acquainted with the mode in which light was impressed upon the retina, and so communicated to the brain, notwithstanding that doubt still existed as to the true theory of the nature of light. Yet, on the other hand, whilst the vibrations of the air were fully understood, very little that is positive has been ascertained as to the mode in which those vibrations are communicated to the brain.

Mr. Toynbee asked permission to say a few words in reply to the remarks of the President. In the first place, it was a mistake to suppose that all the ossicles could be lost without the production of deafness—the presence of the stapes was absolutely requisite to hearing. In the second place, it was only recently that the true action of the stapedius muscle upon the stapes was made out, and the analogy of the base of the stapes to a piston and the inner surface of the fenestra ovalis to a cylinder clearly shown; and thirdly, experiments and dissections had clearly demonstrated that the action of the tensor tympani muscle was to render tense the membrane of the fenestra rotunda by exercising traction on this muscle when the scala vestibuli of the cochlea was exposed, when the fluid in the scala was seen to move outwards; on the contrary, when the tendon of the stapedius muscle was pressed upon, the fluid was seen to recede again.

A paper, by Mr. Arthur E. Durham, was read, on

A CASE IN WHICH A NEW OPERATION FOR THE RADICAL CURE OF HERNIA WAS SUCCESSFULLY PERFORMED.

Stephen H., a sailor, 26 years of age, sought admission to Guy's Hospital for the purpose of being radically cured of an easily-reducible but very troublesome inguino-scrotal hernia on the right side. The hernia had been first noticed six years previously. It had gradually increased in size, and extended into the scrotum. Latterly it had given rise to such constant inconvenience and so much occasional pain that the patient had been quite unable to follow his occupation. He could not wear a truss, although he had repeatedly attempted to do so. At the period of admission to the Hospital the scrotal portion of the hernia was about as large as a hen's egg, or rather larger. The bowel, of which it was evident the hernia mainly consisted, was easily returned into the abdomen, but a slight fulness of the inguinal canal persistently remained. On January 19, chloroform having been fully administered, and the hernia reduced as completely as possible, Mr. Durham proceeded to operate in the following manner:—An incision about two inches and a half in length was made through the skin and superficial fascia, in a direction at right angles to Poupart's ligament, and just over the inner border of the

internal or deep abdominal ring. The tendon of the external abdominal oblique muscle was next divided in a similar direction, but to a somewhat less extent, and in a situation slightly further from the median line of the body. The lower fibres of the internal abdominal oblique or cremaster were then separated longitudinally, and the internal spermatic fascia or fascia propria of the hernia was exposed. A slight incision having been made in the lower and deeper part of this fascia, an aneurism needle was carefully insinuated through the areolar tissue, and by its means a ligature was placed between the sac of the hernia and the important structures of the spermatic cord, and carried through the upper and deeper part of the fascia. The fascia and sac were then drawn gently downwards and towards the median line of the body, and the ligature was tied tightly as high up and as far outwards as possible; in fact, as nearly as could be judged, exactly at the internal or deep ring. The ligature thus included the greater part of the circumference of the fascia propria or internal spermatic fascia just where it becomes continuous with the fascia transversalis, the whole circumference of the sac just at its junction with the general peritoneal lining of the abdominal parietes, and within the sac a small plug-like portion of omentum. In passing the aneurism needle, a slight puncture was unintentionally made into the sac. This puncture, however, when subsequently dilated, afforded the opportunity of ascertaining that the sac did not communicate with the tunica vaginalis testis, but that it contained a small piece of irreducible omentum; this was drawn out and cut off below the ligature. Finally the wound was closed above and below by sutures, which were passed through the sac. The ends of the ligature were left coming out through the middle of the wound. The after progress of the case was most satisfactory. The patient was kept absolutely in the recumbent position for more than six weeks. From first to last he never had a single bad symptom worth mentioning. There was never any abdominal tenderness, constitutional disturbance, or other indication of general peritonitis, nor was there ever much pain about the site of the operation. The upper and lower parts of the wound healed by first intention. The ligature came away on the eighteenth day, and complete closure of the wound speedily followed. On March 29 the patient, having to a certain extent recovered his strength, went into the country. Before leaving the Hospital he was examined by all the members of the Surgical staff as well as by many visitors. There could not be discovered the slightest hernial protrusion nor any abnormal impulse on coughing. The inguinal canal from the internal ring seemed perfectly blocked up by the obliterated sac and new material. This case, although a solitary one, may be considered to prove—first, that the method of operation described is practicable; and secondly, that it is not necessarily attended by danger. The author would add that he believes it to be more scientific in principle than any other method yet adopted, and he hopes, therefore, it may prove more successful in practice.

Mr. Spencer Wells said that the proceeding described to the Society as *new* reminded him very strongly of operations performed centuries ago for the radical cure of reducible hernia. But, as the object of the older operators was to apply a ligature around the neck of the sac, or to obliterate it by scarification or by the introduction of foreign bodies within it, or to destroy it by caustics or the actual cautery, their proceedings proved to be so extremely dangerous, and so often unsuccessful, that when he (Mr. Wells) brought Wutzer's method before the Society in 1854 all operations for the radical cure of hernia were very generally condemned by the Profession. Since 1854, Wutzer's operation had been very frequently practised here, and had often proved unsuccessful. But this was because it had been performed in cases for which it was unsuitable. Where the rings have not been much widened and the canal not much shortened it is a very successful operation, and it is almost free from danger. Unfortunately, it is only applicable to a very small proportion of cases. Mr. Wood's operation is of much wider application, but it is unquestionably a more serious, not to say dangerous, proceeding. The operation performed by Mr. Durham appeared to be even more hazardous. Free division of skin, fascia, and muscle, and the application of a ligature, even if the sac were not accidentally opened, though not in this case followed by any bad symptom, might certainly be expected to lead to danger in a certain proportion of cases. And it became a grave question whether any very serious operation could be justifiable in cases of reducible hernia. If the hernia could be well supported by a truss, no operation attended with danger to life could be sanctioned. When a truss could not be borne, then Wutzer's operation in cases to which it was adapted, or Wood's operation when the rings were wide and canal short, seemed to offer at least an equal prospect of success, and to be much less hazardous, than the operation performed by Mr. Durham.

Mr. Holthouse wished to know the particular reasons for performing this operation for the radical cure of hernia, and what were its advantages over other operations having a similar object. He thought Mr. Wells was in error in believing that it was the same operation which had been done some centuries ago. In the cases to which Mr. Wells referred the sac had been tied at the external ring, and thus a pouch was left open above the ligature, into which a hernia could descend. In Mr. Durham's operation the sac was tied at the internal ring. Mr. Holthouse thought the new operation was inferior to Mr. Wood's, partly because it was less safe, and partly because it dealt only with the hernial sac, and made no provision for drawing together the sides of the canal. Mr. Wood's operation, he added, blends the sac with the walls of the canal, which thus offer a firm resistance against future protrusion.

Mr. Christopher Heath, without wishing to detract from the credit of a successful case, could not but regard the good result in Mr. Durham's operation as in great measure due to the accidental presence of a piece of omentum within the sac, and which, therefore, served to plug the canal. This occurrence could not be looked for in every case, and even if the sac were opened, as was unintentionally done by the operator in his case, it would be scarcely possible to draw omentum down with safety. Mr. Heath thought three months too short a time to show the ultimate success of the operation, and was not surprised to hear that after the inflammation excited and the formation of an abscess there was reported to be considerable thickening of the parts. He knew from his own experience and that of others in Wood's operation that very considerable induration disappeared after a time, and he feared that then the peritoneum would again become stretched and the hernia be reproduced. Another point worthy of consideration, he thought, was the advisability of dividing the muscles to the extent recommended by the author, and feared that it would lead to permanent weakening of the abdominal parietes, as was seen after the operation for ligature of the iliac arteries.

Mr. Hulke asked if the omentum was included intentionally?

Mr. Kingdon said that it was not the fatality of former operations which had led to their disuetude, as Mr. Wells had just remarked, but their inefficacy. The former, as well as the present, operations were based upon a false assumption, —viz., that there was power in the adhesions thereby instituted permanently to prevent a recurrence of hernia. There was not the slightest evidence in favour of such an assumption, but the recorded evidence of Dupuytren and Scarpa was against it. Sooner or later, as Mr. Heath had stated, the adhesions were sure to yield.

Mr. Durham, in reply, said that although he had searched diligently he had failed to find on record the details of any such operation as was described in his paper just read. He therefore ventured to consider his method a new one. With regard to the ancient operations referred to by Mr. Spencer Wells, the descriptions given were for the most part so vague and indefinite as to afford no exact information as to the precise particulars of the methods adopted. In those instances in which the descriptions were more exact, the operations were manifestly coarse and clumsy, and necessarily involved the very sources of danger (such as sloughing of the hernial sac, wasting of the testicle, etc., etc.) which he (Mr. Durham) had been most careful to avoid. The operations most similar to his own were those of Langenbeck and Schmucker. Those Surgeons, however, applied their ligature at the external, not at the internal ring. The most that could have been accomplished by such a proceeding, even if successful so far, must have been the conversion of a scrotal hernia into a bubonocele. No very great gain this. Mr. Durham had tried a new method in this case simply because it did not appear to him worth while to try either of the methods at the present time or recently in vogue—viz., Wutzer's and Wood's. Wutzer's operation had been amply proved by experience to be unsuccessful—nay, worse than unsuccessful. And, indeed, it was so unscientific in principle that the wonder was it should ever have been adopted to any extent. Mr. Wood's method was certainly very ingenious, but his own account of the results of his numerous operations did not seem to him (Mr. Durham) very encouraging. Of the

sixty patients whose cases are detailed in Mr. Wood's book, between forty and fifty (a very large majority) were discharged wearing trusses, and in only six or seven of the fully-recorded cases did it appear to have been considered right to dispense with such mechanical supports. Could a hernia be said to be radically cured in the full and proper sense of the words if the patient were still obliged to wear a truss? Further, in less skilful hands than his own Mr. Wood's method had been shown to be by no means free from danger. With regard to the possible and probable risks of his method, Mr. Durham believed that the danger of meddling with the peritoneum, particularly with such portion as forms the hernial sac, had been very greatly exaggerated. He certainly should hardly have expected Mr. Spencer Wells, of all men, to have been so very fastidious and fearful about touching a little extension from that general abdominal lining which he (Mr. Spencer Wells) was in the habit of cutting into and mopping out so freely, fearlessly, and with so much impunity. The argument derived from the statistics of operations for strangulated hernia was very bad. That a large proportion of cases in which the sac was opened proved fatal was indisputably true; but the explanation was obvious. Those cases in which it was necessary to open the sac were the most dangerous, for they were those in which the strangulation was most severe or had continued longest, and, therefore, those most likely to prove fatal. There was no evidence to show that the mere opening of the sac increased the danger of the operation; indeed, in a great many cases of recovery if the sac had not been opened the hernia could not have been returned, and the patients must have died. In the present case there never was the slightest indication of any dangerous symptom whatever. There was none of the "severe inflammation" and nothing of the "extensive abscess" which Mr. Heath had suggested. In conclusion, it appeared to Mr. Durham that he had done intentionally what Mr. Wood only did accidentally—viz., close the hernial sac at the internal ring. On the other hand, Mr. Wood attempted to accomplish intentionally what he (Mr. Durham) allowed in this case to become accomplished as it might—viz., constriction of the inguinal canal and external abdominal ring. In certain cases the association of the two methods would probably be much more successful than either by itself, and such association he should without hesitation adopt.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 3.

DR. PEACOCK, President.

CASTRATION.

Dr. DUKA, of the Bengal Army, exhibited a specimen not strictly pathological, but of considerable interest, relating to a state of off-hand Asiatic Surgery as it exists even in our days in Bengal and probably other parts of our Indian Empire. The specimen in question was the pubic region of an old eunuch, Edoo by name, aged nearly 60 years, who, as the chief of a gang of eunuchs in the districts of Patna and Monghyr, had the duty of enrolling fresh hands into his confraternity by "doing as he was done by," namely, emasculating such young boys of 6 to 8 years of age as he could obtain possession of, and for so doing he was brought to trial in 1860, and sentenced to a long term of imprisonment, during which time he died in the Monghyr gaol, in 1863, whilst Dr. Duka was in Medical charge of it. We were hitherto under the impression that all eunuchs, as in Turkey and Abyssinia, were deprived merely of their testes; this specimen, however, would show that in India a clean sweep is made of the whole scrotum, testes and the penis as well, leaving a longitudinal cicatrix, closely adhering to the bone, with the urethral orifice at the upper end of it. It is very rare indeed that Europeans in the East ever have the opportunity of seeing these "neuter" individuals of our race, except as attendants at Mahomedan courts; still rarer can our brethren in India obtain a chance of making a preparation like this, which it is presumed is unique of its kind. The specimen is now the property of the Museum of St. George's Hospital.

Dr. CHOLMELEY exhibited

A MASS OF ENLARGED AND DEGENERATED MESENTERIC GLANDS FROM A MAN AGED 54.

The patient had been first seen by Dr. Cholmeley, in conjunction with Mr. E. C. Hulme, under whose care he had been on account of a large double inguinal hernia, in October last. He was suffering from cough, dyspnœa, and emaciation, and was supposed to be consumptive. On the left side percussion was clear, and the respiratory murmur puerile, but somewhat harsh immediately under the clavicle. The right side was absolutely dull and silent as high as the third rib in front, and the spine of the scapula behind; the signs pointed to compression of the lung by an upwardly enlarged liver, rather than to consolidation or to collection of fluid in the pleural cavity. Nutrition and assimilation were much disordered; the abdomen full and tender on manipulation; the bowels relaxed; the stools "offensive and light-coloured." The patient improved in health and strength for some weeks, but then fell back and died exhausted at the end of February. The right lung had expanded considerably, so that fair respiratory murmur could be heard as low as the fifth rib; there were never any physical signs of serious disease of the lung itself. Small scattered tubercles were found in the apices of both lungs, and a few vomicæ of the size of half a pea, and there was an old cicatrix in the left apex. The intestines were matted together, the great omentum rolled up into a thick cordon with the transverse colon; the peritoneum greatly thickened and specked with black pigment; the liver greatly enlarged, in an advanced degree of fatty degeneration, universally adherent to the diaphragm, and prevented from descending below the ribs; the mesenteric glands formed a mass the size of a large cocoanut; some of them were as large as a Bergamot orange, and they were in various stages of tubercular degeneration. There was no tubercle elsewhere. The man had died from tubercular disease, but not from the tubercular disease in the lungs.

Dr. CHOLMELEY next exhibited a specimen of

WARTY GROWTHS IN THE LARYNX, CAUSING DEATH BY ASPHYXIA.

The specimen was taken from a boy, two years of age, who was admitted into the Great Northern Hospital under Dr. Webb, with an history of an ordinary attack of croup. He was much relieved by emetics, but daily had severe attacks of dyspnœa, and never quite lost the hoarse stridulous croupy breathing. Dr. Webb proposed tracheotomy on the second day, but the proposal was negatived in consultation. On the fifth day it was learned that the child had been quite unable to speak or cry, and had had occasional severe attacks of dyspnœa for nine months; and the mother was observed to be very unhealthy-looking, and to have a suspicious-looking scar on the forehead, and marks of extensive ulceration in the fauces. The child had then become very weak and exhausted, and another attack of dyspnœa coming on, tracheotomy was resorted to by one of the Surgeons, but profuse bleeding occurred from a large vein which crossed the front of the trachea, and the child died on the operating table. No inflammatory exudation of any kind was found in the larynx, trachea, or bronchi, but the rima glottidis was choked up by a mass of warty vegetations growing from the true vocal cords and the adjacent mucous membrane; the growths consisted of paramount epithelium.

LARVAL TAPEWORMS IN VEAL AND MUTTON.

Dr. COBBOLD exhibited a small section of the heart and numerous portions of the triceps adductor femoris muscle of a calf in which he had successfully reared the cysticerci or larvæ of the tænia mediocanellata. He stated that these larvæ were quite distinct from those usually found in swine, and that they were even more abundant. The examples of this cysticercus bovis taken from the heart were not so perfectly developed as those in the ordinary muscles of the body, which was owing to the density of the muscular bundles. His experiment was the only one hitherto performed in this country, but he hoped shortly to lay before the Society the results of a second "feeding" in an adult animal of the same species. The cysticerci obtained from mutton (sent to his table) had undergone calcareous degeneration rendering it impossible to determine to what tapeworm species they might be referable. Probably they were distinct, and represented a third species of tænia derived from meat. (Since the meeting Dr. Cobbold has received from Mr. Heisch a specimen of "measle" taken from the interior of a mutton chop. It is armed with a crown of hooks, and is apparently quite distinct from the pork "measle.")

Dr. DICKINSON exhibited a specimen of

RUPTURE OF THE AORTA.

A man, aged 59 years of age, apparently well, was working

on a low scaffolding; he made a sign of distress and extended his hand, fell off the scaffolding, and was picked up dead. He had apparently died from the fall. There was a rent in the early part of the arch of the aorta, and the pericardial sac was full of blood. On the back of the aorta for two inches the two inner coats were absent, and in one part blood had escaped.

The PRESIDENT inquired whether Dr. Dickinson had been able to obtain any history of a syncopic attack prior to that of which the patient died, for looking at the specimen he inferred that such an attack must have occurred at the time of the tear of the internal coats some time previous to death. The specimen bore a close resemblance to some figured by Rokitansky in his work on diseases of the arteries, as cases of cured rupture of the aortic coats.

Dr. DICKINSON showed a specimen of

MALFORMATION OF THE HEART.

The heart was taken from a child who had been the subject of cyanosis. There was one large left ventricle, and with this the two auricles were connected. One right ventricle was quite rudimentary and opened into the left. It was connected with a pervious pulmonary artery.

The PRESIDENT said that from the casual examination which he had made of the case of malformation of the heart exhibited by Dr. Dickinson, it appeared to be an instance of the condition which he had described as "a supernumerary septum in the right ventricle." It would be observed that in the cavity which was laid open, and which was obviously the right ventricle, there was a very decided constriction a short distance below the pulmonic valves, thus separating the large sinus from the small cavity, which is the analogue of the infundibular portion of the ventricle, and presenting an analogy to the form of the heart in the Chelonian reptiles. The aorta and pulmonary artery also both arose from the right ventricle, and the left ventricle communicated with the right. The position of the several cavities was also transferred.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary Examinations for the Fellowship on the 29th and 31st ult., were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and at a meeting of the Council on the 14th inst. were enrolled Fellows of the College, viz.:—

Messrs. Edmund Archer, Cape of Good Hope, diploma of membership dated December 29, 1846. Theodore Duka, Her Majesty's Indian Army, October 7, 1853. Thomas Furneaux Jordan, Birmingham, May 2, 1854. William Darling, New York, November 21, 1856. Francis Falwasser, Army, March 26, 1858. Frederick Howard Marsh, St. Bartholomew's Hospital, June 3, 1861. Louis Stromeyer Little, Brook-street, Grosvenor-square, April 22, 1862. Alexander Bruce, Albert-terrace, April 26, 1864, and William George Vawdrey Lush, Wilton, near Salisbury, April 27, 1864.

Only one candidate failed to acquit himself to the satisfaction of the Court. At the same meeting of the Council, the following member having been *elected* a Fellow at a previous meeting of the Council, was admitted, viz.:—

John Morrill, Newhaven, June 12, 1840.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 7, 1866:—

Narcis Richard Haswell, Helton, Cornwall; Henry John Branson, Scarborough; Dixon Brombridge, Snaith, Yorkshire: John Rees James, Llanelly, Carmarthenshire; Frederic Stewart Colquhoun, Tiverton, Devon; Edward James Leverton, Truro, Cornwall.

The following gentlemen also on the same day passed their First Examination:—

John Giles, St. Bartholomew's Hospital; George Moore, General Hospital, Birmingham; Charles Nutt, Guy's Hospital; William Bevan Lewis, Guy's Hospital; George Stokell, Guy's Hospital.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of Candidates who passed the Examination as Pharmaceutical Chemists, June 13:—

Parson Custance Baker, Holt; John Day, Retford; John Hugh Davies, Newcastle-on-Tyne; John Goucher, Wellington, Salop; Thomy Pasnin, Mauritius; Thomas Barker Horner, Woolwich; John James Thorn, Crediton; Henry Allcock Averill, Stafford; George Baxter, Chester; John Temlett Long, Bristol; Richard Pheysey, Waterloo.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CONSTABLE, JOHN H. C., L.K.Q.C.P. Ire., &c., has been elected District Medical Officer to visit out-patients to the Royal South London Dispensary.

KEALY, J. R., M.D., has been appointed Surgeon to the Portmouth Hospital.

PLATT, W. H., L.R.C.P. Edin., has been appointed House Surgeon to the Scarborough Dispensary.

WHITE, J. R., has been appointed House-Surgeon to the Kent County Ophthalmic Hospital, Maidstone.

YOUNG, EDWARD PARKER, M.R.C.S., L.S.A., and L.M., has been appointed Surgeon to the Westbourne Dispensary and Maternity.

BIRTHS.

DEBENHAM.—On June 7, at Heath House, Stepney, the wife of R. Debenham, M.R.C.S., of a son.

DIVERS.—On June 6, the wife of E. Divers, M.D., (of Queen's College, Birmingham), of a son.

NORTON.—On June 6, at 112, Westbourne-grove, the wife of A. C. Norton, M.D., of a daughter.

RUDALL.—On April 26, at Melbourne, Australia, the wife of J. T. Rudall, F.R.C.S.E., of a son.

SMITH.—On June 2, at Burbage, Wilts, the wife of C. Swaby Smith, M.R.C.S., of a daughter.

MARRIAGES.

BURY—WHITE.—On May 30, at the parish church, Spalding, W. H. Bury, M.D., to Harriet White.

EASTCOTT—ROBERTS.—On June 2, at St. Stephen's, Westbourne-park, J. C. Eastcott, Surgeon R.N., to Emile Catharine, only surviving daughter of W. Roberts, Esq.

KING—SMITH.—On April 21, at St. George's Church, Prince of Wales Island, J. B. King, M.D., Assistant-Surgeon H.M. Indian Army, to Joanna, second daughter of the late H. W. Smith, Esq., of Island Hall.

KITCHING—ATKINSON.—On May 8, at Picaltsdorf, Cape Colony, T. Kitchin, M.R.C.S., to Lydia Jane, youngest daughter of the Rev. J. Atkinson, Picaltsdorf.

KNOTT—MILWARD.—On June 7, at the parish church, Bidford, M. O'Malley Knott, M.D., to Sophia, eldest daughter of J. Milward, of Tower-hill, Bidford.

DEATHS.

AUSTIN, M. F., M.R.C.S. Eng., at 15, Red Lion-street, Clerkenwell, on May 25, aged 79.

THOMPSON, T. D., L.S.A., on June 8, aged 55.

TUNALEY, C., M.D., at 1, Millbrook-place, Harrington-square, on June 5, aged 58.

URE, ALEXANDER, F.R.C.S., at 18, Upper Seymour-street, Portman-square, on June 13.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Altrincham Union.—Mr. Earle has resigned the Workhouse; salary £50 per annum.

Aylesbury Union.—Mr. Brown has resigned the Waddesdon District; area 16,829; population 2978; salary £85 per annum.

Bury Union.—The Heap District is vacant; area 8996; population 22,537 salary £60 per annum. Mr. Sellers has resigned the First Pilkington District; area 2468; population 4304; salary £20 per annum. Also the Second Pilkington District, area 3000: population 8000; salary £30 per annum.

APPOINTMENTS.

Easingwold Union.—John C. Robinson, M.R.C.S.E., L.R.C.P Edin., of the Coxwold District.

Keighley Union.—Percy Milligan, M.R.C.S.E., L.S.A., to the South Keighley District and the Workhouse.

Knaresborough Union.—Thomas Trowsdale, M.R.C.S.E., L.R.C.P. Edin., to the Harrogate District.

Lincoln Union.—George W. Glasier, M.R.C.S.E., L.S.A., L.M., to the Eleventh District.

Presteigne Union.—Tom Oliver Hunt, M.R.C.S.E., to the Union.

Ticehurst Union.—William M. Harmer, M.R.C.P. Edin., L.F.P. and S. Glasg., L.S.A., to the Salehurst and Etchingham District.

ROYAL COLLEGE OF PHYSICIANS.—The President and Fellows of the College have issued cards of invitation to a *conversazione* at the College on Wednesday evening, June 27. The Harveian Oration is to be delivered in English by Dr. Paget on Tuesday, June 26, at 4 o'clock.

OXFORD HONOURS TO MEDICAL MEN.—On Wednesday, June 13, the Honorary Degree of D.C.L. was conferred by the University on Sir J. G. Simpson, M.D., of Edinburgh, and on Dr. J. D. Hooker, of Kew Gardens.

MR. WILLIAM MCGILL has bequeathed to the Royal Infirmary, Edinburgh, a property of the value of £10,000, the rents to be applied to the purposes of the charity.

Accident to a Surgeon.—The Mayor of Chard (Mr. Spicer, a Surgeon) was thrown from his gig in that town on Sunday week, and was so terribly cut about the head that a neighbour, not recognising him, ran to his house for Medical aid. Mr. Spicer is, however, recovering.

Pharmaceutical Exhibition.—An exhibition of objects relating to pharmacy is to be held at Nottingham during the meeting of the British Pharmaceutical Conference. The meeting of the Conference will commence on Tuesday, August 21, being the time of the meeting of the British Association for the Advancement of Science. Professor Bentley will preside.

The Odontological Society held its monthly meeting at its rooms, Soho-square, on the 4th inst. Dr. Richardson gave further explanations of his plan for producing local anæsthesia, and also described his new styptic, which could be applied by the spray apparatus. Mr. Balkwill read a paper on arranging artificial teeth for the purpose of mastication.

A case of death from cholera having been alleged to have taken place on board the Peninsular and Oriental Steam Company's ship *Poonah*, which arrived at Southampton on June 10, a full inquiry was instituted by Dr. Wiblin. It was proved that the case was one of English cholera, and that the crew and passengers were in good health.

Cholera at Djeddah.—A telegram dated Alexandria, June 9, states that "Between the 26th and 27th ult. more than 100 deaths from cholera occurred at Djeddah."

The Cholera at New York.—The following telegram dated New York, May 30, appeared in the *Times* of Saturday, June 6:—"The steamer *Union*, from Liverpool, arrived yesterday at the New York quarantine. Thirty deaths from cholera had occurred on board during her passage." Another telegram dated June 2 states that "On that day twenty-six new cases occurred in New York quarantine."

The Nuisances Removal Act, No. 1, 1866, entitled a Bill to amend the Nuisances Removal and Diseases Prevention Act, 1860, brought in by Mr. Knatchbull-Hugessen and Sir George Grey, and ordered, by the House of Commons, to be printed, May 17, 1866, has only three clauses, as follows:—"1. The sixteenth section of the Act of the twenty-third and twenty-fourth Victoria, chapter seventy-seven, shall be and is hereby repealed. 2. No Justice of the Peace shall be deemed incapable of acting in cases under the Nuisances Removal Act, or the Act of the twenty-third and twenty-fourth Victoria, chapter seventy-seven, by reason of his being a member of any body thereby declared to be the authority to execute the said Act, or by reason of his being a contributor or liable to contribute to any rate or fund out of which it is thereby provided that all charges and expenses incurred in executing the said Act, and not recovered as therein provided, shall be defrayed. 3. This Act may be cited as "The Nuisances Removal Act, 5 (No. 1), 1866."

At the present moment, when the condition of the metropolitan Workhouses is arresting so much public attention, we extract with pleasure the following report from the *Cork Constitution* of June 8.—

"Fermoy Union, Wednesday, Richard Carroll, Esq., J.P., Chairman of the Board, presided.

"The Workhouse Schools and Children.—The Clerk read the report of the Head Inspector of National Schools, as follows:—

"'I am of opinion that the state of this school is very satisfactory, and reflects great credit not only upon the teacher, but on the Board of Guardians, who evidently *take a pride in having the children well cared for*. The latter are remarkably clean in person, and tidily and comfortably dressed, and unquestionably are the *most cheerful and the healthiest looking children* I have *ever seen in any workhouse*.'"

Proposed Medical Club—(From a Correspondent).—It is proposed to establish in London a new club, to be called the "Sydenham," for the convenience of members of the Medical Profesion, securing, at a minimum cost, all the advantages of a modern club. The want of such an institution has long been felt, especially by provincial Practitioners, and those of their brethren in the various public services and the mercantile marine—the want of a house that they can make their temporary home, and where they may at the same time enjoy the advantage of London Professional society. It is anticipated that an entrance fee of five guineas, with an annual subscription of three guineas, for members residing within the metropolitan postal district; and an entrance of three guineas, with a subscription of one guinea, for those beyond, will be found sufficient; it being expressly understood that these rates will be available only on the part of those joining the club at its commencement. Though the terms of donation and subscription will be thus comparatively so much lower than those of other clubs, it may be expected that, in respect of comfort and convenience, the Sydenham will not be inferior to any in London. It is further worthy of note that at Calcutta, Madras, and Bombay "general clubs," on the principle here announced, have been in eminently successful operation for many years. Sleeping accommodation will be provided for extra-metropolitan members, and for limited periods only.

Elections at the College of Surgeons. — The retiring members of the Council, Messrs. Hilton and Luke, will not be allowed to resume their seats at the Council table without some opposition, as on Monday last, when the time expired for sending in applications, the names of the following candidates had been received, the names appearing in seniority of Fellowship, viz.:—Mr. William James Erasmus Wilson, F.R.S., of Henrietta-street, Cavendish-square, Consulting Surgeon to St. Pancras Infirmary, etc.; nominated by Sir J. R. Martin, and Messrs. J. E. Erichsen, H. Thompson, G. Critchett, W. Adams, and T. W. Nunn. Mr. Charles Hawkins, of Savile-row, the Metropolitan Inspector of Anatomy, and Consulting Surgeon to Queen Charlotte's Hospital, etc.; nominated by Messrs. T. Tatum, P. G. Hewett, G. Pollock, H. Lee, T. Holmes, and B. E. Brodhurst; and Mr. Henry Spencer Smith, of Queen Anne-street, Cavendish-square, Surgeon to, and Lecturer on Surgery in, St. Mary's Hospital; nominated by Messrs. J. Birkett, H. Coote, H. Thompson, G. Pollock, C. H. Moore, and J. R. Lane. The senior candidate, Mr. James Luke, appears, from the Calendar of the College, to have been elected on the Council so long ago as 1846, has twice filled the President's chair, and occupied a seat in the Court of Examiners since 1851. The case is different with regard to Mr. John Hilton, F.R.S., the other retiring candidate, who is in the active practice of his Profession, teaches in one of our largest metropolitan schools, and who has only just been elected an examiner; he, moreover, deservedly fills the Vice-President's chair, and may fairly aspire to the highest office; it would be manifestly unjust to displace this gentleman, and it will be gratifying to Mr. Hilton's friends to know that his return may be considered secure. This feeling, however, should not induce the Fellows to relax in their efforts to place him at the head of the poll. The election is fixed for Thursday, July 5th, at 2 o'clock. The Fellows' festival will take place the same evening at the Albion Tavern; Mr. Wormald, President of the College, has been requested to occupy the chair.

Serious Charges against a Medical Assistant.—At the Farnham Police Court on Tuesday last, Lake Young, *alias* William Augustus Young, was brought up on remand, before F. R. Thresher, Esq., and Major Spring, charged with embezzlement, felony, and obtaining goods under false pretences. It appeared from the evidence of Dr. W. Davies, of York Town, Frimley, with whom the prisoner had recently been engaged, that in the month of April last the prisoner obtained his situation as assistant upon what afterwards proved to be false representations and a false certificate. A month's probation was mutually agreed upon, and it was the duty of the prisoner to attend patients and dispense medicine. At the expiration of the month, however, the prisoner was discharged, but for what cause it did not appear. Shortly after his leaving the situation it was discovered that an entry had been made in the day-book of Medicine supplied to a tradesman near Sandhurst, which it afterwards transpired had been paid for, and not accounted for by the prisoner, by whom the entry was made. Suspicion resulted from this omission which led to further inquiry, and it was then ascertained that several things belonging to the Surgery were missing, including a caustic pencil case and several Medical works. It was also found that the prisoner had obtained wearing apparel and other goods to a considerable amount from the tradespeople by means of false pretences—one of which was that he was engaged permanently as a Medical Practitioner, and was desirous of opening accounts. The police were communicated with, and it was found that he had succeeded in obtaining a fresh situation, under an assumed name, as Assistant Surgeon to Dr. T. L. Hales Smith, of Fetter-lane, Fleet-street, London, where he was apprehended by Sergeant Hyde, of the Surrey constabulary. Search was made in the prisoner's rooms, and several pawnbrokers' duplicates were found. The officer pro-

duced a list of the articles missing from Dr. Davies' Surgery, and on allusion being made to the caustic pencil case, Dr. Smith at once stated that it was presented to him by the prisoner shortly after his engagement. The prisoner cross-examined the several witnesses with all the ingenuity and skill of a barrister, but did not succeed in shaking their testimony. The prisoner in defence admitted having given the caustic pencil-case to Dr. Smith, but emphatically denied taking it from Dr. Davies' Surgery with any felonious intent. He also stated that it belonged to the old stock of the Orphanage Asylum at Frimley, of which establishment Dr. Davies was Medical officer; that he had used it in the Profession generally, but did not attach any particular value to it. The prisoner was formally remanded for the completion of depositions.

PUBLIC HEALTH.—The Government Bill upon this subject now before the House of Commons contains some clauses that should be generally known. Among nuisances to be abated by the authorities empowered to execute the Nuisances Removal Acts these are to be included:—A house or room so overcrowded as to be dangerous or prejudicial to health; a factory or work-place not already under the operation of the Factories or Bakehouses Acts not kept in a cleanly state, or not ventilated in such a manner as to render harmless as far as practicable any gases, dust, or other impurities generated in the course of the work that are injurious or dangerous to health; a fireplace or furnace for working engines by steam, or in any mill, factory, etc., which does not so far as is practicable consume its own smoke. But this last part of the clause is not to come into operation for a year in places where at present there is no law for compelling such consumption of smoke. A penalty not exceeding £5 is imposed for exposure in any public place or public conveyance of any person suffering from a dangerous infectious disorder without proper precaution against spreading it; and there is a like penalty on the owner or driver of a public conveyance who does not immediately provide for its disinfection after it has with his knowledge conveyed any such sufferer. Carriages for the conveyance of such persons may be provided by the local authorities. The sewer authorities may compel the owner of any house in their district which is without effectual drainage to remedy that defect. Various other powers are given by the Bill to the sanitary authorities for the sake of the public health.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending May 19.	Week ending May 26.	Week ending June 2.	Back cases reported in the week ending June 2, 1866.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

This Return shows that 960 attacks were reported to have occurred during the week ended June 2, being a decrease of 247 on the previous week.

A considerable, but varying, number of "back cases" are reported every week. These cases, however, do not necessarily relate to the previous week only; they generally comprehend arrears of from six to eight weeks, and, in some instances, a longer period.

Note.—6 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Bucks, 1; Cumberland, 1; Lincoln, 1; Stafford, 1; for the Metropolis, 1; and for Scotland, 1. These inspectors returned 81 cases last week.

AMONG minor reforms, let us decapitate, if we can, all our Assistant-Physicians and Assistant-Surgeons, at home and abroad; and, rejecting the misleading frontispiece "assistant," leave them what they are, Physicians and Surgeons. Let us unite for adequate remuneration for labour. No false sentiment about the nobility of doing for nothing work which it is hoped will prove indirectly the source of fees, and which it is inwardly felt ought to be directly paid. "The labourer is worthy of his hire"—"A fair day's wage for a fair day's work," may not be very poetical, but they have the genuine smack of an honest British instinct.—*Address at the London Hospital Medical College, by Walter Rivington, M.S.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The articles on Cholera Literature will be resumed in our next number, including notices of Dr. Macpherson's valuable work on "Cholera in its Home," Mr. Baker's edition of Dr. Southwood Smith, and Dr. Anstie's Notes on Epidemics.

A Rural M.R.C.S.—Get *Ollendorf's* French System. Any bookseller can supply it.

A Medical Student.—1. Yes; so the present Regulations say.—2. Odling and Williamson.—3. Cyanide of potassium.

Mr. Thompson.—Mr. Hancock's lectures were brought to a close on Friday.

Small Pox Hospital.—Inoculation was first tried on criminals in 1727.

"*Dr. Macaulay.*"—A portrait of Banister may be seen in the collection gathered at the South Kensington Museum, to which it has been lent, with others, by the College of Surgeons.

University of New York.—The Council of this Institution have just unanimously elected Dr. William Darling, F.R.C.S. Eng., to the Professorship of General and Descriptive Anatomy in the University.

A Naval Surgeon.—It was stated a few nights ago in the House of Commons that only three individuals had entered the Naval Medical Service since January last.

J. H. and a Metropolitan Fellow.—You are not the only correspondents complaining of the dinner to the Fellows taking place in London in July, when there are such favoured places as Greenwich and Richmond where it might be eaten in coolness and comfort.

A Provincial Fellow.—We are informed that the usual circulars have been sent to all the Fellows in the United Kingdom whose addresses are known at the College. In your own case it appears that last year the circular was returned through the "Dead Letter Office" endorsed "Gone away—left no address." Your name only, without address, appears in the College list; you should, therefore, at once write to Mr. Trimmer, the Secretary, who will rectify the mistake.

Erratum.—P. 609, second column, line 56, for "Syme," read "Lister of Glasgow."

GRIFFIN TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In consequence of the paucity of answers in favour thereof, the Committee of the above fund have given up the idea of a banquet to Mr. Griffin. As doubtless the College election will bring some Medical men to London, it is intended to make the presentation of the testimonial on July 5th proximo, unless the Poor Law Board should fix some other day to receive Mr. Griffin's deputation. In this latter case the testimonial will be given him immediately after the interview with the President. The time and place will be duly notified by printed circular. The testimonial is now on view at the manufacturers', Messrs. Mappin and Webb, 71 and 72, Cornhill. Intending subscribers, who have not forwarded me either their subscriptions or their *cartes de visite*, will obligingly do so without delay.

I am, &c.,

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, June 13, 1866.

DR. MACLOUGHLIN ON "SYPHILIS"?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Medical Committee, appointed on my suggestion by the Admiralty and by the War Office, to study and to report if there is a syphilitic virus, and if so, what are its pathognomic symptoms on the genitals and on any other part of the body, and what is its rational plan of Medical treatment—have published the evidence of the Medical witnesses which they have examined, and they have also published the conclusions to which they have arrived. But they have not published the treatment which they recommend for this so-called syphilitic disease. Therefore, in the interest of the public and in the interest of Medical science, permit me, through the *Medical Times and Gazette*, to request the Medical Profession will be pleased to suspend their judgment on the above Report until the Committee have published the plan of Medical treatment they have decided to recommend, and until an answer is published to the above Report.

I am, &c.,

DAVID MACLOUGHLIN, M.D.,
Member of the Legion of Honour.

36, Bruton-street, Berkeley-square, W., June 9.

ON THE TREATMENT OF WHOOPING-COUGH BY THE TOPICAL APPLICATION OF NITRATE OF SILVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It is not my intention to enter into the pathology of whooping cough, but merely to point out how this troublesome affection may speedily be relieved by simple means. From the uncertain success attending the use of the various remedies, I was induced to try the topical application of a solution of nitrate of silver, ℈j., ℈ij., ad. ʒi., to the larynx, (which I believe was first recommended by Dr. E. Watson, of Glasgow), together with the administration of a mixture of chloric ether and morphia in doses proportionate to the age of the patient. The relief obtained from this mode of treatment after the failure of other means has induced me to continue its use, and from the experience of upwards of fifty cases

during the last five years, I have every reason to be satisfied with it. The plan I adopt is that recommended by Dr. Horace Green, of New York, in follicular disease of the pharyngo-laryngeal membrane, and described by Dr. J. H. Bennett ("Principles and Practice of Medicine," second edition, page 591). The effect is, in the majority of cases, most marked; the peculiar spasmodic cough is changed in a few days, and frequently in the course of a week the patient is well.

I am, &c., FRED. H. MORRIS, M.D.

Cheltenham, June 5th, 1866.

A WHALLEY TO THE RESCUE.

Ho! Whalley and Newdegate rise and give aid,
And your efforts in Parliament throw into shade,
To the Medical Council be up and away,
For it's fast coming under Dominican sway!

A LAY OF THE FIRST EXAMINATION.

Scene: Edinburgh. Time: the present.

With Ellis and Quain I've dissected,
And worked at my Holden at night,
Until, like a vessel injected,
My brain with my learning is tight.
And what with extensor and flexor,
Nerves, arteries, muscles, and veins,
The subject's the greatest perplexer
To all but the mightiest brains.

The muscles attempting to state, I
Just mix them all up in my mind,
I make the levator palati
Arise from the coccyx behind;
And then, as a crowning disaster,
When asked by a tutor last week,
I said that of course the cremaster
Contracted the lips and the cheek.

The nerves are, excuse me, infernal;
The brachial plexus I trace,
And cut the cutaneous external,
Dissecting at too great a pace—
And on through the body, each plexus
Gets harder and harder to me,
Oh, why were they classed so to vex us
Poor fellows who seek an M.D?

I'm yearning for chemical knowledge,
For oxides, and nitrates, and all;
They don't want such stuff for the College,
And little will do for the Hall.
Work o'er, as a gentle corrective,
At Rutherford's(a) classes I show
Affinity truly elective
For whisky mixed well with HO.

I'm sure I've made due preparation
In physiological lore,
I've read up the nerves of sensation
Till Bennett can teach me no more.
While still in my dreams I am hearing
My lectures again and again,
And Bennett at Virchow is sneering
With Leucocythæmic disdain.

When strolling with some pretty cousin,
Whose eyes are as bright as each flower,
And gathering plants by the dozen,
Botanical knowledge is power.
And yet, to be faithful recorder,
At eight in the morning I find
The name of each natural order
A very unnatural "grind."

When calmly enjoying the oyster,
Fresh come from its Newhaven home,
And making each morsel the moister
With "half-and-half," headed with foam,
To think it's called "gasteropodic,"
The bivalve I lately enjoyed,
Will make a sensation spasmodic
Arise in the crico-thyroid.

And oh, were my troubles but over,
And oh, was I once an M.D.,
I'd feel myself fairly "in clover,"
And rush to the far-foaming sea.
And ah, how Belinda would meet me,
With smiles far too witching to last,
And how my old comrades would greet me,
Were passing a thing of the past.

CIVIS ACADEMIÆ EDINBURGENSIS.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged by your allowing me, through the medium of your journal, to inform the Poor-law Medical officers, and I may say the Profession generally, for it concerns all, that the Vaccination Bill has passed through the Select Committee, and is again before the House of Commons.

In my communications to the Select Committee I suggested alterations in the title and preamble, and in nineteen clauses, or proposed to substitute nine new clauses. On examining the Bill, I find the title and preamble still stand without Wales being mentioned, but twenty three clauses have been altered, verbally and otherwise, and one clause (5) added; the four forms in the schedule have also verbal alterations. Allow me here to state that all my suggestions have not been adopted. With due appreciation of the value of the efforts made by the meeting held at the Freemasons' Tavern on April 10, and by private individuals, still it appears to me that the efforts made by the Poor-law Medical Reform Association have had considerable influence—First, in actually stopping the Bill, when about to go into Committee of the House of Commons, by means of a pamphlet forwarded to each member and by private communications, and secondly, by suggestions made to the Select Committee itself; but that influence could never have been brought to bear had not money been subscribed to pay the expenses of printing, etc. I have no hesitation in saying that the amendments now proposed in the Vaccination Bill in a pecuniary point of view will amply repay the members of the Poor-law Medical Reform Association for all the money they have subscribed during the last ten years, and I hope will stimulate the entire body of Poor-law Medical officers to subscribe to the funds of the Association, in order to enable it to prosecute with vigour the changes sought in the general administration of the Medical relief of the poor. The seed has been sown, the eyes of the public have been opened, a large body of the House of Commons now listen to us, and the time cannot be far distant when very considerable changes must be made in the Medical relief of the poor. Clauses 5 and 6 in the amended Vaccination Bill (quoted below) will show the pecuniary changes proposed on and after January 1, 1867.

The public vaccinators are to receive not less than 1s. 6d. for each successful primary vaccination performed in a workhouse; this is a gain, as at present no fee is legally payable. The 1s. 6d. fee now paid for vaccinations performed at a station within one mile of the residence of the Medical officer is not increased, but 6d. is added to each fee for all vaccinations performed at a station over one mile and under two miles distant, thus making the fee 2s. Beyond two miles the fee which is now 2s. 6d. is to be not less than 3s. In addition to these payments, it is proposed by Clause 5 to pay 1s. extra for each child whom the vaccinator has successfully vaccinated; but that will depend on the "number and quality" of the vaccinations, on the "reports" made to the Lords of H.M. Council, and the time to which the "award" relates. This clause is ambiguous, but on inquiry I find this payment is intended to depend upon the manner in which the vaccination is carried out—that is, if done in accordance with the approval of the Inspectors. My correspondent says, "If you glance at any of the Inspectors' reports you will see on what system they go in judging the vaccination of a place, and by their Reports the Medical Officer of the Privy Council would be guided to recommend the payments in question. They would be additional payments, made on the principle of payment for results. I hope it will be of general benefit to the public vaccinator, whose interests will be identical with those of the public." The revaccination of those previously successfully vaccinated will be under special arrangements, and only paid for at two-thirds of the fee of successful primary vaccination. I regret we have not obtained more, but if we do our duty well, and Clause 5 be fairly carried out, the Bill will be a gain to us of some thousands per annum, and I feel sure place the public vaccination of this country on a more satisfactory footing. That the Bill might have been more efficiently amended cannot admit of a doubt, but official influence was too strong for us; and a satirical private print, forwarded to me by a member of the Select Committee (printed by Standidge and Co.—worth looking at) representing Poor-law vaccinators receiving £200,000 a year, the Registrars £20,000 a year, Simon, Bruce, and Co. £10,000 a year, etc. etc., had its weight in preventing our receiving that redress which we desired. I have again addressed the Poor-law Board, asking that a deputation of Poor-law Medical officers may be permitted to wait upon them on July 5th, which I trust may be granted.

I am, &c. RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, June 9, 1866.

"*Clause* 5.—On reports made to the Lords of her Majesty's Council with regard to the number and quality of the vaccinations performed in the several vaccination districts of England, or any of them, the said Lords may from time to time, out of monies provided by Parliament, and under regulations to be approved by the Lords Commissioners of her Majesty's Treasury, authorise to be paid to any public vaccinators in addition to the payments received by them from guardians or overseers, gratuities, not exceeding in any case the rate of 1s. for each child whom the vaccinator has successfully vaccinated during the time to which the award of the said Lords of the Council relates."

"*Clause* 6.—Every such contract for vaccination shall provide for payment in respect only of the successful vaccination of persons, and so that the rate of payment for primary vaccination shall be not less than the following—that is to say, for every such vaccination done at an appointed station situated at or within one mile from the residence of the vaccinator or in the workhouse of the union or parish, not less than one shilling and sixpence, and for every such vaccination done at any station over one mile and under two miles distant from his residence, not less than two shillings, and for every such vaccination done at any station over two miles distant from his residence, not less than three shillings: such distance being measured according to the nearest public carriage road."

THE UNITED ENGLISH AND SCOTTISH LIFE ASSURANCE COMPANY AND THEIR MODE OF APPOINTING MEDICAL REFEREES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I enclose the following for your inspection, and, if of sufficient importance, for insertion in your journal. Having had during the last few years similar applications from insurance offices, I think it is quite time to call attention to such a system of appointing referees. I wish to refer particularly to the following:—viz., "Referee to insure in the office for not less than £600!" thus taking "greater interest in its welfare!" and the offer to have "your name as the local referee in all the advertisements and circulars of the company!!"

I am, &c., FRED. W. P. JAGO.

3, St. Andrew's-terrace, Plymouth.

(Copy.)

"5, Union-terrace, Plymouth, June 6, 1866.

"Sir,—I have been requested by the directors of the United English and Scottish Life Assurance Company to ask you if you would feel inclined to act as their Medical referee for these towns and their neighbourhood, with a remuneration fee of one guinea for each examination. The directors have laid it down as a rule that the Medical gentlemen of the Company insure their own lives or the life of some one of their family with the same, for at least £600, so as to make them constituents of the Company, and therefore taking greater interest in its welfare. Should you entertain this proposal, please let me have your decision at your earliest convenience, when I will, if favourable, at once report to the directors, and insert your name as the local referee in all the advertisements and circulars of the Company. Hoping to hear soon from you, I have the honour to be, Sir, your obedient servant,

"FREDERICK SCHADE.

"To F. W. Jago, Esq., Surgeon, 2, Frankfort-street, Plymouth."

(a) *Taverna Edinburgensis.*

"No. 3, St. Andrew's-terrace, Plymouth, June 7, 1866.

"Sir,—I have to acknowledge the receipt of your letter of yesterday, asking me to become the Medical referee for the United English and Scottish Life Assurance Company, on condition that I first insure in the office for £600. It makes a very material difference to any one accepting your offer whether your proposal has been made to him only as a *bonâ fide* referee, or whether a similar note has been sent to other Medical men in Plymouth. Before replying to you I shall feel obliged by an explanation.—I am, Sir, yours obediently, "FRED. W. P. JAGO.

"Mr. F. Schade, 5, Union-terrace, Plymouth."

The following is the reply, headed conf. (confidential):—

"Sir,—In acknowledging receipt of your letter of the 7th instant, I beg to state that I have sent a letter similar to the one addressed to you to some other Medical gentlemen in Plymouth, as the Company requires *two* referees. Should you object to this, I am sorry, on the Company's account, that it will lose your valuable assistance in promoting its success.

"Awaiting your final decision, I am, Sir, your obedient servant,

"FREDERICK SCHADE.

"To Mr. Fred. W. P. Jago, Surgeon, 3, St. Andrew's-terrace, Plymouth."

"3, St. Andrew's-terrace, Plymouth, June 7, 1866.

"Sir,—Having had applications from others on previous occasions to be appointed referee, *provided I insured my own life*, was the reason of my inquiry as to the real nature of your letter to me.

"As was suspected, the chief aim seems to be to obtain *insurances*, and not so much the Medical referees, by sending *circulars* to various Medical men in this town. I cannot consider your letter as 'confidential,' being convinced that such applications from insurance offices should be freely and openly discussed and exposed.

"The method adopted is an ingenious one for extending business, and I am happy to find that that of the United English and Scottish Life Assurance Company requires two Medical referees for Plymouth. I must remind you that your first letter speaks only of one, as it says that if I will insure my life you will 'at once' report to the directors, and insert my name as *the* local referee 'in all the advertisements and circulars of the Company!' How tempting! This brilliant prospect is best seen at a distance, and I beg therefore to decline insuring my life for the sake of a few fees. I am, Sir, yours truly,

"Mr. F. Schade. FRED. W. P. JAGO."

"5, Union-terrace, Plymouth, June 7.

"SIR,—In reply to your note of to-day, I beg to express my astonishment at the way you want to turn matters, and to make it appear now as if I only had written to you for the sake of the assurance, and not to secure you as a Medical referee to the Company.

"The condition I mentioned to you is fixed by the Directors, and therefore I have only to act accordingly, but you are certainly very wrong in your ideas on this subject—I must repudiate them altogether; at any rate, you have no occasion to express yourself in such offending language, because you have nothing to complain of. If you have no intention to insure your life, leave it alone, but don't offend the agent of the Company, who is not responsible for the instructions received from the Directors.

"You say my first letter only speaks of one referee, but this is not the fact. In addressing you as a single person, I must speak in the singular and not in the plural; insert your name as the local referee, and if you like, I can show you the letters received from the managing director of the Company. Expressing my regret at your misrepresenting my intention in this way, I am, Sir, your obedient servant,

"Mr. F. W. P. Jago, "FREDERICK SCHADE.

"3, St. Andrew's-terrace, Plymouth."

Here the correspondence ends, and I leave it to your readers to judge in a matter of some importance to Medical men. The agent has applied to himself what only concerns him as an agent, and I don't think I have misrepresented or misunderstood anything. Nor should the office ask any one to be *the* Medical referee on condition that he insure for not less than £600, when it turns out that others here (as confessed by the agent and from my own inquiries) have had similar letters sent to them at the same time. Who would be *the* Medical referee if *all* accepted the offer (as they might) on the Company's terms?

Being interested in the office because insured therein, is a plausible, but bad argument, and degrading as used towards the Profession. I am simple enough to think that a disinterested Medical referee is likely to be more impartial.

That about publishing the name of the referee reminds one of the rattle in the tail of the rattlesnake—at all events, it is what "any (Medical) fellow *can* understand." I am, &c.,

FRED. W. P. JAGO, M.B. Lond.

ERECT VISION FROM INVERTED IMAGE ON THE RETINA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Before we offer our explanation on this much-disputed subject, we shall speak generally of the structure of the retina. This consists principally of two distinct portions: first, the expansion of the optic nerve in front; and second, a peculiar apparatus behind, consisting of what are generally called the "cones and rods" and the "granules and vesicles," the latter bodies being in front of the former. The relative position of the nerve expansion and the hind apparatus of the retina has long been misunderstood; but lately it has been finally decided as above mentioned.

It has also been made known to physiologists that the two portions of the retina are as distinct in function as in structure. The anterior portion: the expansion of the optic nerve is not at all concerned in receiving premarily the stimulus of light. This is evident from the fact that the optic disc, the point of entrance of the optic nerve, where there is none of that hind apparatus above described, is most deficient in the power of receiving visual impression, while the "yellow spot," where no other structure is present except the "cones," is the most sensible portion of the entire retina. From the above, it follows unequivocally that the stimulus of light cannot act primarily on the optic nerve expansion, but only on the apparatus behind it; and, therefore, the image of the object that is seen is not formed upon it, but upon that apparatus; consequently the inverted images of objects are behind the expansion of the optic nerve, and not upon it, nor in front of it. Now, it can be easily understood that the hind apparatus upon which the inverted images are depicted may so act upon the expansion of the optic nerve as to produce impression of erect images upon it, which is then communicated to the percipient principle by the nerve in that condition.

The explanation of this phenomenon which has been given by Drs. Muller and Volkman is inconsistent with that pervading character of all Nature's plans of work, which is absolute truthfulness and simplicity, while that of Dr. Carpenter is, for other reasons, alike unnatural. But we shall examine these explanations minutely.

On the Explanations of Erect Vision from Inverted Image on the Retina.—It is hardly possible, neither necessary, to go over all of the multitudinous explanations which have ever been proposed of this singular phenomenon. I shall, therefore, select only three which have been recently put forth, and are more or less accepted by the public, and shall consider them *seriatim*.

One of these, held by Sir D. Brewster and enunciated by him as follows:—"The lines of visible direction necessarily cross each other at the centre of visible direction, so that those from the lower part of the image go to the upper part of the object, and those from the upper part of the image to the lower part of the objects, . . . so that any inverted image necessarily produces an erect object.—"*Optics," by Sir D. Brewster: Cause of Erect Vision from an Inverted Image.*

Everybody will see this explanation distinctly means that the percipient principlo arrives at the knowledge of the figures of an object, directly from the object itself, and is unaffected by its image on "the recipient portion"(a) of the retina, whatever its condition may be, inverted or erect; and the explanation will hold good if such were the case; but who will say that such is the fact? On the other hand, none would deny that all the knowledge which the percipient principle derives of an object from vision merely, is obtained only from its image on the retinal recipient portion, quite unaffected by the object itself. But this explanation implies much more than this; for what is meant by the "lines of visible direction?" They are certainly not the same as the rays of light thrown by an object upon the retina, for the passage of the latter is described as quite contrary to that of the former; but we are told that these so-called "lines of visible direction" procced from the part of the "recipient apparatus" affected by the rays of light in their track and crossing each other as they do. Now, we may ask what are these lines of visible direction? As far as we are aware, they are nothing visible or tangible, and, in fact, do not belong to any portion of the material apparatus of vision. They may belong to the part which the percipient principle takes in the act of vision. At least, this view of them has been taken by Dr. Carpenter, in his Physiology, par. 610. He says, "We immediately refer the cause of the excitation of any spot of the retina by a luminous impression to an objective source in the 'line of direction,' which passes from that spot through the centre of direction." This hypothesis is virtually the same as the "mental projection" of Professor Muller, only expressed in a complicated manner by adding the phrase "line of direction." It means nothing more or less than that the mind, instead of deriving the knowledge of an object from its image on the recipient apparatus, which is inverted, knows directly the object itself, as it is external to ourselves. Every one will see that, however positively the upholders of the explanation under consideration may deny this bare nature of their hypothesis, yet this is really what they mean. Obviously preposterous as this hypothesis is, it is yet held by some; I shall, therefore, mention the objections which are opposed to it.

First. We are conscious of having no such "lines of visible direction" or "projection."

Second. It places vision external to the mind at the external object, for it must be beyond the point where the so-called "lines of visible direction" cross each other in order to be erect.

Third. In case of this hypothesis being true, the mind will have the knowledge of distance of objects, which is the same as the length of the lines of visible direction from mere vision, but we know we have it not.

I may, therefore, draw the conclusion that no such thing as "lines of visible direction" exist, and that erect vision from inverted image on the recipient apparatus is no effort of the mind.

The second explanation is held by Dr. Carpenter, and expressed by him as follows:—"The visual perception is obviously not a mere transfer of the sensorial impression, but is a mental state excited by it, and, therefore, related to it as an effect to its cause; and we know no reason why it should be less natural for the retinal picture to suggest to the mind the notion of erect position than for it to have the contrary effect."—*Dr. Carpenter's Physiology, par.* 610.

Before we examine this hypothesis more minutely, we shall make a remark which is obvious from a mere superficial reading of the above statement—namely, that even as explained and demanded by the author, the chance of erect or inverted vision from the inverted picture in the eyes is evenly divided on either side; that is, there is as much probability at best for the hypothesis of erect as of inverted vision. But every one who has an adequate sense of the precision and determination of purpose with which Nature works, will see that she will hardly leave such a serious point at issue to be decided by chance; but this is merely to rouse suspicion, and lead us to inquire more diligently into the real state of things in this explanation.

It is expressly told by the author, a few lines preceding the quotation, that in vision "our consciousness is not impressed with the discordant image on the retina." In fact, he says that the retinal picture has nothing more to do in the act of vision than to excite a mental state. But every one is aware of the miserable position of this theory; for although it enables the author to explain away the difficulty of reconciling the discrepancy in position between the retinal and visual picture, it creates another difficulty, which is infinitely more grave than the one it obviates; for, it leaves to account for the fact, why do we perceive some definite, and fixed, and invariable image or figure at all in vision, since the retinal image does only but excite a (any) mental state? Then again, on pricking the optic nerve with a pin we excite a mental state, but we do not see a definite figure, but only an indefinite mass of light. Can there be a more clear demonstration of the fact that the retinal picture is essential to the vision of objects?

No doubt Dr. Carpenter has been misled by the experiments of Dr. Serre. His experiments certainly prove that when pressure is made by the point of the finger, or by any other circular surface, upon a part of the globe, over the interior of which the retina is continuous, the spectrum or phosphene (as it is termed by Dr. Serre) is also circular, and the compressing body, on the other hand, be square at its extremity, the "phosphene" is also square; and if it be triangular, the phosphene is triangular too. This only proves that the recipient apparatus is susceptible of being impressed with images of objects, by other physical stimulus besides light, as pressure, when made over it. But it by no means proves that the retinal picture is not the cause of the visual image. Dr. Carpenter is no doubt aware of these imperfections in his hypothesis,

(a) In order to avoid confusion, the hind apparatus of the retina, on which images of objects are formed, is called the "recipient portion" of the retina.

and therefore he has supplemented it with the preceding explanation of Sir D. Brewster.

Third Explanation, held by Drs. Müller and Volkmann. I mention it only to say that it requires no long serious attempt at refutation, it being opposed to the very first principles which are the basis of all our knowledge. It has long been abandoned, after it had served its purpose in the absence of a better one.

Before we leave this subject, we shall explain the cause of our "sense of direction" in vision. We have proved before that there is no such thing as "lines of visible direction." Notwithstanding, we can easily explain the cause of "sense of direction" without them. The "cones and rods" which we have shown are the apparatus for the primary reception of light, are arranged with a certain degree of obliquity, so as to be inclined to a point in the retina. This point is the "centre of visual direction." This phrase is, of course, here used in a sense quite different from that in which it is used by the upholders of the theory of "lines of visible direction." We use it to mean the point in the retina towards which the "cones and rods" are inclined, and which may be its centre or a little to one or the other side of it. The rays of light thrown by an object upon the recipient apparatus, the "cones and rods," make varying angles with this centre of visual direction; and these angles are the only index to the direction of external objects.

For the benefit of readers, we shall add the following summary of the whole discussion:—

1. The retina consists of two distinct structures, quite different in function from each other: the one anterior, consisting of the expansion of the optic nerve, and the other posterior, consisting of what are called "cones and rods" and "granules and vesicles."

2. The posterior portion only is susceptible of being acted upon by physical stimuli, which produce images of objects upon it, but in an inverted position.

3. The anterior portion, the expansion of the optic nerve, is susceptible of being acted upon only by the posterior apparatus, which is capable of inducing that condition in it which produces vision.

4. All our knowledge of the external objects which we derive from mere vision, is obtained from their images on the recipient apparatus of the retina, and therefore such images are essential to vision.

5. The change of position of visual image from inverted to erect is effected by the action of the recipient apparatus upon the expansion of the optic nerve.

6. Visual direction does not depend upon the so-called "lines of visual direction," which have no existence in nature, but upon the angles which rays of light make with the centre of visual direction, which we have explained, is either the central point of the recipient apparatus, or any other point in it, to which the "rods and cones" are inclined.

7. It is a fact in metaphysics that from mere sight we can have no knowledge of distance; and second, that so entirely is our knowledge of external objects from mere vision dependent upon their retinal images, that we could not know from mere vision whether the objects we perceive in vision existed external to ourselves or not; that is, we could have no idea of the external world from mere vision.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·878 in. The atmospheric pressure declined to 29·66 in. on Sunday, and rose to 30·11 in. on Friday.

The general direction of the wind was S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 56·2°.

APPOINTMENTS FOR THE WEEK.

June 16. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

18. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

19. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.
ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.

20. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

21. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

22. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

CLINICAL LECTURE ON A CASE OF LITHOTOMY.

By JOHN ADAMS, F.R.C.S., M.R.C.S.,
Surgeon to the London Hospital.

Gentlemen,—I take the opportunity to direct your attention to the case of a boy of about 9 years of age on whom I operated some ten days ago, and who is now able to pass his water *per urethram*, having progressed very satisfactorily from the time of the operation; and I call your attention to the case on account of its extreme simplicity, and because I think there is usually too much anxiety expressed in such cases. The operation of lithotomy is so enveloped in supposed difficulties, and is attended with so many imaginary risks, that by some it is altogether declined. I think this is quite wrong, and I am firmly impressed with the idea that if a few simple circumstances are attended to, no Surgeon with such a knowledge of anatomy as every Surgeon ought to possess need decline the operation on the score of its difficulties. Let us now consider the case before us. A little boy, aged 8 or 9, was brought to the Hospital about a fortnight ago, complaining of a frequent desire to make water, and micturition was always accompanied by great pain, which was more severe after the passing of the water. I suspected that there was a stone in the bladder, and I satisfied myself that he had no phymosis, which, you are aware, induces by reflex irritation most of the symptoms of stone. With the steel sound I felt the stone at once, and admitted him into the Hospital, directing that a few grains of carbonate of soda should be given him thrice daily, and that he should take some castor oil occasionally, and that he should be kept in bed. The soda has a soothing effect on the neck of the bladder, which is the most sensitive part of the viscus, and I think in this way it does good—indeed, so powerful is its influence in this respect that it often happens that all the symptoms of stone vanish under its use, and the patient is reluctant to allow any further interference in his case.

In this little boy some mitigation of his sufferings occurred; but, being certain that a stone was in the bladder, I cut him, and removed a stone about the size of a filbert, and composed of the lithate of ammonia.

You will probably have observed that no water was injected into the bladder, as I felt sure that some urine still remained, and I was not solicitous on that point, and that, when he was tied up (the necessity for which in children under chloroform is by no means apparent), I passed the staff, and, after a moderately-sized opening made deeply into the ischio-rectal space, the membraneous part of the urethra was opened, and the incision into the neck of the bladder was made with Blizard's knife carried along the groove of the staff. I followed the instrument with my left forefinger into the bladder, and felt the stone and removed it with the forceps. If I had had any doubt about the entry of my finger into the bladder, which may by possibility happen in the adult, where there is a deep perinæum, I should not have removed the staff, but I should have carried a blunt gorget along its groove as far as it would pass, and run the forceps along it until I had satisfied myself that I had felt the stone with the forceps. This is never requisite in a child, for, although the bladder is not so near the perinæum as a person ignorant of anatomy might suppose, the interior of the bladder can always be reached by the Surgeon's forefinger; at any rate, I advise you never to introduce your forceps until you are certain that you are in the bladder, for this is a fatal error, and, if persisted in, it will lead most assuredly to the destruction of your patient. It would be infinitely better to desist at once from the operation, however unpleasant this may be, than to be groping in the dark and trying to find the stone, which of course, under such circumstances, you cannot do.

In this little boy there was some bleeding, so I secured one artery with a ligature, and I passed a piece of lint deeply into the wound to be retained two hours only, which stopped all bleeding, and I sent him to bed. He has had no bad symptom. I cannot help thinking that patients are often damaged by too much solicitude; they are made to run the gauntlet of so much meddlesome interference that they very often don't get fair play. Thus a patient is sounded, and a stone is felt, and he is brought into the theatre for operation, when the Surgeon passes the sound and first feels the stone indistinctly, and then it eludes the sound altogether; then the unlucky patient is poked about first by one and then by others, still the stone is unperceived. Then the bladder is injected, and the sounding takes place again, and at last the patient is sent to bed, and he dies of peritonitis, or the bladder becomes so much inflamed that the Surgeon cannot cut him, and he sinks under his disease. Gentlemen, having felt the stone once distinctly, and once again, however indistinctly, just prior to the operation, don't ask all the bystanders to annoy your patient by turning the sound right and left, pushing it backwards and dragging it forwards, first with this sound and then with that, but act upon your own conviction, and proceed to cut, and you will not be disappointed. You see, therefore, that patients may die without the operation, and I remember Mr. Headington, formerly a Surgeon of this Hospital, used to relate the case of a child who died after rough sounding, and whose death was attributed to the inflammation of the bladder, in consequence of the stone having been broken up into many fragments, an explanation which it is difficult to reconcile with our present knowledge of the effects of stone-breaking in lithotrity, which is usually followed by a diminution of symptoms; but the child died unoperated on. All Surgeons of experience counsel a free external incision and a limited internal incision through the neck of the bladder, and the advice is sound and quite in accordance with experience. The opening into this boy's bladder was only sufficient to allow the forefinger to pass, but the stone was small, about the size of a filbert, and was readily extracted. In the summer I cut a man in whom the stone weighed seven ounces, and in this case the opening into the bladder was no larger than what I have stated, nevertheless the stone was extracted with comparative facility, and the patient recovered, the external opening being of very large size. In such cases the neck of the bladder and prostate are most probably lacerated, although they both yield considerably. From my own experience, I am sure this is a very important point, and I am certain that death is often the result of a neglect of it. I remember to have lost two patients from inattention to this, and they have made a forcible impression on my mind. I do not boast of any extraordinary experience or success, but most of the cases I have operated on have been children, and these generally do well if the operation is performed without violence; but in the one instance alluded to I thought I could extract the stone with my finger, and foolishly enlarged the opening I had made into the bladder by cutting; the consequence was this—the opening into the bladder never healed, and the child died after a lingering illness, worn out by abscesses between the rectum and bladder, which I could not cure, although I freely laid them open.

The other case was that of an adult, on whom I operated four years since, and removed without difficulty four calculi of moderate size; but the man was sent to me again, with symptoms of stone, two years afterwards, and I cut him again, expecting no difficulty in the case. I removed through a limited incision three moderate sized stones, but I found a very large one left behind, and, as I could not get this away easily, I most reluctantly enlarged the opening into the bladder and got the stone out. This man did well for some time, but he had abscesses about the bladder and rectum, and pelvic cellulitis and inflamed hips and buttocks; and, although he left the Hospital, and went to his native county, Norfolk, in a fair state of health, with the opening into his bladder nearly healed, he eventually sank, as I understand. I attribute this patient's death to bad cutting, and will never again enlarge the incision originally made into the neck of the bladder, however much I may be urged to do so. I am quite convinced that the safety of the patient much depends on the nature of your incision into the bladder, and that if you can't get a stone out where the incision is small, you can do no good by enlarging it by cutting it. The stone, if of large size, when drawn through the opening dilates it, and probably enlarges it by laceration, but this is better than cutting. The only exception that I can see to this rule is where the prostate is large and rigid, and where it would be impossible to enlarge the opening without cutting.

When I finished the operation I sent the patient to bed, but I did not tie the legs together; and why? Because I not only thought it unnecessary, but positively injurious. I remember well that, formerly the legs of a patient after lithotomy were always tied closely together, and I have ever seen the buttocks

strapped together with adhesive plaster. Mark well what may happen if this be done. When the Surgeon comes down four or five hours afterwards to see the patient he finds him in great distress, with a quick pulse, possibly vomiting, and complaining of unusual pain in the belly, he finds also that no urine has passed by the wound; he atributes this condition to the blocking up of the wound by coagula, and he therefore oils his forefinger, passes it through the wound into the bladder, breaks down the coagula and thus liberates the pent-up urine, the cause of all the mischief, and the patient is relieved at once. You may ask, what are the best instruments to use in lithotomy? and the answer is not easy because there are so many in use and there is such variety according to the ideas of different Surgeons, and what is safe in one man's hands may not be so in another's; although I am quite of opinion that if you know your anatomy, and have sufficient confidence in this knowledge, you may use what instrument you please. I have never used any other means of cutting than the lateral operation, in which the incision into the bladder has been made with Blizard's knife. This is a beak knife, and runs readily along the groove of the staff into the bladder. Some use the gorget, but this instrument is going out of fashion. Others use the rectangular staff of Buchanan; this, I confess, I do not like, but it appears very safe. Some use a straight staff and a single scalpel to make both the external incision and the lateral cut into the bladder; the only inconvenience which I see in these instruments is that the knife has more than once been made to transfix the posterior part of the bladder (a fatal error); and, lastly, you may employ the mesian incision, as you have often seen here. This last is a very neat and ready method of reaching the bladder, and in children it can be done with great safety. I do not follow it because it is not worth while to change a plan I have always pursued unless I find that success can be attained much more readily by any new method. But you, as young men and experienced anatomists, may select that plan which you think advisable, being assured that to cut well for stone is by no means so difficult as to perform many other operations which are usually regarded as of far less magnitude. Besides which you have the opportunity of testing at this and the other metropolitan Hospitals the success of every variety of operation for the removal of stone from the bladder.

ORIGINAL COMMUNICATIONS.

OBSERVATIONS ON THE

"GRANULAR MATTER" AND "COMPLEX ALBUMINOID MATTER"

REFERRED TO IN SECTION II. OF THE THIRD REPORT OF THE COMMISSION APPOINTED TO INQUIRE INTO THE ORIGIN AND NATURE, ETC., OF THE CATTLE PLAGUE.

By LIONEL S. BEALE, M.B., F.R.S.

"And now I seem to hear Galen admonishing us, that we should agree about the things, and not dispute greatly about the words."

In this paper I shall venture to offer some observations upon part of Section 2 of the Commissioners' Report, in which the "nature of the disease" is considered.

It is not to have been expected that the scientific members of the Commission should have carefully read through every line of the lengthy reports they have received, or that they should have mastered every minute detail communicated to them; but, on the other hand, they must have acquainted themselves with the general tenor of the observations contained in the reports to which they have referred, and therefore any opinions, statements, or comments in their third report can hardly have been made lightly or without due deliberation.

After stating that portions of infected blood-textures and mucous discharges have been examined by me with the aid of the highest magnifying powers that exist, the Commissioners state what I have *not* found (a). "He has found no definitely *formed (!)* substance that can *certainly (!)* be said to be the cause of the cattle plague." He finds "no *new* appearance *decidedly (!)* characteristic of the disease."

And this, according to the Commissioners, is what I have found,—*granular matter!* "He finds a great increase of granular matter (b)." This really seems to be all that the Commissioners have been able to extract from my report, and they give due prominence to it. If not all, certainly that which, according to them, appeared most worthy of the attention of the public, and therefore I conclude, in their opinion, the most original and perhaps the most intelligible portion of my work. The next sentence in the paragraph, at the beginning of which I regret to say my name figures, is the following:—

"Possibly this *granular matter* may be the poison; possibly, again, *it* may exist in particles of definite form, and of a size still smaller than $\frac{1}{100000}$th of an inch, but which might be perceived if it were possible to construct instruments of still higher magnifying powers; more probably it is matter of a kind which *is and will always be undiscoverable by the microscope.*"

Here we have the following propositions:—First, that *this* granular matter (not defined by the Commissioners) *may be* the poison; secondly, that the poison *may* exist in particles of definite form smaller than the $\frac{1}{100000}$th of an inch, and that these particles *might be (!)* detected if it were *possible (!)* to construct microscopes of still higher magnifying powers than the $\frac{1}{60}$th; thirdly, that it is more probable that the poison is matter of a kind which *is* and will *always be (!) undiscoverable* by the microscope. The Commissioners ought surely to have stated to the public and to scientific men the circumstances which have led them to conclude that the matter in question will *always* be undiscoverable by magnifying powers which have not yet been constructed.

I think there is no doubt that any person of ordinary intelligence who read through the paragraph would draw the following inferences:—That Dr. Beale had examined blood textures, etc., with the highest magnifying powers made, and had found granular matter; but that although this granular matter might be the poison, it probably was not, and seeing that granular matter is very widely diffused, of very varied character, composition, and properties, entering into the composition of all kinds of dust, *débris*, and indefinite stuff, the general conclusion such a person would arrive at would not probably be very easily expressed, but might he not write it thus ·0.—?

The scientific members of this Commission have stated what in their opinion I have not found and what I have found in the course of the inquiry undertaken at their request. It is not for me to appeal against the extraordinary remarks they have considered it right to make. The value or worthlessness of this, as of every other scientific inquiry, will in time be determined by scientific men here and abroad.

Not content, however, with offering the very decided opinion that the poison will always be *undiscoverable* by the microscope, the failure of the instrument must be most decidedly expressed. The writer sternly remarks, in the commencement of another paragraph, "As the *microscope* fails us," but then, as if freed from painful restraint, adds exultingly—"we turn to *chemistry* to detect the substance!" The microscope has *failed* utterly, but chemistry, although perhaps a little behindhand, is advancing with rapid strides. The microscope will never detect the substance, but although chemistry has not as yet done so, no doubt she will by-and-by. "Chemistry" has not *hitherto* separated the poison;" "no chemical test *as yet* exists by which it can be recognised." Again, "Chemistry has *as yet* found in cattle plague *no complex albuminoid matter in a state of rapid chemical change capable of communicating its own action to the albumen of the serum of the blood and of the textures of cattle.*" Now, what can all this mean? Has any one who has studied this question, even cursorily, met with any facts to justify the opinion that there is the slightest probability that such poisons as those of cattle plague, or of typhus, scarlatina, small pox, etc., will ever be detected by chemical tests or separated by analysis? And yet if the expressions employed have any meaning at all, they surely point to the inference that chemistry will some day find in cattle plague a *complex albuminoid matter* in a state of rapid chemical change, capable of communicating its own action to the albumen of the serum of the blood; and not only so, but that it is in this purely chemical way, by this transference of rapid chemical change, that these poisons really do act upon the blood. It is most important that if any facts have been discovered in favour of this conclusion that they should be known, and the Commissioners

(a) The italics in all the extracts are my own.

(b) At first I was inclined to think that the word "granular" was a mere misprint for "germinal," as each word contains the same number of letters, but the context renders this most improbable.

ought certainly to have referred to the observations which have led them to use the expressions alluded to. I will ask pointedly if, in the course of this investigation, one single fact has been discovered which tends to render it probable that such poisons may be fairly regarded as complex albuminoid matters in a state of rapid chemical change and capable of communicating their own action to albumen and textures? I confess it will surprise me if in any one of the reports furnished to the Commissioners there is a trace of evidence or even an opinion expressed in favour of this old chemical doctrine of Liebig's, now almost entirely abandoned. In another place the Commissioners talk of "an *increased* zymotic action in the blood and in the textures." What, I would ask, is meant by zymotic action in the *textures?*

Such expressions ought not to be used carelessly and without consideration. If they astound some persons, they serve but to confuse and perplex simple-minded people who wish to learn, and are apt to excite ridicule and create prejudices against those who devote themselves to thorough scientific work. It is only fair that those who employ them should be pressed to define plainly what they mean. It would be too hard, perhaps, to inquire what textures of the body were the seat of zymotic action. Fancy zymosis of the fibrous, muscular, or nervous textures, or fermentation of the bones or brain; then as to the *increased* zymosis! But enough. It appears to me that the Commissioners have thus raised not only "*doubtful*" but very doubtful *points*, instead of marking out "briefly and plainly" the results of "observation and experiment."

CASE OF QUOTIDIAN AGUE; PAROXYSMS ARRESTED BY A SINGLE FULL DOSE OF QUININE.

WITH THERMOMETRIC OBSERVATIONS IN CO-RELATION WITH THE PULSE AND RESPIRATION.

By F. W. PAVY, M.D., F.R.S.,
Assistant-Physician and Lecturer on Physiology at Guy's Hospital.

THE *Medical Times and Gazette* has occupied a foremost position in England in advocating the employment of the thermometer as a means of affording information in disease. The following case forms an exemplification of the extent of variation of temperature that may be in the course of disease within a few hours produced, and of the precision with which thermal manifestations transpire. The case was reported and the observations carefully conducted, by my clinical clerk, Mr. Gill.

John C , aged 9, admitted April 28 into John Ward, under Dr. Pavy. Is a delicate, sallow-looking boy, belonging to the Shoreditch Union. Has been latterly at the schools at Brentwood, but two days ago was brought up to the Workhouse in Shoreditch, and on his father observing him to be ill, he was removed and brought for admission into Guy's Hospital.

At 6 p.m. on the day of admission his temperature was found to be 105·8°. Pulse and respiration rapid. Skin perspiring. Tongue clean in front, furred posteriorly. The chest sounds were normal. Urine, sp. gr. 1025; contained no albumen, but had deposited lithates. He had not much appetite, but a great craving for liquids. Bowels natural; spleen much enlarged. He was ordered for the present to take ʒj. of the saline mixture of the Guy's Pharmacopœia every six hours.

April 29.—11 a.m.: Temperature 98·4°, pulse 116, respiration 27. 6.30 p.m.: Temperature 105·4°, pulse 148, respiration 45. 8.15 p.m.: Temperature 101·8°, pulse 136, respiration 32.

30th.—11 a.m.: Temperature 98·6°, pulse 108, respiration 38. 6.45 p.m.: Temperature 104·4°, pulse 148, respiration 35. 9 p.m.: Temperature 101·4°, pulse 140, respiration 33.

May 1.—11 a.m.: Temperature 97·2°, pulse 106, respiration 28. 4 p.m.: Temperature 103·2°, pulse 145, respiration 31. Notwithstanding this elevation of temperature, the patient is shivering and complaining of feeling very cold. He is lying in bed, with his legs drawn up into a heap and his head under the bed clothes. Skin in a state of cutis anserina; great thirst, and distress of countenance. 5.15 p.m.: Temperature 104·1°, pulse 148, respiration 32; perspiring profusely; expression of distress has passed off. 7.35 p.m.: Temperature 101·8°, pulse 138, respiration 31; perspiration standing in drops on his face, and his shirt quite wet with it.

2nd.—10.30 a.m.: Temperature 98·4°, pulse 104, respiration 24. 1 30 p.m.: Temperature 99·5°, pulse 108, respiration 27. 3.20 p.m.: Temperature 105·4°, pulse 168, respiration 30; is beginning to shiver. 4.20 p.m.: Temperature 104 6°, pulse 148, respiration 28. 6 p.m.: Temperature 102·6°, pulse 142, respiration 34; sweating moderately.

3rd.—11 a.m.: Temperature 97·6°, pulse 104, respiration 26. 2 p.m.: Temperature 98·8°, pulse 120, respiration 34. 5 p.m.: Temperature 105·5°, pulse 168, respiration 34. 6.30 p.m.: Temperature 103·4°, pulse 140, respiration 35. 9 p.m.: Temperature 100°, pulse 116, respiration 30.

4th.—11.30 a.m.: Temperature 98·6°, pulse 108, respiration 27. 2.15 p.m.: Temperature 104°, pulse 148, respiration 40. 4.45 p.m.: Temperature 103·4, pulse 148, respiration 32. 8 p.m.: Temperature 100·2°, pulse 108, respiration 30.

5th.—10 a.m.: Temperature 97·4°, pulse 96, respiration 28. Up to this time the only medicine taken by the patient was the saline mixture prescribed on his admission. To-day, at 2 p.m., a pill, containing eight grains of quinine, was administered. 6 p.m.: Temperature 101·8°, pulse 148, respiration 30, feels pretty well. 8 p.m.: Temperature 100·1°, pulse 114, respiration 30. The day has passed through without any shivering fit.

6th.—10 a.m.: Temperature 98·2°, pulse 104, respiration 26. 8 p.m.: No further quinine was given, and the patient had no paroxysm to-day.

7th.—11 a.m.: Temperature 98·6°, pulse 96, respiration 26. 7 p.m.: Temperature 99·4°, pulse 100, respiration 28; no paroxysm.

8th.—No paroxysm; feels pretty well.

9th.—No paroxysm; temperature not reaching above 99°.

21st.—The patient has continued without any return of his ague, and without any medicine since the dose of quinine that was administered on the 5th. The spleen maintains its original size. The hypodermic employment of quinine was now ordered, a grain and a-half to be injected every day.

27th.—The injection has been repeated every day, but the spleen, the outline of which had been mapped out with ink, presents no perceptible diminution in size. To discontinue the injection, and to take three grains of quinine in solution three times a day.

June 2.—Spleen much smaller.

5th.—Spleen scarcely larger than its natural size. The boy appears well, and is quite free from any sign of ague.

35, Grosvenor-street, Grosvenor-square.

NOTES ON THE PHYSIOLOGY AND PATHOLOGY OF LANGUAGE.

REMARKS ON THOSE CASES OF DISEASE OF THE NERVOUS SYSTEM, IN WHICH DEFECT OF EXPRESSION IS THE MOST STRIKING SYMPTOM.

By J. HUGHLINGS JACKSON, M.D.,
Assistant-Physician to the London Hospital and to the Hospital for Epilepsy and Paralysis.

THERE are two modes of expression, one emotional and the other intellectual. By one we show what we feel and by the other we tell what we think. We may show that we are surprised, angry, grieved, or astonished by the former, but by the latter we give to another by signs (generally words) a notion of our thoughts on things. Now, in some cases of disease of the hemisphere (always, in my experience, near to and involving the left corpus striatum), intellectual expression is wanting, and emotional expression is well preserved. But we may make the statement broader still, at least in some cases. In some cases of defect of speech the patient seems to have lost much of his power to do anything he is told to do, even with those muscles that are not paralysed. Thus a patient will be unable to put out his tongue when we ask him, although he will use it well in semi-involuntary actions, *e.g.*, eating and swallowing. He will not make the particular grimace he is told to do, even when we make one for him to imitate. There is power in his muscles and in the centres for the co-ordination of muscular groups, but he—the whole man, or the "will"—cannot set them a-going. Such a patient may do a thing well at one time and not at another. In a few cases the patients do not do things so simple as moving the hand (*i.e.*, the non-paralysed hand) when they are told. This sort of difficulty generally, however, clears up long before power to talk returns. There is in health a great difference in the power individuals have to do things they are told to do—*e.g.*, to draw in their breath.

I wish here to urge on students who are studying cases in which defects of expression are the most striking symptoms, to work at them from healthy language and through slight

defects down to total inability to express anything in any way. Again, we must think of them as defects of mind, as well as of that part or phase of mind which enables us to think aloud in words. And we must never forget that in disease of the hemisphere we may have now and then, besides mental symptoms, amaurosis, epileptiform seizures, bilious vomiting, retracted belly, congestion of the lungs, constipation, and irregular pulse; for the brain is not only the "organ of mind," but it is the nervous system of the nervous system. It need scarcely be said that words, especially such as "mind," sensory, motor, &c., fetter our thoughts as well as define them.

Although the difference in the execution of voluntary and involuntary movements is very striking in some cases of loss of speech, the degree of loss of power to utter words must not be taken as a certain index of this difference. The difference probably depends on the difference in quantity of brain damaged near to (as well as in the exact relation of the part damaged to) the highest part of the motor tract, the point of emission of the orders of the "will" to muscles and to centres for muscular groups. Any one who has tried to use the ophthalmoscope, in many cases where speech is lost or defective, will find how great the difference is in different cases. Thus one of my patients in the London Hospital had power only to say "yes" and "no," and yet the examination of his eyes was an easy matter. He has since rapidly recovered, and soon regained power to make signs for what he wanted. He had lost power to execute, not all movements, but those movements which are most artificial. Dogberry believed that reading and writing (and doubtless talking, although he did not say so) came by nature, but I suppose everybody else believes they are acquired by education. This patient cannot write, but he can copy correctly from a book with his left hand.

A few months ago a patient came under my care who could only say "pooh! pooh!" and an examination of his eyes was almost impracticable. He made efforts, but he never did what I told him, whether it was to look in a particular way or to keep his eyes still. Instead of opening them, he opened his mouth, or screwed up his face, or shut his eye, and could not be got to look in any particular direction, although he seemed on the alert to act, and was all the time doing something with his muscles. In this case I have little doubt that more of the brain was affected, and more of the corpus striatum than in the other patient. This patient is almost as bad now as he was six months ago, and still never does anything I ask him to do.

In a third patient who (and who, by the way, is hemiplegic on the left side, and now has much recovered speech) was unable to talk, the ophthalmoscopical examination was at first almost impracticable. Now, it may be said that the patients do not know what we wish them to do. But the last-mentioned patient, when told to "look at my finger," seemed to know what was wanted, for when I was about to give up in despair, he took hold of my little finger, as I guessed, deprecatingly, and as much as to say he knew what was wanted, but could not do it. There can, however, be no certainty in this instance. It may be my fancy. But it will be observed that a speechless patient who cannot put out his tongue when told will sometimes actually put his fingers in his mouth as if to help to get it out; and yet not unfrequently when we are tired of urging him, he will lick his lips with it. Now, as a rule, the worst of these patients can generally smile, and all such involuntary processes go on well enough. I say generally, for a Physician who has seen many cases of defective speech will be obliged to use such words as "generally." I can call to mind but one speechless patient who did not become able to smile; but this patient (now under my care) never does anything but look about him, and eat and drink, and utter the word "yes" when anything is said to him. He will, however, cry "Oh!" and grin when his rigid (right) paralysed arm is extended. He takes his food when it is put near him; but when the nurse (at my request) "forgets" to give him his breakfast, he never makes any signs for it, although he follows her about with his eyes. He will, however, I have little doubt, begin to smile soon. He has only been ill a month.

These patients can do things which require scarcely any, if any, education to do, or for which, in other words, the centres exist ready to co-ordinate muscles. It would seem that the centres for the emotional and the semi-voluntary and involuntary actions are in the pons, medulla oblongata, and spinal cord; but where the power is that sets them a-going is not clear.

There are plenty of facts to show that in disease of the corpus striatum those muscles less under the control of the "will" escape, and that through this, the highest part of the motor tract, we are able to direct our *limbs*(a) voluntarily. The views of Mr. Dunn on the relation of defects of speech to disease of the corpus striatum are, I think, of great value in this connexion. Again, there is no more difficulty in supposing that there are convolutions near the corpus striatum for superintending those delicate movements of the hands which are under the immediate control of the mind, than that there is one, as Broca suggests, for movements of the tongue in purely mental operations. The phenomena of chorea, I believe, point to this conclusion.

I must here say that I believe less in some of the views propounded by Broca than I did, although I think the scientific world is under vast obligation to him for giving precision to an important inquiry. Yet I cannot but think that my disagreement with M. Broca, as well as many of the differences of opinion on this subject, are to a great extent due to different ways of putting the same thing. (See quotation from M. Broca's pamphlet.) Indeed, I think the evidence I have collected goes to confirm many of his statements as to facts, but I have for some time ceased to go with him in a few of his inferences. (See *Lancet*, November 26, 1864.) I think, then, that the so-called "faculty" of language has no existence, and that disease near the corpus striatum produces defect of expression (by words, writing, signs, etc.) to a great extent, because this is the way out from the hemisphere to organs which the will can set in motion. Hence, as I believe, disease of the convolutions near the corpus striatum is the cause of chorea, which, as regards the limbs, is not so much a disorder of mere motion as disorder of those movements which are voluntary and educated, or at least co-ordinated.

On the education of voluntary movements Bain has some most valuable remarks, and with reference to his views it is not unimportant to draw attention to the fact that chorea is a rare disease either before these movements have been learned or after they have been fully acquired. Unilateral epilepsy seems to replace and sometimes, I think, to displace chorea, and both run into actual hemiplegia occasionally.

So much for the superficial distinctions as regards the nature of (and seat of the centres for) voluntary and involuntary motion, and now for the resemblances of the two.

It may seem to be a wilful contradiction, but we find that a patient *does* things involuntarily which he cannot do voluntarily. At all events, these so-called speechless patients give utterance not merely to words, but to words in a relation which gives them at least the appearance of language. I have elsewhere spoken of swearing and of other similar ejaculatory sentences. These seem to border on emotional actions, or, as I have already put it metaphorically, "oaths are phrases which emotion has filched from the intellect to express itself in a more definite way than it could do by mere loudness of tone or manner." We scarcely say anything when we swear, although we utter words in relation. The secret of the perfect utterance of these phrases which in "speechless" patients are obviously not voluntary, is that they are easily elaborated by long habit, and can thus be brought out by a slight stimulus. Such facts seem to me to be of great importance as illustrating Laycock's doctrine on the reflex function of the brain. Indeed, the study of swearing, in spite of the nastiness of this habit, is one of the very greatest interest and importance, in our attempts to trace the gradations of motion, thought, and language.

But I now wish to speak of utterances which are perhaps of the same category as the others, but which seem to be rather expressions of the whole mind, as thinking of particular things, and yet which, contradictory as it may seem, the mind cannot get out when it likes. It will be found that patients who usually cannot talk will sometimes utter a real sentence. Laycock ("Mind and Brain," vol. ii., p. 433) has some most important observations on this subject. He says (and this, I think, helps to show the continuity, with differentiation, of these utterances with emotional utterances

(a) I use the word "limb" here, not only in the usual sense, but in the sense of an appendage to a vertebra. I have elsewhere tried to show that the nervous system may be divided on a plan corresponding to the divisions of the skeleton on Owen's scheme. The "centres" for laughing, winking, &c. (being, as I imagine, homologous with those functionally less important which are situated in the cord), are for muscles, &c., connected or in relation with the segment, whilst the corpus striatum is the centre for the muscles of the appendages of the segments. I think, (since the views Dr. Broadbent has recently brought forward) that these centres are probably doubly connected with the brain, *i. e.*, each with each side of the brain. The circulatory system, however, does not appear to follow any such order of continuity of function. Its arrangement in the brain rather indicates the relation of parts in their nutrition, and probably in their development. I shall wait for a future opportunity of explaining what I mean by the word "centre."

like interjections), that "a person usually speechless, under violent emotions may speak. A similar thing is observed with regard to laughter. A person with local disease cannot laugh voluntarily, but he can involuntarily." We had at the Hospital for Epilepsy and Paralysis a patient who could not keep from laughing, even when asking for help in his distress.

The patient, who utters the sound "pooh, pooh!" never said a single word to any of the nurses or students of the Hospital for some months, yet his son assures me that his father once, by saying the word "master's," told him where his tools were, and that he once said, with difficulty of articulation, but with intelligibility, "How is Alice getting on?" Although I have always given place to such statements by patients' friends, I confess that I have more than once almost felt that I was giving place to error in recording in my notes statements made to me about the occasional utterances of patients who would never speak to me. I have recorded (See "Royal London Ophthalmic Hospital Reports," vol. iv., part 4) the case of a "speechless" patient who was said to have one day asked for chops, although I confess I did not then believe it. I do now. My past unbelief was brought to my mind forcibly the other day. A most intelligent student gave me the particulars of the case of a patient who died with disease of the left hemisphere. Soon afterwards I was talking to this gentleman of such utterance as I have mentioned. He remarked to me that this patient's wife had, with indignation at his (the student's) incredulity, affirmed that her husband, otherwise always speechless, said, "God bless you, my dear." Now, my friend was quite justified in being very incredulous, but I ventured to tell him that it was better to record such statements, although on the authority solely of the relater.

Dr. Martin, of St. Bartholomew's Hospital, has had the great kindness to allow me to mention a case of loss of speech which occurred in his practice. It is the more important, since Dr. Andrew tells me Dr. Martin clearly located the disease, and predicted its nature during the man's life. I have Dr. Martin's permission to make use of the case, but the following quotation from the notes I got from the patient's wife will serve my present purpose:—"She told me the following as the only words she had heard him say besides 'No,' since he lost his speech (March 8) to his death (May 15): 'Five nights, six nights, seven nights, and then five nights out of seven.'" These words she assured me he spoke very clearly indeed, and she fancied he wanted to tell her something, but what it was she could only guess.

In nearly all the cases recently observed of loss of speech with hemiplegia the paralysis has been on the right side of the body, indicating disease of the left side of the brain. To explain this, Dr. Moxon suggests that the left side of the brain only is educated, although there is "an organ of language" on each side. I believe this hypothesis is essentially a most important one, but I differ from it in one way, although, of course, I can be but speculating. I think both sides are probably educated, but that the left is the one that begins to act, and that those educated utterances, which are in a sense involuntary, have become so by habit—*i.e.*, frequent education, and may be the result of action of the right side only. How from the right side they are set a-going I do not know any more than I know how a person laughs, not only without effort, but even when he tries to keep quiet.

M. Baillarger has already, I find, considered this question in an admirable manner. He says—"L'analyse des phénomènes conduit à reconnaître, dans certain cas de ce genre, que l'incitation verbale involuntaire persiste, mais que l'incitation verbale voluntaire est abolie. Quant à la perversion de la faculté du langage charactérisée par la pronunciation de mots incohérents, la lésion consiste encore dans la substitution de la parole automatique à l'incitation verbale voluntaire." In the following sentence *apropos* of a particular case, he speaks more generally—"Il est bien évident quici l'incitation motrice voluntaire etail abolie et que l'incitation motrice spontanée persistait" M. Baillarger refers to cases recorded in Dr. Forbes Winslow's remarkable and valuable work "Obscure Diseases of the Brain."

M. Baillarger has also made some very important observations on incoherence in cases of loss of power to talk voluntarily. It has occurred to me to try to produce an artificial incoherence in "speechless" patients by partial chloroform narcosis. M. Baillarger quotes from Gratiolet a statement to the effect that the frontal convolutions on the left side are in advance of those on the right in their development. Hence, if this be so, the left side of the brain is sooner ready for learning. It is the elder brother.

At first glance there seems to be an utter difference betwixt a smile and such an ejaculation as an oath, and a greater still betwixt a smile and such a sentence as "How is Alice getting on?"(b) There may seem to be an equally great difference betwixt ataxy of articulation and uttering wrong names for things. I have already, in some remarks on a case of chorea, referred to this subject (*Medical Times and Gazette*, January 28, 1865). "It is in some classes of cases of disease of the nervous system hard to say where obviously motor symptoms end and where the purely mental ones begin. Thus there is (in cases of hemiplegia on the right side) every gradation betwixt, on the one hand, a total loss of power to express ideas, or a loss of knowledge of the relation of words to things, and on the other, apparently scarcely more than an ataxy of articulation. And sometimes in the same case we find that the patient makes mistakes in words, and also articulates badly." It is not difficult to show that ataxy of articulation and so-called loss of memory for words are really defects of the same kind, and that the loss of the sign the speechless patient had for a thing is the loss of power to reproduce in his organs (in health from his brain, through series of centres, to the end of his tongue), the *movements* he has learned for that sign, or, at least, the "motor impulse," and that damage near the corpus striatum affects language and thought, not because any so-called faculty resides there (or anywhere, except in the whole brain or whole body), but because more or less of parts which help in making symbols are broken up. The fact that people do not put their tongues in motion when they think may seem to be a great difficulty; but I hope to show that it is not so great a one as is imagined. This will be but a particular expansion of the views which Bain has long taught, and which, indeed, he has applied to speech. "When we recall," he says, "the impression of a word or a sentence, if we do not speak it out, we feel the twitter of the organs just about to come to that point. The articulatory parts—the larynx, the tongue, the lips—are all sensibly excited; a *suppressed articulation* is, in fact, the material of our recollection, the intellectual manifestation, the *idea* of speech." The italics are in the original.

M. Broca makes the following remarks, which amount, in principle, nearly to the same thing, in a pamphlet he was good enough to send me a year or two ago. (Extrait des *Bulletins de la Société Anatomique*, juillet, 1863.) "Pour expliquer comment un aphémique comprend de langage parlé, sans pouvoir cependant répéter les mots qu'il vient d'entendre, on pourrait dire qu'il a perdu, non la mémoire des mots, *mais la mémoire des moyens de coordination que l'on emploie pour articuler les mots.*" The use of the word memory in the sense of its being a distinct faculty, is, I think, likely to lead to some confusion. Spencer says, ". . . such a succession of states [*motor impulses*, the results of conflicting impressions] constitutes *remembrance* of the various motor changes which thus become incipient—constitutes a *memory*." . . . "Thus then the nascent nervous excitements that arise during this conflict of tendencies, are really so many *ideas* of the motor changes which, if stronger, they would cause—a *recollection* of such changes; and thus memory necessarily comes into existence whenever automatic action is imperfect." According to this definition, memory is the obtruding of some of the motor impulses on the consciousness, but I suppose M. Broca means by memory of words the connexion the seats of motor impulses (co-ordinating centres, or whatever they may be called) for words have with that other part of the nervous system (whatever and wherever it may be) which sets them a-going.

Dr. Fournié has also written admirably on this subject, and indeed on the whole question of language. I follow him in principle, although I differ from him in some details, which, however, I daresay he may not think to be details. I must, however, leave this part of the subject for the present, and take it up from the point of the relation of sensation to motion, and of each of these to centres.

That the convolutions near the corpus striatum have to do with guiding muscles in articulation, there can, I think, be little doubt, and we may make the subject of study wider by inquiring (which I think we may do in the case of chorea) if they are not for *corresponding actions*—not mere movement—of the muscles of the limbs as well. That the corpus

(b) I would here refer the reader to Mr. Herbert Spencer's "Principles of Psychology," and especially to the chapters "The Growth of Intelligence," "Reflex Action," "Instinct," and "Memory." The facts related in this paper seem to me to be in harmony with certain views Mr. Spencer has put forward in those chapters.

striatum is the centre chiefly for the limbs, as apart from the trunk, pathology, I think, leaves no doubt. In this connection it is important to mention that Laura Bridgman, when she dreamed, "talked" in finger language, and doubtless she thought by signs she made with her fingers (and their brain connexions). As we generally think in the movements of our articulatory organs, or in the motor impulses, to move them, so she "talked" and thought in the way she was taught.

Dr. William Thomson, the present Archbishop of York, writes ("An Outline of the Necessary Laws of Thought"): "Those among the deaf and dumb who have been taught by the pains of an enlightened humanity to converse and to think must use, instead of the remembered words which we employ, the remembered images of hands in the various combinations of finger-speech [here the italics are mine] *as the symbols of their thoughts.* The deaf and blind, taught the names of objects from raised letters, must think, not by associations of sound, but by touch."

Of course, we do not either speak or think in words or signs only, but in words or signs referring to one another in a particular manner (see Waitz' "Anthropology"), any more than we move single muscles, but muscles co-ordinated to a particular end. Indeed, words in sentences lose their individual meaning—if single words can be strictly said to have any meaning—and the whole sentence becomes a unit, not a word-heap.

Dogberry thought such things as reading and writing come by nature, but we now believe that even the easy flow of talk of the most loquacious is essentially an entirely artificial process, and that even (granting there is truth in the pooh-pooh! and bow-wow theories) the origin of signs—*i.e.*, words—had little in it that was like anything instinctive. The Archbishop of York says, "In the fullest sense, language is a divine gift, but the power and not the results of its exercise, the germ and not the tree, was imparted." I am quite aware that written words and finger words are said to be signs of signs, but they belong to the same category as language does, in that writing is an artificial process, and distinct, at least in degree, from such actions as smiling, respiration, and gesticulations.

I think it will be found that the nearer the disease is to the corpus striatum the more likely is the defect of articulation to be the striking thing, and the further off, the more likely is it to be one of mistakes of words. This is not contradictory to what I have elsewhere said (*Lancet*, November 26, 1864) as to the degree of difficulty in expression depending on the *quantity* of brain damaged "about the highest part of the motor tract, the corpus striatum—the point of emission of the orders of the 'will' to the muscles." I think, too (although I have yet but little evidence on the point), that in cases of embolism of branches of the middle cerebral artery, we shall find the difficulty to be in "finding" the right word (*i. e.*, in making the right signs) rather than in the process of manufacturing the signs, and for this reason that convolutions at a distance are more likely to be damaged, and again, that the damage is wide-spread, and often slighter in degree. Finally, I think we have good grounds for investigating if the arterial supply is not so *developed* as to *re*-unite in *actions* parts which have been differently cultivated in *function*. What Professor Bain call an emotional wave, I think of under the fancy of an arterial wave. I think the occurrence of a particular action is probably due to the local stoppage in this wave. I think so because there is, I believe, evidence to show that subjective movements and sensations in disease are due to local debility of nerve tissue, as Radcliffe has long taught. Moreover, we may, I think, on Radcliffe's hypothesis, at least more easily, explain periodicity and intermissions in such diseases as chorea, epilepsy, ague, etc.

The vascularity of the region of the corpus striatum is, I think, a fact of much significance in the wider study of the relations of nutritive life and functional activity. The subjective sensation of smell (of colour, etc.) (the so-called aura in some epileptiform attacks), I liken to a sort of involuntary memory of past impressions and the spasm of the muscles of the hand—the so-called aura or partial fit—which occurs in some patients who are liable to unilateral epileptiform seizures to one of motor impulses. The subjective sensations of disease differ, however, from the rememberings of health and the contending actions of the whole of the muscles of the hand—the extensors striving with flexors, and the stronger getting most of their way—differ from particular purposive movements. In disease it is as if a row of keys were struck down together in mere order of continuity, producing not music, but noise; whilst the revived sensations and motions (or motor impulses) of health are like chords formed of a few notes related in harmony. That there must be some process by which one part of the nervous system arouses in the nervous systems of sense and in the various motor apparatus past impressions there can, I think, be little doubt, and I would suggest that one link in the mechanism of this process may be the contraction of muscular coated vessels supplied by ganglionic nerves; or, more generally, that within certain limits life and function are in an inverse ratio. Of one thing I feel pretty confident, that disordered function in some epileptiform seizures occurs in parts of the brain which lie in arterial regions, and I have little doubt that clinical evidence points to Radcliffe's conclusion that the part of the nervous system related to muscles convulsed in epileptiform attacks is, from some cause or other, below par. In the subjective sensations called *phosphenes*, produced by pressure on the globe of the eye, there is, I think, demonstrable evidence that there is less blood in the retina as firmer pressure makes the optic disc bloodless. Yet I do not wish to argue much from this fact at present, as I have no certainty that the part pressed on is more anæmic than the rest of the retina.

From this point let me again urge students, who wish to make cases things to think from, to avoid the too free use of technicalities and to study one case by the light of many. It is, I think, important to study chorea and epilepsy in reference to speech as well as to study cases of what may be called pure aphasia or aphemia.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SPECIAL REPORT ON THE TREATMENT OF FRACTURES IN THE LONDON HOSPITALS.

FRACTURES OF THE LEG.

Mr. Holthouse, in his article on fractures of the lower extremity in "Holmes's System of Surgery,"(a) in speaking of fractures of the leg, says, "Perhaps there are no fractures more easy or more difficult to treat than those of the leg, a starch bandage or laying the limb on a pillow being all that is necessary in some cases; while the utmost ingenuity and the most constant supervision is required in others." Bearing these remarks in mind, we shall proceed to describe the various methods of putting up these fractures that we have seen in use in the Hospitals we have visited. We shall commence, then, with

FRACTURES OF THE TIBIA.

Fracture of the Head of the Tibia into the Knee-joint.—This, unassociated with fracture of the condyles of the femur or compound fracture into the joint, is a comparatively rare accident. The treatment generally adopted for it is simply that of laying the limb out straight on a back splint and raising it, so that the muscles acting on the joint may be relaxed. In order to keep the joint at rest, gutta-percha, leather, or pasteboard splints may be applied to the sides of the knee. The limb should then be swung. Passive motion may be commenced in about a month or six weeks.

Fractures of the Shaft of the Tibia.—In cases of fractured shaft where the displacement is, if any, slight, after the fragments have been accurately adjusted, the limb is put up immediately by some Surgeons in plaster of Paris or starch bandages, the methods of applying which we have already described in a former paper. This early putting up of fractures in the stiff apparatus should only be had recourse to when, as we have before observed, the displacement is slight and the integuments are not severely bruised.

With regard to the splints and contrivances in use for putting up the more complicated forms of fracture, we can only say that we have seen those of the most simple possible construction; these, and the methods of fixing them to the limb, we now proceed to describe. We mention them here particularly with the tibia, as it is in fractures of that bone that they are most frequently used; but it will be seen that

(a) "Holmes's System of Surgery," vol. ii., p. 28.

the same methods apply equally well to fractures of the fibula or of both bones together.

In cases, then, of fractured shaft, when the fragments have been placed in apposition (which they may be judged to be, when the ball of the great toe is in a line with the inner border of the patella), a very common method of putting the fracture up is that of applying two side splints with foot pieces to either side of the limb. These, having been of course previously well padded, may be kept in position by taking a turn or two of bandage, first round the foot and ankle, and then round the foot-piece. The bandage should not be continued the whole way up the limb, as it is of importance in all cases of fracture that the actual seat of injury should be exposed to view; a few turns round the upper part of the leg-pieces will be sufficient to retain the splints in position. The limb may either be swung or placed between sand-bags; if the latter, a wire cage should be put over it to keep off the pressure of the bed-clothes. These splints may either be hollowed out or plain. Sometimes only a single side splint with a foot piece is applied to the outer side of the limb, the leg being slightly flexed, and placed on its side.

McIntyre's iron splint, or Liston's modification of it, is much used in some Hospitals. Care should be taken in applying the splint, that it be thoroughly well padded throughout, and that cotton wool or tow be inserted between it and any of the soft parts that may be subjected to pressure. No part of the splint should press upon the heel, as this part of the foot frequently becomes ulcerated from the carelessness with which this splint is applied. In applying it, after the foot and ankle have been carefully bandaged to the foot piece, and the thigh to the thigh piece, it is not necessary to cover the limb entirely with bandage. The apparatus should be swung either from a common cradle or Salter's swing. Mr. Erichsen says, "In some cases of fracture of the bones of the leg, however, M'Intyre's apparatus is not applicable. This is more particularly the case when the fracture is very oblique, from above downwards and from before backwards. Under these circumstances, the fragments cannot be got into good position, so long as the limb is kept extended and resting on its posterior surface, the bones riding considerably, and one or other of the fractured ends pressing upon the skin in such a way as often to threaten ulceration."(b) In some Hospitals, in addition to the two side splints above mentioned, a back splint, with a foot piece (capable of being fixed in the required position by a screw) corresponding with the sole of the foot, and with the leg piece extending as far up as the ham, is used. The splints may be retained in position either by bandage or fillets.

At St. Bartholomew's, Mr. Paget uses the following method:—The limb is placed upon an ordinary iron back splint; to this it is secured at the foot and knee by means of wide pieces of gutta percha moulded to the shape of the limb, and laced under the splint by narrow tape. Two straight wooden side splints are then applied; these are buckled together at their lower extremity (which is exactly on a level with the sole) by means of a thin leather strap passing across the sole from the one to the other. In the remainder of their length, which reaches up the thigh to the same point as the back splint, they are fastened more or less tightly, according to the degree of lateral pressure which it is thought advisable to apply to the limb, by two or three webbing straps and buckles. The leg is then "swung" in the usual manner. It will be seen that this way of putting up fractures of the leg recommends itself by its simplicity, and if the term may be allowed, by its conciseness. No bandage at all is employed, and the limb is left wholly free from all pressure that can interfere with the circulation. The exact condition of the limb, and the relative position of the fragments can at any time be ascertained, and as the side splints are fixed independently of the back splint, they can be removed either during occasional sponging of the limb, or for any other purpose.

In cases of oblique fracture, with projection of the lower end of the upper fragment, the management of which is generally very difficult, Mr. Hutchinson finds that the simple expedient of raising the leg obviates this trouble.

Fracture of the Inner Malleolus.—Side splints, or a single splint applied on the side opposite to the fracture.

FRACTURES OF THE FIBULA.

Fracture in the Upper Part.—The displacement here generally is so slight that plaster of Paris or dextrine bandages may be used at once, or the limb may be placed in McIntyre's or side splints.

Fracture of the Lower End, or Pott's Fracture—the foot being dislocated outwards, and the tip of the inner malleolus broken off, or the internal lateral ligament ruptured.—The most general method is to put the limb up on a Dupuytren's splint, which is like a short Liston's splint with a couple of notches at the lower end, through which the bandages pass to produce slight extension.

In applying this apparatus, which is adapted to the inner side of the leg, care must be taken to pad the splint well, especially opposite to the seat of fracture, which padding should fill up the hollow formed by the curve of the leg as it lies on the splint, and so act as a fulcrum over which extension can be made. A few turns of bandage should then be made round the foot and through the notches. The bandages should not be continued up higher than the ankle, and the upper part should be bound securely to the leg just above the calf. Sometimes an ordinary side splint with a foot-piece is used, but it should be carefully padded in the way mentioned above, as the object to be attained is the throwing out of the upper end of the lower fragment. After union the dextrine or plaster of Paris bandage should be applied.

Fractures of both Bones.—Any of the above-mentioned splints are in general use. A very simple method we saw in use at the *Dreadnought* Hospital ship, in cases of fracture of both bones. It is very easily applied, and can be readily taken down without disturbing the setting of the fracture. A piece of stout sheeting is to be rolled in opposite directions, so that two pillows or junks are formed by the rolled extremities; upon this the patient's limb is laid. Then a fillet is passed behind the sheeting, and similar ones under the limb. Next two well padded side splints, with foot-pieces, are adapted to either side of the leg, and secured by buckling the fillet passing under the leg. Next the external sheeting is rolled up in opposite directions, until the rollers correspond with the outside of the splint, and the fillet under it buckled over all. The foot may be secured to the first piece by a turn of bandage. Hester's apparatus we have seen very generally used in the Westminster Hospital. In Mr. Heath's valuable work "On Minor Surgery" is the following account of the manner of applying it. He says, "It combines the advantages of the side splint with those of the swing, as the splint is suspended from rollers and a cradle, which allow of the free movements of the patient. In making use of it, the knee is first firmly fixed, a pad being placed below the tubercle of the tibia, and another above the head of the fibula, the foot being well strapped to the footboard. Extension is then made by means of a screw underneath, and thus shortening is effectually prevented, whilst the side splints, when screwed on, keep the limb perfectly steady."

We lately saw, under the care of Mr. Hutchinson, in the London Hospital, a child, about 4 years old, who had, in falling, broken both bones of the leg, and we were told that a second case of the same kind had a short time previously been under treatment. The limb was put up in splints, and "swung" in the usual way. This accident is so rare that it deserves to be mentioned. Every one must have observed that while in adults fractures of the bones of the leg are much more common than fractures of the femur, in children just the reverse is the fact. Fractures of the femur are very common, indeed much more so than in the adult, while fractures of the leg are very rare. We have often asked for an explanation of these facts, but have not yet met with one which is altogether satisfactory. It seems probable that they depend to some extent on the different way in which children and adults fall, the former generally coming to the ground with the legs doubled under, so that the weight of the body falls, through the knees, on the femur, while adults more commonly sustain fracture while the weight of the trunk is being transmitted to the ground through the bones of the leg.

(To be continued.)

(b) Erichsen's "Science and Art of Surgery," p. 251, *et seq.*

THE amateur morning concert for the benefit of the London Infirmary for Epilepsy and Paralysis, Charles-street, Portman-square, came off on Tuesday, the 12th inst., at Willis's Rooms, which were crowded by a large and fashionable audience. Amongst the performers were Lady John Manners, Mrs. Althaus, Mrs. Sheffield Neave, the Misses Alderson, the Misses Baillie, Miss Conner, and many other distinguished amateur vocalists and instrumentalists. About £180 was realised on the occasion.

SATURDAY, JUNE 23.

THE PUBLIC HEALTH BILL.

We called attention last week to a Public Health Bill introduced into the House of Commons by Mr. Bruce, Mr. Fortescue, and Sir George Grey, and which, therefore, may be regarded as embodying the views of the Government, and of the active spirits in the Sanitary Department of the Privy Council Office, as to what is necessary to be done. Perhaps we should be more correct in saying what it is expedient to ask Parliament for in the way of amendment of our sanitary laws. The Bill aims at extending to the provinces some of the more important provisions as to town and house drainage, which we in the metropolis have had the advantage of for some years under the special Acts of Parliament by which our local government is constituted. Another object is the extension to Ireland, not only of the operation of this Bill, but of the Nuisances Removal Acts, which, faulty as they are, have nevertheless done some service to the English public. Thirdly, an attempt is made to amend these latter Acts, and to introduce for the benefit of the country at large some additional clauses calculated to meet a few glaring deficiencies in the present law. Generally speaking, then, this effort of Mr. Bruce is praiseworthy, and Ireland especially may be thankful if the Bill passes. Some such legislation is greatly needed in that portion of Her Majesty's dominions. Politicians are guided by motives which we, as men of science and as Medical Practitioners, cannot always appreciate; one thing, however, is certain that, whereas we have tolerably clear notions of what is really needed, such persons as Mr. Bruce who undertake to improve the state of the law have in addition to gauge the temper of Parliament, and to consider how much they dare to ask for without incurring the risk of an entire refusal. Without saying, therefore, that we are quite satisfied with the Public Health Bill, we are willing to give Mr. Bruce and his coadjutors full credit for their good intentions, and to accept, as far as it goes, the instalment of amendment in sanitary law which is offered to us.

What is really needed is quite another affair; it is fully set forth in a series of suggestions drawn up last year by the Metropolitan Medical Officers of Health, published by Mr. Simon as an Appendix to his Report, and submitted to Mr. Bruce in an interview which they had with him upon the subject a few months ago. We are happy to observe that some of these suggestions have been incorporated into the Bill. Let us briefly refer to the proposed amendments.

1. As respects overcrowded dwellings, it is proposed to regard as a "nuisance" any house or *part of a house* so overcrowded as to be dangerous or prejudicial to the health of the inmates. This amendment gives direct legal sanction to an interpretation of what is meant by an overcrowded house generally adopted by the police magistrates in the metropolis. Another clause is intended to obviate an inconvenience of the present law by throwing upon the defendant the onus of proving that the persons occupying the overcrowded house or room are members of the same family. 2. An attempt is made to extend the most important sanitary provisions of the Factories Acts, so far as they relate to cleanliness and ventilation, to factories, workshops, and work places of any kind. Should this clause pass through Parliament, it will be productive of unmixed good. This clause, and the overcrowding clause together, will, we apprehend, enable sanitary authorities to do all that is necessary for obviating the horrible state of things so often found in the workrooms of large tailoring, millinery, and the like establishments. 3. It proposes to give to what is termed in this Bill the "nuisance authority" control over the nuisance arising from factory smoke. In the metropolis the police take cognisance at present of this source of annoyance. We should like to see some means adopted for preventing the nuisances arising from low private chimneys also, as those of low washhouses, stables, etc., which are in most towns to be found here and there pouring their smoke almost into the very windows of taller houses, and preventing thus their free ventilation by compelling the occupier in self-defence to keep his windows on that side constantly closed. 4. Although house-to-house inspections are made by sanitary officers in some districts at the present time, there is a good deal of doubt as to whether they are strictly legal, and whether they might not be successfully resisted. In some metropolitan parishes the Vestries and District Boards refuse to allow their officers to visit any premises, however manifestly unwholesome, except on complaint. The 23rd clause of this Bill overcomes any such scruple, by stating that "it shall be the duty of the nuisance authority to make from time to time, either by itself or its officers, inspection of the district, *with a view to ascertain* what nuisances exist." This clause has our unqualified approbation. 5. It is proposed to empower the nuisance authority to require owners of houses to cleanse, limewhite, and disinfect wherever it appears that these processes would tend to prevent or check infectious diseases; and, in the event of the order not being complied with, that the delinquent shall be liable to a fine for disobedience to the authority. The necessity for this enactment will appear from the fact that we are acquainted with one instance in which a Medical Officer of Health had actually to argue before a police magistrate in order to convince him that *mere* dirt (as he termed it) was calculated to promote disease. The infliction of a fine for disobedience to the notice of the local boards is a new feature in sanitary legislation, and should be extended to other matters beside cleansing and disinfection—to such faults, for instance, as broken-in drains, overflowing cesspools, and other like dangerous nuisances. At present the fine can only be inflicted for disobedience to the order of a magistrate, and is not actually a cumulative fine, as this clause would render it. The result has been most disheartening delays, and, after all, the virtual victory of the defendant. It is further proposed that any order of the justices for entry to inspect premises shall be in force until all necessary works are completed. 6. The Bill contains several provisions calculated to prove useful in dealing with infectious diseases. For instance, it would empower the nuisance authority to remove from any room occupied by more than one family any person suffering from an infectious disorder—a provision which seems to us not to go quite far enough, since to be of any general applicability it should extend to houses occupied by several families; it would empower the justices to remove to a proper dead-house any dead body of one who has died from an infectious disease, and which is retained to the danger of health in a room where persons live and sleep; it would provide a summary process for the punishment of persons exposing themselves while suffering from infectious diseases in any public place, and also for enforcing the disinfection of public conveyances contaminated by the use of such persons, and for preventing the improper disposal of clothing, etc.,

which has been used by them. It further enables the same authority to make provision for the reception of such persons in Hospitals, etc. The last, however, is a permissive clause, which there is, we fear, no chance whatever of any local authority ever making use of. We have already had too much of permissive legislation in sanitary matters, and know its full value. 8. Among the miscellaneous clauses there is one by which, on application made by a nuisance authority, the Secretary of State may empower them to make regulations for the regulation and registration of houses let in separate lodgings. Strangely enough, as the clause is drawn, the Metropolis is excluded; let us hope not intentionally. Nowhere is the exercise of such a power more necessary. Lastly, there are some provisions over which all will rejoice greatly should Parliament in its wisdom declare that they shall be law. These provisions are of a nature to compel nuisance authorities to do their duty without having recourse to the expensive process of applying for a *mandamus* in the Court of Queen's Bench. Let the Vestries of Clerkenwell, Bethnal-green, and St. George's, Southwark, look to it, for their negligence and the negligence of similarly constituted Boards will no longer be winked at. Owners of small house property will no longer be enabled to protect themselves and destroy the health and lives of the poor by getting elected as members of their local Board.

THE CASE OF PERIONOWSKI *v.* FREEMAN AND ANOTHER.

This action, brought by a patient of St. George's Hospital against Mr. Holmes, the Surgeon to that institution, and Mr. Freeman, another of the Medical Officers, is certainly, in its broad aspect, one of the most unjust and vexatious suits ever heard in a court of justice. The following are the facts of the case:—The plaintiff, a Pole, at the time an inmate of one of the wards of St. George's Hospital, was ordered a hot vapour bath by his Surgeon, Mr. Holmes, who prescribed it for him when making his usual round in the wards. After seeing the plaintiff and ordering the bath, Mr. Holmes, in the natural course of things, would pass to other cases requiring his attention, and dismiss for the time the matter from his mind. It is no part of the duty of the Surgeon of a large Hospital to see that his orders are carried out by the attendants in the wards, and he cannot be held responsible for any accident which may occur through misadventure or neglect. After Mr. Holmes and Mr. Freeman had left the man, however, the Hospital nurses—who, it must be remembered, are not chosen for their office by the Surgeons of the Hospital, who are not paid by them, and who therefore are in no real sense their servants—placed the plaintiff in a bath, where, through their carelessness or ignorance, or both, an injury was inflicted on him by scalding. For this injury the plaintiff on leaving the Hospital brought an action, not against the nurses or their employers, but against the Surgeons, who had clearly nothing to do with the matter. It is true that the plaintiff declared that Messrs. Holmes and Freeman had not left the ward when the bath was administered, and that they must have seen or heard his struggles or screams. Both gentlemen, however, clearly proved that they were not present, and the fact that the man was really scalded is sufficient *primâ facie* evidence that neither of them could have been within hearing. The action, therefore, was unjust and ungrateful in the highest degree. It deserves the strongest reprobation, and Messrs. Holmes and Freeman are entitled to all sympathy as having been made the victims of so vexatious and unwarrantable a proceeding.

But the case has another aspect. The jury, although returning an unhesitating verdict for the defendants, appended to that verdict an opinion that the plaintiff had been ill-used. And who can deny the truth of their conclusion? The plain fact is, that a sick man was absolutely put into hot water by the nurses of St. George's Hospital, and in spite of his screams and struggles—for who will doubt that when he found himself being scalded he both screamed and struggled?—was kept there a sufficient time to be so effectually injured that the scalds were visible, as proved by the evidence of the defendants, "a few days" afterwards. Now the supposition of wilful cruelty in such a case is, of course, entirely out of the question; but we do say that this could only have happened from want of care, to say the least, on the part of the nurses, which, under such circumstances, is deplorable. It will be remembered that this is the Hospital where a large section of the Governors are afraid of introducing a sisterhood of trained nurses, on the ground of dreading the effect on the patients' souls; this case, we think, should make them fear the effect of their present system on the patients' bodies, with which, as Hospital authorities, they are primarily concerned. Amongst the revelations of the Metropolitan Workhouse Infirmaries is there any single thing worse than this? Do they scald people *nolentes volentes* at the Strand or Paddington?

Abominable as the system brought to light in many of the London Workhouses is, we suspect strongly that other people are to blame for it besides the Guardians. It is a fact, that heretofore the Poor-law Board have consistently and pertinaciously opposed all attempts to introduce anything but the most sordid appliances and accommodation for the pauper. Everything cheerful, kindly, æsthetic has been religiously excluded. Workhouse authorities, even if they wished it, have never been allowed to develope any plan for the comfort of the sick, and aged, and infirm which would carry them beyond the iron boundary of Poor-law regulation. The present system is but the natural growth of that which has been fostered and encouraged by the Poor-law Administration; and for the Poor-law Board now to cast all the blame on the Guardians, and to turn on them all the public anger which their system most justly has aroused, is simply atrocious. We are no apologists for Guardians such as those of the Strand Union; but we must not forget that under a different system of Poor-law government and administration such a state of things as has been there revealed would be simply impossible. A Workhouse Master, speaking to a friend of ours the other day, said, "We can get anything we like *now*; but we might have asked and asked again in vain a year or two ago."

This, however, is a digression. The plaintiff in the case of Perionowski *v.* Freeman and Holmes had, it is clear, a perfect right to bring an action, although he had no right to bring one against his Medical attendants. The suit should have been brought against the Authorities of St. George's Hospital, who are responsible for the present system of nursing there. Messrs. Holmes and Freeman have, of course, been put to considerable expense in providing their defence. The least the Hospital Authorities can do is to defray every shilling of their costs.

THE NIGHTINGALE FUND.

Not long since an article appeared in the *Pall Mall Gazette* containing certain strictures upon the management of this Fund, which appeared to us somewhat hypercritical, and to which we should before this have taken exception had not the demand on our space largely exceeded our power of supply for many weeks past. The *Pall Mall Gazette* objects that "the expense of management and collateral outlay have been so large, while the actual results have been so disproportionately small."

Now we may be certain that criticism of this kind is the offspring of unfamiliarity with the difficulties involved in permanently establishing a scheme of training nurses which shall be at the same time economical, rapid in action, and efficient. Those who are acquainted with the characteristics of a skilful nurse know that her training is not to be brought

about by simply placing her for a few months in the wards of an ordinary Hospital. It is a matter of intelligently directed, persistent — not intermittent — teaching by competent instructors, and this is impossible unless the pupil is under proper superintendence, both morally and otherwise. Hence the primary want is felt to be for persons properly qualified to act as lady-superintendents, and these can of necessity only be supplied by slow degrees and at considerable cost. Then the Council find other impediments in the way of realising such numerical results as would satisfy their critics. They complain of the lack of proper candidates for training; and of those selected, although the utmost care is taken in preliminary inquiries, no less than 40 per cent. within five years have, after more or less probation, failed to acquit themselves satisfactorily. More than ordinary intelligence, and unimpeachable moral conduct, are indispensable qualifications requisite to the making of a good nurse, and the area of selection is consequently limited. Moreover, when the nurse has been trained and is turned out ready for work, the wage which is ordinarily offered her is inadequate, but this is certainly no fault of the Council. There will always be difficulty in this respect, until the pay is made worth the service required, and the scale ought to be graduated so as to make promotion depend on efficiency and experience.

It should be remembered, however, that the shortcoming of numerical and economical results in the management of the Fund of which the *Pall Mall Gazette* complains, is mainly attributable to the excellence at which Miss Nightingale aims. She would raise the standard of education and character among nurses as a class, and this can only be effected by small beginnings, and necessarily, while the thing is in its infancy, at an expense which appears disproportionate. She prefers to do a little effectually and according to her own advanced ideas rather than to make a great show with no real public advantage.

MIDWIVES IN FRANCE.

The *Journal de la Société de Statistique de Paris* for April contains an article by Dr. Viallet on "Midwives in France, and the necessity for opening a school of Midwifery in each department," which very properly directs attention to an important want in the Medical service particularly of country districts by the deficiency of duly instructed midwives.

Unhappily there can be no doubt whatever that few countries are as well off in that respect as they ought to be, and it is a matter for profound thankfulness that child-birth is not oftener attended with fatal results, considering the very unnatural conditions under which great numbers of mothers bring forth children. In the rural districts of England the women of the poorer classes are, in a majority of instances, unable to obtain any assistance at the time of their delivery from the parish Doctor, who is wanted in a hundred opposite ways at once, and all the necessary requirements are, therefore, left to be fulfilled by uneducated, uninstructed nurses, whose heads are oftentimes full of crotchets very much in opposition to Medical science.

Dr. Viallet laments that the same state of things prevails in the poorer districts of France, and he points to the establishment of a school of midwifery in every department as being the only way of supplying properly instructed midwives in number sufficient for the service of the poor. He gives no data from which we can estimate the fatality of child-birth in France, but he asserts generally that in the *cantons pauvres et isolés* the number of women who die in child-birth or from diseases incidental thereto is very considerable. In this country, taking a series of years, the deaths of mothers from child-birth, etc., have averaged 5 per annum for every thousand children born alive; and for many reasons it is probable that this rate is below the European standard.

If Dr. Viallet's statement of the number of Medical men in France be correct, the amount of Professional aid available for the whole population is twice as great in England as in France for the 19,800 Medical men (including 6300 *officiers de santé*), which he states is the full complement of the service of the Empire, would average but 1 to every 2000 persons, whilst with us the proportion is about 1 to every 1000.

With regard to midwives, however, the balance seems to be in favour of our neighbours. The French census of occupations is so badly arranged that it is impossible to ascertain the exact number of *sages-femmes*, but Dr. Viallet puts them at less than 5000, or 1 to every 7000 of the population; in England their numbers declined from 2021 in 1851, to 1913 in 1861, when the average ratio was 1 midwife to every 10,000 persons. Dr. Viallet estimates that at least 13,000 midwives are required in France so as to allow for 1 to every 3000 inhabitants, and this certainly is a moderate estimate. Comparing the number of declared midwives with the yearly births in the two countries, we find that the average ratio is about 1 midwife to 400 births in England, and 1 to 200 in France. Dr. Viallet would have not less than 1 midwife to 80 births, and it cannot be said that he asks too much.

He gives an instance of the effect of closing the midwifery course of instruction in Aveyron, where, in 1847—the date when the course was discontinued—there were 112 midwives; in 1859, when by Dr. Viallet's influence the lectures were recommenced, the number had diminished to 74, of whom many were upwards of 70 years of age. In the five subsequent years, Dr. Viallet has prepared forty-five midwives for the service of the department, but at least 50 more, he says, are necessary to satisfy all wants and to fill up vacancies caused by death. In some of the departments it appears that the midwives have the direction of the School of Midwifery, and the Medical men are considered to be under their orders! Dr. Viallet is cognizant of the same difficulty with regard to the establishment of a midwife in a poor district which the Council of the Nightingale fund experience here, but he very pertinently asks, "*Pourquoi la commune ou les communes réunies du canton (dans les campagnes) ne leur accorderaient-elles pas une subvention? La sage-femme n'est-elle pas aussi nécessaire que le maître d'école? Ne s'agit-il pas de sauvegarder la vie des mères et de leurs enfants?*"

Undoubtedly some such course as Dr. Viallet suggests must be adopted in poor, thinly populated districts where it is sought to establish a midwifery nurse. It is useless to take an intelligent woman, train her for a special calling, and then send her to some out-of-the-way place with only the wages of an ordinary domestic servant. In many cases she would be more valuable even than the schoolmaster, and her services should be adequately remunerated.

The supply of trained nurses, both for the sick and for midwifery, is a very important question, and Dr. Viallet's endeavours to increase that supply in France will have the heartiest good wishes of the Medical Profession in England.

THE THERMOMETER IN DIAGNOSIS.

In the previous articles laid before our readers we have seen that the temperature of the body is raised in all acute specific fevers, in acute inflammation of any of the organs of the body, in ague, and also in tuberculosis. Fever is also present in many other diseases. Of these we shall subsequently speak.

We have seen that many of the diseases that simulate phthisis cause no elevation of the temperature, and that this absence of any abnormal elevation of the temperature enables us to decide that the patient is not the subject of tubercular disease. If, on the other hand, the temperature be abnormally elevated, it is highly probable that the tubercle is being deposited in one or other of the organs of the patient. If this elevation should be due to some febrile disease other than tuberculosis, which may be acci-

dentally present, this can usually be detected. Still in some cases the detection of such an intercurrent disease may be difficult or impossible. How can we exclude this source of error? This question we shall now attempt to answer.

But few diseases can cause a daily elevation of three or four weeks' duration. Acute inflammations cease, and the temperature consequently falls, long before this period has elapsed. The same remark applies to most of the acute specific fevers. The temperature in typhoid fever generally becomes normal by the twenty-fifth or thirtieth day of the disease. The diseases at present known to be able to cause such a long continued elevation of the temperature as that above mentioned (namely, a month or more) are tuberculosis (the deposition of tubercle in any of the organs of the body), rheumatism, ague, abscesses, suppuration (such as occurs in empyema, large open psoas abscesses, etc.), and certain forms of chronic induration of the lung with ulceration of the bronchi and the formation of cavities.

Under the term tuberculosis we include scrofulous pneumonia, the product of which disease was formerly, and still is by some, considered to be one of the forms of yellow tubercle.

All these diseases, with the exception of tuberculosis, are accompanied by such characteristic symptoms that we have usually no difficulty in forming a correct diagnosis. Rheumatism makes itself known by the pain in the joint, or by the physical sign of peri- or endo-carditis. The symptoms of ague are mostly so characteristic that the disease can seldom be mistaken, abscesses, empyema, profuse suppuration, can always be detected (abscesses may evade detection, however, for some time). Of all the diseases mentioned, chronic induration of the lungs, both in respect of physical signs and symptoms, closely simulates phthisis. In a subsequent paper we hope to show that by means of the temperature this disease can be correctly diagnosed, and how it can be distinguished from tuberculous disease of the lungs.

The length of time, therefore, that the elevation of the temperature continues affords us much help in making our diagnosis. If this elevation has continued some time—say a month—the number of diseases we have to decide between is small, and these for the most part have characteristic symptoms, and thus the diagnosis becomes easy. Tuberculosis, however, may exist, as we have seen, without any physical signs being present, and at the same time the symptoms may be very slight and utterly insufficient for a correct diagnosis. In such a case, if the patient continue febrile for a month or six weeks, the disease is in all probability tubercular.

The question, therefore, that we put to ourselves at the commencement of this article is answered.

In cases where we are in doubt whether the patient suffers from phthisis or not, if the temperature be elevated, tubercle is probably being deposited in one or more of the organs of the body. Such elevation may be due to some co-existing febrile disease not tubercular; but such a disease mostly ceases in a few days, and in the case of typhoid fever mostly at the end of the fourth week. If, therefore, the temperature continues to rise daily for more than a month, we are justified in diagnosing in such a case (provided none of the other diseases capable of producing a chronic elevation of the temperature be present) that the patient is tubercular.

It may be said that before a month has elapsed the physical signs and symptoms will be so marked that all difficulty of diagnosis will have ceased. Such, however, is not the case, for tuberculosis of the lungs or other organs of the body may continue for a much longer period than that mentioned, and yet produce no physical signs, while the symptoms, moreover, may be slight and utterly insufficient to insure a correct diagnosis.

Hence it follows that in some cases the temperature of the body affords us the earliest indication that tubercle is being deposited in the body; *for if we have a chronic elevation of the temperature, and this be not due to rheumatism, ague, suppuration, or chronic induration of the lung, such an elevation must be considered to be due to a tubercular deposit in the body.*

THE FELLOWSHIP OF THE COLLEGE OF PHYSICIANS.

The names of the gentlemen proposed by the Council for the Fellowship of the College of Physicians have been sent to us. Some of the juniors are men of promise, but we do not hesitate to say that, with one or two exceptions, none of the selected possess claims equal to those of many who have been passed over. If the Fellowship of this time-honoured Institution is to be regarded as a mark of Professional standing, and not to wear the aspect of favouritism exercised by a few men, acting more or less in concert, and voting in secret, it is high time that the mode of election be altered. On a not very distant occasion the Fellows at large when called on to confirm the selection of the Council, refusing to be led by them, rejected the names proposed. Such was a legitimate and useful exercise of authority.

With one exception, there is no name in the present list of longer standing as a Member than of 1858, and no fewer than four of 1860. To many the names of some of the selected will be suggestive of the cause of their proposed early elevation. But have the claims of many gentlemen in every way qualified for the honour been duly considered? It must be answered without hesitation—they have not. Some highly educated, honourable men, who have done good work for the Profession, and who passed the ordeal of examination at the College, are excluded. If, on the other hand, we turn to the list of Fellows, it would be as easy to point to a number whose claims to admission, except on the principle of *Lucus a non lucendo*, it would be difficult to establish.

It is high time, we repeat, that access to the College Fellowship be made to rest on some more equitable basis than the present one. Admission by examination as at the College of Surgeons, a mode of selection which has been successfully adopted in some important offices of the State, is, perhaps, on the whole, the best.

THE WEEK.

A BARONETCY CONFERRED ON THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

The whole Profession will receive with great gratification the following announcement, which we take from the London *Gazette* of Tuesday, June 19. We think that we are representing a unanimous feeling when we state our belief, that had the whole Medical body been asked on whom of their number they would desire a baronetcy should be conferred, they would at once have returned the answer, "on Dr. Watson." It is not merely that Dr. Watson, as President of the Royal College of Physicians, represents the highest Medical corporation in the State, or that his skill as a Physician has insured him the confidence of the highest ranks, not excepting that of Royalty; but it is that to Professional merit unsurpassed he has added all social virtues, all the high qualities of heart and intellect which should distinguish one who is singled out by his Sovereign as the representative of a learned and generous Profession:—

"Whitehall, June 18.—The Queen has directed letters patent to be passed granting the dignity of a Baronet of the United Kingdom unto Thomas Watson, of Henrietta-street, Cavendish-square, in the parish of St. Marylebone, and county of Middlesex, Doctor of Medicine, President of the Royal College of Physicians, and one of her Majesty's Physicians Extraordinary, and the heirs male of his body lawfully begotten."

THE ARMSTRONG FUND DINNER.

The Committee for raising a fund to defray the legal expenses of the Messrs. Armstrong in the late trial, "Rudman *versus*

Armstrong and another," held their final meeting at the Rosherville Hotel on Tuesday last. The Messrs. Southgate, the able legal defenders of Dr. Armstrong, were present, and on the vote of the Committee to that effect, Mr. Hunt, the Honorary Treasurer, handed over the full amount of the costs. When, in addition to this, the Committee expenses were paid, a small balance remained, which the Committee voted to the Gravesend Infirmary. The business over, the members of the Committee entertained Dr. Armstrong and Mr. Armstrong at a dinner, at which nearly forty gentlemen were present. The Mayor of Gravesend, the solicitors of Dr. Armstrong, the Rev. Mr. Scarth, and several other influential residents of the town and neighbourhood were also there.

Dr. Richardson presided, and in proposing the health of the Messrs. Armstrong, which was most enthusiastically responded to, pointed out that these demonstrations of Professional unity were the surest means of preventing trials of the nature they had that day met to oppose. The Messrs. Armstrong replied in feeling terms, and after a most pleasant evening, the members separated.

BILL FOR THE REGULATION OF SCIENTIFIC WITNESSES.

A VERY important and much-needed Bill is about to be introduced, not into the House of Commons, but (during the present paralysed state of that body) into the Court of Sewers of the City of London, and there is little doubt that if formally sanctioned there, as it has already been in substance, that it will very soon become the law of the whole land. It is, we understand, to be introduced by personages so distinguished as Mr. Rudkin and Mr. Deputy Bunnell, and, according to the draught we have seen, will stand thus:—"*Preamble.*—Whereas it is expedient for promoters of gas bills, water bills, and railway bills, and for other speculators and projectors to make out their case by the evidence of scientific men, and whereas scientific men, if duly paid, hired, or retained, ought to give such evidence as suits the case of their employers, hirers, and retainers, be it therefore enacted, &c., as follows:—1. All scruples of conscience are abolished from and after the passing of this Act. 2. Every oath administered to a scientific witness shall be considered as binding only so far as suits the case of his hirers or employers. 3. Every scientific witness who shall decline to give such evidence as he is required to give shall be subject to fine and imprisonment; and if he be a public servant or official, shall be suspended from the duties and emoluments of his office. 4. Whereas, one Letheby, who is Health Officer and Gas Analyst to the City of London, did contumaciously refuse, as aforesaid, to swear as his employers desired him, that the said Letheby be appointed to his offices for three months at a time only, and that he be admonished to show better behaviour for the future. The present Act to be retrospective and prospective."—See the Proceedings in the City of London Court of Sewers, as reported in the *Journal of Gas Lighting*, June 12.

THE CASE OF HELEN FORESTER.

WE regret that there has been a miscarriage of justice in a case recently tried at the Central Criminal Court, from, as it would seem, the peculiar stringency of the law respecting dying declarations. The case was that of the woman, Helen Forester, who was charged with having caused the death of Ann Venables, *alias* Sloman, by making use of an instrument to procure abortion. The following account of the case conveys the useful lesson that the law will not admit any statement as a dying declaration unless it can be proved that the person uttering it has at the time lost all hope of recovery:—

"The deceased, who was a married woman and the mother of several children, went to the prisoner in April last, and gave her £3 to procure a miscarriage of the child of which she was then five months pregnant; the miscarriage was caused, but the operation then performed upon her by the prisoner was alleged to have produced her death in about a fortnight afterwards.

"Mr. Daly, as before, appeared for the prosecution, and Mr. Montague Williams and Mr. Straight for the defence.

"Mr. Augustus Brown, M.D., of Belitha-villas, said that about 10 o'clock on the night of the 26th of April he was called to attend the deceased. She lived at 8, Barnsbury-grove, Barnsbury-park. She was in a very excited state of mind when he first saw her. She had had a painful hæmorrhage, her body appeared swollen, and her pulse was beating at the rate of 120. From these symptoms he augured that she had been recently delivered. It was impossible to say how long she had been in the family-way. She died on the evening of the 6th of May. He made a *post mortem* examination, in company with two other Medical men, Mr. Morrison and Dr. Walker. They found that the uterus had been lacerated and punctured through, by which inflammation was caused, and eventually death. She made a statement, but at the time she did so he did not tell her she would die. On the night he first saw her she told him she was sure she would die. She lived 10 days afterwards.

"Mr. Justice Byles asked what were her words, as nearly as the witness could tell?

"The witness replied that her exact words were, 'I am sure to die.' Again, before she made the statement, she expressed an opinion that she would not recover. That was a day or two before she made the statement. Witness told her she was very seriously ill. He wrote the statement she made, and it was embodied in the depositions.

"Mr. Daly tendered this statement in evidence, and asked that it might be read.

"Mr. M. Williams objected on the ground that under the circumstances in which it was made it could not be received.

"Mr. Justice Byles yielded for the present to the objection, and thought Mr. Williams ought to exercise his right at once of cross-examining the witness.

"Witness, in cross-examination, said he did not tell her she would die before she made the statement. He told her she was in great danger; that as long as there was life there was hope; but that they, as her Medical advisers, had lost all hope of her recovery. That was immediately before she made the statement. He expressed no opinion about her death before she made it. She spoke of her friends, and wished them to be written to. He sent for a magistrate, but he did not attend.

"By Mr. Daly: She said she knew she should die before the statement was made.

"Mr. Justice Byles: What was the last expression by her with reference to her state before you actually wrote her words down?

"Witness: 'I am sure I shall die.'

"What was the last expression of your opinion as to her state before you wrote what you did?—I told her she would not recover.

"Mr. Daly again tendered the statement as evidence; and

"Mr. Williams objected, as before, that it was not receivable under the circumstances in which it was made. He remarked that the witness, without meaning it, had contradicted himself two or three times.

"Mr. Justice Byles said there was undoubtedly an inconsistency in the witness's evidence.

"Mr. Williams submitted that to render the statement receivable it must be shown that Mrs. Sloman, at the time she made it, had lost all hope of recovery. He called attention to a case reported in 7th 'Carrington and Payne,' p. 254, third edition, where Mr. Justice Coleridge held that he thought he ought not to receive the statement of a deceased person, though the latter said before it was made that 'she thought she would not recover;' the exact words used by Mrs. Sloman, and, accordingly, the Judge rejected it. In page 253 of the same volume Baron Hullock was reported to have held that the principle on which a declaration was receivable as evidence was, that the party making it was *in articulo mortis* at the time, and that it was made under an impression of almost immediate dissolution. Upon these two cases, he submitted that the statement could not be received.

"Mr Justice Byles thought that, in order to render it receivable, it was necessary, among other requisites, to show that Mrs. Sloman was under the impression at the time that her death was impending, or under the impression that she had received an injury from which death must ensue, or, as the popular phrase went, that she then believed she was at the point of death.

Mr. Daly quoted a passage from "Archbold," in which the authorities on this point were all collected, and where it was stated that dying declarations were receivable if the person making them believed he was in a dying state at the time, even though he did not die for eleven days afterwards.

Mr. Justice Byles held that the person making them must either be, or suppose himself to be, in a dying state. He had thought at first to reserve this point, but now he should not do so. He would decide at once that the objection was a valid one, and that the statement tendered could not be received. He could not decide in favour of the prosecution unless he believed that the woman knew she was in a dying state at the time she made it. The evidence of the Medical man was not to be reconciled, and the statement here made was not upon oath.

Mr. Daly admitted that the Medical man had contradicted himself.

"Mr. Justice Byles said he must reject that statement, because he did not see clearly that Mrs. Sloman knew she was passing out of this world, and that all terrestrial things, so far as she was concerned, were coming to an end.

"Mr. Daly admitted that if the statement were rejected the case for the prosecution must fail.

"Mr. Justice Byles then told the jury that, assuming upon the evidence that the unfortunate deceased died from the criminal attempt made upon her to procure abortion, there was no evidence to prove who made that attempt, and the prisoner must be acquitted.

"The jury immediately returned a verdict of "Not Guilty."

"The same prisoner and her daughter, Caroline Forester, were then indicted on the Coroner's inquisition (the bill against the latter prisoner having been thrown out by the grand jury) for the manslaughter of Mrs. Sloman.

"Upon this indictment Mr. Daly offered no evidence.

"A verdict of 'Not Guilty' was taken, and both the prisoners were discharged.

FROM ABROAD.—M. GUERIN ON THE SUBCUTANEOUS METHOD.

M. Jules Guérin, the veteran author of the "subcutaneous method," not satisfied that his views have even yet become thoroughly comprehended, constantly reiterated though they have been, read last week a paper at the Academy of Medicine, in which he summarily re-stated them, and which he introduced in the following terms:—

"During the now well nigh thirty years that I have made known the fundamental difference presented by the cicatrisation of wounds under the skin and exposed to the air, I have had frequent occasion to convince myself that this difference is not always sufficiently appreciated, and that the expressions which I proposed to characterise it have not always been accepted in the sense and extent which I assigned to them. Quite recently, on the occasion of my laying a communication before the Academy on the 'Treatment of Exposed Wounds by Pneumatic Occlusion,' I met with, on the part of one of the most able of my colleagues (M. Velpeau), a renewed manifestation of that difference of opinion, which dates on his part as far back as the original exposition of my ideas on the immediate organisation of subcutaneous wounds. Such diversity would justify this new development of so important a question in pathological physiology, were I not likewise led to it by the necessity of specifying in a more complete manner the order of the phenomena which constitute the scientific basis of the new Surgical method which I have recently proposed. (*Medical Times and Gazette*, Feb. 17, p. 180.)

"I now am about to recapitulate in a definite manner the facts and considerations which are fitted to establish,—1. That the physiological process which I have designated by the term *immediate organisation* of subcutaneous wounds is a process essentially different from the process of cicatrisation of wounds when exposed to the air. 2. That this process, wrongly considered as the product of *adhesive inflammation*, or of the *agglutination* of surfaces brought into contact, is, from its initial phenomenon until its last stage, the analogue of the primary formative process of organs. 3. That the immediate organisation of wounds subtracted from contact with the air is really the result of the absence of such contact, just as the suppurative process of inflammation, which inevitably precedes the cicatrisation of exposed wounds, is truly the effect and result of contact with the air. 4. Finally, the methods which are privileged to induce the immediate organisation of wounds owe this to the property which they have of preserving the wounds from contact with the air; and that consequently their essential character, their originality, and their efficacy are derived far less from the material dispositions of the operative procedures than from the complete knowledge of the principle which constitutes their basis, and the appropriation of procedures which are well calculated to correspond to this principle and to develope its benefits.

"Such are the four propositions which appear to me, when suitably developed and confirmed by the various proofs upon which they are based, capable of carrying conviction into every mind as to the fundamental character of the physiological process by which wounds are cicatrised when sheltered from contact with the air, and the originality of the methods which have given rise to this result."

PARLIAMENTARY.—ARMY AND NAVY MEDICAL OFFICERS—CAPITAL PUNISHMENT BILL—LUNACY ACT (SCOTLAND) AMENDMENT BILL—MEDICAL ATTENDANCE AT POLICE STATIONS.

In the House of Commons, on Thursday, June 14,

Colonel North asked the Secretary to the Treasury whether the recommendations of the Committee presided over by Admiral Sir Alexander Milne, relative to the Medical Officers of the Navy and Army, and upon which the authorities both of the Navy and Army had been for some time in communication with the Treasury, were likely to be decided upon shortly. He begged to remind the House that the Committee reported early in February.

Mr. Childers: In reply to my hon. friend, I have to state that the circumstances are these:—In July last the College of Physicians wrote to the War Office complaining that the *status* of Army Surgeons was unsatisfactory, and to the Admiralty that Navy Surgeons were, both as to pay and rank, not on a par with Army Surgeons. In consequence, the War Office and the Admiralty appointed a Departmental Committee, consisting of military and naval officers, and of Medical men recommended by the Colleges of Physicians and Surgeons, to inquire into the rank, pay, and position of the Surgeons of the two services. The Treasury were not parties to the inquiry, and they have as yet only been officially in communication with the Admiralty on the subject. When we are in possession of the definite views of both the departments, we shall be in a condition to deal with the cases of both the Army and Navy Surgeons at the same time. The question is a very important one, involves a large amount of money, and requires careful consideration.

Colonel North asked whether no communication had been received from the War Office.

Mr. Childers said the War Department had not yet made their recommendations upon the report of the Committee; but he personally had been in communication with his noble friend.

In the House of Lords on Friday,

Upon the re-committal of the Law of Capital Punishments Bill, Lord St. Leonards took occasion to urge several objections against private executions, and argued that the deterrent, and consequently the beneficial influence of capital punishment would be diminished by a departure from the present system of public executions.

The Duke of Richmond and the Lord Chancellor, on the other hand, agreed that, however beneficial public trials might be, public executions were objectionable; and Lord Dunsany urged the adoption of precautions to ensure the efficacious application of the capital law, incidentally remarking, as an Irish grievance, that the only skilful hangman was an Englishman, who was never sent over to perform his duties in Ireland.

Lord Romney favoured public executions as public warnings; but

The Bishop of Oxford took a different view, doubting the deterrent effects of public executions.

Upon a division, the clause empowering private executions was agreed to by 75 to 25.

After some further discussion upon details, the Bill passed through committee.

Upon the report of amendments on the Lunacy Act (Scotland) Amendment Bill being brought up,

The Earl of Shaftesbury moved that a clause should be inserted in the Bill empowering the directors of any chartered Lunatic Asylum in Scotland to grant retiring allowances out of the funds at their disposal to any of their officers who had served for fifteen years, and who were more than 50 years of age. In the interest of the lunatics, as well as of their attendants, it was of importance that the faithful and laborious

services of the latter should be compensated by the reduction of the term of service requisite to entitle them to a retiring allowance from twenty to fifteen years, as had already been done in England.

The Report was then agreed to, and the clause was inserted. We trust that this clause will include the Medical officers of the Lunatic Asylums.

On Monday, June 18,

The Marquis Townshend asked whether any instructions had recently been given to the police relative to the treatment of persons in a state of insensibility taken to police stations.

Lord Stanley of Alderley was understood to say that the police had been instructed on such occasions to send for Medical assistance.

The Lunacy Acts (Scotland) Amendment Bill was read a third time and passed.

SYPHILITIC INOCULATION.—A FEW REMARKS BY THE WRITER OF "MODERN SYPHILOGRAPHERS."

In an age so eminently characterised by a critical and experimental tone of thought as the present, it is not surprising that the etiology, pathology, and therapeutics of syphilitic diseases have undergone a rigid examination. Different, and, in many instances, conflicting views, are held and taught. A spirit of dogma has been supplanted by one of scepticism, and from scepticism to heterodoxy the step is short.

So far from controversy, however, retarding the progress of truth, it accelerates its movement. The writer disclaims entirely any feeling of enmity or prejudice to a system of treatment because it is new. He desires that the therapeutical effects of Syphilisation should be fully and fairly tried.

The question as to the identity or non-identity of the virus producing the indurated constitutional and the soft local chancre, possesses no interest apart from a scientific one. So long as a Surgeon practically recognises a distinction, well and good; but so long as he ignores it altogether, and treats all venereal ulcers by mercury, he does so at a grievous and unnecessary cost on his patient's time and strength.

There are some facts connected with the Etiology and Pathology of venereal sores, which appear to be more capable of explanation upon the theory of the non-identity of the causes—of which the local soft venereal ulcer and that which is the precursor of general syphilitic manifestations are the effects; but there are, undoubtedly, other facts which are susceptible of the opposite conclusion. The proper attitude for the present is a suspension of judgment, but such an attitude is of course very distasteful to all those who have already made up their own minds. If we take a hundred cases at random, it will be found, as a rule, that, in the case of the indurated sore, a far longer interval has elapsed between the date of the infecting coitus and the manifestation of any diseased action, than in the other form. It is not at all uncommon to see an induration appear at the base of a soft ulcer, and to witness an indurated chancre evolved on the same structure as a soft one, but always subsequently, and never the reverse. If the specific cause be identical in both cases, why does it not occasionally happen that the indurated sore precedes the soft?

It will be said, perhaps, that the inflammatory reaction, the ulceration and secretion of pus, mark the activity of the process and the peculiar potency of the virus by which it was induced, while they indicate the reason of the constitutional immunity. The poison disintegrates the tissue, and discharges itself in the pus products, instead of producing a local deposit of firm lymph, which offers a barrier to its local elimination. But is it so? Although there are many authorities who believe that you can prevent constitutional manifestations by an early cauterisation or excision of the chancre, yet, the results have not been so encouraging as to make the practice a common one. Our own experience is, that if you destroy a lesion in its initial stage, before its character is developed, you will sometimes have induration appearing at the site of the wound; and if you remove an indurated sore by these methods you may have the same thing, or an artificial ulcer only, but you will not save the patient's system in either case. Again, if we induce the most rapid ulceration and suppuration in a hard sore, or upon the surface of an ulcer before it has assumed hardness, we cannot protect the system by it; nor is the patient saved from constitutional syphilis if a suppurating bubo complicates the primary lesion, providing that lesion be of the infecting character.

Assuming the virus to be same in both cases of sore, how can we explain the fact that you can successfully inoculate the indurated with the pus of the soft sore? It would be impossible to re-vaccinate at the site of a successful vaccination. But, in the instance before us, the same, or a variety only of the same poison, can be made to reproduce its effects not only on the same soil, but even when implanted upon the self-same spot of that soil where the morbid effect has been already set up. When you succeed in inoculating the pus from a hard sore, you do not induce another hard, but a soft sore. Why should not such inoculations reproduce the specific deposit? Indurations on the penis and other parts of the body may undoubtedly appear as secondary syphilitic manifestations, and these sometimes accurately resemble hard chancres, and this proves that there is no absolute insusceptibility on the part of the system to reproduce the lymph which forms the induration.

Chancre-isation appears to us a more correct term than syphilisation—at any rate for the present.

We do not dwell upon the history of these diseases. True syphilis—constitutional syphilis—might have been present in the world since the time of Cain's curse; but no one has succeeded in tracing an account of it. We have, on the other hand, the evidence of men living at the close of the fifteenth century, who described the main differences between the old local, soft, and the—to them—new, infecting, indurated chancre. Clinically, the best observers are agreed in this—that, in their symptoms and consequences, the two forms of sore offer points of contrast. It sometimes requires tact, experience, and some careful watching on our parts, to determine the character of a venereal ulcer; but the hardening process is, we suspect, almost invariably present in some degree—in the chancre, its cicatrix, or the neighbouring glands.

That a previously syphilised individual should contract a chancre with modified characters—a soft ulcer—from inoculation with the secretions of a syphilitic lesion (if such inoculation has any effect at all) we can well believe, because instances of it have often occurred in our own practice. The product of the inoculation is then an abortive effect, such as we usually obtain by revaccinating an adult who has been previously vaccinated in childhood. What would be the effect of vaccinating infants from such an aborted vaccine pustule we do not know. It may be, that the pus of such a sore,—derived from a prostitute who has once been the subject of constitutional syphilis, but who does not at the time labour under its manifestations,—is the cause of the local soft sore in the infected individual; but we really know nothing of the causes, and next to nothing of the origin, of these diseases.

The most we can do is to trace the descent of the two affections, in order to discover whether they are separate or distinct, or interchangeable. It is confessedly difficult to do this; but if it could be proved that the virus of the local soft sore, derived from a soil untainted by constitutional syphilitic manifestations, could give rise to the indurated one and secondaries in another individual, the ground would be cut from under the feet of the so-called dualists. But precision and exactness are required, because it is imperative that the virus used be that of the local soft sore, and nothing but that. The source of the contagion must neither be suffering from

constitutional syphilis nor exhibit subsequent manifestations of that disease, as a consequenee of the lesion from which the virus was obtained.

We have been on the "look out" for evidence on theso points, and so far as we have any satisfactory data at all it seems to us that syphilis produces syphilis, and the chancroid poison chancroid. There can be no doubt that the secretions of the hard sore are sometimes inoculable in a syphilitic soil, and this fact is pointed to as conclusive evidence of the identity of the virus in the two forms of primary lesion. And it certainly is strong, although not conclusive evidenee. The infecting power of the syphilitic virus appears to diminish very markedly the farther it is removed from the primary lesion. As modified chaneres present themselves in patients recovered from syphilis, so you might induce such chancres in a person suffering from secondary symptoms by the inoculation of pus obtained from the hard chancre of another individual, even more easily, perhaps, than by auto-inoculation. If, however, that pus were inserted in virgin ground, it would, we suspeet, always produee an indurated infecting sore, and none other.

Now let me add a few words upon the subject of mercury. By none would another and a better method of treating syphilis be more welcomed than by us Surgeons. We are fully alive to the shortcomings of mercury, spite of what Dr. M'Loughlin may write. If the verdict be in favour of the great therapeutic superiority of syphilisation, it will soon be adopted. For the present we hesitate.

There is one form of this disease which demands a word. There is no primary lesion of uncertain character to fight about; the nature of the case is plain. We allude to infantile syphilis.

What may be the exact impression left upon the minds of our leading Physicians we know not, but, to judge from the number of sueh cases in the out-patient department of our great Hospitals, and the very common—almost unanimous—employment of mercury in some form or other for their treatment, we shall not be far wrong in assuming that its great therapeutic influence is generally recognised.

The rapidity and eomparative certainty with which the manifestations of infantile syphilis disappear under mercury have made a very strong impression on our own mind. Delay in its employment is so much time wasted, and worse than wasted, because its administration is sometimes too late when the syphilitic cachexia is advanced and pronounced. There is, too, this circumstance attending its use: you can almost foretel the amelioration which will take place from week to week, and you can corroborate the truth of your prophecy by the observation of the patient; and there are very few drugs in the Pharmacopœia of which you can say as much.

We think that there must be great difficulties in the way of practising syphilisation in this country, except in our Lock Hospitals and Public Services. A Medical friend, who witnessed the process of syphilisation as pursued on a patient by M. Bidenkap, at the Richmond Hospital, Dublin, told us that the results obtained there, by inoculating the secretions from hard sores, were so negative or unsatisfactory that M. Bidenkap had recourse to some chancre virus obtained from Norway. After some two months' inoculation, the patient's syphilitic symptoms did not appear to be at all ameliorated, and the numerous cicatrices on his body were not an encouraging speetaele for other patients to pursue the same treatment.

Western Medical and Surgical Society of London.—At the annual meeting, held on June 1, the following officers were elected for the next session:—*President*—Dr. Fuller. *Vice Presidents*—Mr. P. Hewett, Dr. Marcet, Mr. T. Dickinson, Dr. Anstie. *Council*—Dr. Way, Mr. Vasey, Dr. D. Davies, Mr. Traer, Mr. Knight, Dr. Daniell, Dr. Blandford, Mr. T. Holmes, Mr. J. R. Lane, Dr. Morell Mackenzie, Mr. Naylor, Dr. Fyfe. *Treasurer*—Dr. Baines. *Honorary Librarian*—Dr. Godwin. *Honorary Secretaries*—Mr. Milner and Mr. C. Hunter. *Auditors*—Mr. T. Taylor and Mr. Hall.

TREATMENT OF CATTLE PLAGUE BY INJECTION OF ARTIFICIAL CHYLE.

Dr. Richardson has forwarded to the Government of Ireland his proposition, made in January last to the Home Secretary, Sir George Grey, for the treatment of animals suffering from cattle plague. This proposition has already been before the Profession for several months, but has scarcely received the attention we should have expected. We may, therefore, place in the hands of our readers the following facts, taken from the correspondence between the author of the proposed method, the Home Secretary, and the Royal Commissioners. In his first letter, which was addressed to Sir George Grey, and was forwarded on the 16th of January last, Dr. Richardson writes to ask if Her Majesty's Government would allow him for experiment a hundred head of cattle suffering from the Rinderpest at various stages of the disease, together with the means of subjecting the animals to treatment. For his purpose he should simply require aecommodation in a healthy shed or stable for five or six animals at one time, with proper food for the animals, medicines, two keepers, and a reporter of cases. The only further favour he asks is that two or three scientific eommissioners should be deputed to watch the results of the treatment, and to certify to the correctness of those results on his report. He adds that previous to taking this step he had placed all the details of his proposed inquiry before the President of the Royal College of Physicians, and the President, after carefully eonsidering these details, had expressed his opinion that the proposal altogether was based on sound scientific principles, and was of a nature to deserve earnest eonsideration. This letter led to the placing of the proposition before the Royal Commissioners who were then sitting. The proposition was accompanied with explanatory notes, certain of which we subjoin.

In the first place, as to the curability of the disease, Dr. Richardson offered the following arguments:—

"I premise that the disease is curable, and for the following reasons:—

"1. According to my observation it is a disease affecting one set of organs only—the organs of vegetative life. The secondary changes which oceur appear to me to be due altogether to a modified oxidation of the blood. In so far as I can gather, derangement of the nervous centres is no essential part of the malady. I look on these facts as tending to simplify very much every suggestion in respect to treatment, and as affording hope of the discovery of a means of cure.

"2. I observe that there are many instances of a spontaneous recovery in affected animals, a fact which I think especially favours—nay, indeed, proves the possibility of cure. Three days ago I saw two animals, of the same breed and age, in the same stall, fed on the same kind of food, breathing the same kind of air, and suffering from the malady in the same stage and in the same degree of severity. To-day I find that one of these animals died seven hours after I saw it, while the second animal—both having been treated alike—began, soon after the first died, to recover, and did recover so rapidly that now it is comparatively well. If the disease were incurable, why did not both these animals die? It is plain that there is a period during which the malady may be said naturally to last, and that the mode in which that period shall end turns on the power of the animal to pass through the said period. If, while its force is largely expended in eliminating from its body the morbid products that are common to the malady, the animal can also produee sufficient force to sustain a low form of life, it will begin to recover so soon as the elimination of diseased product is perfected. If it fail to produce sufficient force to sustain both elimination and the power necessary to keep the heart and the chest muscles in action, it will die. In plain words, the natural cure of the disease is elimination; and whether the cure be effective or not turns on the ability of the animal to sustain the eliminative process and its own natural processes at one and the same time. I hold, then, that art should step in and should do so little, and yet so much, as should place all animals on a par in respeet to their power of sustaining natural recovery.

"The means I would suggest for the scientific treatment

of the cattle plague are based on the principles I have laid down in the preceding paragraphs. There are, in my opinion, two clear lines of treatment open, applicable to two special periods of the malady. In the first stage, while the force of the animal has been but little interfered with or reduced, it would be advisable, I think, to increase the process of elimination and to secure as rapidly as possible the removal of the poison from the organism. In the second and later stages, it would be correct to sustain the animal force so that time might be gained for the perfection of the process of elimination.

"I believe it is possible to carry out both these intentions by means that are rational in principle and easy in application."

Having described a method of securing elimination by subcutaneous injection, Dr. Richardson continues :—

"To carry out the second intention of treatment, I suggest the artificial feeding of the animals during the later stages of the malady, so as to enable them to live on through the period of natural elimination of the poison. As the disorder presents itself to my mind, the circumstance of recovery turns in every case on the sustainment of secreting force by the animal; while the sustainment of secreting force, in its turn, depends on the power of the animal to take in and apply the source or store of force—food and drink. The common experience is to the effect that if the animals can be fed they live; if they refuse food, or if taking food it remains undigested in the first stomach, they die. In plain words, the blood not being supplied with new force burns out, and as is common in all this class of epidemic disorders, there is thus produced a condition which I have elsewhere designated as asphyxia commencing in the blood; the blood is not oxidised, the animal fire declines, and death—inertia—is the result. How, then, can this condition be met? In the first place, it can largely be met by paying great attention to the feeding and nursing of the animals. If the animals are placed in a warm room, and if they are steadily and persistently fed with food warmed to 96° Fahr., finely cut up, and well softened and diluted with water, the chance of recovery is unquestionably increased. Evidence of a very satisfactory nature on this point admits of being collected.

"But there are many cases in which, though food be introduced into the alimentary system of the animal, it undergoes there no proper digestion nor absorption, the surface of the alimentary canal being itself unnatural and unable to perform its ordinary functions. In these cases feeding by the mouth is of little service. Here I think art ought to step in and render important aid.

"I propose that in these instances the animal *should be fed artificially through the veins*, with a fluid resembling that which it manufactures in its own digestive organs, and throws into its own veins, I mean *an artificial chyle*.

"That an animal can be fed through the veins is a fact proved by experiment. I have fed a dog with blood through the jugular vein for many days together, and into a young dog, that was feeding ordinarily on milk, I have successfully injected milk in the place of blood. Dr. Bovell, of Toronto, in 1854, injected milk even into the veins of men in the last stage of cholera, and with very satisfactory results. We might, therefore, safely inject either blood or milk into the veins of cattle in the later stages of Rinderpest with promise of advantage.

"There would, however, at all times stand in the way the practical difficulty of obtaining blood or milk on a sufficiently extensive scale. My plan, therefore, is to substitute for the fluids an artificial chyle made by subjecting the ordinary food of cattle to artificial digestion out of the body.

"I have produced a fluid for this purpose so closely analogous to natural chyle that it would be difficult to distinguish it from the natural fluid by common observation. This artificial chyle has a specific gravity of 1,030, a dirty-white colour, and an albuminous consistency; it contains albumen and solid matters to the extent of 8 per cent.

"This fluid, warmed to 96° Fahr., I propose to use as food for animals in the later stages of the disease, by injecting it into the external jugular vein in the neck.

The operation of injection would be as simple as that of ordinary blood-letting. It would merely be necessary to insert a bougie into, and tie it firmly in, the vein, securing the vein above by a firm ligature. The feeding tube in the vein, if provided with a stopcock, need not be removed for many hours, so that several supplies of food might be introduced by the same channel. In introducing the food, it would be best not to use a syringe, but to place the liquid in a gallon barrel, provided with a quarter-inch tap. A tube of india-rubber should pass from the tap to the bougie in the vein, the tube being filled first so as to exclude the air. Then the fluid being allowed to flow, an elevation of two feet above the animal would give sufficient pressure of current to feed the vein."

The Secretary of the Commissioners acknowledged the receipt of these suggestions on February 8, and intimated that they had been placed in the hands of Dr. Bence Jones, as chairman of the experimental committee.

How far the experiment of artificial feeding through the veins would have succeeded we cannot of course say, though we regret that so simple a means was not tried, and we would urge the Irish Government to test the matter fairly and faithfully. We need scarcely add that Dr. Richardson's plan anticipates by many months the suggested curative measures, by transfusion, which have appeared in the *Times* and other papers during the past month.

REVIEWS.

A Treatise on the Principles and Practice of Medicine, Designed for the Use of Practitioners and Students of Medicine. By Austin Flint, M.D., Professor of the Principles and Practice of Medicine at the Belle Vue Hospital Medical College, and in the Long Island College Hospital, etc. Philadelphia: Henry C. Lea. 1866. Pp. 867.

The first teaching that a student receives at the schools is necessarily dogmatic. It must and ought to be so. It is for each man to correct and modify the opinions first inculcated by his own careful observation and experience. The book before us is of that class that students thus usually read when attending their first course of lectures on Medicine, and avoiding as it does the discussion of controverted questions, while it presents a very fair summary of the present condition of Medical science and art, we have no hesitation in expressing a favourable opinion of it.

Regarding it as embodying the results of Dr. Flint's own experience, there are one or two points which we shall refer to as of general Professional interest. And, first, as to cholera, a subject of importance just now. Like the majority of the Profession in Great Britain, Dr. Flint insists upon the necessity for arresting by astringent remedies the progress o any intestinal flux that may occur during an epidemic season, and recommends that any constipation that it may be desirable to overcome at such a time should be treated rather with enemata than with purgatives. The last, however, is a matter which each Practitioner must decide when the special instance is before him, and upon the basis of the peculiarity of the particular case. We are indisposed to endorse the above as an absolute rule of practice. What we wish to call special attention to is that Dr. Flint's experience, as given in the succeeding quotation, is that of all who have had anything to do with the public arrangements made under similar circumstances to the present:—"The great difficulty as regards the prevention of cholera is in the prompt application of simple, but effectual, treatment in all cases of diarrhœa during the epidemic. Very many pay no attention to the premonitory diarrhœa through ignorance, and not a few of those better informed neglect it either from recklessness or because they cannot appreciate the fact that a disorder so slight and ordinary can be a precursor of a malady of such gravity as cholera. Public announcements by handbills, articles in newspapers, etc., of the importance of promptly resorting to treatment for diarrhœa fail in accomplishing the object. The only effectual plan is to organise a sanitary benevolent police, and provide for one or two domiciliary visits daily at every house within the limits of the epidemic, the purpose of the visits being to inquire if any one be affected with diarrhœa, to impress the importance of immediate attention to it, and, when circumstances render it necessary, to supply at once appropriate remedies. This plan, faithfully carried out, would, I believe, demonstrate that cholera is in a great measure preventible."—P. 428.

Dr. Flint writes thus respecting the use of mercury in acute peritonitis:—"It is, perhaps, questionable whether in so grave an affection as acute peritonitis we are fully warranted in omitting this remedy. I must confess, however, that for some years past it has not entered into the treatment of the cases of

which I have had charge."—P. 452. His reticence exhibited in the first part of this quotation is then merely in accordance with a practice not yet abandoned generally in the United States. He gives no rule as to the quantity of opium to be given when the opium treatment is adopted, except that, avoiding, of course, undue narcotism, the opiate given in a full dose at first is to be repeated at intervals of from two to three hours in doses sufficient to prevent return of pain. Our own practice is guided very much by the condition of the pupil in severe cases. Narcotism is not easily brought about; the opium seems rather to favour wakefulness, and our custom is to contract the pupil, and to take care to keep it contracted as long as the activity of the disease persists. The quantity of opium necessary to be given for this purpose is a matter of little importance, and need not create any dread of overdosing in the mind of the Practitioner, so long as the doses are sufficiently divided and the patient visited sufficiently often. We are also glad to have our own opinion confirmed by the experience of Dr. Flint as to the uselessness of mercurialising pericarditic patients. We have long ago dropped mercury out of our list of remedies in pericarditis. Dr. Flint says—"In treating of this point in my work on 'Disease of the Heart,' I expressed myself with a certain amount of reserve; but further reflection and observation have prepared me to take a more decided position against the importance of this measure (mercurialisation). Since that work was written (and, indeed, for the most part previously) I have treated the cases of pericarditis which have come under my observation without mercury, and I have found no reason to be dissatisfied with its omission."—P. 270. He gives the number of cases, their complications and results, in proof of his success, adding (and we entirely concur with him), "Opium is invaluable in this as in other acute inflammations."

We shall conclude by the extract of a case of importation of typhoid fever. We are rather astonished that Dr. Flint sees in it nothing more than an instance of the communication of the disease by contagion, laying no stress whatever upon the important fact as to the use of the well-water or the possible contamination of it by the excretions of the first patient. The case is so interesting that we shall give it in full:—"Many instances of the kind have been reported; but the most remarkable of any on record came under my observation in 1843 in a little settlement called North Boston, situated eighteen miles from the city of Buffalo, consisting of nine families, all being within an area of 100 rods in diameter; but the few houses in which the disease occurred were closely grouped together around a tavern, the house farthest removed from the tavern being only ten rods distant. A stranger from New England, travelling in a stage coach which passed through this settlement, had been ill for several days, and on arriving at this stopping place was unable to proceed further. He remained at the tavern, and after a few days died. He was seen by several Physicians of the vicinity; and there can be no doubt that his disease was the same as that with which others were subsequently affected. Up to this time typhoid fever had never been known in that neighbourhood. The sick stranger was seen by the members of all the families in immediate proximity to the tavern with a single exception. One family, named Stearn, having quarrelled with the tavern-keeper, had no intercourse with the family of the latter, and very little with the other families, all of whom were tenants of the tavern-keeper. No members of the family of Stearn either saw the sick stranger or any of those who were taken ill after the stranger's death. Members of the family of the tavern-keeper were the first to become affected, the first case occurring twenty-three days after the arrival of the stranger. Other cases speedily occurred in the surrounding families. In a month, more than half the population, numbering forty-three, had been affected, and ten had died. Of the families immediately surrounding the tavern, that of Stearn's alone escaped; no case occurred in this family. The occurrence of the disease produced great excitement in the neighbourhood. Poisoning was suspected, and Stearns was charged with having poisoned a well used in common by all the families except his own. A fact which encouraged this suspicion was, the common well being owned by the tavern-keeper, he had refused permission to use it to Stearns, who had in consequence to dig a well for his own use. An examination of the water from the common well showed it to be perfectly pure. The disease was undoubtedly typhoid fever. Visiting this settlement during the prevalence of the disease, and recording the symptoms of several cases then in progress, the clinical history furnished abundant evidence of the nature of the disease. Moreover, I made an examination of the body of one of those who died with the disease, and found the Peyerian patches ulcerated and the mesenteric glands greatly enlarged."—P. 711.

Dr. J. Moore Neligan's Practical Treatise on Diseases of the Skin. Second edition, enlarged and revised. By T. W. Belcher, M.A., M.D Dub., B.M., M.A. Oxon., Fellow, Censor, Examiner in Materia Medica and Medical Jurisprudence, and in Arts, and Hon. Librarian King and Queen's College of Physicians in Ireland; Physician to the Dublin Dispensary for Skin Diseases, etc. 1866. Dublin: Fannin and Co. London: Longmans and Co.

The late Dr. Neligan's Treatise must be well known to many of our readers as one of the numerous modern works on the diseases of the skin which have rescued the treatment of these maladies from the quacks, or from being a narrow specialism, and established it as a part of the domain of scientific Medicine, and so fully has this been accomplished that the production of a work on the diseases of the skin—of the external lung, if we may so term it—no more marks a Physician necessarily as a specialist than does his having enriched the literature of the internal lungs. A very striking proof of the earnestness with which diseases of the skin have been studied, and of the extent of that study, is seen in the fact that the "Bibliographical Index" added by Dr. Belcher to this work covers sixteen pages.

It is generally sufficient, when any work attains a second edition, simply to mention the fact, which is in itself notice and comment; but Dr. Belcher has done so much by way of "revision and enlargement" for Dr. Neligan's Treatise, that his edition of it demands a fuller notice. We cannot better give an idea of what he has done for the work than by quoting from his Preface the following list of "additions now made:"—

"1. A Copious Table of Contents. 2. Considerable Additions to chap. i., on Classification; chiefly as regards the modern nosologies of Hardy, Hebra, Buchanan, and others. 3. Derivations and meanings of technical terms, and their synonyms. 4. References to Dr. Neligan's 'Atlas of Cutaneous Diseases,' as also to the plates of Cazenave and Hebra. 5. References to Professor Macnamara's Sixth Edition of Dr. Neligan's Materia Medica. 6. Quotations from, and references to, authorities in every case. 7. Explanations of the peculiar modes of treatment, and in some cases the prescriptions, of the best home and foreign dermatologists. 8. An entire translation of the numerous prescriptions of the first edition, with those now added, into the technical language of the British Pharmacopœia. 9. Posological table of the most important, and mostly poisonous, medicines used in the treatment of cutaneous diseases. 10. A Copious Bibliographical Index of the Chief Authorities quoted."

Notices of many diseases, not alluded to in the first edition, have been added; such as of rubeola, scarlatina, variola and its allies, furunculus, anthrax, pustula maligna, lepra Hebræorum, elephantiasis, pellegra, morbus Addisonii, etc. The chapter on Parasitic Diseases, or Dermatophytæ, has been revised, and considerably added to; also that on Diseases of the Hair and Nails, and that on Therapeutics; and the General Index has been enlarged and re-written. All the work has been done well, and the result is a very useful and trustworthy "practical treatise." Dr. Belcher brings to his work considerable experience and knowledge of skin disease, and an extensive acquaintance with the literature of the subject; this last he draws on very freely and largely, and he is most careful in acknowledging on every occasion the writers to whom he and Dr. Neligan have been indebted. The works of Mr. Erasmus Wilson and Dr. Tilbury Fox have been found especially useful—they are referred to on almost every subject. Almost the only objection we have to make to the work is to the "phraseology employed." Where Dr. Belcher gives his personal opinion and experience, his remarks "are given in the third person singular," which produces a rather awkward and rugged effect. We cannot but think that he had better have written in the first person, as Dr. Neligan did, and enclose his remarks in brackets. But of the value of the book there will be, we think, only one opinion, and we believe Dr. Belcher will find that he is justified in his "trust that the work will not only suit the busy Practitioner, the man of one book (on this subject), for whom this volume is primarily designed, but also the industrious Medical student, the Practitioner 'getting up' a paper for a Medical society, and the lecturer, for ready reference and saving of valuable time."

Atlas of Portraits of Diseases of the Skin. Issued by the New Sydenham Society. Fifth Fasiculus.

This fasieulus contains three portraits—those of Pityriasis Versicolor, Pemphigus, and Psoriasis Vulgaris, var. Inveterata. They are "drawn from nature" by E. Burgess, and chromolithographed by W. West. The portrait of Pityriasis Versicolor is really good, and the others better than usual. It is the best number of the Atlas yet published, we think, and we are happy in being able to give it a word of hearty commendation.

A Companion to the British Pharmacopœia, comparing the Strength of the various Preparations with those of the London, Edinburgh, and Dublin, United States, and other Foreign Pharmacopœias; with Practical Hints on Prescribing. By Peter Squire, F.L.S., Chemist in the Establishment of the Queen, etc. Third Edition. Churchill and Sons. 1866. Pp. 262.

In reviewing the former editions of this work, we spoke in the highest terms of the matter, of the style, and of the general *get up* of the publication. It was a book perfect at all points, and now has not been improved so much as enlarged by the addition of fresh matters of practical interest. The author has corrected it so as to introduce the preparations of the seventh edition of the Prussian Pharmacopœia. As we have said before, the book is so exquisitely arranged as to type and headings that the busiest man can find what he wants in a minute. He finds all the essence of the British Pharmacopœia, and a comparative statement of the analogous preparations in all other known Pharmacopœias. He finds also all the popular non-officinal preparations (chlorodyne, etc.), which ought to be in the P. B., but are not. Practical hints, such as only could be supplied by a man in the daily habit of dealing with drugs, are largely added to this edition. For instance, Mr. Squire tells the chemist what mucilage will make a good emulsion; how he may best make pepsine into pills; how to make the Mist. Ferri Comp.; what are the substitutes for lard; and how to dissolve quinine without turbidity. Above all, it contains such an addition of formulæ useful to the prescriber that we shall not be surprised at the speedy appearance of a fourth edition.

On Disease of the Right Side of the Heart. By Thomas Mee Daldy, Member of the Royal College of Physicians of England, late President of the Hunterian Society. London: Bell and Daldy, 186, Fleet-street. 1866.

This book contains much novelty, and, we believe, real originality. There are parts of it open to much criticism, and very many to cavil. We believe, however, that it is the result of honest work and of much consideration. Dr. Daldy is not a man who writes for the sake of writing, but evidently for the better reason that he feels he has a long while observed certain facts which have not been sufficiently studied by the Profession, and because he has deduced from them some principles of treatment which he thinks will be of real use in practice. We will give his conclusions, and leave our readers to study the arguments on which they are founded:—

"1st. That feebleness of the right heart, and especially of its auricle (utterly independent of obstruction *a fronte*) is a phase of disease constantly presented to our notice, but not sufficiently observed.

"2nd. That dulness on percussion to the right of the junction of the xiphoid cartilage with the lower third of the sternum, and the propagation of the heart-sounds in the direction of the right clavicle, conjoined with the derangement of the circulation of one or more distant organs, are the diagnostic signs of an habitually distended right auricle.

"3rd. That the pathological condition to which I refer—viz., the reduction of the muscular structure of the auricle to something like elastic tissue (not fatty degeneration) is not readily recognisable on necroscopic examination, unless the abnormal distensibility of the auricle during life be carefully borne in mind.

"4th. That this feeble condition of the right heart is frequently hereditary, and traceable through two or even three generations.

"5th. That it gives rise to the following definite results:—(α) The habitual congestive headache from which many persons suffer through their whole life. (β) The vertigo so constantly ascribed to determination of blood to the head, but really consequent upon impeded return of blood from the head. (γ) Deterioration of the brain-tissue (called softening) by impeding the return of blood through the *superior* vena cava, comparable to the results which occur to the tissues of the lower extremities, and of the organs below the level of the heart when the right auricle is unable readily to receive the blood from the *inferior vena cava;* or, viewed from the other side of the circulation, to the results of embolism, feeble left ventricle, or any other cause interfering with the due supply of arterial blood *to* the capillaries. (δ) Mania."

Journal of Social Science. March, 1866.

This number contains much of general and Medical interest. There is a paper by Mr. Hare suggesting an improved constitution of local governing bodies, with special reference to the local government of the metropolis. It also supplies us with the proceedings of the Metropolitan Association of Medical Officers of Health during the current year, including Dr. Montgomery's paper on the origin and propagation of cholera in India by means of religious festivals and pilgrimages, Mr. Beggs' paper upon the dwellings of the poor, and a memorandum of a plan of united action in the case of an epidemic of cholera which was adopted at a recent meeting of the Association, and which is intended for distribution amongst the members of vestries, etc., as embodying the views of the metropolitan Health Officers as to what ought to be done to meet it.

Die Seelenstörungen in ihrem Wesen und ihrer Behandlung. Von Dr. Ed. Ricker. Erlangen: Enke.

Mental Derangements: their Nature and Treatment. By Dr. Ed. Ricker. Erlangen: Enke. Pp. 146.

This little work is an essay which obtained a prize offered by the "German Society for Psychiatry and Legal Psychology," and is published by this Society. The prize was offered for the best treatise on mental alienation, written in a style which would fit it for use among the general public, and we must say that the conditions have been well complied with. Containing as it does only well-known facts, illustrated by well-marked cases, it does not require any lengthy notice at our hands, and we shall only say that it consists of six chapters—the first devoted to mind and body, and how these are brought into connexion; the second on these in a state of disease; the third on the various forms of insanity, with their diagnosis; the fourth on the causation of insanity; the fifth on its treatment; and the last on asylums. The whole is written in a pleasing style, in plain and readily intelligible German, and is well adapted to the wants of any student of mental disorders turning his attention to German for the first time.

GENERAL CORRESPONDENCE.

THE RADICAL CURE OF HERNIA.

Letter from Mr. John Wood.

[To the Editor of the Medical Times and Gazette.]

Sir,—In your Journal of last week is a report of the debate at the Royal Medico-Chirurgical Society upon a new operation for the radical cure of hernia, by Mr. Durham, which I was unavoidably prevented from attending. Some remarks were therein made upon the method of cure practised by me, which appear to have originated in a misapprehension of the real facts, and which I feel, therefore, that I can properly make the subject of this communication.

I have now performed my operation in upwards of 160 cases, chiefly (and almost weekly) in the theatre of King's College Hospital, where the cases may be followed by any one interested in the matter. Out of this number I have had only one death (the case of pyæmia detailed in my work on "Rupture"). Serious symptoms of any kind are now so rare as at once to excite attention and remark. This rate of mortality no competent and candid judge will consider worthy of being entitled as "dangerous," even in an operation of expediency as distinguished from one of necessity.

In the practice of other Surgeons I have seen or heard of a fatal result in three instances. In these the causes of death (as in most cases the causes of failure) have seemed to me so clearly apparent, and so perfectly avoidable by skill and experience, that I am led to consider that, though useful as warnings, they by no means constitute a valid argument against

the operation. The six cases referred to as the only ones treated by me entirely without truss were so treated as experiments, to test the reality and efficiency of the result obtainable by operation alone and unsupported, and in this they were successful. This, however, by no means justifies one in discarding the prudence of some truss support for a short time after the operation, to afford the new adhesions time and opportunity to contract and strengthen. So far as an earnest desire to get at the truth has hitherto enabled me to attain it, I find that the proportion of my success is 65 to 70 per cent. The subject of one very large case, who was operated on nearly five years ago, and who has since then done continuous hard work as a porter, without truss, for two or three years, was shown at King's College Hospital last week, quite well and free from protrusion. Others as good have been also exhibited there from time to time, as the *habitués* of the Hospital well know. Conclusions as to Wutzer's operation I may safely leave to the judgment of the Profession, already pretty plainly pronounced. With respect to that advocated by the author of the paper, I will only remark that proceedings closely similar have been practised here and abroad with such fatality and want of success that they were relinquished; but that if the author, after further experience than that afforded by one exceptional case, is more successful, I shall be very glad to greet him with welcome, and so I believe will all Surgeons who feel that an accumulation of results of this kind is worth much more in our progressive art than either old-fashioned prejudices or prophetic theories.

In conclusion, I must needs claim for my method of operating the power of placing the ligature not "accidentally" but at the pleasure of the Surgeon (if well skilled in anatomy and experienced in hernia), quite as close to the deep opening or internal ring of the rupture, more safely, and quite as completely as by the plan described by the author of the paper. I am, &c. John Wood.

4, Montague-street, Russell-square, W.C., June 18.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, May 22, 1866.

Dr. Alderson, F.R.S., President.

Mr. G. Gaskoin contributed a paper on

CONTINUED INOCULATION AND RECENT VIEWS ON SYPHILIS.

In noticing the inoculation of syphilis on warm-blooded animals as first effected by M. Auzias Turenne in the year 1844, this paper instanced the jealous opposition these experiments encountered at the hands of leading syphilographers in Paris, who were already pledged to a different set of views. This prejudice was increased to a more active antagonism when, as he pursued his demonstrations, M. Auzias alighted on the discovery of a natural limit to the number of these inoculations. The law of immunity from the assault of a particular virus acquired by repeated inoculation of the same was proclaimed by M. Auzias in a paper addressed to the Academy of Sciences at Paris in the year 1850, and his ideas having by this time become matured by reflection as well as by experiment, the terms of the address were so ample as to appear ostentatious; a handle was thus afforded to ill-will and to Parisian ridicule, of which those in possession of the field did not fail to take advantage at his expense. The academical censure, however, which fell on syphilisation in France was not a premeditated attack, but arose out of circumstances foreign to this question; it was a *contre-coup* of other discussion, and it occurred as follows:—A young German Physician, L——n, having acquired syphilis experimentally, consulted both M. Auzias and M. Ricord, and these gentlemen conjointly made one or two inoculations on him, which L——n repeated afterwards a few times with great irregularity. When these sores wore temporarily a bad appearance, M. Ricord, under the influence of prejudice against M. Auzias, brought the patient under the eyes of the Academy of Medicine; not very considerately as far as he himself was concerned, for L——'s case was an unmistakable proof of contagion from secondary syphilis. M. Velpeau, the eminent Surgeon, with a view to the discomfiture of M. Ricord on this question of contagion, moved for a report on the case—a report which, maintained in its first view, could hardly have terminated otherwise than in a censure of M. Ricord's fundamental doctrine of the non-contagion of secondary syphilitic affections, an opinion which he had borrowed from the work of John Hunter, and engrafted on the Medical mind of France long after it had become effete in this country. M. Ricord, however, whose influence was then paramount both with the press and in the Profession, and extraordinarily great in the Academy, with great skill managed to displace the question; the committee of reporters constituted themselves a jury for examining the doctrines of M. Auzias, and condemned syphilisation at a time when materials for opinion were not procurable. Messrs. Malgaigne and Depouil got severely handled for upholding the right of free inquiry, and a veto and an anathema were placed on syphilisation by the press and by the verdict of the Academy throughout France. The consequence of this intrigue was, it is wonderful to say, accepted as law by Europe, if we except Piedmont and Norway. In the first-named country the Cavalier Sperino was already, in spite of much violent opposition, in the path of clinical observation. In none of these countries did the governments lend themselves as instruments of oppression to thought or action; the barrier to progress of ideas arose purely out of Professional interests and prejudice. The paper went on to state that more recently in France these questions have undergone revision: M. Auzias holds a well-merited scientific position; the late Dr. Melchior Roberts obtained permission to practise syphilisation in the public Hospitals of Marseilles, and was gratified by his success; Messrs. Nélaton, Gibert, and Gosselin have made essays in the same line of treatment; M. Bazin laments the want of freedom to carry out his intention. Certain of the French societies and publications have seemed favourable to this method, but the public will be with difficulty reassured. After noticing the apparent benefit of material culture in modifying syphilis in England as compared to other countries, the labours of Dr. Wm. Boeck in Norway, both as regards leprosy and syphilis, were briefly alluded to. Reference was made to the French school of syphilography as little favourable to native talent, borrowing first the ideas of Hunter and now of Carmichael. The doctrine of non-contagion of secondaries, the keystone of Ricord's teaching, received its *coup de grâce* in the year 1859, when the Home Minister, on the instance of M. Auzias Turenne, demanded a report from the Academy of Medicine; and to this report M. Ricord, as a member of the committee, was fain to accede on the 31st of May of that year, conceding the fact of the contagion of secondary syphilis, and putting an end, it is to be hoped, to a renewal of scandals which have fallen heavily on many innocent individuals. The pretension of the French school to rest diagnosis on the inoculability of the chancre was declared to be futile. Their "*chancre mixte*," or mixed chancre, is a species brought into being to support that view. By such means it would seem the subject is made unnecessarily complicated, and the faculty of observation discouraged. A case was adduced of a young man in the Lock Hospital, with hard, dry chancre and secondaries. In this patient the chancre was stimulated into secretion by savine ointment. He was inoculated daily from this sore on the arms, with few intermissions, for the space of seventeen days. At the end of that time a positive result was obtained, and the matter of the ensuing inoculation was carried into a series of eight generations. The same matter was brought into use in syphilising other Hospital patients, and was returned to him from one of these at an early period of his syphilisation, when it went through a further series of seventeen inoculations. In due course immunity was obtained. The patient is in robust health, and apparently cured of his disease.

Dr. Drysdale had at first been prejudiced against syphilisation, but had changed his opinion, and believed the inoculations to be of value. He passed a high eulogium on the experiments of Dr. Boeck. He argued that as syphilis might be like variola, inoculation might do good; and reminded the Society that small-pox was much diminished in severity by the practice of inoculation; and this might to some extent hold good in some instances with respect to syphilisation. As to its being a curative agent—had we a better? was there a better?

Mr. Henry Lee stated that the facts referred to in the paper were very few. Mr. Gaskoin had mentioned that the indurated syphilitic sore had been inoculated upon animals; and he had referred to the case of a patient named D—— as

having been inoculated from his own indurated sore. With regard to the first point, he had given no proof whatever to support his assertion; and with regard to the latter, he had omitted the important fact that D—— was inoculated at the same time, and by the same lancet, with the secretion from a suppurating sore. Before we could reason upon the effects of syphilitic inoculation we must define our terms. It was not easily demonstrated that the secretion of an indurated sore could be inoculated upon a syphilitic subject. If inoculated, that which resulted was a non-indurated sore: and even granting, for the sake of argument, that this was really the inoculation of the infecting kind of syphilis, it yet remained to be demonstrated that a patient's constitution was susceptible to the action of the poison. The term "syphilisation" was not appropriate until these actions could be defined. It had been stated by Dr. Drysdale that the treatment by syphilisation (so-called) was very uniformly successful; we had, however, no proof of this hitherto in England. It was well known that some deaths had taken place under the treatment. It was also known that in other cases the treatment had been discontinued; and we had yet to learn in how many cases relapses would occur. With regard to the immunity said to be produced by repeated inoculation, a time did no doubt arrive when inoculations failed; but a similar immunity might, by perseverance, be produced to the action of blisters, croton oil, or tartarised antimony. In all these cases the immunity was but temporary. If we allowed a certain interval to elapse, we could again produce the syphilitic pustule, the blister, or the characteristic effects of the croton oil or tartarised antimony. He (Mr. Lee) considered that nothing had been proved, during the past year, with regard to the absorption of the syphilitic poison into the constitution of a patient already syphilitic.

Mr. James Lane said there were two things to be considered in discussing the question of syphilisation—one was its practical value as a method of treatment; the other was its value in elucidating difficult questions in the pathology of syphilis. With reference to its therapeutic effect, he had carefully watched all the cases which had been under treatment at the female Lock Hospital; but their number had not yet been sufficient to enable him to express an independent opinion from his own observation. It was a subject requiring a long and patient attention, and calm and unprejudiced judgment. Mention had been made, as he thought somewhat unfairly, of deaths which had occurred in this country in patients submitted to syphilisation; but these deaths being, as he explained, in no way attributable to the treatment, he trusted their unfortunate occurrence would not be allowed to operate to its prejudice. He very much feared that one death, if not more, might shortly occur, in consequence of a serious epidemic of sloughing phagedena which was present in the Hospital at this moment, and which had affected some of the patients undergoing syphilisation in common with the others. Looking at syphilisation from the scientific as contrasted with the practical point of view, there were two things specially worthy of remark: one was the immunity obtained by repeated inoculations; the other was the inoculability of the indurated sore on a syphilitic patient. With respect to the immunity which had been so much disputed, he had no hesitation, from what he had seen, in testifying to its reality; and it was a point well worthy of notice, now that the unity or duality of the syphilitic poison was being so much discussed, that the immunity was obtainable, whether the matter used for inoculation had been derived originally from hard or soft sores. Whichever matter was employed, the immunity extended to both, and the time required for its production was on the average about three months. The inoculability of the indurated sore on a syphilitic patient was well illustrated by the case of D., which had been related in the paper. This, with other cases which have recently occurred in the Lock Hospital, would have fully convinced him of the inoculability of the hard sore, if he had ever had any doubt upon the subject. Mr. Lee, in his remarks, had, to Mr. Lane's surprise, said that this patient, D., was the only one whom Dr. Boeck had succeeded in inoculating from an indurated sore. This man had not been Dr. Boeck's patient at all, but Mr. Walter Coulson's; and it was by the latter that the successful inoculations were made in his case. Dr. Boeck had, however, under his (Mr. Lane's) observation, inoculated a female patient from D.'s indurated sore, and obtained a positive result of a most unequivocal character, having made six punctures, all of which were successful, and which were afterwards carried through a lengthened series. Mr. Lee had suggested doubts about the genuineness of D.'s case, because he was being inoculated at the same time with matter from soft sores; and Mr. Lee thought some mixture of the two kinds of matter might possibly have taken place. He (Mr. Lane) was not disposed to attach much weight to this objection; but, however it might be as regarded the man, the case of the female was free even from this suspicion, for she was inoculated from D.'s indurated sore two days before he had been inoculated with any matter from soft sores, and no soft matter had ever been used upon herself. In addition to this case by Dr. Boeck, he had himself had a case of successful inoculation from an indurated sore; and he had witnessed a third by Mr. Gascoyen. Besides these three, which were inoculations on syphilitic patients, there had been two cases of auto-inoculation by Mr. Walter Coulson at the Lock Hospital: one being the case of D., which was questioned for the reason alluded to; the other being a case in which Mr. Coulson succeeded on the fifth trial, and in which he believed Mr. Lee himself had been unable to detect a flaw. But they were told that the indurated sore was only inoculable when artificially irritated—with savine ointment, for instance,—and that therefore it was not true syphilis which was inoculated. If it was not syphilis, what was it? Was it savine ointment from which this long series of ulcers exactly resembling soft chancres was obtained? It must be either the one or the other. To his mind, the repeated production of non-indurated sores by inoculation from indurated sores was one of the strongest points in favour of the unity of the syphilitic poison, and completely negatived the idea that each variety always produced its like. He hoped at some future day to lay before the Society an account of all the cases which had been treated by syphilisation at the Lock Hospital, and thus to bring the subject again under their notice.

Mr. Hulke made some remarks condemnatory of the reading of long papers, chiefly of an historical character, and containing scarcely any facts. The paper before the Society had occupied twenty-three minutes in reading; but the facts it contained might have been stated in three minutes. He thought the secretaries should have the power of curtailing such papers.

Mr. Gaskoin said it was true he did not present himself before the Society with any pretensions to originality on this occasion. His object was to place beyond the reach of cavil and to record important facts which, however established on clinical evidence, had been openly denied; and at the same time, by a review of occurrences not very remote, to show how scientific opinions were subject to be dictated and controlled by one man or a knot of men. He wished to oppose himself to the current of *à priori* decisions and to the tyranny of preconceived ideas. It certainly did not speak highly of the prospects of Medical science among us when we had to protect ourselves in our right to observe; and yet the London school used to be one of observation—or at least that of Brodie, in which he had been trained. It was not in the interests of "syphilisation," but of observation, that he spoke. It was a fact beyond dispute that we had no school of syphilography in London; we were content to borrow from the French professors, and our opinions were governed by their intrigues. The moderate degree of attention the subject excited proved how little English Practitioners were equal to the task of observation; and no less did the false estimate formed as to the severity of a disease which was one of the most formidable that afflict humanity show how little, in this field at least, observation was the order of the day.

At the meeting of the Society on May 8,

Mr. Moore introduced a young man, aged eighteen, who had been born with a completely fissured palate and upper lip, and with the right nostril open throughout into the mouth. The hare-lip was closed by Mr. Moore when the patient was six weeks old, and in his subsequent growth the separated alveolar ridge had come into contact without actually uniting. The fissure at present therefore began at the level of a line drawn across between the lateral incisor teeth; it widened to the breadth of nearly an inch, and ended by a double uvula. With the view of avoiding an operation, Mr. Moore requested Mr. Turner, Assistant Dental Surgeon to the Middlesex Hospital, to attempt to fill up the gap.

Mr. Turner exhibited to the Society the obturator which he had constructed. It consisted of a piece of soft or partially cooked india-rubber, adjusted to the free margins of the cleft, and overlapping both their upper and under surfaces; a pendulous portion filled up the space between the halves of the divided uvula, allowing them free action in front of it. The apparatus was fixed to one tooth on either side of the mouth

by a metallic bar, which fitted across the palate. Mr. Turner thought this to be the most complete mechanical contrivance yet applied to the correction of deficiencies of the palate, and likely ultimately to supersede the ordinary plastic operation. By its use the trouble and pain of the operation, with its attendant risks of complications and failures, were avoided; and the natural arch of the palate, which the plastic operation more or less depressed according to the width of the fissure, was preserved. Where, moreover, the paucity of soft tissue round the fissure of the hard palate rendered complete occlusion difficult, if not impossible, the patient might, after all, be compelled to use an artificial palate. (This obturator was the invention of Dr. Kingsley, an American dentist, by whom it was introduced into this country.)

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, April 4, 1866.

Dr. Barnes, President.

The following gentlemen were elected Fellows:—Drs. J. Carless, Astley Cooper, Horniblow, Sheraton, T. J. Walker, A. Wiltshire, John Wilkins; Messrs. A. J. Lowe, R. Roberts.

Dr. Gervis exhibited a specimen of a Fœtus possessing many points of interest in its physiological development.

Dr. Meadows exhibited a specimen of Cystic Development of the Fallopian Tubes consequent on obstruction at the ostium uterinum. The left tube contained two cysts; the right, one. They were each about the size of a small walnut, and filled with a thick brownish fluid. The patient had died of pelvic peritonitis, the result of menstrual suppression from cold.

Dr. Meadows also showed a new Intra-uterine Stem. It consisted simply of a solid glass rod, the size of No. 6 catheter, two inches long, and having a flat disc at the vaginal end. He had been led to adopt this form from the inconvenience sometimes arising from the irritation of the ordinary metal or ebonite stems, glass being not only cleaner and free from corrosion, but for these reasons more easily borne than either of the others.

Mr. Marshall, of Dover, related a case of

DISEASE OF THE PLACENTA;

with notes by Dr. Graily Hewitt, who considered that the condition of the placenta was not one of fatty degeneration, but likely to be the result of effusion of lymph at a period probably two or three months antecedent to delivery. The yellow layer described had the appearance of syphilitic disease; but there was no history of that disease having affected the patient. The drawing before the Fellows well illustrated the chief features of the specimen.

The President considered the case not so very uncommon. The physiological explanation consisted in the fact of there being an excess of fibrin in the blood of pregnant women. He believed the case to be neither one of fatty nor of fibrous degeneration, but one in which fibrin had been thrown out. The yellow layer and whole appearance of the placenta did not, in his opinion, necessarily indicate the existence of syphilis in the system.

Dr. Greenhalgh gave the history of a case of

OBSTRUCTIVE DYSMENORRHŒA.

He considered dysmenorrhœa to be either congenital or induced; and the stricture to be of two kinds, absolute or relative. After referring to the various modes of treatment, the author stated that, in the case under consideration, he had had extreme difficulty in passing a sound. He was obliged to draw the uterus down by Sims's needle, and then made use of his (Dr. Greenhalgh's) metrotome. In the course of four days after the operation the patient complained of an ill-defined pain all over her. She gradually got worse, vomiting came on, and she died on the ninth day after the operation. At the post-mortem, peritonitis of a low form, with considerable tubercular deposit, was found; the uterus was bound down by old adhesions, and the incision had not gone right though the os internum. Her death was considered to be due to her want of care after the operation. The author concluded by referring to all the cases he had operated on, which had usually done well, and stated his strong objection to the introduction of sponge-tents after operating.

Dr. Barnes considered that the danger rested in cutting the os internum. He thought very little danger was to be feared from incision of the os externum. The cervix uteri might be treated by dilatation. He agreed with Dr. Greenhalgh that absolute rest was necessary after operation, and believed that the case would be a lesson to all, and make them adopt every precaution, or even hesitate to incise the internal os.

Dr. Routh expressed his thanks to Dr. Greenhalgh for bringing the case before the Society. He thought the operation was one of danger, and required the greatest possible care both before and after. The case was a very unfortunate one, from the length of time occupied in operating, as also from there being no loss of blood; he always liked to see three or four ounces lost. He did not think there was any danger from cutting the internal os when the fundus uteri was free from inflammation. Fatal cases were known after passing the ordinary sound.

Dr. Rogers agreed with all that Dr. Routh had said. He considered the internal os to be frequently the seat of stricture. He added his testimony to the danger that sometimes attended incision of the cervix, and stated that he had also lost a case after operation.

Dr. Rasch said that he had never met with a case where there was stricture of the internal os, nor had he ever failed to pass a sound. Cases said to be strictured he had found flexed, which on being reduced admitted the sound.

Dr. Meadows remarked upon the necessity of ascertaining, as far as possible, the condition not only of the uterus, but of its appendages also, in all cases where operative measures were contemplated. He believed that in those cases where a fatal result had followed even so simple a proceeding as the passage of the uterine sound, some organic lesion would be found to have been the cause of the mischief, the uterus being exceedingly sensitive of any interference under these circumstances. Unfortunately the diagnosis of some of these conditions was often very difficult, and the real state of the case was only discoverable on a post-mortem examination. In Dr. Greenhalgh's case there was reason to suppose that some displacement of the uterus existed, and the history was one indicative of previous metro-peritonitis. This being so, and the fundus uteri having become adherent in its malposition, he would regard such a case as positively contra-indicating any operative interference. He believed that in all cases of flexion of the uterus, especially when of long standing, or of version when replacement was a matter of difficulty, the use of the knife was very likely to lead to evil and even fatal results.

Dr. Gervis, Dr. Head, Dr. Balls, Dr. Eastlake, and Mr. Baker Brown, jun., also took part in the discussion.

Dr. Greenhalgh having replied to the various speakers the meeting adjourned.

WESTERN MEDICAL AND SURGICAL SOCIETY.

Friday, March 2.

Mr. Pollock, President, in the Chair.

Dr. Martyn related a

CASE OF DOUBLE FEMORAL HERNIA.

Miss P., aged 70, of spare habit, had been healthy generally, except that she suffered from a swelling in each groin. As these swellings disappeared occasionally and did not give her pain, she attached no importance to them. On January 4 (Thursday), she awoke in the morning with violent pain in her belly, and sickness. The sickness and pain continued more or less until Dr. Martyn was called in on Monday evening, January 8. There had been no movement of the bowels or passage of wind per anum from the time of the attack. Dr. Martyn found his patient walking the room, holding her belly with her hands and stooping much. This posture, coupled with the history of the attack, he considerd, marked the case as one of strangulated bowel. She had taken two or three doses of purgative medicine. The quantity vomited had been very great, but, so far, not feculent. Placing the patient on her bed, he found a lump in the site of the crural canal on each side; that on the left of the size of a walnut, that on the right a little larger. The left was hard, and felt much like an enlarged gland. It afforded no impulse on forced cough; was not tender. The right was also hard, but there was a sligh impulse and some tenderness. The belly was tender, pulse quick, tongue brown and dry. He could not reduce the swellings by taxis, and then urged that an operation should be immediately performed, but the patient would not consent. He then applied an ice-bag to the more tender hernia; gave

opium, and ice to swallow. Tuesday, 9th.—Patient suffering much less; sickness, scarcely any; but in the evening of this day some feculent matter was discharged from the stomach. 10th.—Dr. Martyn operated, selecting the right groin as the seat of stricture; the result justified him. He found here a knuckle of intestine tightly strictured, and some omentum. The bowel was very dark, but still shiny. He divided the stricture and reduced the bowel. Chloroform was given; the patient vomited soon after. She then improved very much, became comfortable and warm; slept and took food. She passed wind per anum, but there was no stool. On the third day the wound became offensive. She gradually grew worse. Some vomiting returned; injected a little warm water, but no motion followed. On the fourth day after the operation, she passed no water; became sleepy, and died comatose on the sixth day. *Post-mortem.*—Found the left hernia was old omentum alone. On exposing the bowels, some were seen to be full and some empty. There was evidence of inflammation, some adhesion, etc. The full bowel was of a dark chocolate colour down to the part strictured; here the bowel was free; near to the crural ring the contents evidently had not passed the strictured part. The bowel at this point was of a much darker colour, and had doubtless suffered too much from the original stricture to perform its function. The strictured part of the intestine was shown to the Society.

The PRESIDENT remarked that the case was one of the greatest interest, from the fact that an irreducible femoral hernia existed on both sides; he had only met with one such case. In such cases, when the patient is unable to guide you as to the seat of stricture, and other signs are obscure, great judgment is demanded as to where to operate. He farther said that the operation in strangulated femoral hernia could scarcely be too early done; he would not defer it after sickness sets in.

BOOKS RECEIVED.

Who Am I? By C. Jones, author of "Warning." London: Trübners. No date. Pp. 156.

*** The writer believes that he possesses a true interpretation of the Bible, which we suppose is to be found in this book. We say we suppose, because a busy Professional life gives us no leisure to read "Who am I" with great care; and a few hasty dips entirely fail.

Walsall Cottage Hospital.

*** The annual report of the institution, which was established in 1863 to render prompt surgical aid and good nursing in connection with mining and the management of machinery about Walsall. Since the opening, nearly 2000 cases have received attention—289 in- and 1690 being out-patients.

On the Seeds of Pharbitis Nil (Choisy). By E. J. Waring, M.D., F.L.S. Reprinted from the "Pharmaceutical Journal." Pp. 4.

*** An account of a drug derived from a good family of purgatives (Convolvulaceæ). The plant is common in India, and the seeds have an action analogous to jalap. The author suggests that in India especially it might be used with advantage, as rendering Practitioners independent of imported articles.

MEDICAL NEWS.

QUEEN'S UNIVERSITY IN IRELAND.—At a meeting of the Senate of the above University, held on Wednesday, the 20th inst., in the Council Chamber, Dublin Castle, the following Degrees in Medicine and Surgery were conferred by the Right Hon. the Lord Chancellor of Ireland, Vice-Chancellor of the University:—

Doctors in Medicine.

Thomas St. John Clerke, of Queen's College, Cork; William Collins, of Queen's College, Cork; George John Gibson, of Queen's College, Cork; John Macaulay, of Queen's College, Belfast; Newenham Edward Maher, of Queen's College, Galway; Edwin Field Nelson, of Queen's College, Belfast; Samuel Parke, of Queen's College, Belfast; James Edward Saunderson, B.A., of Queen's College, Galway; William Sharpe, of Queen's College, Galway and Belfast; George V. Wood, of Queen's College, Cork, Belfast, and Galway; Alexander Young, of Queen's College, Belfast.

Masters in Surgery.

William Collins, of Queen's College, Cork; Barry Delaney, M.D., of Queen's College, Cork; Alexander Filson, B.A., M.D., of Queen's College, Belfast; George John Gibson, of Queen's College, Cork.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on Friday, June 15, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Arthur Wolcot, Nankivell, Torquay; Frederick William Humphreys, 19, Trinity-square; Thomas George Palmer Hallett, 6, Queen's-crescent, Haverstock-hill; Henry May, Birmingham; Thomas Webster, Redland, near Bristol; Richard Eaton Power, Portsea; Daniel Walter Parsons, Liverpool; Francis Oppert, M.D. Berlin, 31, Great Russell-street.

At the same meeting the following were reported by the examiners to have passed their Primary Examination:—

William Toulmin, Guy's Hospital; Frederick Walter Smith, St. Thomas's Hospital.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 14, 1866:—

James Forbes Sargent, 6, Bentinck-terrace, Regent's-park; Thomas Harvey, 338, Waterloo-road; Georg Frederick Julius Schott, Francfort-on-the Main; Jonathan Atkinson Harrison, Wirksworth, Derbyshire; George Jesse Barnabas Stevens, Stroud, Kent: George Spearman, Plymouth; William French Thurston, 2, South Bank, Notting-hill; John Hancocke Wathen, Fishguard, Pembroke.

The following gentlemen also on the same day passed their First Examination:—

William Jebson Stothard, Guy's Hospital; John Frederic Codrington, Guy's Hospital; Alexander Paull Fiddian, King's College.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BOND, T., M.D., has been elected Resident Medical Officer to the Public Dispensary, Carey-street.

BRIETZCKE, H., L.R.C.P.L., has been appointed House-Surgeon to the Public Hospital, Sheffield.

GARGERY, C., M.R.C.S.E., has been appointed Resident Medical Officer to the Worcester Dispensary.

MOIR, J., L.R.C.P. Edin., has been elected Assistant House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester.

PEARSE, G. E. L., M.R.C.S.E., has been appointed Senior House-Surgeon to the Royal Infirmary and Dispensary, Manchester.

RISK, F. S., L.K.Q.C.P.I., has been elected Resident Medical Officer to the Isle of Man Hospital and Dispensary.

BIRTHS.

CURTIS.—On June 15, at 8, Camden-place, Cork, the wife of J. G. Curtis, M.D., of a daughter.

ROOKE.—On June 11, at Cheltenham, the wife of T. M. Rooke, M.D., of a son.

MARRIAGES.

DRYSDALE—NORTH.—On June 12, at St. James's, New Brighton, J. J. Drysdale, M.D., to Emily, eldest daughter of J. North, Esq., of Lonebart, Cheshire.

FOWLER—COTGRAVE.—On June 12, R. S. Fowler, M.R.C.S., of Bath, to Elizabeth Burgess, eldest daughter of Lieut.-Col. Cotgrave, R.A.

LAWSON—SOLOMON.—On June 13, at Kensington, Henry Lawson, M.D., of Woodfield-lodge, Streatham, to Ella, widow of the late Abraham Solomon, Esq. No cards.

STRANGE—PIRRIE.—On May 24, at 253, Union-street, Aberdeen, W. H. Strange, M.D., of Belsize Park, London, to Anna Jane, third daughter of W. Pirrie, M.D., of Aberdeen.

DEATHS.

CHILDECOTT, W, M.R.C.S., at Holmwood, Dorking, on June 1, aged 67.

DRAWBRIDGE, JOHN H., M.R.C.S., at 1, Upper Hill-street, Liverpool, aged 71.

TRIPE, CORNELIUS, M.D., at Laira, recently.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Bethnal-green Parish.—Mr. Haycock has resigned the Fourth District salary £100 per annum; no fees.

Hackney Union.—Mr. Howell has resigned the Workhouse; salary £180 per annum.

APPOINTMENTS.

Helston Union.—Charles Forrester Bullmore, M.R.C.S.E., L.S.A., L.M., to the Wendron District.

SCOTTISH UNIVERSITIES.—A Parliamentary return gives the number of members on the books of the General Council of the Universities of Scotland, whether by degree or by attendance on classes during the requisite number of sessions. Edinburgh is returned as having 2400 names on its register; Glasgow, 1165; Aberdeen, 898; St. Andrew's, 369.

SKILLED NURSES.—The Prussian Government have applied to the Deaconess Institution at Kaiserworth to send them sixteen deaconesses to superintend the nursing of the army.

THE ROYAL IRISH ACADEMY.—The following have been elected members of the Royal Irish Academy:—J. A. Baker, F.R.C.S.I.; E. H. Bennett, M.D.; F. R. Cruise, M.D.

ALUMINIUM.—A trial has just been made at Florence o a cuirass in aluminium, which is as light as an ordinary waist coat, nearly as flexible, and is capable of turning a musket ball fired at the distance of thirty-eight paces and of resisting a bayonet thrust from the heaviest hand. Each cuirass costs only 25f. Two regiments are to be immediately provided with them.

HOPKINS *v.* THE LONDON AND NORTH-WESTERN RAILWAY COMPANY.—COURT OF QUEEN'S BENCH, WESTMINSTER, June 14.—This was an action by a dairyman to recover compensation for injuries sustained through the negligence of the defendants' servants, by which, on August 30 last, a luggage train ran into an exeursion train near Chester, in which the plaintiff was a passenger. The plaintiff was considerably knocked about and bruised by the concussion, and was rendered insensible. Since that period he had been subject to singing in the ears, his sight has been affected, and the nervous system has evidently been injured. He was advised that he could not safely continue to carry on his business, which, through his inability to attend to it personally, had not been so profitably eonducted. The defendants admitted the injury to have been caused by the negligence of their servants, and paid a nominal sum into eourt. The case for the defendants was that the plaintiff's injuries were much exaggerated. Four Medical witnesses were called for the plaintiff and three on behalf of the company. The jury returned a verdict for the plaintiff, damages £1000.

BRITISH MEDICAL ASSOCIATION. — LANCASHIRE AND CHESHIRE BRANCH.—The thirtieth annual meeting of this branch of the British Medical Association was held on Wednesday, in the Medical Institution, Mount pleasant. There were present a considerable number of the Profession belonging to Liverpool and other towns in the neighbourhood. In the absence of Mr. T. Turner, of Manchester, the retiring President, Mr. T. Mellor, one of the retiring Vice-Presidents, moved that Dr. A. T. H. Waters, of Liverpool, the President-elect, take the chair. The proposition was carried unanimously. The President then delivered a long and able address to the members. After returning his thanks for the honour which the Branch had conferred on him in electing him President, he said it was a remark which they by no means unfrequently heard that Medicine made no advance; but if they looked back for the period of fifty years, and compared the practice which then prevailed to that of the present day, he ventured to say that there was no one who would deny that, in many respects, undoubted improvement had taken place. On so important a subject as this he would speak with feelings of diffidence; but if he might venture on an opinion with reference to the characteristics of modern Medicine, he thought he might say that they had learned to pay more regard to the constitutional condition of their patients, and to address their remedies with greater precision to those states than was the case even twenty or thirty years ago.—Dr. Henry Simpson, of Manchester, read the annual report of the branch. The financial statement showed a balance in the hands of the secretary of £25 6s. 2d. Dr. Vose moved that the next meeting of the branch be held in the city of Chester, that Mr. John Harrison be appointed President elect, and that Mr. Britten and Mr. William Roberts be the Vice-presidents elect.—Dr. Wilkinson, of Manchester, seconded the motion, which was unanimously agreed to.—On the motion of Dr. Edward Waters, of Chester, seconded by Mr. J. P. Langshaw, the following gentlemen were appointed the local secretaries, namely—Mr. W. H. Manifold, Liverpool; Mr. C. Johnson, jun., Lancaster; and Mr. J. Sharp, Warrington—At half past four o'clock about 50 gentlemen belonging to the Medical Profession assembled at the Adelphi Hotel, where they partook of an excellent dinner, which was served up in the elegant style for which that establishment has been for so many years noted. Dr. Waters, the President of the Branch, presided.

A SCENE IN CALLINGTON MARKET.—On the last market day at the quiet town of Callington an amusing scene occurred. It appears that one of the gentry who vend worm lozenges—worms being of course at the root of all diseases—was expatiating on the virtues of his nostrums, and in relating instances of their curative powers, he mentioned with no small delight a case in which he had been the means of saving the life of a patient of the greatest Physician in the West of England, Dr. Budd, who had dismissed the patient as incurable. Unfortunately for the quack, "the greatest Physician in the West of England" was passing near his stall at the time, and hearing his name mentioned was naturally arrested at the sound, and listened. The Doctor's temper was roused, and just saying "Let me get at him," then and there administered sundry kicks on the nethermost person of the unfortunate quack, which had the effect of putting him *hors de combat*. Roars of laughter greeted the onset of the valiant Doctor, in the midst of which the vendor beat a hasty retreat. The Doctor enjoyed the scene as much as the bystanders, and related the circumstance with much gusto many times during the day.—*From Western Mercury.*

THE various manners in which different insects provide for the wants of the young are most remarkable; and all the more so because these wants are so different from those of the perfect animals themselves. Thus, the butterfly which lives on honey, and did live on leaves, lays her eggs on a twig. She seems to feel that honey will not suit her young, and that the leaves will wither and fall before another spring comes round. The gnat, which lives in the air and feeds on blood, lays her eggs on the surface of water; and the sugar-loving housefly knows that very different food is necessary for her young. The nut-weevil chooses the embryo of the nut; the goat-moth the bark of the willow; the rhipiphora braves the dangers of the wasp's nest: the œstrus lays on cattle; the ichneumon in caterpillars; the gall-fly in the still almost imperceptible bud; and some insects even in the eggs of others. Generally, the larvæ forage for themselves; but, in some eases, the mother supplies her young with food. Thus, the solitary wasp builds a cell and fills it with other insects. If, however, she imprisoned them while alive, their struggles would infallibly destroy her egg; if she killed them, they would soon decay, and the young larva, when hatched, would find, instead of a store of wholesome food, a mere mass of corruption. To avoid these two evils, the wasp stings her victim in such a manner as to pierce the centre of the nervous system, and the poison has the quality of paralysing the victim without killing it. Thus deprived of all manner of movement, but still alive, it remains some weeks motionless and yet fresh. But, perhaps the ants are the most remarkable of all. They tend their young, they build houses, they make wars, they keep slaves, they have domestic animals, and it is even said that in some cases they cultivate the ground. Nor must it be supposed that even now the habits of insects are anything like thoroughly known to us. In spite of Reaumur and De Geer, the two Hubers, and many other excellent observers, there is in this subject still a wide field for patient and eonscientious labour; the observations already made have been far from exhausting the mine, though amply sufficient to prove the richness of the ore.—*Sir J. Lubbock on the Metamorphoses of Insects.*

MR. IBBETSON ON FOSSIL TEETH.—In the paper upon fossil teeth of fishes in the Palæozoic and lower members of the Mesozoic rocks, read before the Odontological Society by Mr. Ibbetson, a few preliminary remarks were made upon the faithful history of the animal kingdom furnished by fossil teeth generally; and in examining the fauna of the different rocks, the advantage of commencing with the most ancient and taking them in their order of stratigraphical super-position rather than proceeding from the most recent to the earlier beds, was clearly stated. Adopting this method, the leading species, genera, and families of the class fishes were noticed according to the order of their succession in *time*, not in *rank*, as they appeared in the various formations from the Silurian beds to the Lias. Of the 8000 or more known species of fishes, about 1000 belong to the Ganoid and Placoid orders, and to which those found below the Lias are limited, no instance of any of the 7000 or more species of either the Ctenoid or Cycloid orders being known below the Oolitic series. The existence of fishes was formerly believed to date from the Bala beds of the Cambrian rocks, but what were supposed to be the defensive spines of the Onchus Murchisonii have since been proved to be the caudal appendages of a Crustacean. The earliest known evidence of their existence is furnished by fragments of jaws with teeth found in the Ludlow group of the upper Silurian deposits. The affinities of these fragmentary remains have not been clearly determined. Agassiz refers them with a doubt to the genera Plectrodus and Sclerodus of his Placoid order. Murchison in the last edition of his Siluria—on the authority of Sir Philip Egerton—supposes them to belong to a small species of Ganoid fish; whilst Mr. J. W. Salter suggests that they may

have belonged to Pteraspis or Cephalaspis, the teeth of these genera—even if they possessed such organs—being yet unknown. The earliest evidence of the existence of the class whose affinities can be defined, is furnished by the teeth of several genera of fishes in the Devonian rocks, in which occur Ctenoptychius and Ctenodus genera of the family of Cestracionts, and belonging to the order Plagiostomi. The various species of the different genera of Cestracionts were enumerated as they respectively occur in the successive rocks from the Devonian to the Lias, Acrodus was referred to as possessing special interest, from the faithful interpretation which is afforded of the genus by its consanguinity with the Cestracian Phillippi of the Australian seas, the sole existing representative of this family of fishes, so rich in genera and species in the Palæozoic and Mesozoic ages. The species and genera of the Hybodontidæ were next noticed. In entering upon the order Ganoidei, Pteraspis and Cephalaspis were referred to as existing in beds of earlier date than those in which Plectrodus and Sclerodus are found; therefore in the event of the suggestion of Mr. J. W. Salter being confirmed, these genera would become the earliest known indication of the Class fishes. The species and genera of the Families Cælacanthi, Dipteridæ, Acanthodei, Sauroidei, Lepidoidei, and Pycnodontei were all referred to as they respectively occur in *time*, and the dental distinctions of the various species and genera were noticed. Occasion was taken to refer to the removal by Professor Owen of the genus Placodus—found in the Muschelkalk—from the family Pycnodontei, and by Professor Huxley, of the genus Stagonolepis—found in the Devonian rocks—from the family Dipteridæ, of the class Fishes, to the class Reptiles, and the dental characters and other correlations of structure upon which the amended classifications were established, were pointed out. The paper was illustrated by a valuable collection of fossils, and a number of beautifully executed diagrams.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending May 26.	Week ending June 2.	Week ending June 9.	Back cases reported in the week ending June 9, 1866.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.

Totals .	1207	960	987	396	248025	79997	124160	32658	11210

This Return shows that 987 attacks were reported to have occurred during the week ended June 9, being an increase of 27 on the previous week.

Correcting the total by adding an estimated average of attacks commencing during the week, but which may be subsequently included under the heading "Back Cases," the number for the week will be 1234.

Note.—3 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Lancaster, 1; Lincoln, 1; and for the Metropolis, 1. These inspectors returned 14 cases last week.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Jüncker's paper on Nyctalopia shall be inserted immediately.

An article on *Cholera Literature*, including reviews of Macpherson, Greenwood, Anstie, Southwood Smith, Pearce, Rowell, and others, is unavoidably postponed till next week.

The Memorandum of the Medical Officers of Health of the Metropolis, on a Plan of United Action in Cases of Cholera, is to be procured very cheaply of the printer, Mr. Fieldsou, 6, North-street, Manchester-square, W.

Dr. J. M'Gregor Croft.—Garibaldi's taking the field is a mere political movement, with which the Medical Profession, as a Profession, have no sympathy.

G. P., Ordnance Survey Office.—That gentleman is a legally qualified Medical Practitioner, but we have no knowledge of his plan of treatment.

King's College Associate.—Sir Edward Hulse was created a Baronet in 1738. There is a good mezzotint portrait of the gentleman.

Varida, M.D.—The Princess Amelia and the Princess Caroline were *inoculated* for the small pox in 1722. The King of Spain, Louis I., and the Duchess of Bedford died in 1724 of the disease.

A Country Surgeon.—You are too late in your application, as the examinations commenced on Tuesday last, as you will see in another column of this journal. Write to the Apothecaries' Hall.

The Oldest Member.—The titles in 1744 were "Master and Wardens," when John Medley was Master, and Jos. Sandford, Humphry Negus, and William Cheselden were Wardens of the Barbers-Surgeons. The Company held its meetings in Monkwell-street, City. The separation of the Barbers and Surgeons took place in the following year. There is a painting of Cheselden in the Council-room of the College of Surgeons.

Mr. Campbell.—The late Mr. Ure, of St. Mary's Hospital, was a candidate for a seat in the Council of the College of Surgeons in July last, when he polled 20 votes. He intended offering himself again this year, notwithstanding his illness, but was a day too late in his application for the necessary papers, and died on the following day.

A Fellow and Dr. S.—There was an examination in classics, etc., on Tuesday and following days for the Fellowship of the College of Surgeons. The long-promised regulations are now ready, and may be obtained on application to the Secretary.

M.B. Univ. Cantab.—It is stated that some members of the Medical Council of Education and Registration attended the recent preliminary examinations both for the Fellowship and Membership.

R. N., Portsmouth.—The first number of the *Medical Times* made its appearance at an earlier date—viz., September 28, 1839. The papers on Admiralty Injustice to Naval Surgeons, and on Relative Rank and Pay, appeared with many others on the same subject in vol. xix. for 1849, and were contributed by a gentleman still on the staff of this journal, and not by the gentleman named.

Lithotomist, Borough.—Mrs. Stephens received £5000 from Parliament for communicating the secret of her solvent for stone in the bladder. It was useless. Mr. Henry Smith removed from the bladder of a young man, in King's College Hospital on Friday last, a glass tube used for the purpose of carrying flowers in the coats of our modern dandies, but which the patient had used for improper purposes. The gentleman named would no doubt recommend castration as freely as he does clitorotomy to cure the vice.

Widow of a Deceased Surgeon.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We beg to acknowledge with thanks the following contributions for the "Widow of a Deceased Surgeon," and to be allowed to renew our appeal on behalf of this distressed family:—Sir William Fergusson, £1 1s.; Dr. S. L. Gill, £1 1s.; H. J., £2 2s.; Mr. Braude, £1; D. D. B. H., £1; J. B. (Edinburgh), 10s.; Dr. John Watson, 10s.; R. B. P., 5s.

We are, &c.,
Signed for HENRY LETHEBY.
W. SPENCER WATSON.

27, Montague-street, Russell-square, June 20.

Medical Service in the Austrian Army.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Kindly insert in your widely-circulated paper the following regulations relating to the entry of Surgeons to the Austrian services:—Army.—Entry-pay: 7 florins (14 shillings). Rank and Title: On entry, Lieutenant; after probation, Captain; Surgeon of Regiment; Major. After the War: 1. Retire with bonus; 2. Absorption into army as vacancies occur. *Note.*—All rations found. Navy, similar to Army.

I am, &c.,
AN OLD SUBSCRIBER.

Poor-law Medical Reform Association.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me again to trespass on your valuable space to inform the Poor-law Medical officers that I have to-day received from the Poor-law Board a reply to my letters of May 17 and June 7, which is as follows:—"I am directed to state that your observations on the proposed Bill on Poor-law Medical Relief will receive the consideration of the Board. They are, however, unable to appoint a time for the attendance of a deputation on the subject. Enfield, Secretary." From the foregoing reply, and from what we read in the journals, I think it more than probable that some general measure for the amendment of the Medical relief of the poor is in contemplation by the Poor law Board.

I have applied to several Members of Parliament to bring in the Bill proposed by the Association, copies of which were sent to the subscribers in March last; but the general opinion appears to be that, situated as Parliament now is, with the Reform Bill before it, no private Member would have a chance of carrying a Bill of the kind this session unless it had the support of the Poor-law Board, or be brought on by that Body as a Government measure. Under these circumstances, we must wait and carefully watch the movements of the Poor-law Board in Parliament, and it is just possible we may, whilst united and with money in hand, find ourselves sufficiently powerful to amend any Bill brought in by them should it not meet our views. This course was eminently successful with the Vaccination Bill, and, although we have not been able to make it all we could wish, still we have been the means of inducing the Select Committee to make improvements in it, which will benefit the public vaccinators of England and Wales to the extent of some thousands per annum, and amply repay the Association for the labour of the last ten years, even should no other reform be accomplished; but I feel confident other beneficial measures are still in store for us. I am, &c.,

12, Royal-terrace, Weymouth, June 13. RICHARD GRIFFIN.

Griffin Testimonial.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you kindly insert this circular which has been posted to every Poor Law Medical Officer in England and Wales, and also to every subscriber to the Griffin Testimonial Fund?

I am, &c., Robert Fowler.

145, Bishopsgate-street, June 20, 1866.

"Griffin Testimonial.

"Dear Sir,—I beg to inform you that the presentation of the above will take place at a public meeting, to be held at the Freemasons' Tavern, Great Queen-street, on Thursday, July 5th proximo, at 3 p.m. in the day.

"If you have not forwarded me your subscription to the Fund, I would respectfully ask that you at once do so.

"Let each and all thus show some slight appreciation of, and some gratitude for, those untiring energies which, during the last ten or eleven years, our champion has bestowed on the cause of Poor Law Medical Reform. I enclose a copy of Mr. Griffin's last letter to the journals, to show you how continually watchful he is of our interests.

"If also you have not sent me your *carte de visite* (as very many of the subscribers have done), I hope to receive it in time for the photographic album of Mr. Griffin's friends and admirers, with which it is decided additionally to present him. Let your *carte de visite* have your designation, profession, title, and (if a Poor Law Medical Officer) the name of your Union plainly written on the back.

"Should it be your intention to attend the meeting (no banquet), it would be a great convenience if you would inform me thereof on or before the 30th instant.

"The testimonial is now on view at the manufacturers', Messrs. Mappin and Webb, 71 and 72, Cornhill. "Yours faithfully,

"Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, June 20, 1866."

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN MAY, 1866.

The following are the Returns of the Metropolitan Association of Medical Officers of Health:—

	Total Solid Matter per Gallon.	Loss by Ignition.(a)	Oxydisable Organic Matter.(b)	Hardness.	
				Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction . .	19·10	1·04	0·31	14·0	3·5
West Middlesex . .	18 39	0·80	0·29	14·0	3·5
Southwark and Vauxhall.	19·06	1·04	0·39	14·5	3·5
Chelsea	18·87	0·81	0·27	14·0	3·5
Lambeth	18·99	0·99	0·32	14·0	3·5
Other Companies.					
Kent	28·32	1·13	0 05	18·5	7·5
New River . . .	17·84	0·68	0·22	14·0	4·5
East London . . .	21·68	0·79	0·38	14·5	4·0

(a) The loss by ignition represents a variety of volatile matters as well as organic matter, as ammoniacal salts, moisture, and the volatile constituents of nitrates and nitrites.

(b) The oxydisable organic matter is determined by a standard solution of permanganate of potash, the available oxygen of which is to the organic matter as 1 is to 8; and the results are controlled by the examination of the colour of the water when seen through a glass tube two feet in length and two inches in diameter.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·710 in.
Mean temperature	58·5
Highest point of thermometer	83 S
Lowest point of thermometer	47·6
Mean dew-point temperature	51·6
General direction of wind	S.W. & W.S.W.
Whole amount of rain in the week	0·14

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·710 in. The pressure of the atmosphere was 29·99 in. on Sunday morning, and fell to 29·35 in. on Saturday.

The general direction of the wind was S.W. and W.S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 61·0°.

APPOINTMENTS FOR THE WEEK.

June 23. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p m.

25. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

26. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

Ethnological Society of London, 8 p.m. Sir John Lubbock, Bart., "On Remarkable Archæological Discoveries in Ireland." Professor Steenstrup and Sir J. Lubbock, Bart., "On the Ancient Manufacture of Stone Implements at Pressigny."

Royal Medical and Chirurgical Society, 8½ p.m. Meeting.

27. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

28. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmie, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædie Hospital, 2 p.m.; West London Hospital, 2 p.m.

29. Friday.

Operations, Westminster Ophthalmie, 1½ p.m.

ORIGINAL LECTURES.

NOTES ON

SOME OF THE MORE RARE FORMS OF FRACTURES AND DISLOCATIONS,

BEING EXTRACTS FROM LECTURES (CLINICAL AND OTHERWISE) DELIVERED AT

The London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the Hospital and Lecturer on Surgery.

(Continued from page 518.)

GENTLEMEN,—The youngest student amongst us ought to be perfectly familiar with the contour and positions of the styloid processes of the ulna and radius. He carries them about with him, and can refresh his memory at a moment's notice. Any one having a clear notion as to these points need never make the common mistake of a fracture just above the wrist for a dislocation at the wrist. The resemblance of the fracture to the dislocation is, as far as the eye is concerned, very close; but the diagnosis by the finger ought to be quite easy. If it is a fracture, or what comes to the same thing, a detachment of the epiphysis, then these styloid processes remain in their normal relations to the carpus; if it be a dislocation, the carpus is displaced from them, usually behind them. Dislocations at the wrist are, as is now well known, very rare. I have never myself seen one. A few years ago one occurred amongst my patients, and was reduced by the House-Surgeon before I saw the case. From the account given to me I think there was no room for scepticism that this was a *bonâ fide* case of dislocation backwards from a fall on the palm of the hand. The patient was an adult; reduction was easily effected and maintained. I have in my lectures frequently repeated the statement that I have never seen a dislocated wrist, and in consequence, on several occasions, different gentlemen have very kindly offered me opportunities of doing so. To my great disappointment, however, in each of these I have found that the lesion had been mistaken, and that it was really a separation of the lower epiphysis of the radius.

As far, therefore, as dislocations at the wrist joint are concerned, I have nothing to say excepting in regard to the diagnosis. In many of the fractures, and in all the detachments of epiphysis, the line of separation is almost transverse, and leaves only a short fragment still in apposition with the carpal bones. In these the displacement is usually only partial, but now and then it is complete, so that the lower fragment rides on the posterior aspect of the upper one. It is in these, when the displacement is great, perhaps complete, that a suspicion of dislocation is most likely to occur. Very often in these cases of fracture no crepitus can be elicited. The recognition of the relation of the styloid process of the radius to the carpus and to the shaft is, therefore, the all-important symptom. We will turn now to fractures in the lower part of the radius. These common injuries are very important, on account of the difficulties which often attend their satisfactory treatment. They have also since the time when Mr. Colles drew attention to their peculiar features, afforded materials for much learned controversy. My own belief is that we have tried in reference to what is now called Colles' fracture to be much more precise than nature permits, and that we have needlessly encumbered ourselves with theories. I will try to simplify the subject, and if in so doing it becomes less definite and more vague than many published accounts would make it, the blame will not, I think, be mine.

In the first place let us remark that when Mr. Colles wrote his description of the common form of fracture which now bears his name, he had not dissected a single specimen. His knowledge of it was of the same kind as we can, any of us, obtain in fair plenty in our receiving-room. Mr. Colles wrote not to speculate as to whether the distortion is caused by impaction or by muscular action, still less to theorise as to which single muscle was at fault, but to draw attention to the fact *that fractures in the lower extremity of the radius were common and were often mistaken for mere sprains.*(a)

(a) "The injury to which I wish to direct the attention of Surgeons has not, as far as I know, been described by any author; indeed, the form of the carpal extremity of the radius would rather incline us to question its being liable to fracture. The absence of crepitus, and of the other common symptoms of fracture, together with the swelling which instantly arises in this as in most other injuries of the wrist, render the difficulty of ascertaining the real nature of the case very considerable."—Mr. Colles' paper in *Edin. Med. Surg. Journal*, vol. x., April, 1814.

Every one familiar with Surgical practice will admit the correctness of this statement, and also the general accuracy of Mr. Colles' description. Injuries to the lower extremity of the radius are common at all ages, and they are usually attended by great thickening just above the wrist, by considerable distortion with projection of the end of the ulna, and displacement of the carpus and hand backwards and to the radial border. At first, crepitus cannot be obtained, but you can usually rectify the deformity by direct extension, and having done so, you can by rotating the lower fragment then elicit this conclusive sign of fracture. Thus much is certain, and most of you have practical familiarity with the facts to which I refer.

Now we come to the uncertain and debateable points. When fracture in the lower end of the radius occurs is it usually found at any one particular point, or may it vary much in different cases? How high above the wrist joint does it usually occur, and is it transverse or oblique? Is the lower fragment usually in one piece, or is it comminuted? and, lastly, what is the chief cause of the peculiar and unmanageable displacement? To these queries several others concerning points of detail might be added.

If we turn to authors we shall find very various replies on these points. Mr. Colles thought that the fracture occurred an inch and a half above the joint. Dr. Robert Smith says that it is never higher than an inch, and usually not so high. Some writers, including Dr. Smith and Mr. Callender(b), speak as if the fracture were always directly transverse, and rarely attended by comminution; others hold different views. Lastly, the differences of opinion as to whether or not impaction is commonly present are most curious. Voillemier proved that it was. Dr. Robert Smith confuted him by reference to specimens; and now Mr. Callender, by reference to specimens, confutes Dr. Smith. How can we explain these strange discrepancies? In the first place, I think that we have been far too ready to infer that this form of fracture commonly conforms to one and the same type. The truth is, that fractures of the lower end of the radius, like fractures of the head of the humerus and of the head of the femur, and other bones at their expanded extremities, assume great variety as to their direction; scarcely two are exactly alike. As I have said, it is not fair in any author to attempt to restrict the term Colles' fracture to transverse fractures three-quarters of an inch above the carpus; these are only one division of the group. The features which all fractures in the lower part of the radius have in common are—the character of the deformity, the difficulty in producing crepitus, and the difficulties in maintaining efficient reduction. These are the features to which Mr. Colles drew attention, and his name, if applied to any, must be applied to the whole group. Another fruitful source of error is the habit of trusting to the examination of old specimens for deductions as to the position of the fragments in a recent fracture. A delusive appearance of impaction is produced in a great number of specimens after union is perfected, although no impaction existed at the time. When I use the term impaction, I mean to imply penetration of one fragment by the other *and fixation*. Penetration is a very common event in all fractures near to joints—in other words, near to large surfaces of cancellous tissue. Penetration with fixation of the fragments, the one into the other, so that they are immovable, is, I believe, exceedingly rare. In the living subject we are constantly misled on this point by the mere locking of fragments together by muscular action. This locking together of fragments may, when the surfaces of bone involved are large, easily be so complete as to prevent movement, and prevent the production of crepitus, whilst yet if you were to dissect the specimen you would find that the fragments were quite loose. I had an opportunity recently of showing you a specimen of a united fracture of the neck of the femur, apparently a most beautiful example of impaction. The neck of the bone was driven into the cancellous tissue at the base of the great trochanter, and there firmly fixed. Yet, in this instance we had had the patient under observation from the first, and we knew for certain that, so far from there having been any true impaction, the fragments were as freely moveable on each other as they could possibly be. I have little doubt that a similar history attaches to most of the supposed specimens of impaction in our museums. The only proof, then, which we can accept of true impaction is the examination

(b) See a very able and interesting report on Injuries near to Joints in the first volume of the St. Bartholomew's Reports. Mr. Callender bases his report on a painstaking examination of all the specimens in London museums.

either of a dead recent specimen by dissection, or of the living under chloroform. I am not arguing about a mere word, I am endeavouring to establish a distinction of great importance in practice. As regards the existence of impaction in recent fractures of the carpal end of the radius, I have myself never seen a good example of it. I have dissected two cases in which the fragments were firmly locked together by muscular force, but in both as soon as the bones were denuded of soft coverings the fragments were quite loose.

That penetration of the lower fragment by the upper one occurs in most of the cases in which any material degree of displacement attends this injury, there can be no doubt, and this peneration will, of course, be at the back of the bone, seeing that it is here that the fragments are bent towards each other. But this penetration is not attended by any fixation, and is rarely of any material depth.

Another source of error, which I feel sure that those who have written precise descriptions as to muscular agency in displacement have fallen into, is, that of not making allowance for the effect of rigor mortis. In examining one of these injuries after death, you will, I believe, usually find that the fragments are so locked together that you cannot without great force produce any movement. All the muscles are rigid, and those towards the side to which the fragments are bent, of course, stand out prominently. They could not possibly do otherwise. If you divide them in succession, you will find that it is not until you divide the last that the fragments are liberated—*ergo*, it was this last which, during life, caused the displacement and produced the fixation—a most unwarranted conclusion.

To arrive at correct conclusions respecting this accident, we must, I think, reject all pathological evidence excepting that afforded by recent specimens, and we must avail ourselves also of every opportunity of putting the clinical and pathological facts in their due relation with each other.

During the last few years at this Hospital I believe that seven or eight good specimens of recent fracture of the lower part of the radius have been dissected—one by Mr. Couper, three or four by Mr. Dove, and three by myself. In all of them the characteristic displacement was present during life; and had the patients recovered we should have considered them as examples of the fracture to which Mr. Colles called the attention of the Profession. In all of these the fragments were more or less locked together; in none was there any real impaction, and in every one the lower fragment was comminuted. We have in the Museum one well-marked specimen of a transverse fracture half an inch above the joint without comminution. It would appear that in this instance the displacement was in the usual direction, but not to any great extent, and there is no impaction. Unfortunately no history has been preserved with this specimen.

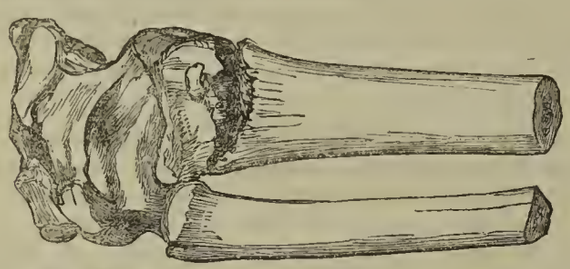

Fig. I.—Transverse fracture of radius, about half an inch above the wrist. Some displacement of lower fragment backwards, leaving the fracture gaping in front. From a specimen in the London Hospital Museum.

We have another showing a recent fracture extending obliquely into the wrist joint, and detaching the styloid process of the radius with its adjacent parts, and a third which is an

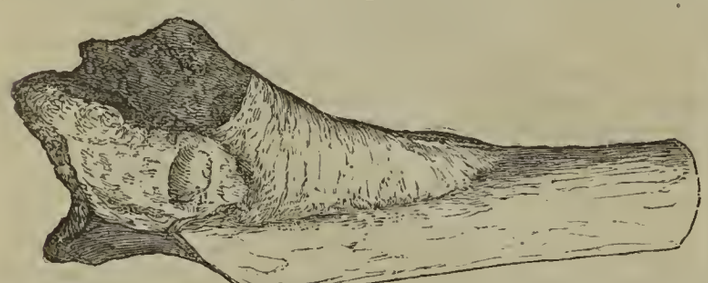

Fig. II.—United fracture of the lower part of radius, probably about half an inch above the wrist, and transverse. The lower fragment has been displaced backwards, and there is a large deposit of new bone on the dorsal aspect.

excellent example of the alteration in the shape of the bone resulting in union in malposition.

It appears to me that in seeking to explain the displacement in this fracture the chief cause has been comparatively lost sight of. This cause is not the influence of muscles whether extensors, supinators, or pronators, nor yet the occurrence of impaction, but simply the direction of the original violence. You have but to reflect upon the manner in which this accident is produced. A person falls forwards on to the palm of his hand, the radius gives way at some part within its lowest inch, and of course the lower fragment would be pressed backwards; the weight of the shoulder received upon the upper fragment drives the latter with great force downwards, almost always penetrating, and very often splitting the lower fragment. If the line of fracture is oblique in its antero-posterior direction, the obliquity is sure to be from behind downwards and forwards. The surface of the bone at its back, and the adjacent cancellous tissue would be crushed. The radius in consequence of this crushing and penetration of fragments will be somewhat shortened; hence the prominence of the ulna, and as the direction of the force is sure to have been from the hand towards the trunk, the hand and carpal fragment must necessarily be driven towards the radial border, thus further explaining the twisting over of the hand in this direction which is so characteristic of the deformity. You have but to put your own hand in the position supposed, and you will easily understand what I mean.

Thus, then, it is certain that the original displacement is purely and simply the result of the violence, and that the muscles have nothing to do with it. If we can suppose it possible that a bone were broken through without any displacement occurring at the time, then the different sets of muscles would antagonise one another, and firmly lock the fragments together, but would be quite unable to effect any special displacement. If, however, displacement have once occurred, then it is easy to understand how muscular action may reproduce it over and over again, after reduction by the Surgeon. The bones will tend to slip back into the hollow which has been made for them. All the lines of obliquity in the fracture will facilitate their passing in this one direction, and will tend to prevent their passing in any other. Excepting in comparatively rare instances, in which a bone is broken near the thinnest part of its extent, in which the line of fracture is nearly transverse, and in which the two fragments are liberated from each other very completely, it is very unusual for muscles to effect any displacement, excepting in the direction of the original violence. I make this as a general statement, applicable to all fractures; what you have to do is to get to understand the direction of the original force, caring comparatively little about the influence of special sets of muscles. In many instances different sets of muscles will tend to counterbalance each other, and the result will be a *movement en totalité*—that is, a displacement of the whole of the part of the member below the site of fracture, in that direction into which it can most easily slip. It will slip again where it slipped at first, and the original displacement will thus be reproduced. These remarks are especially applicable to Colles's fracture of the radius.

ORIGINAL COMMUNICATIONS.

STRANGULATED FEMORAL HERNIA IN A MALE SUBJECT.

By J. FAYRER, M.D., F.R.S.E.,
Surgeon to the Medical College Hospital, Calcutta, and Consulting Surgeon to the Howrah General Hospital.

On April 8, 1866, I was asked by Dr. Bird, of Howrah, to see a case of strangulated hernia in the Howrah Hospital. The patient was a Madras Portuguese servant, of about 25 years of age. He had been admitted into Hospital at about 5 a.m. on that day. It appears that, the previous night, whilst chasing a cat he fell and injured the lower part of his abdomen. He felt great pain at the time, and a swelling in the groin immediately appeared. This rapidly became intensely painful, accompanied by great abdominal pain, especially in the umbilical region, and vomiting. Dr. Bird ascertained that he had ruptured himself, and, under the influence of chloroform, he tried to reduce the hernia. The tumour appeared to subside somewhat, but the symptoms were not relieved. The tumour became so painful that he could not

bear it to be touched; vomiting continued, and great constitutional depression set in, indicated by rapid, feeble pulse and cold, damp skin. With this there was tympanitis and abdominal tenderness. In this condition I found him: the pulse was 120, feeble, and thread-like. He was very restless. The pain was not only severe in the groin, but over the whole abdomen. It was evident that there was no inguinal hernia, for the swelling was below Poupart's ligament. It was irregular, soft, nodulated, and intensely painful when touched. I could not isolate any one spot as more painful than another, nor could I make out any particularly tender inguinal gland. These glands were all painful, but it was evident from the general symptoms that there was a strangulated hernia somewhere; so after putting him under chloroform and trying the taxis without success, I determined, with Dr. Bird's consent, to cut down on the seat of the probable strangulation. Accordingly, I made a ⊤-shaped incision, the upper limb just below Poupart's ligament, the vertical one over the femoral canal. I found that the inguinal glands were enlarged, and the lymphatics dilated, a quantity of pale pinkish fluid flowing from the wound. On dividing the cribriform fascia a very small knuckle of intestine was found protruding through the femoral ring. I divided the seat of constriction—Gimbernat's ligament—carefully with a probe-pointed bistoury; the protrusion at once returned. There was no hæmorrhage. I stitched the wound, and applied a pad and bandage. The symptoms soon passed away; the most urgent were at once relieved, and on the 22nd of the month Dr. Bird wrote to inform me that the wound had healed and the patient had recovered.

Remarks.—This is a very interesting case, a femoral hernia occurring in a man, and caused, as it apparently was, by a fall, is a most unusual occurrence. The enlarged inguinal glands and the great pain on pressure in the groin were peculiar concomitants. They might, indeed, have almost explained all the suffering, only the suddenness of the attack, and the progressive symptoms of strangulated hernia, were so marked that I put aside all other considerations, and made an incision down to the probable seat of strangulation. I knew it could do no harm if there were no strangulated hernia, and on the other hand, if there were, it was the only chance of saving life. I found the protrusion very small, it is true, but all the more dangerous on that account. The stricture was divided, and the danger all passed away.

SATURDAY, JUNE 30.

DESECRATION OF LONDON GRAVEYARDS.

Why should we trouble ourselves about the digging up of dead bodies, it may be asked? Are we afraid of pernicious vapours, and if so is not Mr. Condy at hand with his oxygenating water to destroy smell, and Dr. Angus Smith with his carbolic acid to render it less noxious? There is certainly something in this, the physical side of the question; but there is more in the moral side. Our population want lessons in decency, in gentleness, and reverence. We want them to respect humanity in all forms, even the lowest; and we believe that people who are brutal to the dead will be so to the living likewise. If we wanted to make a labouring man a drunkard, a wife beater, one who would not honour his aged parents, nor take care of his helpless children, we should set him to work upon digging up a closely-packed graveyard and "fortify him with liquors" to enable him to go through the degrading and noisome task. The Rev. Mr. Arrowsmith, writing to the *Times* on the digging up of the St. Giles's Cemetery, says:—

"When, late in the evening of the 13th inst., I advised you on this subject, about a dozen, or perhaps a score, of bodies had been exhumed; it was the uppermost tier of a huge pile of dead. By ten o'clock next morning I should suppose that the remains of at least fifty corpses had been tossed together. The miners had struck upon a rich vein of dead men. Shells of coffins packed like hat boxes, with a thin layer of earth between, cropped out all round; cavities where heads had lain were coated and fringed with bushy hair, and a treacly ooze was sobbing from the rifts in the broken coffins. Even the strong-stomached, case-hardened navvy was softened and sickened. It became evident that, on sanitary grounds alone, no time should be lost, for although fortified with liquors, the men could not be expected to sustain the nauseous stench without imminent risk to health, and the whole neighbourhood might be involved, as the surrounding air to a considerable distance was rapidly becoming tainted. My curate at once went in quest of the officers of health, Drs. Hillier and Buchanan, who, upon examination of the spot, in their turn hastened to find the solicitor of the rector of St. Giles. That gentleman, not without some pressure, consented to accompany them to seek an interview with the Midland Company's solicitor, who was hardly prevailed upon to issue an order for the stoppage of the disinterment."

We ought to do honour to Mr. Arrowsmith for his efforts to check this desecration, which is, to tell the truth, no credit to the Church of England. Whether we think of the solemn act of Episcopal consecration by which ground is set apart for ever for the repose of the mortal remains of the faithful, or at the enormous incomes derived from burial fees in times past, or at the confessed abuses and covetousness which were the shame of all burial-grounds within living memory, we should have expected the Bishop of London and the clergy of St. Pancras to have been foremost in opposing such traffic in men's bones.

It is well known that every burial-ground of our old London churches has been filled over and over again, and that it would be difficult to find a yard or a foot of soil in any of them, to a considerable depth below the surface, which is not made up of human remains. From century to century, from year to year, the number of the dead had increased with the increasing population, and yet our churchyards were still compelled to make room for more, until the Legislature some few years ago interfered and closed them.

To the almost compulsory desecration of removing remains to make room for other burials, succeeded another phase of desecration—the conversion of the abodes of death to other uses. This is the special subject of our present inquiry. We must premise, however, that such conversion of the metropolitan graveyards has been going on for centuries, though scarcely in so indecent a form, and many a block of buildings, many a thoroughfare and street, now stand or pass over the graves of the mouldering dead.

The burial grounds of St. Giles's and Old St. Pancras are now the scene of wholesale desecration. The Midland Railway Extension was empowered by Act of Parliament to make way as it liked, and, of course, the question was to do so as cheaply as possible. Two courses were open—either to avoid the churchyards and go through the property of the living, at the usual great cost of compensation, or to go through the property of the dead at a comparatively much smaller figure.

For the round sum of £20,000 the Vestry of the parish conceded the right of desecration, and the works are now in operation—with rather alarming prospects, however, for the Company.

A few days ago the navvies turned up some four or five hundred remains at the corner of St. Giles's burial ground;

and on Thursday last delved into another vein of decaying mortality, in what was formerly a part of Old St. Pancras Churchyard. Visiting the scene of desecration, we noticed that one of the skulls turned up exhibited not only remarkable proportions, as though indicative of some extraordinary physical and mental peculiarity, but showed on the left side of the forehead what appeared to be the clean perforation of a bullet, evidently fired from above. The frontal bone was of extraordinary thickness, and those of the other parts of the body corresponded to the large development of the skull.

The part of the ground where these human remains were found had been closed to burials ever since 1792, when the Vestry of the day felt compelled to purchase a portion of an adjoining field to extend their burial-ground.

Now, within five years after making this purchase of fresh ground, it was deemed expedient to build a house for the sexton. The question then arose, where was it to be built? On the new ground or on the closed churchyard with its thousand thousand graves? Cupidity decided that it should be built over the graves, and this was accordingly done, as made evident by the recent exhumation. From being the sexton's house, the premises passed into other occupation, and finally formed part of Bessemer's manufactory, through which the Midland Extension is proceeding.

The formidable nature of the dilemma into which the railway company has fallen will appear when we state that the design is not only to construct a railway over these burial-grounds—and already the great beams are fixed over many a venerable tomb—but to *tunnel* them at the depth of ten feet below the surface! Imagine the tunnelling of a burial-ground! Surely it must have been known that many a family grave is sunk from eighteen to twenty feet below the surface, and that at the depth of ten feet is precisely the average level where they will have to bore through a festering mass of decomposing humanity!

We need not state that considerable excitement exists on all sides, and that the relatives of the dead reposing in these ancient burial places are making anxious inquiries respecting the fate of the cherished remains, hitherto respected. The matter has been brought under the notice of the Home Secretary, who has deemed it his duty to order an inspection of the ground to be made by Dr. Holland, the Inspector under the Burial Act.

Doubtless those concerned in the business imagined that doings of this nature might pass unnoticed in a locality at present so low and poor; but they might, perhaps, have remembered that St. Pancras is one of the most ancient burial-grounds in England; that it contains the remains of some of the most distinguished individuals, both native and foreign. Curiously enough, an inscription on the tomb of one of the latter runs as follows:—"A foreign land preserves his ashes with respect; the gratitude of his king and country embalms his memory." This is the tomb of Philip St. Martin, Count de Front, Sardinian Ambassador in 1812.

Only half a century ago St. Pancras was one of the fashionable burial-grounds of the metropolis. In the archives of the Heralds' College will be found the description of the grand processions which attended the burials of the notabilities whose remains repose in the churchyard of this venerable church—the representative of the last church in which Mass was said at the Reformation; and the last Roman Catholic incumbent, according to a legend, starved himself to death rather than resign his cure. At all events, it is certain that a preference has always been shown to this burial-ground by distinguished Roman Catholics, both native and foreign. Here were buried the former Earls of Arundel, the Cliffords, and a large number of notable and titled foreigners, members of that church,—among the rest, Louis Charles, Comte D'Hervilly, Field-Marshal of France; Philip Claude, Comte de Montboisier, Lieutenant-General in the French army; François Claude Amour, Marquis de Bouillé (whose remains were removed a few years ago); and several other French bishops, and an archbishop of Narbonne; Louis Claude Bigor de St. Croix, the last minister of Louis XVI.; Marie Louise D'Esparbes de Lussan, Comtesse de Polastron, Dâme de Palais to the Queen of France.

We need scarcely state that most of these distinguished foreigners were refugees, chiefly after the great French Revolution.

Amongst our English notabilities reposing in St. Pancras' churchyard are Lord Baltimore, Lord Widrington, Thomas, Earl of Limerick, a Somerset, a Vere, a Waldegrave, a Gray, a Montague, a Walpole, and Abergavenny, besides those already mentioned.

Here repose a Belasyse, whose name has been altered into *Belsize*, giving name to the great property in the vicinity of Belsize Park; Lady Barbara Barnewall, the granddaughter of Oliver Cromwell; Lady Henrietta Waldegrave, mother of the Countess of Powis (the present representative of the family recently visited the tomb of her ancestress); a daughter of the Hon. Edward Carlton, Knight Harbinger to James II. (Harbinger means the functionary who preceded Majesty on its journeys to prepare appropriate quarters); Cooper, "the English Vandyke," who painted the miniature of Oliver Cromwell; Daniel Clarke, Master Cook to Queen Elizabeth and King James I. for nine-and-twenty years; Woollet, the engraver, on whose tomb an eminent artist wrote the following words in pencil:—"He engraved well, but is not well engraved," and to whom a monument was subsequently erected in Westminster Abbey. Finally, here also repose the remains of the famous Mary Wolstoncroft Godwin (authoress of "The Rights of Woman"), the mother of the wife of the poet P. B. Shelley.

THE FEMALE MEDICAL SOCIETY.

The journals of last Tuesday inform us that "The Female Medical Society" held its second annual meeting at the Hanover-square Rooms on the preceding day—the Earl of Shaftesbury in the chair. The objects of the Society were defined to be as follows:—"1. To promote the employment of educated women in the practice of Midwifery and the treatment of the diseases of women and children. 2. To provide for women facilities for learning Midwifery, etc., like those which have long been in the possession of men; and 3. To establish a publicly-recognised board of examiners, so that women who have pursued an appropriate course of study and passed an adequate examination may be distinguished from others. According to the report which was read, a long series of statistics show conclusively that the mortality in childbirth among patients attended by even the present uneducated midwives is less than half that which occurs among patients attended by Medical gentlemen in general practice. This startling disparity in the mortality of mothers is explained by the fact that puerperal fever is often produced among lying-in patients by the accidental conveyance of infection from other patients, and the corollary was put prominently forward that Midwifery should be separated from the general practice of Medicine and Surgery, and that as a general rule this branch of Medicine should be left in the hands of properly-educated women."

We say nothing now upon the question of the desirability of resigning the practice of midwifery into the hands of women, but protest against the statements which have reference to the mortality of puerperics, for they constitute a gross slander upon the Profession at large, and are founded upon a total misrepresentation of the truth. We pointed out last October the fallacy of the supposition that the mortality in childbirth amongst patients attended by midwives was less than amongst those attended by Medical men, and that the conveyance of poison from woman to woman was much more

likely to occur through the instrumentality of female as compared with male Practitioners. It must be recollected also that in those cases attended by midwives in which dangerous conditions arise, the Medical man's aid is always requested, and the mortality under these circumstances is always credited to the class of cases said to be attended by the Medical man.

One chief object in referring to this matter is to note the real intentions of the several gentlemen whose names appeared as the supporters of the movement. We mention Lord Shaftesbury and Dr. W. Farr especially as having been present at the annual meeting. It might at first sight be supposed that the report correctly interprets the sentiments of these philanthropists. This, however, is utterly and entirely erroneous, as the reporter might have known. Dr. Farr, we are enabled to state, denies that any statistics exist by which the random statement as to the excessive mortality of women attended by Medical men can be substantiated, nor does he hold that opinion. Dr. Farr's sole motive—and a right one too—is to support any movement by which educated and intelligent nurses can be provided, in lieu of ignorant ones. He is altogether opposed to any scheme which in the least degree tends to weaken the paramount control of the Medical man in all obstetric cases. Dr. Farr, therefore, does not in the least countenance the employment of midwives instead of the Practitioner, and Lord Shaftesbury, in his concluding remarks, was most careful to impress upon the officials of the Society the necessity of not overstretching the proper office of women in midwifery.

THE WEEK.

THE HARVEIAN ORATION AT THE ROYAL COLLEGE OF PHYSICIANS.

The annual oration was delivered in English on Tuesday last at the College of Physicians to a large audience by Dr. Paget, of Cambridge. Dr. Paget began by citing the words in Harvey's deed of endowment that the orator was "to exhort the members of the College to study and search out the secrets of Nature by way of experiment." He put the exhortation into the form of examples of the ways in which Medicine had actually been advanced "by way of experiment," and after alluding in eulogistic terms to the dignified position occupied by the President of the College as an observer of disease, and the unanimous approval by the Profession of the honours lately conferred upon him, proceeded to point out the paths by which workers in former times have discovered truth, and the three most characteristic ways in which Medicine has been advanced in accordance with the spirit of Harvey's words—viz., (1) through the sciences of Physiology and Pathology; (2) by the immediate practical study of disease and generalisations from a large experience; and (3) by the immediate application to practice of a single observed fact. In illustration of these three modes of progress the orator gave at some length the examples of Harvey's discovery of the circulation of the blood, Sydenham's clinical investigations in Practical Medicine, and Jenner's discovery of vaccination. Harvey's discovery is often spoken of as a simple inference, as one of those truths of science that are floating abroad ready to be caught, almost perchance, by some lucky observer; whilst in reality it was an evidence of great powers of mind and originality of investigation. Fabricius, four years before Harvey was born, had discovered the valves of vessels, but more than half a century elapsed ere Harvey's great work appeared. In the interim, no one had made use of the fact made out by Fabricius. Harvey had to work out slowly and step by step the basis upon which his final proposition rested, and the intellectual merits of his discovery seem very great when we remember the nature and peculiarities of all the attendant circumstances connected with it. Physiological doctrines were not such as to help forward his discovery; the notions in regard to vessels and tissues were very erroneous. The heart was not known in its office as a propeller; its substance was not recognised as muscular; its movements had never been observed; ideas on the functions of the arteries were, as we now think, absurd; vessels were supposedly the channels for the circulation of what the ancients called "spirits." Notions upon nutrition were crude enough; it was believed that the tissues were nourished entirely by the simple ebb and flow of the contents of the vessels, especially the veins. Thus Harvey had to break through all these doctrines and take his stand upon a new theory of philosophy altogether. The proofs of his discovery were made up of a series of propositions and inferences, worked out with no little difficulty. The inference that the blood passed from the arteries to the veins was a triumph of pure reason. Harvey, well aware of the value of analogical evidence, made himself as proficient as he was able in comparative and morbid anatomy—in fact, master of the current knowledge of his day, and the facts which formed the ground of his reasoning and of his own seeking were in accordance therewith. The influence of Harvey's discovery, the orator observed, on physiology, was great; it shook the doctrines of authority, and vindicated not only the value of experiment, but the importance of attending to the principle of mechanical action in the body. The immediate influence on practical Medicine was small; the practice of the time, as at present, was in advance of theory, and had been arrived at as the result of simple observation; phenomena had been already utilised, though their causes remained obscure. Medicine is not peculiar in this respect; the exigencies of society, cupidity, and the like, lead to successful invention, especially in the field of mechanics. The boomerang and the screw propeller are used successfully now, but the explanations of their actions are still matters awaiting solution. Sydenham's writings and career illustrated the second mode of advancing Medical knowledge, and the vaccination of Jenner the realisation and application of a single fact at once to practical Medicine. The latter suggests that possibly other means of protection against disease analogous to the protective power of vaccination might be discovered. Having by his three first examples illustrated the intellectual powers and processes by which Medicine had been successfully advanced, Dr. Paget concluded his finished oration with one more instance of the proper moral qualities and temper of mind of the Physician. This example was the improvement in the treatment of the insane, the principal heroes being Pinel and Conolly. The spirit that animated these two men was necessary for the true progress of their efforts. It is that which prompted a Larrey to invent an ambulance, and which enables the Physician to prosecute his studies and his duties amidst the sharpest ravages of plagues and epidemics.

MANSLAUGHTER BY A BONESETTER.

A coroner's jury have returned a verdict of manslaughter against one Matthews Bennett, a Leicester bone-setter. The deceased was named James Squires, and was a man of 66 years of age, and his shoulder was said to have been dislocated for four months. He had one interview with the bone-setter at a public-house in Leicester, who, with the assistance of sixteen men, pulled the limb about for a considerable time. The patient died on the same evening, and the condition in which the bone-setter and his assistants had left him will be best understood by the following report of Dr. Nuttall's evidence before the Coroner:—

"Mr. H. Nuttall said, I am an M.D. and Surgeon in this borough. On Monday, the 11th inst., about half-past eight in the evening, I was requested by the first witness to go and see his father, who was at this house, and, as he believed, in a dying condition. I accompanied him, and on examining deceased I found him dead, but quite warm. The lips and

countenance were pale. The right arm was very much swollen, and there was a recent abrasion on the front of the shoulder, near to the armpit. On examining the right elbow, I found it fractured and dislocated. On the following morning I received instructions from the Coroner's officer to make a post-mortem examination of the body. In the afternoon of that day, assisted by Mr. Ward, a Surgeon, I commenced to do so, and on making an incision through the skin and superficial layers on the front part of the right shoulder, we discovered a quantity of blood, some being in a liquid state, and some coagulated. Without proceeding further in the operation, I sent for Mr. Lankester, another Surgeon. When he arrived we continued our dissection, and after clearing away the blood before spoken of, and carefully dissecting down to the muscles, we discovered the larger pectoral muscle, or muscle which takes its origin from the collar bone and four or five first ribs, and is inserted into the upper part of the arm, torn nearly entirely through, about two and a half inches from its insertion. We found also the plexus of nerves which pass from the spine to the arm torn through at about an inch or an inch and a half below the collar-bone. The large artery which passes from within the body to the arm was also torn through at a point nearly corresponding to that where the nerves were ruptured. Continuing our dissection down the upper arm, we found several small patches of echymosis or effusion of blood in the tissues which lie between the skin and the muscles. At the elbow we found a dislocation of the upper arm, on to the front part of the lower arm or ulna. The internal ligament which holds together the upper and lower arms was separated from its attachment to the upper arm, carrying away some fragments of bone with it. There were also one or two loose fragments of bone with effusion in the tissues close to the joint. We then directed our attention to the shoulder-joint itself, and found that the head of the humerus or upper arm was anchylosed, or had grown to the cup and neck of the scapula or blade-bone. It was, therefore, partially dislocated, and it appeared to us that this dislocation had been brought about by the cup in which during health the head of the arm-bone rests having been fractured, thereby allowing the head to become fixed in between the two fractured portions, a considerable quantity of new bone having been formed, by means of which exceedingly firm union had taken place between the arm bone and scapula. We then examined all the great organs of the body, the lungs, heart, stomach, liver, kidneys, etc., and found them perfectly healthy. The brain was also healthy. Judging from the amount of injury done to the larger pectoral muscle, the artery and plexus of nerves, and to the elbow-joint, I am of opinion that death took place by syncope or fainting, which was produced by the injuries done to the structures named. It would require very great force to produce these injuries. Deceased was a very muscular man, and the pectoral muscle would not give way without very great force. The injuries had been inflicted certainly within a few hours of death. There was no evidence of any injury received at the time deceased was at the Loughborough Dispensary. I consider the force of from twelve to sixteen men employed on the occasion was most unjustifiably great. The dislocation at the elbow was recent."

PERINOWSKI *v.* FREEMAN AND ANOTHER.

THE Profession will be glad to learn that the legal expenses of Messrs. Holmes and Freeman in the recent action are to be defrayed entirely at the expense of St. George's Hospital. We need not repeat that a more unjust action as regards the defendants was never brought into Court, and although they cannot be compensated for the annoyance that it must have caused them, it is satisfactory to know that they will be in no way pecuniary losers by it. The authorities of the Hospital having thus acted in accordance with the dictates of justice, we hope that they will not stop here, but will introduce such changes in the nursing department of their Hospital as will at least prevent the recurrence of similar accidents.

NEW YORK.

A LETTER just received from Dr. Elisha Harris, the Registrar of vital statistics of the Metropolitan Board of Health in New York (dated June 5th) says:—

"We have more than 100 cholera patients anchored ten miles down the bay, and to-day have taken possession of sixty acres of land on shore, eighteen miles from the cities, for the purpose of landing and cleansing the infected companies.

"In the cities we have no epidemic of cholera, but we have occasional deaths from cholera that can in no wise be distinguished from Asiatic cholera. Diarrhœal maladies are prevalent, but they are not fatal."

The mortality in the City of New York in the week ending June 2 was at the rate of twenty-six deaths per annum to every 1000 persons living. In Brooklyn the mortality rate was 19·6 per 1000. The mortality rate of London in the same week was 26 per 1000.

Zymotic diseases caused 21 per cent. of the total deaths in New York, and 25 per cent. in Brooklyn, more than half of the mortality from those diseases being ascribed to scarlatina, diphtheria, and typhus. The average proportion of zymotics in London at the same time of year is 25 per cent. of the deaths from all causes. Accident or negligence was fatal to 6 per cent. of the total deaths in New York, and to 2 per cent. in Brooklyn. The ruling proportion in London at this season is about 3¼ per cent. This corroborates the descriptions which have been given of the dangers of the passage of the Broadway when the traffic is at its highest pressure, and leads us to be thankful that in this respect our streets are not so bad as they might be.

THE KING'S COLLEGE DINNER.

PRESENTATION OF A TESTIMONIAL TO SIR WILLIAM FERGUSSON.

(From a Correspondent.)

I CANNOT pretend, Mr. Editor, to give you a regular reporter's account of this very successful dinner; but I'll try to let absent old King's men know how well it was managed, and give them, if they want any, the temptation to come up next year themselves. Barring the heat of the weather and a thunderstorm, whose vivid flashes were reflected on the silver dessert service, everything went as well as possible. The tables were nicely arranged in three lines, with a cross table at the top for the more eminent of the guests. The chair was occupied by Dr. Druitt (Dr. Budd was ill, and obliged to be absent). On his left was the Rev. Dr. Jelf, for more than twenty years Principal of King's College; and on his right the special guest of the evening, Sir William Fergusson, Bart. There were many King's College Professors, or at least men trained at the College, whose names are household words to the Profession, including Dr. Guy, the able statistician and Medical jurist; Henry Lee, the syphilographer, now of St. George's; Henry Smith, the Surgeon; John Wood, of hernia celebrity; Dr. G. Johnson, of whom Professor Partridge pleasantly said that, like the wise virgins, he was well supplied with *oil* (castor to wit); Salter, of Charing-cross; Professor Garrod; George Lawson and Soelberg Wells, the ophthalmologists; Mr. Nunn, of the Middlesex; Drs. Symes Thompson, Conway Evans, Way, Hood, Sansom, Anstie, Playfair, Liveing, Pollock, Armitage, Hawkesly, Tanner, Meadows, and Murray. There were many men known personally or by report from every part of these islands. Dr. Ross, an old pupil of Sir William's, had come from Inverness; Dr. Macleod, of Ben Rhydding; Dr. Cockburn, of Chatham, who returned thanks for the health of the Army; Dr. Siccama, who returned thanks for the health of the Navy; Mr. Dyer, of Ringwood; Dr. Sheppard, of Colney Hatch; Swain, of Devonport; Bartrum, of Bath; Coobe, of Scarborough; Walters, of Reigate; Davis, of Brentford; Rhodes, of Huddersfield; Godfrey, of Herne Bay; Paley, of Ripon; Elin, of Hertford; Groom, of Wisbeach; Bishop, of Tunbridge; Mathias, of Bridgenorth; Monckton and Hoar, of Maidstone; Saville, of Sunderland; Brace, of Bath; Walton, of Brighton; Monckton, of Rugeley; Jackson, of Nottingham; Bradley and Roche, of Greenwich; Playne and Pearl, of Maidenhead;

Allfrey, of Chislehurst; Rugg, of Clapham; and Geere, of Brighton. There were besides Christopher Heath, Mr. Bellamy, Spencer Watson, and Fairlie Clark, amongst rising Surgeons; Dr. Fowler, of Poor-law fame; and others whom neither memory nor my crib from the honorary secretaries' book have allowed me to bring to mind.

Altogether more than 100 sat down to dinner at half-past seven. In front of the chairman were ranged the very handsome epergne and other pieces of a handsome silver dessert service, with the inscription that they were presented to Sir William Fergusson, Bart., by his pupils and colleagues. This added much to the symmetry and brilliancy of the scene, but was rather an impediment to those who wished to see the notabilities and hear the speeches. And here, before I describe the proceedings in detail, let me say one word as to the tone, bearing, and culture of the assembled friends. I could not conceive of a more merry, nor yet of a quieter and more thoroughly-refined set of guests. For five hours nearly were the proceedings kept up with unflagging interest, and the speeches were listened to and the whole meeting as well organised at last as at first. The music, too, which was contributed by some old King's men, was perfect. They gave us the great treat of good music, song and accompaniment, both rendered by gentlemen, with perfect quietness and good taste, and yet admirable execution. The dinner seemed good; and as I had no headache next day, I need say no more for the wine. The chairman, after dinner, proposed the usual loyal toasts, and hinted emphatically at the superior blessings enjoyed by this favoured land over the Continent. He then proposed the "Church," which was responded to by the Rev. Dr. Jelf, Principal of King's College, in a speech of great good feeling. Then came the Army and Navy and Volunteers, the last of whom returned their thanks by the mouth of Dr. Buzzard in a humorous speech. Then came the toast of the evening. The Chairman, amidst tremendous cheering, proposed the health of Sir William Fergusson, Bart. He began by passing in rapid review the history of the Medical School of King's College; how the political, and social, and religious animosities of George the Fourth's reign were the expression of a want; that the middle classes whose means were slender, and that persons whose religious opinions were not in conformity with the Established Church had been unable to obtain their due share of privileges in education, society, or politics. Then was founded the University of London, whose original institution now flourishes as University College, and which was destined to give a full and liberal education, and the *prestige* of academic rank to those who, for the reasons aforesaid, were unable to obtain them at the elder Universities. No body of men profited more by this than did the Medical Profession; for then first, instead of the old-fashioned "walking the Hospitals" and hearing casual courses of lectures read, was there presented a full course of Professorial instruction in all the sciences which form the basis of Medicine. But fortunately for the world the Conservative party were not behindhand with a counter move. If University College might be supposed to be established by those who wished a new order of things, there was a large and powerful body who, whilst desiring the reform of proved abuses, did not wish to cast off all identity with the past. They desired that our youth should be trained up to revere all that was great and good and solid in Church and State, and at the same time claimed the fullest, freest scope for science and the independent investigation of truth. Hence arose King's College—first suggested, it is said, by an able parish priest, the Rev. Dr. D'Oyley, of Lambeth, and supported by all the Conservatives and Church people—and, as the Chairman observed, "ere the walls had ceased to vibrate with the hammer of the carpenter," courses of Medical lectures began to be delivered, by a staff of the ablest Professors of the day, of whom every King's man was glad to see the buoyant and juvenile Professor of Anatomy not only surviving, but still in the fullest possible vigour. Here, then, was the first stage. The principles of Medicine were taught, and they were combined with something of that discipline which helps to form the Christian gentleman,—the daily recognition of the Creator in the chapel service, and that salutary check on whatever is low, or loose, or riotous, which is given by the fatherly counsel and example of the estimable prelates and clergymen who have adorned the office of Principal. So far a great step was gained; Medical men could get scientific Professional knowledge, combined with the culture which should fit them for the highest society in the land. But there was wanting yet the practical department, in which the Professors should be able to demonstrate at the bedside what they taught in the class-room, and so make the School complete, self-contained, and perfect. For this purpose a Hospital must be built, and the council had the good fortune to secure the services of their distinguished guest of that evening as the first Surgeon to the King's College Hospital. They must not forget the help given by other able men, as Todd, Budd, Partridge, Bowman, Guy; still it might be asserted that the history of the King's College Hospital—he might say the history of modern Surgery—had been closely allied with the doings of Sir William Fergusson. He could not venture to occupy their time by a bare recapitulation of the triumphs in Operative Surgery which had been achieved by their distinguished guest; but as all such acts proceeded from certain antecedent moral causes, he must say a few words on what he believed to be the characteristics of Sir William as a Surgeon and the causes of his success. There was, in the first place, the element of force, the indomitable will, the resolution that a hazardous operation, once begun, shall be completely carried out, and that not by niggling and timid touches, but by going right to the root of the matter, with a resolution typified by that iron grasp of the hand which might be extended, but not increased, by his own "Lion Forceps." Then there was the element of sagacity; the capability of storing up and sorting out for use all the varied cases which his experience met with; the power of bringing to bear the collateral sciences of Anatomy and Physiology on every Surgical operation—as, for instance, the sagacity which prompted him to cut certain little muscles that the flaps might fall easily together after the operation for cleft palate. But, said the Chairman, force and sagacity may make a great Surgeon; they might have made King's College almost as powerful a school as it is; they might have made the fact of being a pupil of Sir W. Fergusson's a passport, as it is, to every Surgical office and honour; they might have made him a Baronet, but they would never have brought you all together as you have come together to-day. There is one more element wanted. It is found in the spirit of tenderness; in that which suggests conservative operations, in the more than feminine grace and delivery with which our distinguished guest can perform the smallest, nicest, neatest, and most trivial operations, just as the steam hammer which now forges an anchor, now gently cracks a walnut. It is the faculty of conciliating what is far better than respect or admiration—the affection of a vast School of Surgeons and colleagues, who now come forward to testify their sympathy with Sir William on the occasion of the honour which the Queen has conferred on him. In their name, Sir William, said the Chairman, I have the honour to present you with the Silver Dessert Service before me, and with this written record of the names of the donors. Generations hence, may some future baronet say, as he looks at them amongst the treasures and muniments of his family, "The founder of our house was clearly an able man; but more, he was beloved by those who knew him." So, amidst much cheering, bumpers were tossed off, and then deep silence prevailed for Sir William's reply; and this I wish I could give with something of the precision of a shorthand writer; for it was one of the most remarkable and useful morsels of autobiography which I ever heard. Sir

William seemed deeply affected, and spoke in homely, plain, inartificial language; but all the more impressively for that. He described his early life, his struggles, and his aspirations. He began, he said, with no large pecuniary resources, no high connexion or those other things which push a man on in the world. But he had set before himself the resolution to attain the highest rank in the Profession; and without looking right or left, he had won it. He mentioned as a quiet anecdote how that, when a student, he had been in company with two friends, and in the course of conversation they were talking about the eminence attained by some first-rate men. "Ah!" said one of them, "not one of us three need look so high." I said nothing, observed Sir William, but I thought to myself, "Speak for yourselves, gentlemen; do as you please, but I'll follow my own plan for all that." They were now village Surgeons in Scotland. But he went on—not by magic, nor by luck, nor by any help from without, but by steady, persevering work, always on the look-out to be learning or doing something. Then a time came when he was invited to London to the King's College Professorship. Some of his acquaintance thought it was presumption and rashness to come, but come he did, and he came with scarcely a friend, save one whom he had always been able to rely on—his esteemed friend Professor Partridge. So he had worked his way steadily upwards; proud of his Profession, of his work, and of his pupils; always striving to do each day's work better than the last. Now he found himself in the proud position of receiving this splendid gift, presented in such terms of eulogy, and which awakened in him the most powerful emotion." I feel, Mr. Editor, that I cannot do justice to Sir William's speech—so quiet, and unassuming, and modest, and yet so pregnant with instruction and comfort; nor need I further occupy your time by saying how Sir William proposed the Chairman's health, and Dr. Henkell that of the Professors, how Mr. Partridge replied in a way to satisfy everybody, and how we lit our cigars at the door, after a capital evening, at about a quarter-past twelve.

REVIEWS.

CHOLERA LITERATURE.

Cholera in its Home; with a Sketch of the Pathology and Treatment of the Disease. By John Macpherson, M.D., etc. London: John Churchill and Sons. 1866.

Notes on Health in Calcutta and Emigrant Ships, including Ventilation, Diet, and Disease. By W. H. Pearse, M.D. Edin. London: John Churchill and Sons. 1866.

Notes on Epidemics: for the Use of the Public. By Francis Edmund Anstie, M.D. London: Jackson, Walford, and Hodder, 27, Paternoster-row. 1866.

On Diseases of the Respiratory Passages and Lungs, etc. By Walter Goodyer Barker, M.B. London: John Churchill and Sons. 1866.

Memorandum of a Plan of United Action in the Case of an Epidemic of Cholera: to be Communicated to Vestries and District Boards, by the Metropolitan Medical Officers of Health. London: Published at 6, North-street, Manchester-square. Price one penny.

The Common Nature of Epidemics and their Relation to Climate and Civilisation; also Remarks on Contagion and Quarantine. From Writings and Official Reports by Southwood Smith, M.D., Physician to the London Fever Hospital. Edited by T. Baker, Esq., of the Inner Temple, Barrister-at-Law. London: N. Trübner and Co., 60, Paternoster-row. 1866. Pp. 130.

On the Unity of the Zymotic or Epidemic Poison and the Nature and Treatment of Cholera. By Henry Greenwood, M.D., M.R.C.P. Lond. Greenwich: Berryon. Pp. 22.

On the Effects of Elevation and Floods on Health, and the General Health of Oxford compared with that of Other Districts. By G. A. Rowell, etc. London: Williams and Norgate. 1866. Pamphlet. Pp. 46.

The first work on our list is by Deputy-Inspector John Macpherson, M.D., whose long experience in India gives him a just claim on our attention. His book is not so much an exhaustive treatise as it is a sketch of the most prominent features of the disease derived from his own observation. And we may note as a fact that men who have seen a few cases in a country where perhaps cholera is an exotic and rare visitant, are usually much better prepared with a perfect theory and satisfactory mode of cure than the men are who have had opportunities of seeing it under the greatest variety of forms, and in its very birthplace. Dr. Macpherson belongs to the latter class. Hence he views with philosophic indifference "the rise and fall of theories and methods of treatment," and, as a practical man, would rather dissuade us from the ready adoption of that multiplicity of "cures" which ignorance and enthusiasm are sure to deluge us with the moment the epidemic makes its appearance. The first part of the book is on etiology, under which the author notices, first, the appreciable atmospheric influences, and their effects on the cholera. A fall of the thermometer and fall of rain are known to check an epidemic. The prevalence of "cholera has a marked influence on the prevalence of other diseases. When cholera is epidemic, they are from one-fourth to one-fifth less prevalent than at other times." Cholera has no relation to epizootics. The Calcutta crows are too clever to run away at cholera times. Cholera, though the same in the main, yet may vary in details in different seasons,—as in the degree of blueness, the early occurrence of collapse, the amount of vomiting, purging, and cramps, the frequency of consecutive fever, and the proportion of deaths. The author next treats of less appreciable causes, as malaria, contagion, prevalence in certain localities, etc. Under the head of predisposing and exciting causes, he notices the greater prevalence of cholera amongst new comers and travellers, although these persons are not equally liable to fever, nor to ordinary bowel complaint. The *fixed* population of Calcutta die in the ratio of nearly two to one non-resident of fever, and nearly three to two of bowel complaint; but of cholera, non-residents die in the ratio of three and a-half to one resident. Depressing causes of all sorts, and especially such as disorder the stomach and bowels, are of most moment in Dr. Macpherson's eyes as predisposing. In his remarks on the diffusion of cholera, he negatives Pettenkofer's *ground-water* theory, shows the difficulty of the water diffusion theory (because cholera declines when the wells begin to be possibly impregnated with fæcal matter through the rains), and gives most support to the *dust* theory, though he sees difficulties even in that. In the second part of the work, devoted to pathology, the symptoms and morbid appearances are detailed from the life, and some facts are noticed which require some theories to be altered to admit them, such as the increase of *internal* heat during the intensest collapse. Although Dr. Macpherson has never seen *cholera sicca*, he does not deny its existence; but it is very clear that the vomiting and purging are not in his opinion the essentials of cholera, although, as he says, the effects of elaterium and of putrid shell-fish are wonderfully like it. Then follows a chapter, entitled a "Sketch of Opinions," in which, as throughout the work, the author shows the most acute and vigorous powers of analysis and criticism. He shows that amongst the phenomena of cholera, obstruction of the pulmonary circulation is by no means proved to be a primary one; that the coldness may be present with a tolerable pulse, and consequently with a tolerable pulmonary circulation; that at the *beginning* of an attack blood flows freely on venesection; that it is not true that the state of the blood bears no relation to the vomiting and purging; and that it is not true that collapse passes off while purging continues. The discordance of these views with those of Dr. G. Johnson is clearly visible; equally so is the author's opinion that we are not bound to accept vomiting and purging necessarily as the efforts of nature to eliminate poison. In the chapter on "Treatment," Dr. Macpherson shows that secondary fever occurs when remedies have been used and when none have been used; consequently that remedies, and especially opium and stimulants, are not the cause of secondary fever, for this occurs under cold water treatment. Early and free use of opium is Dr. Macpherson's sheet anchor; but in the stage of collapse opium is not necessarily mischievous, but inert. In the stage of collapse the author gives drink, and probably small doses of ammonia, but attempts no *coup*, and confesses he has no specific. We have said enough of this book to show its character. Instead of a dozen cases and miles of theory, it is crammed with facts and instances, whilst theory —*i. e.*, the notion that we can account in a consistent manner for causes and symptoms—is treated with a contempt almost

depressing, and with a severity of criticism almost unequalled. The best advice we can give to any one who deludes himself into believing that he has a theory or treatment of cholera is, read Dr. Macpherson.

The preface by Mr. Baker, to the reprint of Dr. Southwood Smith, seems to a Medical mind somewhat enthusiastic, especially when he says, "Never was a country guided through the perils of an epidemic with greater wisdom and energy than Great Britain during the cholera of 1848-49." So far as we remember, the cholera then went through its accustomed *rôle*. It killed the needy, the dissipated, and occasionally the well-to-do, for the first month, and guided *itself* out of this country in the third month to walk in darkness elsewhere. The first part consists of general commentaries upon epidemics, their common nature, and whether they are within human control (p. 58), and, says the author, "From these facts and observations we see that epidemics *are* under our control; we may promote their spread or we may prevent it. We may preserve ourselves from them. *We have done so.* We have banished the most formidable. We may put an end to typhus: we have actually done so." We have encompassed the model dwellings by a barrier which neither typhus, *nor even cholera*, nor any of the other causes of excessive sickness and premature mortality have been able to pass. To the residents within that barrier the chance of life has been almost doubled; to their children it *has* been doubled; and compared with some children of their own class it has been increased fourfold." Dr. Smith was a non-contagionist of the old school and an anti-quarantineer. "Our true course," he says, "is to make diligent search for all localising circumstances, and to remove them, so as to render the locality untenable for the epidemic. But quarantine makes no such search —hence the signal failure of quarantine."

With all respect to Dr. S. Smith and Mr. Baker, we protest against a reproduction in the present day of the squabbles of thirty years since. With regard to "localising causes," there is no Medical man who will be found to deny the necessity of thorough drainage, ventilation, water supply, and all the other items of the sanitary creed. On the other hand, there is no "localising cause" of any disease so potent as the presence of a patient affected therewith. Let us give up the use of the old words, contagion, infection, and quarantine, which have been battered to pieces; but we affirm that "zymotic" diseases are by their very nature "communicable" or "transmissible;" and that the "isolation" of the sick is an essential measure for the safety of those yet sound. To abuse quarantine because it makes no search for localising causes of epidemics, is like abusing a man who has a good deal of loose cash in his house for keeping out thieves. Lock up your cash by all means, but keep out the thieves too.

Doctor Pearse's book is an "inspiration" on the subject of ventilation on ship-board, which is so hard to contrive when "mostly in the tropics near the Equator, often with heavy rains," calms occur. Then "the thermometer below often ranges from 86° to 90°. At the equatorial rain-belt during the cooler rains, the heat is less intense, the thermometer falling three or four degrees below 86° or 90°;" but Dr. Pearse considers that "such a close condition of the 'tween decks is not so hurtful as it has been commonly thought to be; and the most healthy periods of the voyage have been those of the hot, damp calm latitudes." Dr. Pearse seems to rely very much on the 'tween deck atmosphere being the warmer—it will move and be changed, and makes this the basis of his system of ventilation, by wind-sails or chimneys of canvas or iron. Chapter ii. tells us of the coolie emigrant ships. In the iron ship *Oasis* 1116 tons, out of 446 coolie emigrants between Garden Reach and Demerara, the entire voyage taking 105 days, there were *forty-two deaths*. Carefully drawn up tables give the details of this sad story. Dr. Pearse says the "coolie is an ill rice-fed, ague-suffering animal." He adds that "in writing on such subjects, we plunge into a large and dark region." When he tells us of the coolie emigrant's diet, we scarce wonder at the willingness with which the latter leaves a daily *régime* of sixteen varieties of condiments, including mustard oil, coriander seeds, and tumeric. When will English people believe that a Hindoo is not a parrot, and that he would far prefer beef to "dholl" (a kind of pea), and that the very reason he is emigrating is because he is sick of dholl and wants beef? We would endorse the following remarks:— "I feel, in justice to my patient's hope of life, I would do nothing in cholera except in relieving his most pressing wants and supplying him with whatever his instinct might seek or point to . . . the freest supply of cold water if asked for . . . but whatever the patient asked for should be given, and watch made for some gleam from his instinctive desires which might give light or analogy towards a true remedy." "Sad is the fact of the non-efficacy of all treatments. . . . Should I find in any epidemic of cholera that at any period the cases showed a nearer approach to the intermittent course than cholera usually does, *quinine* would be the remedy used." This sufficiently indicates Dr. Pearse's view of treating cholera, but we cannot refrain from quoting the following:—"Our efforts to cure by treating symptoms are of a method worthy only of the very earlier capacity of human intelligence. The mind should seek rather to perceive what *want* there may be, what changed relation *in man's composition;* for this is the potential parent of the first fact or act whose natural and necessary consequences are the series of symptoms we call cholera." "Not viewing an outbreak of cholera on shipboard occurring soon after sailing as in any way related to any 'poison' or 'thing,' I should seek to give the feeble coolie's system rest, quiet, warmth, and sufficient ventilation, carefully avoiding excessive currents of atmosphere, and should act on the same general principles, which would be just in guarding his system's passage into any other somewhat varied deviations, as fever, dysentery, bronchitis, etc." Dr. Pearse speaks most highly of the value of fresh fruits and vegetable acids, and treats the notion of their being causes of cholera as an old woman's delusion. His observations, though obscurely expressed, appear to us often of great value. Diarrhœa and cholera may be expressions of a feebleness—of a want of something to make flesh and blood of healthy composition, just as the oozings of eczema indicate debility and feebly-constituted flesh and blood, and cease on the administration a minute quantity of arsenic. Dr. Pearse treats the search for a "cause" as often mere superstition. The fact is, that the man as he is does not agree with the condition he is in, of diet, temperature, etc. The disease is one of the phenomena indicating discordance. To get rid of the disease, you must not attempt to banish an isolated "cause," but you must put the man into a state to agree with the surroundings, or alter these to agree with the man. Dr. Pearse gives for two shillings a great luxury, and one necessary for mental health —a few new ideas.

Dr. Anstie's dainty little volume is a reprint of an article which appeared in the January number of the *British Quarterly Review*, which he has enlarged. At p. 105, after treating of typhus, the disease of the city, and typhoid, its provincial relative, he tells us of the *transit* of cholera, how it follows closely the lines of most frequent human communication, but how also it appeared in lone St. Kilda, where, Dr. Anstie says very truly, "there seems to have been a complete absence of any possibility of human intercourse with the main land;" and in Coventry, in 1838, where in the middle of winter, when cholera was not prevailing in the county, fifty-five persons perished very rapidly. Dr. Anstie gives a painfully vivid picture of the cholera patient, and with regard to "cures," says it is a noteworthy fact that diarrhœa does not always precede cholera. He tells us also that scarlet fever is always at our doors, and may justify a panic far better than the threatened return of cholera to England.

We notice Dr. Walter Goodyear Barker's volume in this place, for although it is chiefly devoted to diseases of the respiratory organs, he has a section on the relation of influenza to cholera. He regards them (if we understand aright) as parallel or, more properly speaking, convertible diseases—what would be cholera in hot weather becoming influenza in cold. He believes both to be affairs of temperature, and not of poison; in fact, he is so severe on persons who believe in atmospheric poisons that it is evident he has not read the "Third Report of the Cattle Plague Commissioners." Moreover, he is somewhat inconsistent, for he ascribes various diseases to "emanations," and surely these are poisonous. Otherwise, Dr. Barker's is a sensible treatise on diseases of the air-passages produced by cold.

Dr. Greenwood believes that there is an epidemic poison, and that this is malaria, and that this is capable, under different circumstances, of producing all the kinds of epidemic disease. He believes the state of the blood in cholera to be one of thickening, from loss of its watery parts; hence he deprecates stimulants in the stage of collapse, as goading the organs to circulate blood not fit for circulation. Careful nursing, free ventilation, light coverlids, cold water for drink, no friction heat or stimulants, and a grain of calomel every hour are Dr. Greenwood's remedies; and all we can say is, that if we had blue cholera ourselves we should be inclined

*

to send for Dr. Greenwood. On the theory of the disease he says little; but what he says accords with Dr. Macpherson. The extreme collapse, he says, is "not cholera at all, but a sequel, and very fatal one." The profuse incipient diarrhœa, antecedent to collapse, *is* true cholera, and for the treatment of this he gives calomel and opium and aromatics.

Mr. Rowell gives us a useful pamphlet. His point is, that mere low level, floods, and moist site are not causes of unhealthiness *per se;* and he attempts to prove it by showing that the high and dry villages near Oxford are less healthy than the low and wet ones. The greater prevalence of cholera in Oxford in some institutions and places than in others is traced not to level, but to impurity of the drinking water. On this point Mr. Rowell has an observation which is new and striking. He says that if the public can afford to water the streets for the comfort of the rich, they may afford to supply the poor gratis with wholesome water for drinking.

The *Memorandum* drawn up by the Metropolitan Medical Officers of Health seems to have been very carefully revised. It contains a dogmatic statement of the best way to stamp out cholera and a *resumé* of the duties of Boards of Guardians, Town Councils, etc., in the face of a cholera epidemic; with copies of handbills for distribution. Such a publication extensively circulated would tend to allay panic by showing the public what they ought to do to defend themselves.

Photographs (Coloured from Life) of the Diseases of the Skin. Second series, Nos. 1, 2, 3. By Balmanno Squire, M.B. Lond., Surgeon to the West London Dispensary for Diseases of the Skin, &c.

In our last notice of Mr. Balmanno Squire's photographs of skin diseases we praised his illustrations as far more truthful and "life like" than any representations of skin diseases previously published, and some as specially admirable, and hoped that Dr. Squire would feel encouraged to continue his labours. We find the advice we then gave has been followed. In the present series of photographs Mr. Squire has managed to enlarge his scale, without at all sacrificing his clearness of definition. In the first number, one that specially calls for this remark, is represented the face of a man suffering from a so-called *tertiary* syphilitic eruption. In his description of this "tertiary" eruption Mr. Squire thus contrasts the two:

"In comparing this example of cutaneous syphilis with the one previously illustrated, it may be remarked how much more chronic the separate items of the tertiary eruption are, and over how much longer a period the course of the disease extends. It may be noticed, too, that the crusts produced by it are considerably thicker, and that the traces it leaves are far more conspicuous than those of the secondary eruption. In the previous example the general health was not impaired in any perceptible degree; in the present one, the disease was attended with considerable emaciation and debility. The wandering rheumatic pains felt by the subject of the secondary disease are here replaced by the fixed aching pain of the syphilitic node, and by the shooting pains across both temples, which subsided on the appearance of an eruption on the forehead.

"Although the tertiary eruption has, in this instance, *appeared as soon after infection as the secondary disease* did, it is by no means usual for it to do so. In the majority of cases, a year or more intervenes between the period of infection and the evolution of either of the syphilides represented in the photograph."

Why use such words as "secondary" and "tertiary" at all? As Mr. Squire admits, they do not mean what they seem to mean—*i.e.*, *succession*—but only *quality* of eruption, which surely were better expressed by other terms. We would ask Mr. Squire to look back to the earliest article on "Modern Syphilography" which appeared in the *Medical Times and Gazette*, and to Dr. Wilks's argument against the term "secondary."

The second number illustrates a secondary eruption, to which Mr. Squire gives the name of "Ringed Herpoid Syphilide," and he defends his nomenclature thus:—"The eruption," he says, "resembles herpes circinatus in its centrifugal character, and in the fact that its widening rings are surmounted either by vesicles, or (more commonly) by minute scales. In the parasitic disease, however, the area enclosed by the raised circle is, until it heals, harsh, scurfy, and of a pink colour, and the scales present, under the microscope, evidence of the parasitic nature of the eruption; whereas, in the syphilide, the area within the circle is smooth, and, though at first of a pink colour, soon acquires a tawney-grey tint. Furthermore, a microscopical examination of the scurf on the rings shows that no vegetable parasite is concerned in their production."

The third illustration represents a disease to which Mr. Squire is known to have devoted considerable attention. "Prurigo senilis," he says, "is a contagious disease; its duration is indefinite; in a large proportion of the examples that the author has met with it has lasted for several years; in such cases it is often considerably mitigated in winter and exacerbated in summer. It is most common in old persons, commoner in the middle aged than in the adolescent, and least common in children. The author has, however, noted its occurrence at four years of age. It is associated often with cachexia and debility, and is far commoner with the poor than with the rich. The essential cause of the disease is the *Pediculus corporis*. This parasite is, however, not always easy to find: its presence is often unsuspected by the patient, and when known to him is as often denied; hence its invariable co-existence with this form of eruption has, until very recently, escaped the notice of observers. This constant relation of the parasite to the disease, as cause to effect, was first pointed out by the author in 1864."(a)

We have already expressed our admiration of the positive, downright, matter-of-fact tone adopted by Mr. Squire in his explanation and treatment of this form of prurigo.

Surgical Appliances and Minor Operative Surgery. By Thos. Annandale, F.R.C.S. Edin., etc. Maclachlan and Stewart, Edinburgh. 1866. Pp. 246.

A useful handbook, with illustrations; but surely there was *Heath* enough in Scotland without it.

GENERAL CORRESPONDENCE.

THE ELECTION AT THE ROYAL COLLEGE OF SURGEONS.

Letter from Mr. Campbell de Morgan, F.R.S.

[To the Editor of the Medical Times and Gazette.]

Sir,—I am reminded by the approaching election of members into the Council of the College of Surgeons of a duty which I owe to myself as well as to the many friends who have been so good as to urge me to allow myself to be put in nomination.

Why I decline now, as I did last year, to do so may be thought a matter of little consequence to any one but myself, but it involves questions which are of wider interest, and will probably exercise an important influence on the future of the Council.

I confess I much regret that I cannot become a candidate. Very many years ago, I wrote a letter to the Council, pointing out how very inefficient and injurious must be a system which compelled the attendance upon lectures on a large number of subjects, but did not require any evidence whatever of attention to them—for the Council will give no power to the Lecturers to certify to a student's proficiency; and on the subjects of Chemistry, Materia Medica, Medicine, and Midwifery, while attendance on lectures is enforced—no examination takes place at the College. Indeed, the fair conclusion seems to be that, so far as the College is concerned, the students are made for the lecturers, for if a knowledge of these subjects is essential to a Surgeon, surely a licence to practise should not be given unless the licensing body is satisfied that the candidate possesses it. But if it be not essential, why oblige a student to sit on a hard bench for so many hours a day? His time might surely be better employed. Here, however, lies the difficulty. The Court of Examiners, as now constituted, is hardly in a position to examine on the subjects referred to. Hospital Surgeons of some years' standing might very readily be plucked in Chemistry or Materia Medica by any tolerably intelligent second-year student, and it would not be quite right that an examiner should have to learn up his subject for the occasion. Hence, if examinations are held at all on these subjects, there must of necessity be some exoteric examiners, and the system would be broken up.

I should certainly be glad to have an opportunity of advocating in the Council a considerable change in the present system, for some years' additional experience has only the

(a) *Vide* note to the letter-press of No. III. of the former series.

more convinced me of its utter failure, so far as a large majority of students is concerned. And it is only for the majority that enactments need be made at all. The minority will learn what they want to learn if left to themselves.

But I would not be a party to a mode of election which seems to me degrading to the candidate and injurious to the character of the Council. There should, I think, be some difference between the election into the Council of a great scientific and educational body and into a parish vestry. What a strange thing to demand of candidates of between 50 and 60 years of age that they should get six of their fellows, who will be for the most part their juniors, to certify that they are fit and proper persons to be elected. Would there be the slightest risk of any one getting in who could not get fifty Fellows to sign such a paper if they were canvassed to do so? If a man is not well enough known to the Profession to secure a very large amount of support, independent of these recommendations (provided the elections are otherwise properly conducted), no signatures will help him. The recommendation papers are useless, and they are therefore worse, for they jar on a man's self-respect.

There are, however, other and stronger objections to the plan as at present worked. The first is that elections have been secured by canvassing. It will hardly be conducive to the ultimate welfare of the Council if its members obtain their seats by the activity of their friends, whether exerted in the way of private canvassing or of public advocacy by the press. It is, of course, within the province of the journals to point out fairly and impartially the position of the various candidates; but they go beyond their province if they become the partisans of any one candidate. The system of private canvassing is, however, far more objectionable. Those who will not resort to it will be indisposed to put themselves in competition with those who see no objection to such a proceeding.

This electioneering system has carried with it another evil, which is pronounced to be legal under the Charter—that of plumping. The obvious duty of the electors is to fill up all vacancies, not to force a favoured candidate into the Council by indirect means.

These evils may be inevitable necessities, but they inevitably lead to a disinclination to become candidates in some who would value a seat at the Council Board, not for any dignity it would confer on them, but for the opportunity it would give them of aiding the cause of true education, which I believe never wanted aid more than at the present moment.

These causes prevent my offering myself. Some of them unfortunately are preventing others, whose services would be more important, from taking a seat on the Council of the College. I am, &c.

Campbell de Morgan, F.R.S.

DR. MUSPRATT'S CHALYBEATE AT HARROGATE.

Letter from Dr. Muspratt.

[To the Editor of the Medical Times and Gazette.]

Sir,—In your ably-conducted journal of May 12 I find an exhaustive and very interesting article upon "The Medicinal Springs of Harrogate," by Dr. George Kennion, F.R.C.P. In the commencement of his "observations" he kindly alludes to my "important discovery," in July last, of chloride of iron (FeCl) in one of the springs belonging to the "Royal Chalybeate Spa." The presence of this salt in a potable water is *unique*; "thus constituting it a chalybeate water of very great therapeutic value, and one which, in respect to this constituent, is without a prototype." Since the true nature of this spring became patent, its water has been prescribed by Dr. Kennion, Dr. Whitehead, Dr. Herapath, Mr. Baker Brown, Dr. Myrtle, Dr. Bennett, and other leading Physicians and Surgeons, in cases of anæmia of all kinds, whether the result of general cachexia, excessive hæmorrhage, chlorosis, anorexia, incipient phthisis, or from that produced by chronic disease, as gout or rheumatism, or albuminaria; and Dr. Kennion writes:—"Amongst other obvious cases where it may be used with advantage is fatty degeneration of the heart." Dr. Myrtle has found it of service, he tells me, in lupus. In writing of this chloride of iron spring he remarks:—"The curative value cannot be over-estimated in all cases of debility arising from impoverishment of the blood, from whatever cause, is unrivalled. The various forms of scrofula, whether of the system at large or of special organs, may by its means be combated with the best possible results. Above all, chronic glandular swellings seem to yield to its influence, when taken steadily for a period varying from three weeks to three months. It is also speciably serviceable in many forms of weak digestion and dyspepsia, in all functional derangements of the nerves, such as tic, neuralgia, chorea, some forms of epilepsy, and most hysterical affections, and last, not least, in that numerous class of cases termed poor gout, this spa has proved itself to be a most invaluable restorative of health and comfort."

Dr. Herapath designates it "the most extraordinary chalybeate in existence."

Dr. Thomas Scott, of Ben Rhydding, writes, "That it must be a most excellent chalybeate is at once apparent, not only from the amount of iron which it contains, but more especially from the particular *form* in which it is presented, rendering it so easy of assimilation, a matter of paramount importance, inasmuch as while many cases appear before us Medical men in which iron is undoubtedly the remedy required, yet at the same time we are prevented prescribing it in the usual forms on account of the difficulty in assimilating them. In your spring, however, this is remedied, and I feel sure its value will be fully appreciated in the treatment of that large class of diseases in which iron in some form or other is usually administered."

The ferruginous compounds are contained in a gallon of the water as under, and upon these its hygienic effects will almost solely depend:—

	July, 1865. Dr. Muspratt.	Nov., 1865. Dr. Miller.	Mean.
Chloride of iron. .	16·011	14·490	15·250
Carbonate of iron .	10·842	11·620	11·231

The other salts are chlorides of sodium, potassium, calcium, magnesium, lithium, barium, strontium, &c.

The latter three I find now in several of the waters. The Kissingen or Montpellier saline chalybeate gives strong indications of these metals. Hoping you will give insertion to these remarks, I am, &c.

Sheridan Muspratt, M.D., &c.,
Professor of Chemistry.

College of Chemistry, Liverpool, June 14.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 21, 1866:—

Richard Matthews Pryce, Caersws, Montgomery; Duncan Turner, Peter-street, Islington; Richard Wilson Wilcox, 34, Torrington-square; Edward Lodewyk Crowther, Hobarton, Tasmania; Thomas Sanders, Plymouth; Mowbray Jackson, Bowbrickill, Bucks; Barnabas Walter Lamb, Stourport; John Quick, Penzance.

The following gentleman also on the same day passed his First Examination:—

Henry Bland, King's College.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Barker, W. L., L.R.C.P., has been appointed Assistant to the Obstetric Physician, St. George's Hospital.

Fouracre, R. P., M.R.C.S.E., has been appointed Surgeon to the Holloway Dispensary.

Nichol, J. G., M.D., has been appointed House-Surgeon to the Chorley Dispensary.

Pollock, A. Julius, M.D., M.R.C.P., has been elected one of the Physicians to Charing-cross Hospital.

Salter, W. Hyde, M.D., has been appointed Physician to Charing-cross Hospital.

BIRTHS.

Child.—On June 23, at Oxford, the wife of G. W. Child, M.D., of a son.

Davidson.—On June 19, at Erith, the wife of James Davidson, M.D., R.N., of a son.

Diplock.—June 22, at Western House, Oakley-square, S.W., the wife of T. B. Diplock, M.D., of a daughter.

Munro.—On June 26, at Moffat, Dumfriesshire, the wife of James Munro, M.D., of a son.

Valpy.—On June 24, the wife of W. H. Valpy, M.D., of George-street, Hanover-square, of a son, stillborn.

MARRIAGES.

Barnett—Irvine.—On June 20, at the parish church, Clontarf, County Dublin, O. Barnett, Esq., Assistant-Surgeon 11th Hussars, to Lizzie, third daughter of the late Dr. Irvine, Irvinestown, County Fermanagh.

Blaker—Renshaw.—On June 20, at Broadwater, Sussex, E. Shaw Blaker, L.R.C.P. Edin, of Portland, to Julia, daughter of J. Renshaw, Esq., of Dunedin, New Zealand.

Brown—Brown—On June 20, at Biggar, N.B., A. Brown, L.R.C.P., M.R.C.S., of Edinburgh, to Marion Shiels, only daughter of Alexander Brown, Esq.

Gordon—Gregory.—On June 21, at All Saints' Church, Finchley-road, H. D. Gordon, M.D., Surgeon-Major 69th Regiment, to Elizabeth, youngest daughter of the late A. E. Gregory, Esq.

Fulton—Fotheringham.—On June 20, at 127, Queensberry-place, Glasgow, John Fulton, L.F.P.S. Glas, to Mary Bremner, only daughter of T. Fotheringham, Esq., of Glasgow.

Parsons—Sprye.—On June 20, at Konsington Church, C. Parsons, M.D., of Dover, to Venetia Digby Spryc, youngest daughter of Captain Richard Spryc, of Kensington.

Richmond—Marr.—On June 20, at Alderstone House, Midealder, N.B., Sylvester Richmond, M.D., of Northallerton, to Agnes Bruce, eldest daughter of the late James Marr, M.D., of Alderstone.

Saunders—Byass.—On June 19, at the Church of the Holy Trinity, Cuckfield, Sussex, C. E. Saunders, M.D., to Edith, youngest daughter of T. S. Byass, M.D., of Cuckfield.

Salomon—Sampson.—On June 4, at Stockholm, E. C. Victor Salomon, to Caroline Sarah, daughter of the late John Shaw, Esq., of the Mauritius.

Wales—Leaviss.—On June 20, at St. Mark's Church, John Wales, Assistant-Surgeon, Royal Artillery, to Helen Jane, only child of the late Charles Leaviss, of Wilmington.

Weeks—Holman.—On June 21, at East Hothley, Sussex, H. Wecks, of Old Brompton, Kent, to Harriet, youngest daughter of H. Holman, Esq., of East Hothley.

DEATHS.

Argent, S, M.R.C.S., at Hinckley, Leicestershire, on June 18, aged 72.

Birnie, M., M.R.C.S., at Old Aberdeen, on May 31, aged 80.

Blenkinsop, Henry, F.R.C.S.E., at Coton End, Warwick, on June 20, aged 53.

Griffith, Alfred Rawlinson, M.D., at Dickson County, Tennessee, North America, on May 18, aged 37.

Jackson, Henry, F.R.C.S., at St. James's-row, Sheffield, on June 25, aged 60.

Lizars, Alexander J., M.D., F.R.C.S.E. (late Professor of Anatomy in the University of Aberdeen), at Ambleside, Westmoreland, on June 12.

Macfarlane, A. S., at George Town, Demerara, on June 4, aged 58.

Newmarch, Henry, M.S. (late Surgeon Bengal Army), at 74, Micklegate, York, on June 22, aged 68.

Whitty, D. J., M D., at Briton Ferry, on June 15, aged 41.

POOR-LAW MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the last census.

RESIGNATIONS.

Hinckley Union.—The Barbage District is vacant; area 11,035; population 4179 salary £60 per annum.

Lancheste Union.—Mr. Henry W. Watson has resigned the Tanfield District; area 10,297; population 7562; salary £30 per annum.

Reading Union.—Mr. T. L. Walford has resigned the St. Lawrence District; area 349; population 4737; salary £30 per annum.

APPOINTMENTS.

Banbury Union.—Thomas J. Fitzpatrick, L.R.C.S. Ire., L.K. and Q. Coll. Ire., L.M., to the Hornton District.

Bridgwater Union.—Charles Young, M.R.C.S.E., L.S.A., L.M., to the Chilton Polden District.

Croydon Union.—Walter H. Cope, M.R.C.S.F., L S.A., to the Fourth District.

Faversham Union.—George F. Pritchard, L. K. and Q. Coll., Ire., M.R.C.S.E., L.M., to the Fourth District.

Morpeth Union.—Edward A. Hedley, M.R.C.S.E., L.S.A., to the Fourth District.

College of Physicians.—On Wednesday evening the President and Fellows of the Royal College of Physicians gave a *conversazione*, which was attended by a numerous and distinguished company. Amongst the visitors were the Lord Bishop of Oxford, Sir R. Murchison, Prof. Tyndall, Prof. Daubeney, Sir R. Martin, presidents of various learned societies, etc. In the library of the College a number of scientific inventions were exhibited. Among them were Professor Wheatstone's means of communication between carriages on railroads; Professor Abel's specimens of gun cotton, and a lead-coated projectile showing results produced by electrolytic action; Mr. Ansell's apparatus for detecting fire-damp in mines by the diffusion of gases; Oersted's condenser, for showing the liquefaction of gases by pressure and the compressibility of water, sent in by Mr. H. M'Leod. Dr. Lionel Beale and Dr. J. B. Sanderson exhibited specimens and tracings illustrating the anatomy of the liver and the heart. On one of the tables were specimens of Dr. Hassall's flour of meat for the immediate preparation of beef-tea, soups, and other articles of diet. One of these specimens consisted of bran and meat biscuits, and another of meat lozenges in the form of jujubes. Some samples of meat preserved in paraffin by means of Redwood's process attracted considerable attention. This process consists in the immersion of fresh meat in melted paraffin at a temperature of 240 Fahrenheit for a sufficient time to effect a concentration of the juices of the meat and the complete expulsion of air, after which the meat in its condensed state is covered with an external coating of paraffin, with the view of excluding air and preventing decomposition.

The Coming Election at the Royal College of Surgeons.—We are authorised to state that Mr. Spencer Smith, actuated by the wish not to divide the votes of the Liberal party, has determined on not going to the poll this year.

It is stated that 176 persons fell ill of cholera at Stettin on Saturday and Sunday week, of whom half had died.—*Guardian.*

Election of Dr. Hooker at the Académie des Sciences.—Hereditary merit has, we are happy to find, been amply acknowledged in the person of the most scientific of our botanists—Dr. Joseph Hooker. He might easily have succeeded his father as Director of Kew Gardens, even had his capabilities for the office not been so remarkable, as such successions are almost a matter of course with us; but his election by the Académie des Sciences as corresponding member in the Botanical Section, left vacant by his father's death, by thirty-two of the thirty-seven voters present, is an acknowledgment of merit about which there can be no mistake, and an almost unprecedented occurrence in the annals of the Academy.

Queckett Microscopical Society.—The usual monthly meeting was held at University College on Friday last, P. Le Neve Foster, Esq., in the chair. A paper was read by Mr. N. Burgess, "On the Pigment-cells of Plants in some of their Varied Forms and Structure." The author gave the results in full detail of his microscopic researches and numerous dissections, arguing against the almost universally received opinion that the floral organs are modified leaves, the author believing them to be morphologically distinct. The paper occasioned an interesting discussion. Subsequently, Mr. M. C. Cooke introduced to the notice of the Society a micrometer made by Mr. Collins, in which the whole field was graduated, and by which tedious adjustment of objects to the scale can be avoided. After the meeting the usual microscopic conversazione followed.

Cattle Plague in Ireland.—We understand that the Mansion House Cattle Plague Committee (Dublin) have requested the Government to procure the assistance of Dr. Andrew Smart, of Edinburgh, and of Professors Simonds and Gamgee, of London, for the purpose of investigating any other cases of suspected Rinderpest which may arise. The *Irish Times*, in a leader on this subject, remarks:—"We trust that Professor Simonds, Professor Gamgee, and Dr. Smart, of Edinburgh, or, if not all three, one of them, will be commissioned to examine the cases supposed to have occurred here. All who are interested in the prosperity of Ireland will bow to the decision of the gentlemen we have named. They are men of European reputation, and of the most independent and honourable character. At present there exist very serious doubts whether we have had a case of cattle plague in Ireland. . . . . It is financially of great importance that the doubts entertained should be resolved by indisputable authority. If such eminent men as Professor Simonds, or Professor Gamgee, or Dr. Smart pronounce the cases at Drumra and Drennan to be cattle plague, all will determine not to despair, but to co-operate to the very utmost of their power with the Government, and to stamp it out whatever be the cost or sorrow. We are confident that even if the disease at Drumra is proved to be cattle plague, the report of the Commissioners will declare that it is of an exceedingly mild form. If, on the other hand, there is good ground, as we believe there is, for deciding that the disease is not cattle plague, confidence will be restored and an immense loss of property be avoided."—*Daily Review, June* 22.

National Association for the Promotion of Social Science.—The annual business meeting of the members of the Association will be held on Thursday, the 5th of July, at 1, Adam-street, Adelphi, at half-past three o'clock, p.m., to receive a Report from the Council and to elect the officers and standing committees for the ensuing year. The Rev. W. L.

Clay has been appointed by the Council Secretary to the Association. The tenth annual meeting will be held in Manchester, from the 3rd to the 10th of October next. The following are amongst the special questions chosen by the standing Committees of the several departments for discussion at the meeting which have most interest to Medical men:—"What are the best means of extending and securing an international law of copyright? What is the duty of the mother country as regards the protection of inferior races in her colonies and dependencies? What conditions or limitations ought to be imposed upon the power of disposing in perpetuity of property, real or personal, for charitable or other public purposes? Is it desirable to carry out life sentences to the utmost? and if so, in what cases, and under what form of discipline? What are the best means of preventing infanticide? In what other public institutions besides gaols is it expedient that coroners should be required to hold inquests in all cases of death? What means ought to be adopted to prevent the production of smoke in large towns? How can the pollution of rivers, by the refuse and sewage of towns, be best prevented? What legislative or other measures should be employed more effectually to prevent the adulteration of food? Upon what conditions and by what authorities ought licences for the sale of alcoholic liquors to be granted? What measures, legislative and other, should be adopted in order to supply better dwellings for the labouring classes? What means ought to be adopted for improving the management of workhouses?"

Association of Metropolitan Poor-law Medical Officers.—At a preliminary meeting of Poor-law Medical Officers held on June 20, 1866 (Dr. Rogers, of the Strand Union, in the chair), it was moved, seconded, and unanimously resolved:—"1. That an association be formed to be called 'The Metropolitan Poor-law Medical Officers' Association.'" "2. That the following form of address be printed and sent to every parochial Medical Officer within the metropolitan district." "3. That the following gentlemen be appointed officers of the association *pro tem.*:—Dr. Rogers, president; F. Godrich, Esq., treasurer; Dr. Dudfield, hon. secretary."

"Dear Sir,—An Association of Metropolitan Union and District Poor-law Medical Officers has been formed with the object of mutual assistance in difficulties arising out of our duties, and also for the purposes of urging upon our respective local Boards, the Poor-law Board, and the public such revision of our position, as public servants, as our status as members of a learned and scientific Profession demands.

"The present moment is peculiarly opportune for the formation of such an association, inasmuch as recent revelations have clearly demonstrated the absolute necessity of some change in the system of Poor-law Medical relief, and the public are prepared to urge some alteration on the Legislature. Under these circumstances for us to remain quiescent is to allow those who would aid us to form the conclusion that we are indifferent to the just claims of the sick poor, and careless of our position as State servants.

"We consider that a small annual subscription will be sufficient to cover our working expenses.

"Should you feel disposed to join us, you will kindly signify the same to one of the undersigned at your earliest convenience. "We are, etc,

"Joseph Rogers, M.D., President *pro tem*,
"Francis Godrich, Treasurer *pro tem*,
"T. Orme Dudfield, Hon. Sec. *pro tem*.

"P.S.—Another meeting will be shortly held, of which due notice will be given."

Epidemiological Society.—At the annual meeting of the Society the following office bearers were elected for session 1866-67:—*President.*—Dr. Jenner, F.R.S., Physician in Ordinary to Her Majesty the Queen. *Vice-Presidents.*—The Earl of Shaftesbury, K.G.; Lord Lyttleton; Right Hon. W. Cowper, M.P.; Sir John Thwaites; Dr. Gavin Milroy; Henry W. Acland, M.D., F.R.S., Regius Professor of Medicine in the University of Oxford; Alex. Bryson, M.D., F.R.S., R.N., Director General Navy Medical Department; Edwin Chadwick, Esq., C.B.; William D. Chowne, M.D., F.R.C.P., Physician to the Charing-cross Hospital; James Copland, M.D., F.R.S.; William Farr, M.D., F R.S.; J. Brown Gibson, M.D., C.B., Director General Army Medical Department; Sir J. Ranald Martin, C.B., F.R.S., Physician to the Council of India; Charles Murchison, M.D., F.R.C.P., Physician to the London Fever Hospital; Alex. Nisbett, M.D., R.N., Inspector-General of Fleets and Hospitals; John Simon, Esq., F.R.S., Medical Officer of the Privy Council; Sir Andrew Smith, M.D., K.C.B.; Thomas Watson, M.D., F.R.S., President of the Royal College of Physicians. *Treasurer.*—William Camps, M.D., F.S.S., F.L.S., 40, Park-street, Grosvenor-square, W. *General Secretary.*—J. N. Radcliffe, Esq., 70, Guilford-street, Russell-square, W.C. *Secretary for Navy.*—Dr. Mackay, R.N., F.R.S E., Admiralty, Somerset House, W.C. *Secretary for Army.*—Dr. Francis Bowen, late of the Coldstream Guards, 62, Upper Berkeley-street, Portman-square, W. *Foreign and Colonial Secretaries.*—Belgium and France, Dr. Waller Lewis; Germany and Russia, Dr. Hermann Weber; Sweden, Norway, and Denmark, Dr. W. Daniel Moore; Portugal and the Brazils, Dr. Donnett, R.N.; Egypt and Syria, Dr. Camps; East Indies—Bengal Presidency, Dr. John Jackson; Bombay Presidency and Madras Presidency, Dr. Morehead; West Indies and North America, Dr. Dickson, R.N.; China and the Pacific, Dr. Smart, R.N. *Other Members of Council.*—Dr. Aldis; F. J. Burge, Esq.; Staff-Surgeon Crawford, M.D.; Ernest Hart, Esq.; Dr. Hayward; Dr. Letheby; C. F. J. Lord, Esq.; J. F. Marson, Esq.; Dr. Odling, F.R.S.; Dr. Richardson, Dr. Seaton; Dr. J. Burdon Sanderson.

Faculty of Physicians and Surgeons of Glasgow.—Inauguration of Portrait of Dr. William Weir.—A numerous meeting of the fellows of the Faculty of Physicians and Surgeons, both resident and non-resident, and of Dr. Weir's friends, was held in the Faculty Hall, on 19th June, for the purpose of inaugurating a portrait of Dr. Wm. Weir, which is in future to hang in the hall. Dr. J. G. Fleming, President of the Faculty, occupied the chair, supported on the right by Dr. Weir. Dr. Fleming proposed "The health of the Queen," which was duly honoured. Mr. W. H. Hill (clerk) then read the following minute of meeting of Faculty, of date 5th February:—"It was moved by the President, seconded by Dr. Anderson, and carried by acclamation, that as Dr. William Weir completes his fiftieth year of Fellowship on this day, the Faculty resolve to request him to sit for his portrait, to hang in the hall, to mark the appreciation which the Fellows of Faculty entertain of the deep interest he has always taken in the affairs of the corporation, and of the many efficient services he has rendered to it. [The covering which concealed the portrait was removed, and the likeness revealed to view, which was the signal for a general outburst of applause.] Dr. Fleming concluded a speech highly complimentary to Dr. Weir as follows:—"This portrait is most valuable to us as an excellent likeness of our friend, and as enabling us at least to acknowledge that we owe him a debt of gratitude. It will also serve, along with the portrait of our revered friend, Dr. Watson, to show to our successors that this generation at least were not unmindful of good and faithful services. To Dr. Weir that picture must be very valuable, but this demonstration, if I may use the term, must be more so, as indicating to him the respect and esteem in which he is held by his Professional brethren and fellow-citizens. Dr. Weir must have had the usual share of the cares and joys of life. I have no doubt he has often

'Found mankind an unco squad,
And little to be trusted.'

And that his best-laid schemes and most arduous endeavours have come to nought or been ill-requited; but I hope he may consider that some of the bread he cast upon the waters he has this day found—(applause)—and that he experiences the enviable satisfaction of feeling that the compliment we now pay him is an earnest manifestation on our part to his worth and integrity as a man, his accomplishments as a Physician, and to his useful and well-spent life. (Applause.) Before I propose health and happiness to Dr. Weir, I wish to express the hope—and I am sure all present will join with me—that the day may be far distant before any of us who may then be here will require to repair to that portrait to recall more vividly to their memories the characteristic features, and the expression of intelligence, thoughtfulness, and earnestness of purpose which are so truthfully depicted on that canvas." (Applause.) The toast of Dr. Weir's health having been heartily pledged, Dr. Weir made a very feeling reply, in the course of which he said:—"It strikes me with something akin to reverence and awe to think that many years hence, long after I might otherwise have been forgotten, it is possible that some of the Fellows of Faculty of future generations—perhaps a century after the present day—when looking at this memorial of your kindness to me, may say, 'This is the portrait of one of our old members,' or 'William Weir, who

occupied the president's chair so far back as the year 1847 and 1848;' and should such an affair ever occur in the unborn far-distant future it would assuredly be followed by this further remark—"And it was the last production from the pencil of the justly celebrated artist, John Graham Gilbert, who flourished in Scotland during the first half of the nineteenth century.'" "*Floreat Res Medicina*" was then given from the chair, after which the proceedings terminated. The portrait, which is a striking likeness, is executed in the lamented artist's best manner. It hangs on the west wall of the Faculty Hall, close to the portrait of Dr. Watson.

THE following are the last week's Cattle Plague Returns.

Census Divisions.	1. Attacked. Week ending June 2.	Week ending June 9.	Week ending June 16.	Back cases reported in the week ending June 16, 1866.	2. Result of reported Cases from the Commencement of the disease. Attacked.	Killed.	Died.	Recovered.	Unaccounted for.
Metropolitan Dist.	8	10	3	..	7896	3416	3712	318	450

Totals .	960	987	533	407	248965	80597	124187	32989	11192

This Return shows that 533 attacks were reported to have occurred during the week ended June 16, being a decrease of 454 on the previous week.

Correcting the total by adding an estimated average of attacks commencing during the week, but which may be subsequently included under the heading "Back Cases," the number for the week will be 666.

Note.—8 Inspectors who reported cases last week have not reported in time for this return—viz., for the county of Bucks, 1; Chester, 1: Cumberland, 1; Lancaster, 2; Leicester, 1; and Lincoln, 2. These inspectors reported 88 cases last week.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Medicus.—Apply at the Austrian Embassy.

King's.—The *Illustrated London News* will give an engraving of the epergne, etc., presented as a testimonial to Sir Wm. Fergusson.

Associate, King's College.—The operation for popliteal aneurism was first done by Hunter in 1785. He died in 1793.

Small-pox.—Inoculation was introduced in 1722 by the celebrated Lady Mary Wortley Montague.

A Young Writer.—You will derive great assistance in consulting Dr. Roget's Thesaurus of English Words and Phrases.

A Young Practitioner.—Your object might be accomplished through the means of a freehold land and building society.

Obstetrician.—If you consult our advertising columns you will find answers to all the questions. For the other information write to the Secretary.

An Old Fellow by Examination.—The diplomas have since been altered. They now contain the autographs of the ten examiners. The elected Fellows' diploma remains the same. The colour is given to detect erasures.

A Fellow.—If you will refer to your notice, you will find that Thursday next, the 5th, is the day appointed for the election of Fellows into the Council of the College.

Dr. Hammerton.—It was a mistake on the part of our contemporary; the only life members of the Council of the College of Surgeons are Messrs. Lawrence, Swan, and South. The latter is removeable from the Court of Examiners by the Council.

Middlesex Hospital.—Dr. William Hunter and Sir Charles Bell were both members of the staff of your Hospital; the former demonstrated the hernia congenita in 1755, the same year in which the Hospital was founded.

Hunter's Chairs.—A leader on the subject of the sale of John Hunter's chairs by the Council of the College of Surgeons appeared at the time in this journal. The wood of which they were made is unknown; it was brought to this country by the celebrated circumnavigator, Captain Cook. Mahogany was first introduced by a Dr. Gibbons in 1718.

THE OCULIST'S VADE-MECUM.

Nor fell catarrh, trichiasis, or speck,
Can love subdue or fervent feeling check;
Dense staphyloma with protrusive stare
May vision quench and palpabræ impair,
Or cornea conical contract the view,—
Iritic lymph turn vivid pristine blue,—
Glaucoma green, or yellow growth lie back,
Or white of cataract, or brown or black,
Advance obtrusive; still, with glowing pride,
I'll turn to thee, and claim thee for my bride.
Should cysticerci those bright orbs invade,
And revel in their nidus Nature-made,
No jealous feelings would my bosom share
That other beings had found favour there.
Though brilliant sparks of retinitis try
With glare to dazzle and distract thine eye,
Yet shalt thou find my constancy unswerve,
Fixed as the entrance of the optic nerve,—
Strong as sclerotic,—in attachment far
Closer than Bowman's 'lastic lamina;
Retentive as its cordage, and, in growth,
Continued as the cells o'erlaying both;
With age increasing, like the senile arcs,
Which fondly meet, and join in circling marks;
Tho' time impress'd, new pleasures yet shall spring,
Bright as the yellow spot of Soemmering,
To sweeten life;—then, dearest maiden, fly!—
Thou my chaste lens,—protective capsule, I.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The subjoined subscriptions have been further received on behalf of the above fund. The testimonial will be presented at the Freemasons' Tavern at 3 p.m. of Thursday, July 5, and I hope a drawing of it will be found in the *Illustrated London News* of the Saturday or Saturday week following:—

I am, &c.,
ROBERT FOWLER, M.D., Treasurer and Hon. Sec.
145, Bishopsgate Without, June 27, 1866.

P.S.—Medical students are respectfully invited to attend the meeting on July 5 proximo.

(Copy.)

"Dear Sir,—I sent my subscription to the Griffin testimonial twelve months ago. I am grieved and ashamed so small a sum has been subscribed to the testimonial. Although a poor man with a large family, I shall be willing to subscribe a further sum of five pounds if two hundred other gentlemen will do the same to make up a testimonial worthy the labour Mr. Griffin has bestowed upon the cause which interests us all

"I am, dear Sir,
"Yours respectfully,
"Eccles, June 25, 1866. "RICHARD ROE.
"Dr. Fowler."

POOR-LAW MEDICAL REFORM ASSOCIATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It would be prudery on my part to pretend ignorance of the honour to be paid me on July 5, and therefore permit me space to say I hope the meeting will not be confined to the donors of the testimonial

only, but that all Poor-law Medical Officers who can spare the time will attend, in order that I may take that opportunity of personally consulting them as to the steps they desire to pursue in future in regard to Poor-law Medical reform. I am, &c.,

12, Royal-terrace, Weymouth, June 25, 1866. RICHARD GRIFFIN.

P.S.—The meeting will be held at the Freemasons' Tavern, Great Queen-street, on Thursday, July 5, at 3 p.m. If any members of Parliament would honour the meeting with their presence they would be enabled to ascertain the feelings of the Profession on the subject of the Medical relief of the poor.

THE PROPOSED MEDICAL CLUB.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was glad to observe in your impression of Saturday last an announcement of a Medical club, happily designated the "Sydenham." As I happen to have had personal knowledge and experience of the Indian Clubs referred to in the prospectus, I rejoice to find that the "Sydenham" is to be conducted on a similar principle. As this principle, however, may be novel to many of your readers, a statement of the rates of subscription at the Madras Club, of which I was formerly a member, may not be unacceptable.

These were—to residents at Madras 4 Rupees, or 8s., a month; to non-residents, 1 Rupee, or 2s. a month.

From the nature of society in India, being composed almost entirely of the civil and military officers of the various Government services, it follows that an immense majority of the members of the Club were non-residents, and 1 Rupee subscribers. These individual subscriptions, however, so small as to be scarcely felt by the payers (many of whom did not visit the club for years), formed collectively a large annual revenue, and in fact constituted the main-stay of the institution.

A corresponding relation, it is evident, must always obtain between any Medical club whatever that may be established in the Metropolis and its non-resident members, whose actual use of their club must necessarily be limited to those brief holidays that fall to the lot of our Profession.

To these the sleeping accommodation will no doubt prove a most attractive feature, as it is already in the Indian Clubs. Wishing the movement every success, I am, &c.

AL. MAC LEOD, Surgeon-Major Madras Army.

Oriental Club, June 21.

WIDOW OF A DECEASED SURGEON.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We beg to acknowledge, with many thanks, the following further contributions for the "Widow of a Deceased Surgeon":—Dr. H. Stirling, £1; Anonymous (Portsmouth), 5s.; Le Gros Clark, Esq., £3 3s.; H. L., £1; W. Bowman, Esq., £2 2s.; George Critchett, Esq, £1 1s.; Dr. Armstrong (Gravesend), £2 2s.; W. Fairlie Clarke, Esq., 10s. 6d.

We are, &c.,

Signed for HENRY LETHEBY,
W. SPENCER WATSON.

27, Montague-street, Russell-square, June 27.

COMMUNICATIONS have been received from—

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·705 in. The pressure of the atmosphere was 29·35 in. at the beginning of the week, and 30·02 in. at the end of it.

The general direction of the wind was S.W.

* The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the ten years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in Workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 61·0°.

APPOINTMENTS FOR THE WEEK.

June 30. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Royal Free Hospital, 1½ p.m.

July 2. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 9 a.m. and 1.30 p.m.

3. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.

4. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.

OBSTETRICAL SOCIETY OF LONDON (Council, 7 p.m.), 8 p.m. Dr. Routh, "On a New Mode of Treating Epithelial Cancer of the Cervix Uteri and its Cavity." Dr. Tilt, "On the Present Surgical Tendency of Uterine Pathologists, and on Division of the Cervix Uteri." And other Papers.

5. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

6. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

TO MOTHERS AND INVALIDS.

NEAVE'S FARINACEOUS FOOD FOR INFANTS.

This pure and unmedicated Preparation from cereal grains contains a remarkable combination of the flesh-forming, fat-forming or respiratory and bone-forming elements, and is therefore particularly adapted for the Diet of infants. The Manufacturers have received the highest Testimonials from Drs. LANKESTER, HASSALL, LETHEBY, URE, and other eminent Medical Practitioners, and also from parents who have used this Food as a Diet for their children.

Sold in 1 lb. canisters at 1s. per lb., by many of the principal Chemists and Grocers throughout the Kingdom.

Liberal terms to the trade, which may be had on application to the Manufacturers,

NEAVE and CO., FORDINGBRIDGE, SALISBURY.

LONDON AGENTS:—CROSSE & BLACKWELL, Soho-square; TURNER & CO., 77, Fleet-street; BARCLAY & CO., Farringdon-street; W. EDWARDS, St. Paul's-churchyard; J. EPPS, Great Russell-street.

EARL RUSSELL sent to the College of Physicians a communication received by him from Manilla (where Cholera has been raging fearfully), to the effect that, of all remedies tried, Chlorodyne was the most effective.—See "Lancet" and "Brit. Med. Journ." Dec. 31, 1864.

TOWLE'S CHLORODYNE.

OF KNOWN COMPOSITION.

For Formula, &c., see back Numbers.

NOTICE TO THE PROFESSION.

In consequence of the decision of the Board of Inland Revenue, that Chlorodyne is liable to Stamp duty, whether for Retail, Dispensing, or Export, I beg to inform the Profession of the following alterations in my Dispensing sizes, the price of which will now be,—2 oz., 2s. 9d.; 4 oz., 4s. 6d.; and 10 oz., 11s. (stamped.) The Liq. Chloroformi Co., in 2 oz., 4 oz., and 8 oz. bottles, will remain as before. All future orders are requested to be written for the above sizes.

The ½ oz., 1 oz., and 8 oz. sizes are discontinued in order to give the largest possible amount of Chlorodyne for the smallest Stamp Duty. Chlorodyne being frequently sold by weight, I beg to say that such is not the case with my preparation, which, being sent out by the fluid ounce, gives a considerable advantage over purchasing by weight, there being only 12¾ fluid ounces to the pound.

Sole Manufacturer—A. P. TOWLE, STOCKPORT-ROAD, MANCHESTER.

Tasteless Pills. — Cox's Patent. —

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each pill perfectly tasteless, at 1s. 6d. a gross. Postage, one gross 4d., or five gross 1s. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered at 1s. 10d. a gross, or large masses rolled out and covered at 6d. per gross. BURGOYNE and BURBIDGE, 16, Coleman-street, London; and COX and CO., Chemists, Brighton.

Blancard's Pill of Unalterable Iodide

of IRON, approved of by the Paris Academy of Medicine, &c., prepared by BLANCARD, Pharmacien, 40, RUE BONAPARTE, PARIS. The impure or alterable Iodide of Iron is an unsafe and irritating medicine. As proof of the purity and authenticity of the genuine Blancard's Pills, request the seal of reactive silver, and the signature, "Blancard," at the bottom of the green label. "Beware of counterfeits." To be had at all the principal chemists.

General Depôt for England, G. JOZEAU, French Chemist, 49, Haymarket, London. Sold in bottles at 2s. 9d. and 4s. 6d.
